
with the omitted initial segments equal, or $d_n = d'_n = 1$, in which case

$$.d_1d_2\cdots = .\cdots 11000\cdots$$

$$.d'_1d'_2\cdots = .\cdots 10111\cdots$$

and in either case the dyadic rational numbers represented are equal. The other five cases where $.t_1t_2\cdots$ is $.\cdots 10222\cdots$, $.\cdots 20222\cdots$, $.\cdots 01222\cdots$, $.\cdots 11222\cdots$, or $.\cdots 21222\cdots$ can be checked similarly. The cases $.0222\cdots$ and $.1222\cdots$ must be checked separately. 👍

V.3.9.3. PROPOSITION. The function f is continuous.

PROOF: Recall () that if $x_n, x \in \mathbb{R}$, then $x_n \to x$ if and only if, for each k there is an N such that, for all $n \geq N$, the triadic expansion of x_n (at least one expansion if x_n is triadic rational) agrees with the triadic expansion of x (at least one expansion if x is triadic rational) at least up to the k'th decimal place, and similarly for dyadic expansions. Since the first k decimal places of the dyadic expansion of $f(x)$ are completely determined by the first k decimal places of the triadic expansion of x, it follows that if $x_n \to x$, then $f(x_n) \to f(x)$. 👍

V.3.9.4. PROPOSITION. Let $x \in \mathbb{R}$. Then either $D^+f(x) = +\infty$ or $D_+f(x) = -\infty$, and either $D^-f(x) = +\infty$ or $D_-f(x) = -\infty$. In particular, f is not differentiable anywhere.

PROOF: Let $.t_1t_2\cdots$ be the ternary expansion for the fractional part of x not ending in a string of 2's, and let $.d_1d_2\cdots$ be the corresponding expansion of $f(x)$. There are infinitely many n such that $t_{n+1} \leq t_n$ and $t_{n+1} \neq 2$. Fix such an n. Let $t'_{n+1} = 2$ if $t_{n+1} = t_n < 2$ and $t'_{n+1} = t_n$ if $t_{n+1} < t_n$. Then successively choose t'_k for $k > n+1$ so that the number y with integer part the same as x and fractional part

$$.t_1 \cdots t_n t'_{n+1} t'_{n+2} \cdots$$

has image

$$f(y) = .d_1 \cdots d_n d'_{n+1} d_{n+2} \cdots$$

i.e. $d'_{n+1} \neq d_{n+1}$ but $d'_k = d_k$ for all $k \neq n+1$. We then have

$$0 < y - x \leq 3^{-n}$$

$$|f(y) - f(x)| = 2^{-(n+1)}$$

so

$$\left| \frac{f(y) - f(x)}{y - x} \right| \geq \frac{1}{2} \left(\frac{3}{2} \right)^n \quad .$$

Since there are infinitely many such n, the result for $D^+f(x)$ and $D_+f(x)$ follows. The proof for $D^-f(x)$ and $D_-f(x)$ is similar. 👍

V.3.9.5. The function takes values in $[0,1]$, and takes the value 0 at the integers; thus, if x is an integer, we must have $D^-f(x) \leq 0$ and $D_+f(x) \geq 0$, so $D^+f(x) = +\infty$ and $D_-f(x) = -\infty$. Similarly, $f\left(\frac{1}{2}\right) = 1$, so if x is $\frac{1}{2}$ or an integer translate, then $D_-f(x) \geq 0$ and $D^+f(x) \leq 0$, so $D^-f(x) = +\infty$ and $D_+f(x) = -\infty$.

Continuous Functions Differentiable at Only One Point

V.3.9.6. EXAMPLE. Let f be a continuous function from $\mathbb{R}$ to $\mathbb{R}$ which is not differentiable anywhere, e.g. one of the above examples. Set $g(x) = x^2 f(x)$. Then g is a continuous function from $\mathbb{R}$ to $\mathbb{R}$. We claim that g is differentiable at 0, and only at 0.

To see that g is differentiable at 0, note that f is bounded on the interval $[-1, 1]$ since it is continuous there; say $|f(x)| \leq M$ for $|x| \leq 1$. Then, for $0 < |x| \leq 1$, we have

$$\left| \frac{g(x) - g(0)}{x - 0} \right| = \left| \frac{x^2 f(x)}{x} \right| \leq M|x|$$

and thus $g'(0)$ exists and equals 0 by the Squeeze Theorem.

But g is not differentiable anywhere except at 0, since if it were $f(x) = \frac{g(x)}{x^2}$ would also be differentiable there by the Quotient Rule.

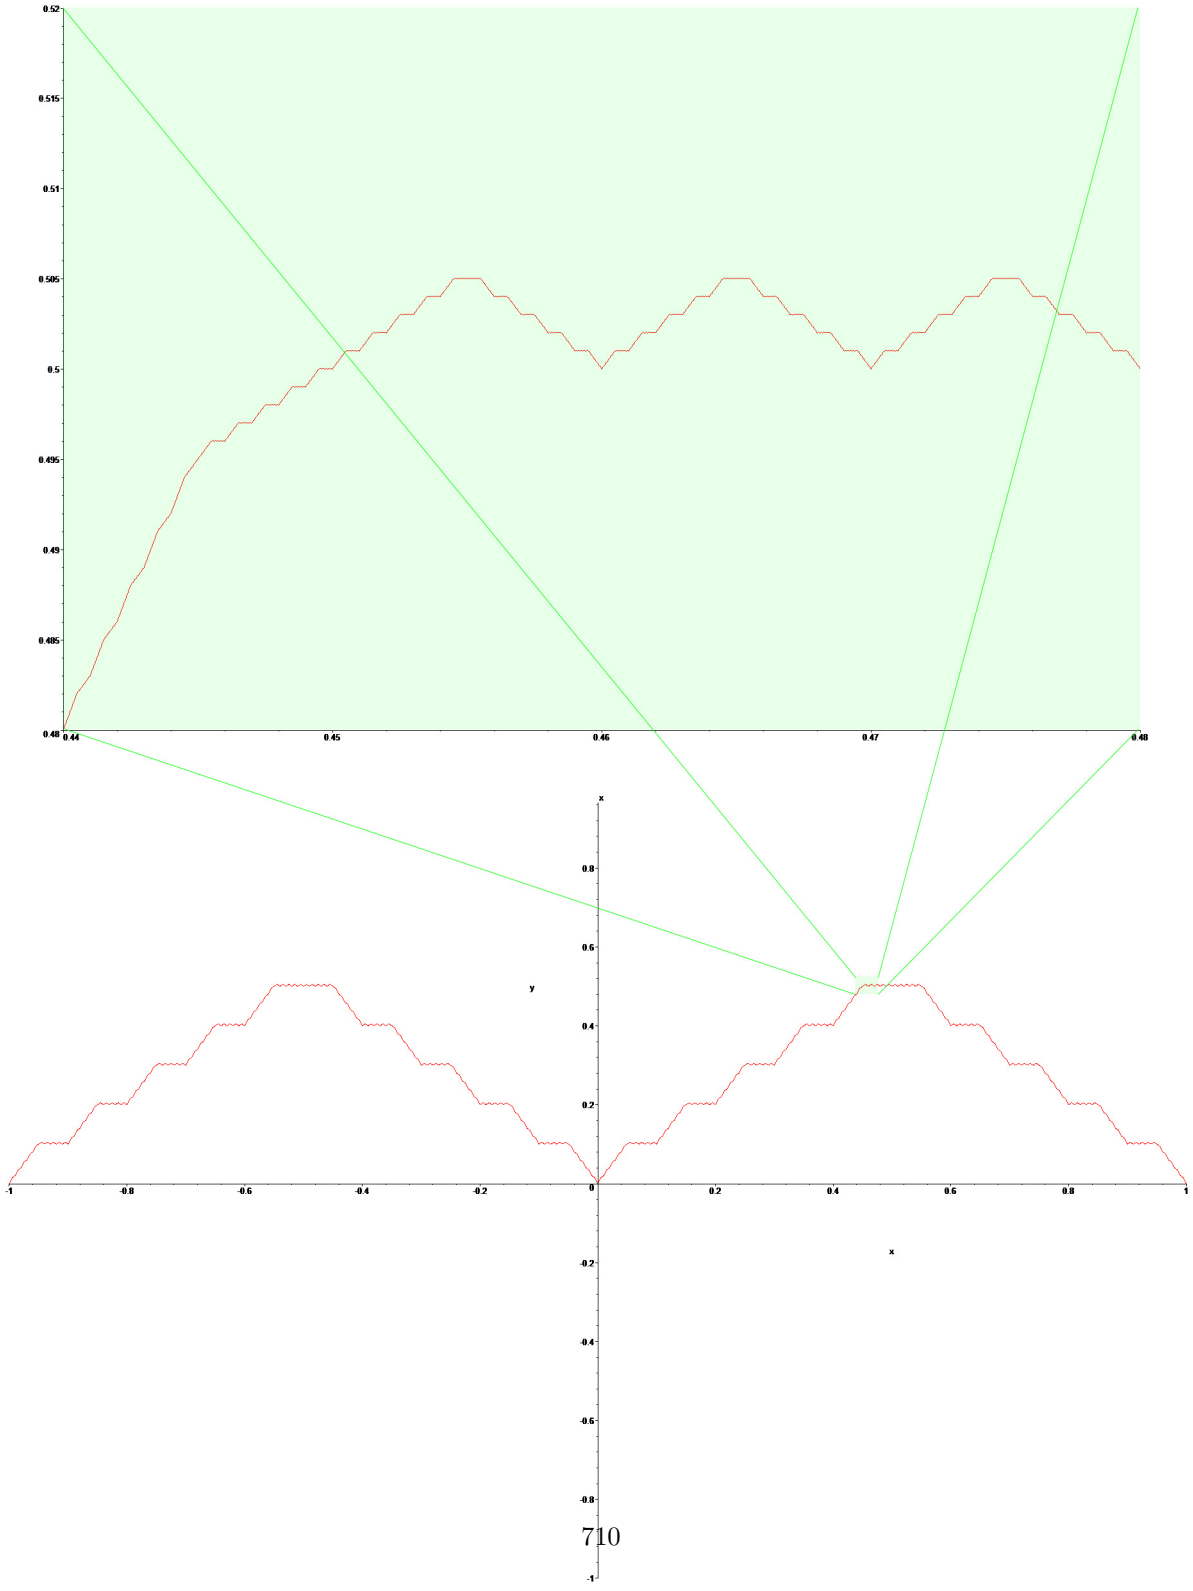

Figure V.6: Maple plot of graph of f

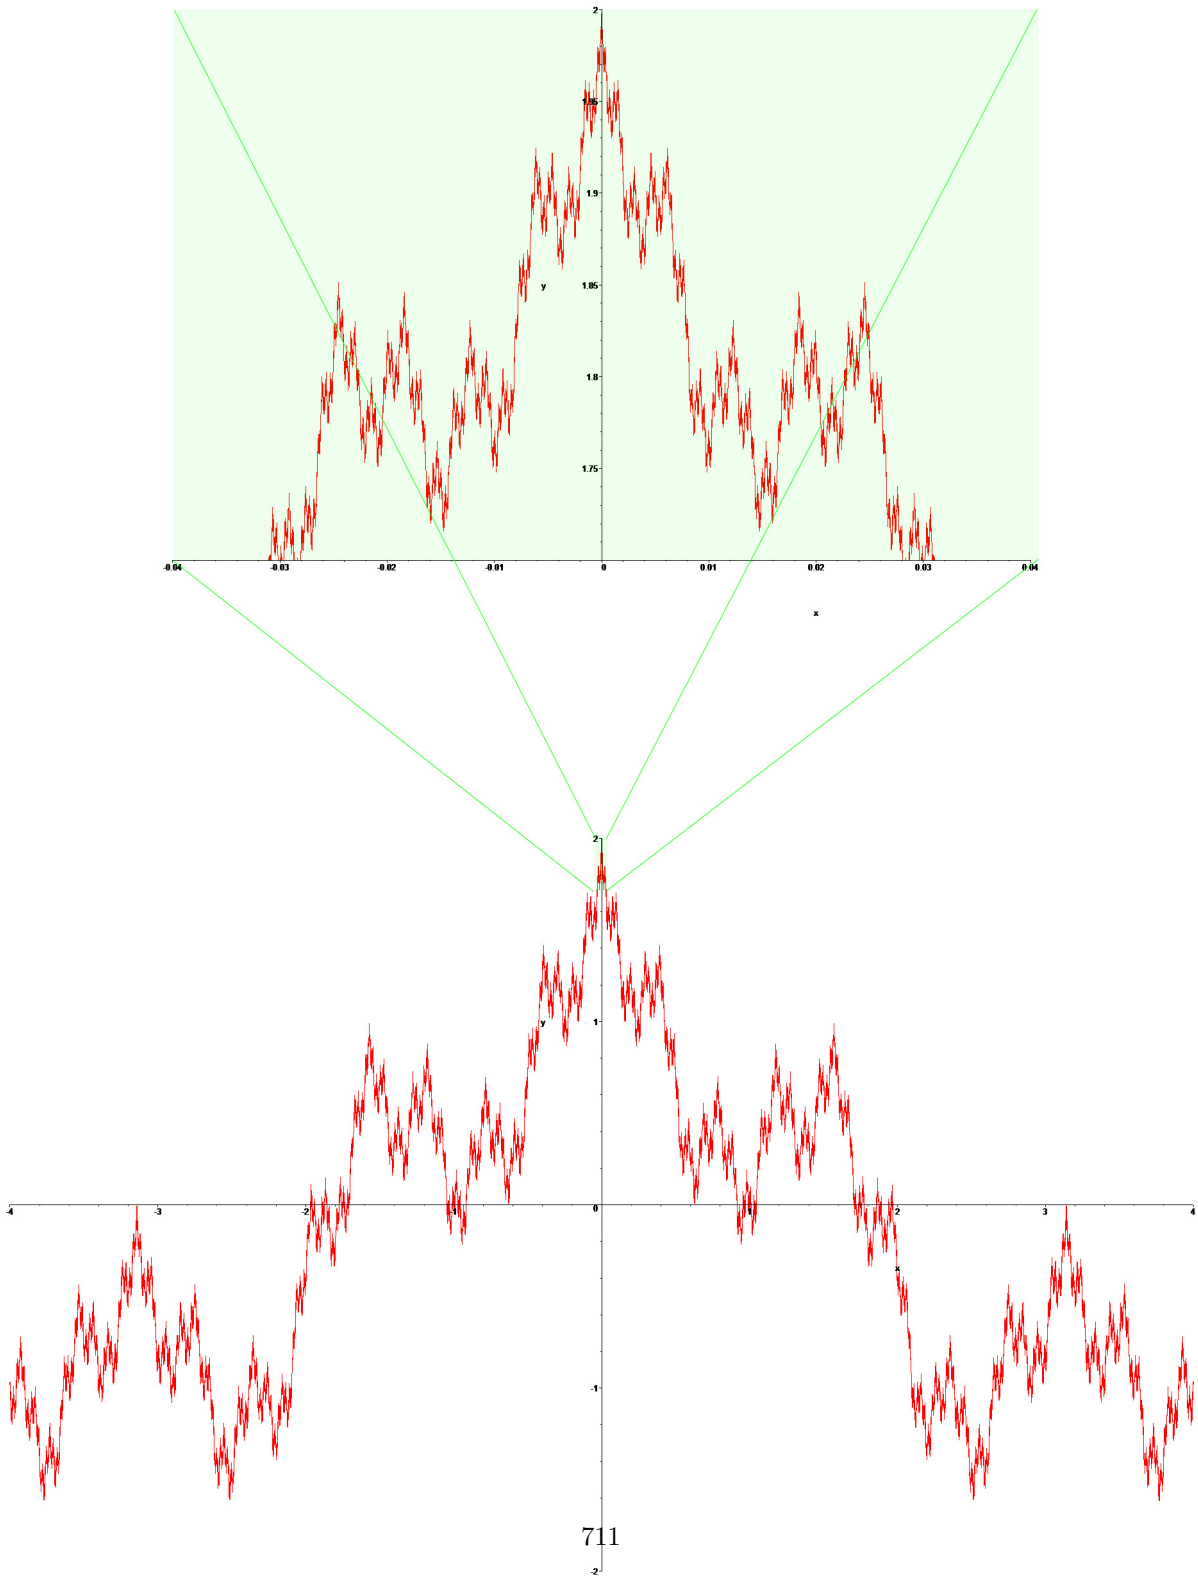

Figure V.7: Maple plot of $f(x) = \sum_{k=1}^{\infty} 2^{-k} \cos(4^k x)$

V.3.10. Exercises

V.3.10.1. Write out the proof of the power rule by writing, for $f(x) = x^n$ ($n \in \mathbb{N}$) and $a \in \mathbb{R}$,

$$f'(a) = \lim_{h\to 0} \frac{f(a+h) - f(a)}{h} = \lim_{h\to 0} \frac{(a+h)^n - a^n}{h}$$

and expanding $(a+h)^n$ using the Binomial Theorem (V.12.5.3.).

V.3.10.2. Write the proof of the full Quotient Rule along the lines of the proofs of V.3.3.4. and V.3.3.11..

V.3.10.3. Here is an alternate derivation of the quotient formula and "proof" of the Quotient Rule which has appeared in some textbooks.

Let f and g be defined in a neighborhood of a and differentiable at a, with $g(a) \neq 0$.
(a) Set $h = \frac{f}{g}$. Then, since g is continuous at a and $g(a) \neq 0$, h is defined in a neighborhood of a, and $f = gh$ on this neighborhood.
(b) By the Product Rule, $f'(a) = g'(a)h(a) + g(a)h'(a)$.
(c) Solve this equation for $h'(a)$ to obtain the Quotient Rule formula.
(d) What is wrong with this argument as a proof of the Quotient Rule? What does this argument actually prove?

V.3.10.4. (a) Show by direct calculation that if $a \neq 0$, then $f(x) = \frac{1}{x}$ is differentiable at a and $f'(a) = -\frac{1}{a^2}$.
(b) Use (a) and the Chain Rule to give an alternate proof of V.3.3.11..
(c) Conclude that the Quotient Rule is a consequence of (a), the Product Rule, and the Chain Rule.

V.3.10.5. What is wrong with the following "proof" of the Chain Rule? [Hint: the problem is very similar to the problem in ().]

Let f be defined on a neighborhood $\mathcal{U}$ of a and differentiable at a, with $f(a) = b$, and let g be defined on a neighborhood $\mathcal{V}$ of b and differentiable at b, with $f(\mathcal{U}) \subseteq \mathcal{V}$. Set $h = g \circ f$ on $\mathcal{U}$.
(a) For $x \in \mathcal{U}$, $x \neq a$, write

$$\frac{h(x) - h(a)}{x - a} = \frac{g(f(x)) - g(f(a))}{f(x) - f(a)} \cdot \frac{f(x) - f(a)}{x - a}$$

(b) For $x \in \mathcal{U}$, write $u = f(x)$. Since $\lim_{x\to a} \frac{f(x)-f(a)}{x-a}$ exists and $\lim_{x\to a}(x-a) = 0$, we have $\lim_{x\to a}(u-b) = 0$.
(c) Combining (a) and (b), we have

$$\lim_{x\to a} \frac{h(x) - h(a)}{x - a} = \left[\lim_{u\to b} \frac{g(u) - g(b)}{u - b}\right] \left[\lim_{x\to a} \frac{f(x) - f(a)}{x - a}\right] = g'(b)f'(a) \ .$$

V.3.10.6. What is wrong with the following "proof" of the Inverse Function Rule? What does this argument actually prove?

Let f be continuous and strictly monotone in a neighborhood of a, and differentiable at a. If $f(a) = b$, then $g = f^{-1}$ is defined, continuous, and strictly monotone in a neighborhood of b by ().
(a) Set $h = g \circ f = f^{-1} \circ f$. Then $h(x) = x$ in a neighborhood of a. Thus h is differentiable at a, and $h'(a) = 1$.
(b) Using the Chain Rule, differentiate h at a to obtain

$$1 = h'(a) = g'(f(a))f'(a) = (f^{-1})'(b)f'(a) \ .$$

(c) If $f'(a) \neq 0$, divide both ends of the equation by $f'(a)$ to obtain

$$(f^{-1})'(b) = \frac{1}{f'(a)} \ .$$

V.3.10.7. Prove the formula $\frac{d}{dx}\left([f(x)]^n\right) = n[f(x)]^{n-1}f'(x)$ for $n \in \mathbb{N}$ by induction using the Product Rule instead of the Chain Rule.

V.3.10.8. (S. Chang[9]) Let $f(x) = \sum_{k=1}^{100} \left[\frac{\sin(2\pi k^2 x)}{4\pi^2 k^5} + \frac{x^2}{2k}\right]$. Note that f is $\mathcal{C}^\infty$ (in fact, analytic) on $\mathbb{R}$. Use a computer algebra system to plot f, f', and f''. Could you have predicted the behavior of f'' from the appearance of the graph of f, or even the graph of f'?

V.3.10.9. (a) Formally define the "derivative" of a polynomial $p(x) = \sum_{k=0}^{n} a_k x^k$ to be

$$p^{\#}(x) = \sum_{k=1}^{n} k a_k x^{k-1} \ .$$

Give a purely algebraic proof that $p \mapsto p^{\#}$ is linear and satisfies the "Product Rule"

$$(pq)^{\#} = p^{\#}q + pq^{\#}$$

for polynomials p and q. (This argument is valid over any field or even any ring.)
(b) Extend the definition of # to the field of rational functions over $\mathbb{R}$ by

$$\left(\frac{p}{q}\right)^{\#} = \frac{qp^{\#} - pq^{\#}}{q^2}$$

for polynomials p and q. Show that the extended # is well defined and also satisfies the product rule, and the quotient rule. See XII.12.2.2..
(c) If f is a polynomial of degree n, expand $f(x+t)$ to obtain

$$f(x+t) = f_0(x) + f_1(x)t + f_2(x)t^2 + \cdots + f_n(x)t^n$$

[9] *American Mathematical Monthly*, v. 119 (October 2012), p. 669.

for polynomials $f_0, f_1, \ldots, f_n$. Show that $f_0 = f$ and $f_1 = f^\#$, and more generally $f_k = \frac{1}{k!} f^{\#\#\cdots\#}$, where the "derivative" is taken k times. This is an algebraic version of Taylor's Theorem (V.10.1.7.).

(d) Let $f(x)$ be a polynomial. Define a polynomial g in two variables by $g(x, y) = f(y) - f(x)$. Show that g is divisible by $y - x$ and if

$$h(x, y) = \frac{g(x, y)}{y - x} = \frac{f(y) - f(x)}{y - x}$$

then $f^\#(x) = h(x, x)$.

The map $\#$ is a derivation (XII.12.1.1.). Compare with III.5.3.7..

V.3.10.10. Let $f(x) = 2x^2 + x^2 \sin \frac{1}{x^2}$ for $x \neq 0$, $f(0) = 0$.

(a) Show that f is differentiable everywhere.

(b) Show that f has a strict local minimum (actually absolute minimum) at 0.

(c) Show that the First Derivative Test (V.3.6.10., V.8.2.6.) fails at 0.

V.3.10.11. There is a unique differentiable function f with $f'(x) = \frac{1}{2}x + x^2 \sin \frac{1}{x^2}$ for $x \neq 0$ and $f(0) = f'(0) = 0$ (V.8.5.9.).

(a) Show that by the first derivative test, f has a local minimum at 0 (which is in fact a strict absolute minimum).

(b) In what sense is the graph of f concave upward around 0?

V.3.10.12. [Gou59] Let f and g be differentiable on an open interval I, and suppose that $f'g = fg'$ on I.

(a) Can we conclude from the quotient rule applied to $\frac{f}{g}$ that $\frac{f}{g}$ is constant on I, i.e. that f is a constant multiple of g on I?

(b) Consider the case where $I = \mathbb{R}$, $g(x) = x^2$ for all x, $f(x) = x^2$ if $x \leq 0$, and $f(x) = 2x^2$ for $x > 0$.

(c) Suppose we assume f and g are $\mathcal{C}^\infty$? [Consider Cauchy's examples V.17.2.3., especially the last two and their reflections.]

V.3.10.13. [Gou59, p. 32] Prove the following theorem:

Theorem. Let f be defined on a neighborhood $\mathcal{U}$ of $a \in \mathbb{R}$ and n-times differentiable at a, with $f(a) = b \in \mathbb{R}$, and let g be defined on a neighborhood $\mathcal{V}$ of b and n-times differentiable at b, with $f(\mathcal{U}) \subseteq \mathcal{V}$. Set $h = g \circ f$ on $\mathcal{U}$. Then h is n-times differentiable at a, and

$$h^{(n)}(a) = \sum_{k=1}^{n} A_{n,k} g^{(k)}(b)$$

where

$$A_{n,k} = \frac{1}{k!} \sum_{j=0}^{k-1} (-1)^j \binom{k}{j} [f(a)]^j \left[\frac{d^n}{dx^n} \left([f(x)]^{k-j} \right) \right] (a) \ .$$

(a) Show that $h^{(n)}(a)$ is of the form $\sum_{k=1}^{n} A_{n,k} g^{(k)}(b)$, where the $A_{n,k}$ are independent of the form of g.

(b) To find the $A_{n,k}$, set $g(u) = u^m$ for $1 \leq m \leq n$ and solve a system of equations. (Try $n = 2$ first.)

(c) Show that this formula is equivalent to Faà di Bruno's formula (V.3.7.8.).

V.3.10.14. Let f be VAN DER WAERDEN'S example (V.3.8.1.).

(a) Let a be a real number whose decimal part is $.d_1d_2d_3\cdots$, where d_n is in the range $0-4$ for n odd and in the range $5-9$ for n even. Show that $D_-f(a) = D_+f(a) = 0$ and $D^-f(a) = D^+f(a) = 1$.

(b) Show that if $m, n \in \mathbb{Z}$, $m < n$, there are uncountably many points a in $[0,1]$ with $D_-f(a) = D_+f(a) = m$ and $D^-f(a) = D^+f(a) = n$. [If $n > 0$, take the first n decimal places in the range $0-4$, the next $n-m$ in the range $5-9$, etc.]

(c) Extend the argument of b to cover the cases where m and/or n is $\pm\infty$. (Both can be $+\infty$ or both $-\infty$, or we can have $m = -\infty$ and $n = +\infty$.)

(d) For how many points a is $D_-f(a) \neq D_+f(a)$ and/or $D^-f(a) \neq D^+f(a)$? What are the possibilities?

V.3.10.15. Let I be an interval in $\mathbb{R}$, and $f : I \to \mathbb{R}$ a one-to-one continuous function.

(a) Show that f cannot have a local maximum or local minimum in the interior of I. [If $a, b, c \in I$, $a < b < c$, and $f(a) < f(b)$, $f(c) < f(b)$, use the Intermediate Value Theorem to show there are x_1, x_2 with $a < x_1 < b < x_2 < c$ and $f(x_1) = f(x_2)$.]

(b) For every $a, b \in I$, $a < b$, f must attain its maximum on $[a,b]$ at a or b, and its minimum at the other.

(c) If there are $a, b, c, d \in I$, $a < b < c < d$, such that f attains its maximum on $[a,b]$ at b and its maximum on $[c,d]$ at c, then f has a local maximum at either b or c, and similarly for minima.

(d) Conclude that f must be either strictly increasing on I or strictly decreasing on I.

V.3.11. Calculus of Finite Differences

> "The analysis of the infinite ... is nothing but a special case of the method of differences, ... wherein the differences are infinitely small ..."
>
> *L. Euler*[10]

> "It appears that Fermat, the true inventor of differential calculus [sic], considered calculus as derived from the calculus of finite differences by neglecting infinitesimals of higher orders as compared with those of a lower order ..."
>
> *Laplace*[11]

In this section, we discuss a discrete version of derivatives. This procedure is important historically as a motivation of much of differential and integral calculus (cf. e.g. [Eul00]), and is still very useful in numerical analysis.

V.3.11.1. We start with a functional relation $y = f(x)$, where f is a function defined, say, on all of $\mathbb{R}$ (simply to make the discussion simpler by not having to worry about domain questions). Fix an $x_0 \in \mathbb{R}$, and an "increment" $h > 0$ (h is often written Δx). Form the sequence

$$x_0, x_1 = x_0 + h, x_2 = x_0 + 2h, \ldots, x_n = x_0 + nh, \ldots$$

which is an arithmetic sequence whose successive differences are each equal to $h = \Delta x$. Set

$$\Delta x_n = x_{n+1} - x_n$$

for each n; of course, $\Delta x_n = h$ for all n since the x_n were chosen evenly spaced.

V.3.11.2. Now form the sequence

$$y_0, y_1, y_2, \ldots$$

where $y_n = f(x_n)$ for each n. This sequence is rarely an arithmetic sequence (it will be arithmetic if f is linear or affine); its properties are closely connected to the properties of the function f. Set

$$\Delta y_n = y_{n+1} - y_n = f(x + (n+1)h) - f(x + nh)$$

for each n. The Δy_n are called the *sequence of first differences* of y (or f) corresponding to the increment $h = \Delta x$. This sequence is rarely constant (it will be constant if f is linear or affine); its properties are closely connected to the properties of the function f. If f is a quadratic polynomial, the first differences will form an arithmetic progression.

V.3.11.3. Go on to form the *second differences*

$$\Delta^2 y_n = \Delta y_{n+1} - \Delta y_n$$

for each n. The second differences are all zero if and only if the first differences are constant, e.g. if f is affine. If f is a quadratic polynomial, the second differences will be constant.

[10] [Eul00, p. 64].
[11] *Lés Intégrales Définies*; cf. [Mor93, 1902].

V.3.11.4. Successively form *higher differences*

$$\Delta^{k+1} y_n = \Delta^k y_{n+1} - \Delta^k y_n$$

for each k and n. The sequence of $(k+1)$'st differences of (y_n) is the sequence of first differences of $(\Delta^k y_n)$. If f is a polynomial of degree $\leq k$, then the sequence of k'th differences will be constant, so the sequence of $(k+1)$'st differences will be 0.

V.3.11.5. The successive differences can be conveniently displayed in a table

$$\begin{array}{ccccccccc}
y_0 & & y_1 & & y_2 & & y_3 & & \cdots \\
& \Delta y_0 & & \Delta y_1 & & \Delta y_2 & & \Delta y_3 & \cdots \\
& & \Delta^2 y_0 & & \Delta^2 y_1 & & \Delta^2 y_2 & & \cdots \\
& & & \Delta^3 y_0 & & \Delta^3 y_1 & & \Delta^3 y_2 & \cdots \\
& & & & \ddots & & \ddots & & \ddots
\end{array}$$

where the first row is computed from the function f and each other entry is the difference of the two entries just above it.

V.3.11.6. We have

$$\Delta y_0 = y_1 - y_0$$
$$\Delta^2 y_0 = (y_2 - y_1) - (y_1 - y_0) = y_2 - 2y_1 - y_0$$
$$\Delta^3 y_0 = y_3 - 3y_2 + 3y_1 - y_0$$

and, for any n,

$$\Delta^n y_0 = \sum_{k=0}^{n} (-1)^k \binom{n}{k} y_{n-k}$$

and, more generally, for any n and m,

$$\Delta^n y_m = \sum_{k=0}^{n} (-1)^k \binom{n}{k} y_{n+m-k}$$

(these formulas can easily be proved by induction). Solving for y_n, we obtain

$$y_n = \sum_{k=0}^{n} \binom{n}{k} \Delta^k y_0$$

and, more generally, for any n and m,

$$y_{n+m} = \sum_{k=0}^{n} \binom{n}{k} \Delta^k y_m$$

(again a straightforward proof by induction).

V.3.11.7. Thus, for any f, x_0, and $n \in \mathbb{N}$,

$$f(x_0 + n\Delta x) = \sum_{k=0}^{n} \binom{n}{k} \Delta^k f$$

where we write $\Delta^k f$ for $\Delta^k f_0$. Thus, if f is defined on the interval $[x_0, x]$, and we take $n \in \mathbb{N}$ and $\Delta x = \frac{x-x_0}{n}$, so $x = x_0 + n\Delta x$ and $n = \frac{x-x_0}{\Delta x}$, we have

$$f(x) = \sum_{k=0}^{n} \frac{n(n-1)\cdots(n-k+1)}{k!} \Delta^k f \approx \sum_{k=0}^{m} \frac{(x-x_0)^k}{k!} \frac{\Delta^k f}{(\Delta x)^k}$$

if m is large and n is much larger, if $\frac{\Delta^k f}{k!(\Delta x)^k} \to 0$ fairly rapidly as $k \to \infty$ (see () for a precise version).

V.3.11.8. The sequence of k'th differences is, roughly speaking, a discrete version of the k'th derivative $f^{(k)}$ (although the differences are defined for any f whether or not it is differentiable or even continuous).

V.3.11.9. EXAMPLES. (i) suppose $f(x) = mx$. Then the table becomes

$$\begin{array}{ccccccccc}
mx_0 & & mx_1 & & mx_2 & & mx_3 & & \cdots \\
& m\Delta x & & m\Delta x & & m\Delta x & & m\Delta x & \cdots \\
& & 0 & & 0 & & 0 & & \cdots \\
& & & 0 & & 0 & & 0 & \cdots \\
& & & & \ddots & & \ddots & & \ddots
\end{array}$$

since $mx_{n+1} - mx_n = m\Delta x$ for all n.
(ii) Let $f(x) = x^2$. Then the table becomes

$$\begin{array}{ccccccccccc}
x_0^2 & & x_1^2 & & x_2^2 & & x_3^2 & & & & \cdots \\
& (x_0+x_1)\Delta x & & (x_1+x_2)\Delta x & & (x_2+x_3)\Delta x & & (x_3+x_4)\Delta x & & & \cdots \\
& & 2(\Delta x)^2 & & 2(\Delta x)^2 & & 2(\Delta x)^2 & & & & \cdots \\
& & & 0 & & 0 & & 0 & & & \cdots \\
& & & & \ddots & & \ddots & & & & \ddots
\end{array}$$

since $x_{n+1}^2 - x_n^2 = (x_n + x_{n+1})(x_{n+1} - x_n) = (x_n + x_{n+1})\Delta x$ for all n. Since $x_{n+1} = x_n + \Delta x$, we have

$\Delta y_n = 2x_n\Delta x + (\Delta x)^2$, so the table becomes

$$\begin{array}{ccccccc}
x_0^2 & & x_1^2 & & x_2^2 & & x_3^2 & & \cdots \\
& 2x_0\Delta x + (\Delta x)^2 & & 2x_1\Delta x + (\Delta x)^2 & & 2x_2\Delta x + (\Delta x)^2 & & 2x_3\Delta x + (\Delta x)^2 & \cdots \\
& & 2(\Delta x)^2 & & 2(\Delta x)^2 & & 2(\Delta x)^2 & & \cdots \\
& & & 0 & & 0 & & 0 & \cdots \\
& & & & \ddots & & \ddots & & \ddots
\end{array}$$

(iii) Let $f(x) = x^k$, $k \in \mathbb{N}$. The binomial theorem shows that

$$\Delta y_n = (x_n + \Delta x)^k - x_n^k = kx_n^{k-1}\Delta x + \binom{k}{2}x_n^{k-2}(\Delta x)^2 + \cdots + kx_n(\Delta x)^{k-1} + (\Delta x)^k$$

$$= (x_n^{k-1} + x_n^{k-2}x_{n+1} + x_n^{k-3}x_{n+1}^2 + \cdots + x_nx_{n+1}^{k-2} + x_{n+1}^{k-1})\Delta x \ .$$

The succeeding rows can be similarly calculated. The general formula is complicated, but the $(k+1)$'st row is constant, $\Delta^k y_n = k!(\Delta x)^k$ for all n, and the succeeding rows are 0.

(iv) Let $f(x) = \frac{1}{x}$. (This is not defined for all $x \in \mathbb{R}$, but we only need that it is defined for $x \geq x_0$ to make the above construction of the differences work, so we just need to take $x_0 > 0$.) Then

$$\Delta y_n = \frac{1}{x_n + \Delta x} - \frac{1}{x_n} = -\frac{1}{x_n(x_n + \Delta x)}\Delta x = -\frac{1}{x_nx_{n+1}}\Delta x$$

$$\Delta^2 y_n = -\frac{1}{x_{n+1}x_{n+2}}\Delta x + \frac{1}{x_nx_{n+1}}\Delta x = \frac{x_{n+2} - x_n}{x_nx_{n+1}x_{n+2}}\Delta x = \frac{2\Delta x}{x_nx_{n+1}x_{n+2}}\Delta x = \frac{2}{x_nx_{n+1}x_{n+2}}(\Delta x)^2$$

and higher differences can be calculated similarly. In this case the rows never become identically zero.

(v) Let $f(x) = \sqrt{x} = x^{1/2}$. Then

$$\Delta y_n = \sqrt{x_n + \Delta x} - \sqrt{x} = (\sqrt{x_n + \Delta x} - \sqrt{x_n})\frac{\sqrt{x_n + \Delta x} + \sqrt{x_n}}{\sqrt{x_n + \Delta x} + \sqrt{x_n}} = \frac{1}{\sqrt{x_n + \Delta x} + \sqrt{x_n}}\Delta x = \frac{1}{\sqrt{x_n} + \sqrt{x_{n+1}}}\Delta x \ .$$

Again, no row of higher differences becomes zero.

(vi) Let $f(x) = a^x$ for fixed $a > 0$ (the comment from (iv) applies to this function). Then the sequence $(y_0, y_1, \dots)$ is a geometric progression with successive ratios $b = a^h$. We have

$$\Delta y_n = a^{x_0 + (n+1)h} - a^{x_0 + nh} = a^{x_0 + nh}(a^h - 1) = cy_n$$

where $c = a^h - 1$. Thus each succeeding row is also a geometric progression.

V.3.11.10. The x_0 is fixed in these calculations. But at the end we want to allow the x_0 to be any number (in the domain), and thus often write x in place of x_0 and y in place of y_0, and hence $\Delta^m y$ in place of $\Delta^m y_0$. Thus the above formulas become:

(i) If $f(x) = mx$, then $\Delta y = m\Delta x$ and $\Delta^k y = 0$ for $k > 1$.

(ii) If $f(x) = x^2$, then $\Delta y = 2x\Delta x + (\Delta x)^2$, $\Delta^2 y = 2(\Delta x)^2$, and $\Delta^m y = 0$ for $m > 2$.

(iii) If $f(x) = x^k$, then

$$\Delta y = kx^{k-1}\Delta x + \binom{k}{2}x^{k-2}(\Delta x)^2 + \cdots + kx(\Delta x)^{k-1} + (\Delta x)^k$$

and $\Delta^k y = k!(\Delta x)^k$.

(iv) If $f(x) = \frac{1}{x}$, then $\Delta y = -\frac{1}{x(x+\Delta x)}\Delta x$.

(v) If $f(x) = \sqrt{x}$, then $\Delta y = \frac{1}{\sqrt{x}+\sqrt{x+\Delta x}}\Delta x$.

(vi) If $f(x) = a^x$, then $\Delta y = ca^x = cy$, where $c = a^{\Delta x} - 1$.

V.3.11.11. The formulas from these examples are analogous to differentiation formulas, and suggest that the derivative of a power function should be a power function whose exponent is reduced by one, and that the derivative of an exponential function should be another exponential function. Here is a nonrigorous but suggestive closer link to differentiation. If we regard $h = \Delta x$ as "infinitesimally small," so that the x_n are essentially equal to $x = x_0$ (at least for n small), in the case $f(x) = x^k$ we have

$$\Delta y_n = (x_n^{k-1} + x_n^{k-2}x_{n+1} + x_n^{k-3}x_{n+1}^2 + \cdots + x_n x_{n+1}^{k-2} + x_{n+1})\Delta x \approx kx^{k-1}\Delta x$$

for small n, and if $f(x) = a^x$ we have

$$\Delta y_n = a^{x+(n+1)h} - a^{x+nh} = a^{x+nh}(a^h - 1) \approx cy\,\Delta x = ca^x\,\Delta x$$

where $c = \lim_{h\to 0}\frac{a^h-1}{h}$.

V.3.11.12. More rigorously, we have

$$f'(x) = \lim_{\Delta x\to 0}\frac{\Delta y}{\Delta x}$$

(to be completely rigorous we should also allow $h < 0$) so in the case where $f(x) = x^k$ we get $f'(x) = kx^{k-1}$, and in the case $f(x) = a^x$ we get

$$f'(x) = a^x\left[\lim_{h\to 0}\frac{a^h - 1}{h}\right] .$$

Of course, these are in fact the correct formulas. Note also that in these cases we have

$$f^{(m)}(x) = \lim_{\Delta x\to 0}\frac{\Delta^m y}{(\Delta x)^m}$$

for all m. This is one of the origins of the notation $\frac{d^m y}{dx^m}$ for $f^{(m)}(x)$.

V.3.11.13. One can also consider the inverse problem, which is the discrete antiderivative problem: given the sequence of first differences (Δy_n), find the sequence (y_n) it comes from. The y_n are not uniquely determined: an arbitrary constant can be added to all the y_n. This amounts to making an arbitrary choice of y_0. Once y_0 has been chosen, there is a unique solution:

$$y_n = y_0 + \sum_{m=0}^{n-1} \Delta y_m \ .$$

Factorial Polynomials

Here is another pretty analogy. Our exposition is adapted from [Mil66]. We will normalize to take $h = \Delta x = 1$.

V.3.11.14. If $n \in \mathbb{N}$, define an n'th degree monic polynomial

$$x^{(n)} = x(x-1)(x-2)\cdots(x-n+1)$$

and $x^{(0)} = 1$. The polynomial $x^{(n)}$ is also called $\pi_n(x)$ in the literature (V.11.7.1.). We have

$$\Delta x^{(n)} = (x+1)^{(n)} - x^{(n)} = (x+1)x(x-1)\cdots(x+n-2) - x(x-1)\cdots(x-n+2)(x-n+1)$$

$$= x(x-1)\cdots(x-n+2)[(x+1)-(x-n+1)] = nx(x-1)\cdots(x-n+2) = nx^{(n-1)}$$

motivating the definition as an interesting one. We also have

$$x^{(n)}(x-n)^{(m)} = x^{(n+m)}$$

for $n, m \in \mathbb{N}$ (and even in $\mathbb{N} \cup \{0\}$).

V.3.11.15. The polynomials $\{x^{(0)}, x^{(1)}, \ldots, x^{(n)}\}$ are clearly linearly independent in P_n () since none is a linear combination of the previous ones, which are of smaller degree. Thus they form a basis for the $(n+1)$-dimensional vector space P_n. The change-of-basis matrix from the usual basis $\{1, x, x^2, \ldots, x^n\}$ is triangular, with 1's on the diagonal. Thus any polynomial of degree n

$$p(x) = a_0 + a_1 x + a_2 x^2 + \cdots + a_n x^n$$

can be written uniquely as a *factorial polynomial*

$$p(x) = b_0 x^{(0)} + b_1 x^{(1)} + b_2 x^{(2)} + \cdots + b_n x^{(n)}$$

and $b_n = a_n$ (and in particular $b_0 x^{(0)} + \cdots + b_n x^{(n)}$ is identically 0 if and only if all b_k are 0). For such a polynomial we have

$$\Delta p = b_1 + 2b_2 x^{(1)} + \cdots + n b_n x^{(n-1)} \ .$$

V.3.11.16. If $p(x) = a_0 + a_1x + a_2x^2 + \cdots + a_nx^n$ is a polynomial of degree $\leq n$, then Taylor's formula () yields that

$$p(x) = p(0) + p'(0)x + \frac{p''(0)}{2!}x^2 + \cdots + p^{(n)}(0)x^n$$

for all x (this formula can be easily proved by noting that $p^{(k)}(0) = k!a_k$ for all k). Similarly, if

$$p(x) = b_0x^{(0)} + b_1x^{(1)} + \cdots + b_nx^{(n)}$$

(note the unfortunate coincidence of notation: $x^{(k)}$ does not denote a derivative here!) a simple calculation shows that

$$\Delta^k p(0) = k!b_k$$

and hence

$$p(x) = p(0) + \Delta p(0)x^{(1)} + \frac{\Delta^2 p(0)}{2!}x^{(2)} + \cdots + \frac{\Delta^n p(0)}{n!}x^{(n)}$$

(this is a purely algebraic formula not involving any derivatives). This formula is called *Newton's formula* (NEWTON is credited with many formulas), and is the difference version of Taylor's formula.

The factorial polynomials have many applications in interpolation theory; cf. V.11.7.1.. Here is an example related to the discussion in I.6.1.26..

V.3.11.17. EXAMPLE. Here is a sample calculation using this formula (from [Mil66]). Suppose we want to find the unique polynomial $p(x)$ of degree ≤ 7 for which $p(0) = 0$, $p(1) = 7$, $p(2) = 26$, $p(3) = 63$, $p(4) = 124$, $p(5) = 215$, $p(6) = 342$, and $p(7) = 511$ (it may not be hard to find this polynomial by inspection or trial and error in this case; cf. I.6.1.38.). Newton's formula gives a systematic way to do it without solving a system of eight linear equations. Make up a table:

x	0	1	2	3	4	5	6	7
$p(x)$	0	7	26	63	124	215	342	511
$\Delta p(x)$	7	19	37	61	91	127	169	
$\Delta^2 p(x)$	12	18	24	30	36	42		
$\Delta^3 p(x)$	6	6	6	6	6			
$\Delta^4 p(x)$	0	0	0	0				

(the table need not be continued farther once a zero row, or even a constant row, is obtained). Thus

$$p(x) = 0 + 7x^{(1)} + \frac{12}{2!}x^{(2)} + \frac{6}{3!}x^{(3)} + 0x^{(4)}$$

$$= 7x + 6x(x-1) + x(x-1)(x-2) = x^3 + 3x^2 + 3x = (x+1)^3 - 1 \ .$$

V.3.11.18. The definition of $x^{(n)}$ can be extended to negative n. The right way to do it is to preserve the formula $x^{(n)}(x-n)^{(m)} = x^{(n+m)}$, i.e. we should have $x^{(-n)}(x+n)^{(n)} = x^0 = 1$ so we define

$$x^{(-n)} = \frac{1}{(x+n)^{(n)}} = \frac{1}{(x+n)(x+n-1)\cdots(x-1)} \ .$$

A simple calculation then verifies that $x^{(n)}(x-n)^{(m)} = x^{(n+m)}$ for all $n, m \in \mathbb{Z}$, and perhaps more importantly

$$\Delta x^{(n)} = n x^{(n-1)}$$

for all $n \in \mathbb{Z}$.

V.3.12. Exercises

V.3.12.1. Stirling Numbers. The coefficients in the change-of-basis matrix between the ordinary power functions x^k and the factorial polynomials $x^{(k)}$ are called *Stirling numbers*. Specifically, if $0 \le r \le n$ we define S_r^n by

$$x^{(n)} = \sum_{r=0}^{n} S_r^n x^r \ .$$

The S_r^n are the *Stirling numbers of the first kind*. We also define $\mathcal{S}_r^n$ by

$$x^n = \sum_{r=0}^{n} \mathcal{S}_r^n x^{(r)} \ .$$

The $\mathcal{S}_r^n$ are the *Stirling numbers of the second kind*. Define $S_r^n = \mathcal{S}_r^n = 0$ for $r > n$.

(a) Show that $S_0^n = \mathcal{S}_0^n = 0$ and $S_n^n = \mathcal{S}_n^n = 1$ for all $n \in \mathbb{N}$.

(b) Show that the following recurrence relations hold for all $n, r \in \mathbb{N}$:

$$S_r^{n+1} = S_{r-1} n - n S_r^n$$

$$\mathcal{S}_r^{n+1} = \mathcal{S}_{r-1}^n + r\mathcal{S}_r^n \ .$$

(c) Show that the Stirling numbers are completely determined by the conditions in (a) and (b) for all n and all r, $1 \le r \le n$.

(d) Compute the Stirling numbers for small n (say, $n \le 6$). They are always integers; Stirling numbers of the second kind are nonnegative, but some Stirling numbers of the first kind are negative.

V.4. Extensions of the Derivative

There are a number of ways to extend the derivative concept which prove to be useful. We discuss several of these generalizations in this section.

V.4.1. One-Sided Derivatives

The first generalization we consider is one-sided derivatives. The definition is quite straightforward:

V.4.1.1. DEFINITION. (i) Let f be a real-valued function on the interval $[x_0, b)$. If

$$\lim_{h\to 0+} \frac{f(x_0+h)-f(x_0)}{h} = \lim_{x\to x_0+} \frac{f(x)-f(x_0)}{x-x_0}$$

exists (as a real number), then f is *right differentiable* at x_0, and this number is the *right derivative* of f at x_0, denoted $D_R f(x_0)$.

(ii) Let f be a real-valued function on the interval $(a, x_0]$. If

$$\lim_{h\to 0-} \frac{f(x_0+h)-f(x_0)}{h} = \lim_{x\to x_0-} \frac{f(x)-f(x_0)}{x-x_0}$$

exists (as a real number), then f is *left differentiable* at x_0, and this number is the *left derivative* of f at x_0, denoted $D_L f(x_0)$.

Various notations are used for left and right derivatives, such as $D_l f$ and f'_- for $D_L f$ and $D_r f$ and f'_+ for $D_R f$.

The next proposition is obvious from ().

V.4.1.2. PROPOSITION. Let f be a real-valued function on an interval (a, b), and $x_0 \in (a, b)$. Then f is differentiable at x_0 if and only if it is both left and right differentiable at x_0 and $D_L f(x_0) = D_R f(x_0)$. We then have

$$f'(x_0) = D_L f(x_0) = D_R f(x_0) \ .$$

We can have left and right derivatives which are not equal, or one or both may fail to exist:

V.4.1.3. EXAMPLES. (i) Let $f(x) = |x|$. Then $D_L f(0) = -1$ and $D_R f(x) = 1$. Thus f is both left and right differentiable at 0, but not differentiable at 0.

(ii) Let $f(x) = \sqrt{x}$ on $[0, \infty)$. Then $D_R f(0)$ does not exist (we sometimes say $D_R f(0) = +\infty$), and $D_L f(0)$ is undefined since f is undefined to the left of 0. So f is neither left or right differentiable at 0.

(iii) Let $f(x) = \sqrt{x}$ for $x \geq 0$ and $f(x) = 0$ for $x < 0$. Then $D_R f(0)$ does not exist and $D_L f(0) = 0$. So f is left differentiable but not right differentiable at 0.

(iv) Let $f(x) = x \sin \frac{1}{x}$ for $x \neq 0$ and $f(0) = 0$. Then neither $D_R f(0)$ nor $D_L f(0)$ exists. So f is neither left or right differentiable at 0.

All these examples are continuous. We have the following slight generalization of (), whose proof is nearly identical and is left to the reader. Recall the definition of left and right continuity ().

V.4.1.4. PROPOSITION. (i) Let f be a real-valued function on an interval $[x_0, b)$. If f is right differentiable at x_0, then f is right continuous at x_0.
(ii) Let f be a real-valued function on an interval $(a, x_0]$. If f is left differentiable at x_0, then f is left continuous at x_0.

Endpoint Differentiability and Differentiability on an Interval

If x_0 is an endpoint of the domain of a function, it does not make sense to say that f is differentiable at x_0. But one-sided differentiability does make sense, and is called *endpoint differentiability* in this context. So we may make the following definition in analogy with ():

V.4.1.5. DEFINITION. Let f be a real-valued function on an interval $[a, b]$. Then f is *differentiable on* $[a, b]$ if it is differentiable at all points of (a, b), right differentiable at a, and left differentiable at b. Differentiability on an interval of the form $[a, b)$ or $(a, b]$ is defined analogously.

V.4.2. Dini Derivatives

A further generalization is very useful. Recall the definition of lim sup and lim inf from ().

V.4.2.1. DEFINITION. (i) Let f be a real-valued function on the interval $[x_0, b)$. Set

$$D^+f(x_0) = \limsup_{h\to 0+} \frac{f(x_0+h)-f(x_0)}{h} = \limsup_{x\to x_0+} \frac{f(x)-f(x_0)}{x-x_0}$$

$$D_+f(x_0) = \liminf_{h\to 0+} \frac{f(x_0+h)-f(x_0)}{h} = \liminf_{x\to x_0+} \frac{f(x)-f(x_0)}{x-x_0}$$

(as extended real numbers). $D^+f(x_0)$ and $D_+f(x_0)$ are the *upper and lower right Dini derivatives* of f at x_0.
(i) Let f be a real-valued function on the interval $(a, x_0]$. Set

$$D^-f(x_0) = \limsup_{h\to 0-} \frac{f(x_0+h)-f(x_0)}{h} = \limsup_{x\to x_0-} \frac{f(x)-f(x_0)}{x-x_0}$$

$$D_-f(x_0) = \liminf_{h\to 0-} \frac{f(x_0+h)-f(x_0)}{h} = \liminf_{x\to x_0-} \frac{f(x)-f(x_0)}{x-x_0}$$

(as extended real numbers). $D^-f(x_0)$ and $D_-f(x_0)$ are the *upper and lower left Dini derivatives* of f at x_0.

V.4.2.2. Note that the Dini derivatives are always defined, provided only that the function is defined on an interval to the appropriate side of x_0. We clearly always have $D_+f(x_0) \le D^+f(x_0)$ and $D_-f(x_0) \le D^-f(x_0)$.

We then have an obvious characterization of left and right differentiability (cf. ()):

V.4.2.3. PROPOSITION. (i) Let f be a real-valued function on an interval $[x_0, b)$. Then f is right differentiable at x_0 if and only if $D^+f(x_0)$ and $D_+f(x_0)$ are equal and finite. We then have

$$D_Rf(x_0) = D^+f(x_0) = D_+f(x_0) \ .$$

(ii) Let f be a real-valued function on an interval $(a, x_0]$. Then f is left differentiable at x_0 if and only if $D^-f(x_0)$ and $D_-f(x_0)$ are equal and finite. We then have

$$D_Lf(x_0) = D^-f(x_0) = D_-f(x_0) \ .$$

(iii) Let f be a real-valued function on an interval (a, b), and $x_0 \in (a, b)$. Then f is differentiable at x_0 if and only if all four Dini derivatives at x_0 are equal and finite. We then have

$$f'(x_0) = D^+f(x_0) = D_+f(x_0) = D^-f(x_0) = D_-f(x_0) \ .$$

V.4.2.4. EXAMPLES. (i) Let $f(x) = |x|$. Then $D^-f(0) = D_-f(0) = -1$ and $D^+f(0) = D_+f(x) = 1$.
(ii) Let $f(x) = \sqrt{x}$ on $[0, \infty)$. Then $D^+f(0) = D_+f(0) = +\infty$, and $D^-f(0)$ and $D_-f(0)$ are undefined since f is undefined to the left of 0.
(iii) Let $f(x) = \sqrt{|x|}$. Then $D^+f(0) = D_+f(0) = +\infty$ and $D^-f(0) = D_-f(0) = -\infty$.
(iv) Let $f(x) = x \sin \frac{1}{x}$ for $x \neq 0$ and $f(0) = 0$. Then $D^+f(0) = D^-f(0) = 1$ and $D_+f(0) = D_-f(0) = -1$.
(v) Let $f(x) = x \sin \frac{1}{x}$ for $x > 0$ and $f(x) = 0$ for $x \leq 0$. Then $D^+f(0) = 1$, $D_+f(0) = -1$, and $D^-f(0) = D_-f(0) = 0$.
(vi) Let $f(x) = \sqrt{x} \sin \frac{1}{x}$ for $x \neq 0$ and $f(0) = 0$. Then $D^+f(0) = D^-f(0) = +\infty$ and $D_+f(0) = D_-f(0) = -\infty$.
(vii) Let $f(x) = x^{1/3}$. Then $D^+f(0) = D_+f(0) = D^-f(0) = D_-f(0) = +\infty$.

We have a version of () also for Dini derivatives:

V.4.2.5. PROPOSITION. (i) Let f be a real-valued function on an interval $[x_0, b)$. If f is not right continuous at x_0, then at least one right Dini derivative at x_0 is infinite.
(ii) Let f be a real-valued function on an interval $(a, x_0]$. If f is not left continuous at x_0, then at least one left Dini derivative at x_0 is infinite.

PROOF: The proofs of both (i) and (ii) consist of four nearly identical cases. We do only one of the cases for (i), and leave the rest of the cases to the reader.

In (i), if f is not right continuous at x_0, then either $f(x_0) \neq \liminf_{x \to x_0+} f(x)$ or $f(x_0) \neq \limsup_{x \to x_0+} f(x)$ (or both). Suppose $f(x_0) < \liminf_{x \to x_0+} f(x)$. Then

$$\liminf_{x \to x_0+} [f(x) - f(x_0)] > 0$$

and, since $\lim_{x\to x_0+} \dfrac{1}{x-x_0} = +\infty$, by () we have

$$D_+f(x_0) = \liminf_{x\to x_0+} \frac{f(x)-f(x_0)}{x-x_0} = +\infty \ .$$

V.4.2.6. Note that the converse is not true by Examples V.4.2.4.(iii),(v),(vi). In fact, there are (many!) continuous functions f on $\mathbb{R}$ for which $D^+f(x) = D^-f(x) = +\infty$ and $D_+f(x) = D_-f(x) = -\infty$ for *every* $x \in \mathbb{R}$ ().

Local Extrema

Here is a general version of V.3.6.3.. The proof is essentially the same.

V.4.2.7. PROPOSITION. Let f be a function on an interval (a,b), and $x_0 \in (a,b)$.
(i) If f has a local maximum at x_0, then $D_-f(x_0) \geq 0$ and $D^+f(x_0) \leq 0$.
(ii) If f has a local minimum at x_0, then $D^-f(x_0) \leq 0$ and $D_+f(x_0) \geq 0$.

This result also applies when x_0 is an endpoint of an interval in the domain of f, except that the Dini derivatives on the outside of the interval are not defined (or not relevant):

V.4.2.8. PROPOSITION. Let f be a real-valued function on $[a,b]$. Then
(i) If f has an endpoint maximum at a, then $D^+f(a) \leq 0$.
(ii) If f has an endpoint minimum at a, then $D_+f(a) \geq 0$.
(iii) If f has an endpoint maximum at b, then $D_-f(a) \geq 0$.
(iv) If f has an endpoint minimum at b, then $D^-f(a) \leq 0$.

V.4.2.9. Converses of these statements are, of course, false; the counterexamples in the differentiable case, such as $f(x) = x^3$ at 0, are also counterexamples here. But there is a version of the First Derivative Test in this generality ().

V.4.2.10. At a single point, there may be no relation between the left and right Dini derivatives. However, at "most" points both upper Dini derivatives are greater than both lower derivatives:

V.4.2.11. THEOREM. Let f be a real-valued function on an open interval I. Set

$$A = \{x \in I : D^- f(x) < D_+ f(x)\}$$

$$B = \{x \in I : D^+ f(x) < D_- f(x)\} \ .$$

Then A and B are countable.

PROOF: We prove that A is countable; the proof for B is essentially identical. Let $x \in A$. Choose $r_x \in \mathbb{Q}$ with $D^- f(x) < r_x < D_+ f(x)$, and then fix $s_x, t_x \in \mathbb{Q} \cap I$ with $s_x < x < t_x$ and

$$\frac{f(y) - f(x)}{y - x} < r_x \text{ for all } y, s_x < y < x$$

$$\frac{f(y) - f(x)}{y - x} > r_x \text{ for all } y, x < y < t_x \ .$$

Then, for any $y \neq x$ with $s_x < y < t_x$, we have

$$f(y) - f(x) > r_x(y - x) \ .$$

Define $\phi : A \to \mathbb{Q}^3$ by $\phi(x) = (r_x, s_x, t_x)$. We show that ϕ is one-to-one; then, since $\mathbb{Q}^3$ is countable, it will follow that A is countable. Suppose $\phi(x) = \phi(z)$ for $x, z \in A$, $x \neq z$. Since $s_x = s_z < z < t_z = t_x$, we have

$$f(z) - f(x) > r_x(z - x) \ .$$

Similarly, since $s_z < x < t_z$, we have

$$f(x) - f(z) > r_z(x - z) \ .$$

But $r_x = r_z$, a contradiction. 👍

We get the following immediate consequence, which is not so obvious geometrically:

V.4.2.12. COROLLARY. Let f be a function on an interval I. Then the set of $x \in I$ for which $D_L f(x)$ and $D_R f(x)$ are both defined (even allowing infinite values) but unequal is countable. In particular, if f is left and right differentiable everywhere in I, then f is differentiable at all but countably many points of I.

A far deeper result is the remarkable theorem proved successively for larger classes of functions by A. DENJOY, GRACE CHISHOLM YOUNG, and S. SAKS:

V.4.2.13. THEOREM. [DENJOY-YOUNG-SAKS] Let f be an arbitrary real-valued function on an interval $[a, b]$. Then for almost all $x \in [a, b]$, one of the following four conditions holds:

(1) f is differentiable at x.

(2) $D^- f(x) = D_+ f(x) \in \mathbb{R}$, $D_- f(x) = -\infty$, and $D^+ f(x) = +\infty$.

(3) $D^+ f(x) = D_- f(x) \in \mathbb{R}$, $D_+ f(x) = -\infty$, and $D^- f(x) = +\infty$.

(4) $D_-f(x) = D_+f(x) = -\infty$ and $D^-f(x) = D^+f(x) = +\infty$.

In particular, for almost all $x \in [a,b]$, either f is differentiable at x or else $\max(D^-f(x), D^+f(x)) = +\infty$ and $\min(D_-f(x), D_+f(x)) = -\infty$.

If f is measurable, then for almost all x, either condition (1) or condition (4) holds (i.e. conditions (2) and (3) hold only on sets of measure zero).

The proof uses some sophisticated machinery, and will be given in (). This result is closely related to a result about approximate tangents to rectifiable sets in geometric measure theory [Mor09, 3.12].

V.4.3. Strong Derivatives

V.4.4. Symmetric First and Second Derivatives

V.4.5. Approximate and Weak Derivatives

V.4.6. Exercises

V.4.6.1. Define a function $f : [0,1) \to [0,1)$ as follows. If $x \in [0,1)$, write

$$x = .d_1d_2d_3\cdots$$

in its decimal expansion not ending in an infinite string of 9's. Set

$$f(x) = .0d_10d_20d_3\cdots\ .$$

(a) Show that f is a strictly increasing function.

(b) Show that f is right continuous everywhere.

(c) Show that f is left continuous except at the decadent rationals ().

(d) Show that $D_Rf(x)$ exists and equals 0 everywhere.

V.5. Exponential and Trigonometric Functions

Anyone who has studied mathematics through calculus knows that exponential and trigonometric functions are of great importance, both theoretical and practical. However, the theoretical subtleties involved in properly defining these functions and establishing their properties are often underappreciated. Since the functions are so important and useful, they are usually introduced in the mathematics curriculum before the necessary tools (from calculus) for a proper treatment are available; and by the time the right tools are discussed, the functions are so familiar that they are often taken for granted. (These comments also apply to the historical development of exponential and trigonometric functions.)

A careful and rigorous treatment of exponential and/or trigonometric functions can be done in several ways. The two most common methods are: (1) defining one of the inverse functions (log or arcsin) as the antiderivative of a familiar function, or (2) using infinite series. In the case of exponential functions, there is a third approach which proceeds directly from algebraic rules of exponents. This third approach is the one we will take for exponential and logarithm functions in this section; see Exercise () for the first approach via integrals, and () for the infinite series approach. Our treatment of trigonometric functions will follow approach (1) (see () for the infinite series approach here).

V.5.1. Rational Exponents

V.5.1.1. Recall that if $x \in \mathbb{R}$ and $n \in \mathbb{N}$, then $x^n = x \cdot x \cdots x$ (n times). If $x \neq 0$, extend this to $n \in \mathbb{Z}$ by $x^0 = 1$ and $x^{-n} = (x^{-1})^n = (x^n)^{-1}$. The usual rules of exponents hold: $x^{m+n} = x^m x^n$, $x^{m-n} = \frac{x^m}{x^n}$, $(x^m)^n = (x^n)^m = x^{mn}$, $(xy)^n = x^n y^n$ for all $x, y \neq 0$ and all $m, n \in \mathbb{Z}$.

If $n \in \mathbb{N}$ and $x > 1$, then $x^n > x > 1$. So if $n \in \mathbb{N}$ and $0 < x < y$, then $x^n < x^n \left(\frac{y}{x}\right)^n = \left(x \cdot \frac{y}{x}\right)^n = y^n$, so $f(x) = x^n$ is strictly increasing on $(0, \infty)$. Similarly, if $n \in \mathbb{Z}$, $n < 0$, then $f(x) = x^n = (x^{-1})^{-n}$ is strictly decreasing on $(0, \infty)$. For any $n \in \mathbb{Z}$, $f(x) = x^n$ is continuous and even differentiable on $(0, \infty)$, and its range is unbounded above and below in $(0, \infty)$ if $n \neq 0$.

Thus, by the IVT, if $n \in \mathbb{Z}$, $n \neq 0$, then the range of $f(x) = x^n$ is all of $(0, \infty)$, and by () f has a continuous inverse function f^{-1} which also maps $(0, \infty)$ onto $(0, \infty)$, and f^{-1} is strictly increasing if $n > 0$, strictly decreasing if $n < 0$. If $x > 0$, write $x^{1/n}$ for $f^{-1}(x)$. If $n > 0$, the definition of $x^{1/n}$ can also be extended to $x = 0$ by setting $0^{1/n} = 0$, and if n is odd, to $x < 0$ by $x^{1/n} = -(-x)^{1/n}$; the extended function is continuous on its domain.

V.5.1.2. Proposition. If $p, q \in \mathbb{Z}$, $q \neq 0$, for $x > 0$ define $x^{p/q} = (x^p)^{1/q}$. We then have:

(i) For $p, q \in \mathbb{Z}$, $q \neq 0$, and $x > 0$, $[(x^p)^{1/q}]^q = x^p = [(x^{1/q})^q]^p = [(x^{1/q})^p]^q$, so $(x^p)^{1/q} = (x^{1/q})^p$ since $f(x) = x^q$ is one-to-one.

(ii) Similarly, if $p, q, r, s \in \mathbb{Z}$, $q, s \neq 0$, and $x > 0$, then $[(x^{p/q})^{r/s}]^{qs} = x^{pr} = [(x^{r/s})^{p/q}]^{qs}$, so $(x^{p/q})^{r/s} = (x^{r/s})^{p/q} = x^{pr/qs}$. In particular, $x^{ps/qs} = x^{p/q}$, and hence x^t is well defined for any $t \in \mathbb{Q}$.

(iii) If $r, s \in \mathbb{Q}$, $x, y \in (0, \infty)$, we have $(x^r)^s = x^{rs}$, $x^{r+s} = x^r x^s$, $x^{r-s} = \frac{x^r}{x^s}$, $(xy)^r = x^r y^r$.

(iv) If $r \in \mathbb{Q}$, $r \neq 0$, the function $f(x) = x^r$ is a composition of two strictly monotone continuous functions from $(0, \infty)$ onto $(0, \infty)$, hence strictly monotone and continuous, strictly increasing if $r > 0$ and strictly decreasing if $r < 0$.

(v) $1^r = 1$ for all $r \in \mathbb{Q}$, so if $x > 1$, then $x^r > 1$ for $r > 0$ and $0 < x^r < 1$ for $r < 0$.

V.5.1.3. PROPOSITION. If $r \in \mathbb{Q}$, then $f(x) = x^r$ is differentiable on $(0, \infty)$, and $f'(x) = rx^{r-1}$ on $(0, \infty)$.

PROOF: If $n \in \mathbb{N}$, then $\frac{d}{dx}(x^n) = nx^{n-1}$ (**??**). The formula also obviously holds if $n = 0$. If $n \in \mathbb{N}$, then using the Quotient Rule x^{-n} is differentiable on $(0, \infty)$ and

$$\frac{d}{dx}\left(x^{-n}\right) = \frac{d}{dx}\left(\frac{1}{x^n}\right) = \frac{0 - nx^{n-1}}{x^{2n}} = -nx^{-n-1}$$

so the formula holds for all $r \in \mathbb{Z}$. If $q \in \mathbb{Z}$, $q \neq 0$, then by the Inverse Function Theorem (**??**) $x^{1/q}$ is differentiable on $(0, \infty)$ and

$$\frac{d}{dx}\left(x^{1/q}\right) = \frac{1}{q(x^{1/q})^{q-1}} = \frac{1}{qx^{1-1/q}} = \frac{1}{q}x^{(1/q)-1}$$

If $r = \frac{p}{q}$, then by the Chain Rule x^r is differentiable on $(0, \infty)$ and

$$\frac{d}{dx}\left(x^{p/q}\right) = \frac{d}{dx}\left((x^p)^{1/q}\right) = \frac{1}{q}(x^p)^{(1/q)-1} \cdot px^{p-1} = \frac{p}{q}x^{[(p/q)-p]+[p-1]} = \frac{p}{q}x^{(p/q)-1}.$$

V.5.2. Irrational Exponents and Exponential Functions

Now fix $b > 1$ and look at the function $f(x) = b^x$ with domain $\mathbb{Q}$.

V.5.2.1. PROPOSITION. b^x is strictly increasing.

PROOF: If $x, y \in \mathbb{Q}$ with $x < y$, then $b^y = b^{x+(y-x)} = b^x b^{y-x}$, and $b^{y-x} > 1$ by (v).

V.5.2.2. PROPOSITION. $\{b^n : n \in \mathbb{N}\}$ is unbounded.

PROOF: If $S = \{b^n : n \in \mathbb{N}\}$ is bounded, let $a = \sup(S)$. Since $b > 1$, $\frac{a}{b} < a$, so there is an $n \in \mathbb{N}$ with $b^n > \frac{a}{b}$. Then $b^{n+1} > a$, a contradiction.

V.5.2.3. COROLLARY. $\lim_{n\to\infty} b^{1/n} = 1$.

PROOF: The sequence $(b^{1/n})$ is decreasing and bounded below by 1, hence $\lim_{n\to\infty} b^{1/n}$ exists and equals $c := \inf_{n\in\mathbb{N}} b^{1/n}$. Then $c \geq 1$ and $c^n \leq b$ for all $n \in \mathbb{N}$, so $c = 1$ by V.5.2.2..

V.5.2.4. PROPOSITION. If $a \in \mathbb{Q}$, then the function $f(x) = b^x$ is uniformly continuous on $(-\infty, a) \cap \mathbb{Q}$.

PROOF: If $\epsilon > 0$, then there is an $n \in \mathbb{N}$ with $b^{1/n} - 1 < b^{-a}\epsilon$. Set $\delta(\epsilon) = 1/n$. Then, if $x, y \in \mathbb{Q}$, $x < y < a$, $y - x < \delta(\epsilon)$, we have

$$0 < b^y - b^x = b^x(b^{y-x} - 1) < b^a(b^{y-x} - 1) < \epsilon.$$

V.5.2.5. COROLLARY. The function $f(x) = b^x$ ($x \in \mathbb{Q}$) extends to a continuous strictly increasing function on all of $\mathbb{R}$, also denoted b^x, with range $(0, \infty)$.

PROOF: The extension is guaranteed by **??**, and is continuous and increasing. To see that it is strictly increasing, let $x, y \in \mathbb{R}$, $x < y$, and let $r, s \in \mathbb{Q}$, $x < r < s < y$. Then $b^x \leq b^r < b^s \leq b^y$. The range is an interval (**??**) which must be all of $(0, \infty)$ by V.5.2.2..

V.5.2.6. DEFINITION. The function $f(x) = b^x$ thus has a continuous strictly increasing inverse function f^{-1} with domain $(0, \infty)$ and range $\mathbb{R}$. The number $f^{-1}(x)$ is called the *logarithm of x with base b*, denoted $\log_b(x)$.

V.5.2.7. PROPOSITION. The following laws of exponents and logarithms hold: if $x, y \in \mathbb{R}$ and $b, c > 1$, then $b^{x+y} = b^x b^y$, $b^{x-y} = \frac{b^x}{b^y}$, $b^{xy} = (b^x)^y$, $(bc)^x = b^x c^x$; if $s, t > 0$, $r \in \mathbb{R}$, then $\log_b(st) = \log_b(s) + \log_b(t)$, $\log_b(s/t) = \log_b(s) - \log_b(t)$, $\log_b(s^r) = r \log_b(s)$. If $c > 1$, then $\log_b(s) = \log_c(s) \log_b(c)$. In particular, $\log_b 1 = 0$ and $\log_b(c) = \frac{1}{\log_c(b)}$.

PROOF: The laws of exponents have already been established for $x, y \in \mathbb{Q}$. They follow for general x, y by continuity: for example, if (x_n) and (y_n) are sequences of rational numbers with $x_n \to x$ and $y_n \to y$, then $b^{x_n} \to b^x$, $b^{y_n} \to b^y$, $b^{x_n + y_n} \to b^{x+y}$, and $b^{x_n} b^{y_n} \to b^x b^y$ by continuity of b^x and standard limit theorems. The laws of logarithms follow from the laws of exponents by setting $x = \log_b(s)$ and $y = \log_b(t)$, so $s = b^x$ and $t = b^y$: for example, $st = b^x b^y = b^{x+y}$, so $\log_b(st) = x + y$. For the last formula, if $z = \log_c(s)$, then $s = c^z = (b^{\log_b c})^z = b^{z \log_b c}$, so $\log_b(s) = z \log_b c$.

If $0 < b < 1$ and $x \in \mathbb{R}$, we can define $b^x = (b^{-1})^{-x}$. Then b^x is strictly decreasing, as is the inverse function $\log_b(x)$. The same rules of exponents and logarithms hold. We can also define $1^x = 1$ for all x.

An important property of the exponential function b^x ($b > 0$, $b \neq 1$) is that it is strictly convex (**??**):

V.5.2.8. LEMMA. If $b > 1$, $k \in \mathbb{R}$, and $x > 0$, then $b^{k+2x} - b^k > 2(b^{k+x} - b^k)$.

PROOF:

$$b^{k+2x} - b^k = b^k(b^{2x} - 1) = b^k(b^x + 1)(b^x - 1) = (b^x + 1)(b^{k+x} - b^k).$$

V.5.2.9. PROPOSITION. If $b > 1$ and $x, y, z \in \mathbb{R}$ with $z < y < x$, then

$$\frac{b^y - b^z}{y - z} < \frac{b^x - b^z}{x - z} < \frac{b^x - b^y}{x - y}.$$

(It follows that $f(x) = b^x$ is a strictly convex function.)

PROOF: Lemma V.5.2.8. means that on any interval $[x_1, x_2]$ with midpoint c, the point (c, b^c) lies below the line between (x_1, b^{x_1}) and (x_2, b^{x_2}). Thus the first inequality follows from repeated applications of V.5.2.8. if $y - z$ is a dyadic rational multiple of $x - z$ (see Exercise 1). By continuity the first inequality holds with a $\leq$ for all x, y, z. To show that the strict inequality holds in general, choose w with $y < w < x$ and $y - z$ a dyadic rational multiple of $w - z$. Then

$$\frac{b^y - b^z}{y - z} < \frac{b^w - b^z}{w - z} \leq \frac{b^x - b^z}{x - z}.$$

For the second inequality, suppose that $\frac{b^x - b^y}{x - y} \leq \frac{b^x - b^z}{x - z}$. Then

$$b^x - b^z = (y - z)\frac{b^y - b^z}{y - z} + (x - y)\frac{b^x - b^y}{x - y} < (y - z)\frac{b^x - b^z}{x - z} + (x - y)\frac{b^x - b^z}{x - z} = b^x - b^z$$

which is a contradiction. 👍

V.5.2.10. COROLLARY. Let $b > 1$, and $0 < z < y < x$. Then

$$\frac{\log_b x - \log_b y}{x - y} < \frac{\log_b x - \log_b z}{x - z} < \frac{\log_b y - \log_b z}{y - z}.$$

Note that V.5.2.9. and V.5.2.10. also hold for $0 < b < 1$. For V.5.2.9.,

$$\frac{(b^{-1})^{-y} - (b^{-1})^{-x}}{-y + x} < \frac{(b^{-1})^{-z} - (b^{-1})^{-x}}{-z + x} < \frac{(b^{-1})^{-z} - (b^{-1})^{-y}}{-z + y}.$$

V.5.3. The Number e

V.5.3.1. LEMMA. If $x > 0$ and $k > 1$, then $(1 + x)^k > 1 + kx$.

PROOF: Fix $k > 1$ rational, and let $f(x) = (1 + x)^k - 1 - kx$ for $x \geq 0$. Then f is differentiable for $x \geq 0$, $f(0) = 0$, and $f'(x) = k(1 + x)^{k-1} - k = k[(1 + x)^{k-1} - 1] > 0$ for $x > 0$. The formula thus holds for k rational, and thus for k irrational with $\geq$ by continuity. To see that the strict inequality holds for general $k > 1$, choose rational r with $1 < r < k$. Then

$$(1 + x)^k = [(1 + x)^r]^{k/r} > [1 + rx]^{k/r} \geq 1 + \frac{k}{r}rx.$$

👍

V.5.3.2. COROLLARY. The function $g(x) = (1+x)^{1/x}$ is decreasing for $x > 0$.

PROOF: Let $x > 0$ and $k > 1$. Then $(1+kx)^{1/kx} < ([1+x]^k)^{1/kx} = (1+x)^{1/x}$. 👍

Thus, to show that $\lim_{x\to 0+}(1+x)^{1/x}$ exists, it suffices to show that $(1+x)^{1/x}$ is bounded for $x > 0$.

V.5.3.3. THEOREM. Let $h(x) = (1+x)^{1+1/x}$ for $x > 0$, and $f(y) = (1-y)^{-1/y} = \frac{1}{(1-y)^{1/y}}$ for $0 < y < 1$. Then

(i) f and h are increasing.

(ii) $g(x) < h(z) = f\left(\frac{z}{1+z}\right)$ for all $x, z > 0$.

(iii) $\lim_{x\to 0+} f(x)$, $\lim_{x\to 0+} g(x)$ and $\lim_{x\to 0+} h(x)$ exist and are equal.

V.5.3.4. LEMMA. Let $b > 1$, $x > 0$, and $0 < y < 1$. Then

$$\log_b([1+x]^{1/x}) = \frac{\log_b(1+x)}{x} < -\frac{\log_b(1-y)}{y} = \log_b\left(\left[\frac{1}{1-y}\right]^{1/y}\right).$$

PROOF: Apply V.5.2.10. to $1-y, 1, 1+x$. 👍

We now prove Theorem V.5.3.3..
PROOF: For (i) and (ii), fix $b > 1$ and for $z > 0$ set $y = \frac{z}{1+z}$. Then $0 < y < 1$ and $z = \frac{1}{1-y} - 1$, and z increases from 0 to $+\infty$ as y increases from 0 to 1. By V.5.2.10., $-\frac{\log_b(1-y)}{y} = \log_b\left(\left[\frac{1}{1-y}\right]^{1/y}\right)$ increases in y for $0 < y < 1$ [if $0 < y_1 < y_2 < 1$, apply V.5.2.10. to $1-y_2, 1-y_1, 1$], so $\log_b([1+z]^{\frac{1+z}{z}})$ increases in z for $z > 0$, proving (i), and V.5.3.4. with y converted to z gives (ii).

Thus $g(x)$ is increasing and bounded above as $x \to 0+$, and $f(x)$ and $h(x)$ are decreasing and bounded below, so $\lim_{x\to 0+} g(x) = \sup_{x>0} g(x)$ and

$$\lim_{x\to 0+} f(x) = \lim_{x\to 0+} h(x) = \inf_{x>0} h(x) = \inf_{x>0} f(x)$$

exist; call the limits d and e respectively. Then $2 = (1+1)^1 < d \le e$, and $\lim_{x\to 0+} \frac{h(x)}{g(x)} = \frac{e}{d}$. But $\frac{h(x)}{g(x)} = 1+x$, so $\lim_{x\to 0+} \frac{h(x)}{g(x)} = 1 = \frac{e}{d}$, $d = e$. 👍

V.5.3.5. DEFINITION. The number e is the limit $\lim_{x\to 0+}(1+x)^{1/x} = \lim_{x\to+\infty}\left(1+\frac{1}{x}\right)^x = \lim_{x\to+\infty}\left(1-\frac{1}{x}\right)^{-x}$.

The number e is one of the most important constants in mathematics, comparable in importance to π.

V.5.3.6. COROLLARY. $e > (1+1)^1 = 2 > 1$, so $f(x) = e^x$ is strictly increasing and continuous, and its inverse function $\ln x = \log_e x$ is continuous.

The function $\ln x$ is called the *natural logarithm function*, and mathematicians usually write it $\log x$.

V.5.3.7. We can of course get better estimates of the numerical value of e using V.5.3.3. for small x: for example, if $x = .01$, we get $2.704 < 1.01^{100} < e < 1.01^{101} < 2.732$. The average of 1.01^{100} and 1.01^{101}, $2.71833\cdots$, is an even better estimate (the geometric mean, $2.71830\cdots$, is better yet). The exact numerical value of e is $2.718281828\cdots$ (the decimal does not continue to repeat; e is an irrational number, in fact transcendental – see III.9.3.1.). There are more efficient ways to compute e using infinite series; see V.5.5.3.–V.5.5.5..

V.5.4. Derivatives of Exponential and Logarithm Functions

V.5.4.1. THEOREM. The function $f(x) = e^x$ is differentiable, and $f'(x) = e^x$.

V.5.4.2. LEMMA. If $f(x) = e^x$, then f is differentiable at 0 and $f'(0) = \lim_{h\to 0} \frac{e^h-1}{h} = 1$.

PROOF: Let $x = e^h - 1$. Then $h = \ln(1+x)$ and $x \to 0$ as $h \to 0$ (i.e. $\lim_{h\to 0} e^h - 1 = 0$ and $\lim_{x\to 0} \ln(1+x) = 0$ by continuity of e^x and $\ln x$), and $x > 0$ if and only if $h > 0$. Thus

$$\lim_{h\to 0+} \frac{e^h-1}{h} = \lim_{x\to 0+} \frac{x}{\ln(1+x)} = \lim_{x\to 0+} \frac{1}{\frac{1}{x}\ln(1+x)} = \lim_{x\to 0+} \frac{1}{\ln\left([1+x]^{1/x}\right)} = \frac{1}{\ln e} = 1$$

since $\lim_{x\to 0+}[1+x]^{1/x} = e$ and $\ln x$ is continuous at e. We also have

$$\lim_{h\to 0-} \frac{e^h-1}{h} = \lim_{h\to 0+} \frac{e^{-h}-1}{-h} = \lim_{h\to 0+} \frac{e^{-h}(1-e^h)}{-h} = \left[\lim_{h\to 0+} e^{-h}\right]\left[\lim_{h\to 0+} \frac{e^h-1}{h}\right] = 1$$

We now prove Theorem V.5.4.1..
PROOF: Fix x. Then

$$f'(x) = \lim_{h\to 0} \frac{e^{x+h}-e^x}{h} = \lim_{h\to 0} \frac{e^x e^h - e^x}{h} = \lim_{h\to 0} \frac{e^x(e^h-1)}{h} = e^x \lim_{h\to 0} \frac{e^h-1}{h} = e^x$$

V.5.4.3. COROLLARY. Let $b > 0$, and $f(x) = b^x$. Then f is differentiable everywhere and $f'(x) = (\ln b)b^x$ for all x.

PROOF: Since $b^x = e^{x\ln b}$, the result follows from V.5.4.1. and the Chain Rule. 

V.5.4.4. COROLLARY. If $b > 0$, $b \neq 1$, then $f(x) = \log_b(x)$ is differentiable on $(0, \infty)$, and $\frac{d}{dx}(\log_b(x)) = \frac{1}{x \ln b}$. In particular, $\frac{d}{dx}(\ln x) = \frac{1}{x}$.

PROOF: This follows immediately from V.5.4.3. and the Inverse Function Theorem:

$$\frac{d}{dx}(\log_b x) = \frac{1}{(\ln b) b^{\log_b x}} = \frac{1}{x \ln b}.$$

V.5.4.5. COROLLARY. For all $r \in \mathbb{R}$, the function $f(x) = x^r$ is differentiable (hence continuous) on $(0, \infty)$, and the formula $\frac{d}{dx}(x^r) = rx^{r-1}$ holds on $(0, \infty)$.

PROOF: Since $x^r = e^{r \ln x}$ for $x > 0$, f is differentiable by V.5.4.1., V.5.4.4., and the Chain Rule, and we have

$$\frac{d}{dx}(x^r) = \frac{d}{dx}\left(e^{r \ln x}\right) = e^{r \ln x} \frac{r}{x} = x^r \frac{r}{x} = rx^{r-1}.$$

V.5.5. Exercises

V.5.5.1. (a) Write out the details of the proof of V.5.1.2.(ii).
(b) Prove the rules of exponents in V.5.1.2.(iii), using arguments similar to those in (i). (Note that the first rule has already been proved in (ii).)

V.5.5.2. (a) Prove the assertion in the first sentence in the proof of V.5.2.9..
(b) Prove the assertion in the second sentence of the proof of V.5.2.9. by induction, using the statement $P(n)$: "For every $u, v, w \in \mathbb{R}$ with $w < v < u$ and $\frac{v-w}{u-w} = \frac{k}{2^n}$ for some $k \in \mathbb{N}$, $k < 2^n$, $\frac{b^v - b^w}{v-w} < \frac{b^u - b^w}{u-w}$."
To prove $P(n+1)$ for a set u, v, w, apply $P(n)$ to either the first or second half of the interval $[w, u]$ depending where v is.

V.5.5.3. Here is an alternate approach to the definition of e (cf. [?, III.4].) Let $x_n = \left(1 + \frac{1}{n}\right)^n$.
(a) Using the Binomial Theorem, show that

$$x_n = 1 + 1 + \frac{1}{2!}\left(1 - \frac{1}{n}\right) + \frac{1}{3!}\left(1 - \frac{1}{n}\right)\left(1 - \frac{2}{n}\right) + \cdots +$$

$$+ \frac{1}{k!}\left(1 - \frac{1}{n}\right)\left(1 - \frac{2}{n}\right)\cdots\left(1 - \frac{k-1}{n}\right) + \cdots + \frac{1}{n!}\left(1 - \frac{1}{n}\right)\left(1 - \frac{2}{n}\right)\cdots\left(1 - \frac{n-1}{n}\right)$$

(b) Using (a), show that $x_n < x_{n+1}$ for any $n \in \mathbb{N}$.
(c) Let $y_n = \sum_{k=0}^{n} \frac{1}{k!}$. Show that $x_n < y_n$ for all n.
(d) Since $k! > 2^{k-1}$ for all $k > 2$, show that $y_n < 2 + \sum_{k=2}^{n} \frac{1}{2^{k-1}} < 3$ for $n > 2$. Thus the sequence (x_n) is a bounded increasing sequence, hence convergent. Call the limit e. Show that $2 < e < 3$.

V.5.5.4. Use the notation of V.5.5.3..
(a) If $1 < k < n$, set

$$z_{k,n} = 1 + 1 + \frac{1}{2!}\left(1 - \frac{1}{n}\right) + \frac{1}{3!}\left(1 - \frac{1}{n}\right)\left(1 - \frac{2}{n}\right) + \cdots +$$

$$+ \frac{1}{k!}\left(1 - \frac{1}{n}\right)\left(1 - \frac{2}{n}\right)\cdots\left(1 - \frac{k-1}{n}\right)$$

Show that $z_{k,n} < x_n$, so $z_{k,n} < e$.
(b) Fix k. Show $\lim_{n\to\infty} z_{k,n} = y_k$. Conclude that $y_k \le e$ for all k. (In fact, since $y_k < y_{k+1} \le e$, we have $y_k < e$ for all k.)
(c) Since $x_k < y_k < e$ for all k, and $\lim_{k\to\infty} x_k = e$, we have $\lim_{k\to\infty} y_k = e$.

V.5.5.5. Use the notation of V.5.5.3.–V.5.5.4.. The sequence (y_n) converges to e fairly rapidly (unlike (x_n), which converges rather slowly):
(a) For each n and each $m > 1$, show that

$$y_{n+m} - y_n = \frac{1}{(n+1)!}\left(1 + \sum_{k=2}^{m} \frac{1}{(n+2)\cdots(n+k)}\right)$$

$$< \frac{1}{(n+1)!}\left(1 + \sum_{k=2}^{\infty} \frac{1}{(n+2)\cdots(n+k)}\right)$$

and thus, since $\lim_{m\to\infty} y_{n+m} = e$, $e - y_n \le \frac{1}{(n+1)!}\left(1 + \sum_{k=2}^{\infty} \frac{1}{(n+2)\cdots(n+k)}\right)$.
(b) By comparing terms and using $\sum_{k=0}^{\infty} r^k = \frac{1}{1-r}$ for $|r| < 1$ (),

$$e - y_n \le \frac{1}{(n+1)!}\left(1 + \sum_{k=2}^{\infty} \frac{1}{(n+2)\cdots(n+k)}\right)$$

$$< \frac{1}{(n+1)!}\sum_{k=0}^{\infty} \frac{1}{(n+2)^k} = \frac{1}{(n+1)!}\frac{n+2}{n+1} = \frac{1}{n!}\frac{n+2}{(n+1)^2}$$

Thus, for example, $e - y_{10} < \frac{12}{10!\cdot 11^2} \approx 2.7 \times 10^{-8}$, so y_{10} agrees with e to 7 decimal places. $e - y_{100} < \frac{102}{100!\cdot 101^2} \approx 10^{-156}$, so y_{100} (which can be quickly computed on a programmable hand calculator) agrees with e to at least 155 decimal places. (In contrast, $x_{100} = 2.704\cdots$ only agrees with e to one decimal place.)
(c) Since $\frac{n(n+2)}{(n+1)^2} = \frac{n^2+2n}{n^2+2n+1} < 1$, we have $y_n < e < y_n + \frac{1}{n!\cdot n}$. We can write $e = y_n + \frac{\theta_n}{n!\cdot n}$ for some θ_n, $0 < \theta_n < 1$.
(d) Using (b) and $y_{n+1} < e$, show that

$$\frac{n}{n+1} < \theta_n < \frac{n^2+2n}{n^2+2n+1}$$

and thus $\theta_n \to 1$ as $n \to \infty$.

V.5.5.6. Continue to use the notation of V.5.5.3.–V.5.5.5.. Show that e is irrational as follows. Suppose $e = \frac{m}{n}$. Then

$$\frac{m}{n} = 1 + \frac{1}{2!} + \cdots + \frac{1}{n!} + \frac{\theta_n}{n! \cdot n}$$

Multiply both sides by $n!$ to conclude that $\frac{\theta_n}{n}$ is an integer. This is a contradiction since $0 < \theta_n < 1$.

V.5.5.7. Compute the derivative of $f(x) = \log x$ directly as follows. Fix $a > 0$.

(a) Write

$$\frac{f(a+h) - f(a)}{h} = \frac{1}{h} \log\left(\frac{a+h}{a}\right) = \frac{1}{h} \log\left(1 + \frac{h}{a}\right) \ .$$

(b) Make the substitution $x = \frac{a}{h}$, so that $\frac{1}{h} = \frac{x}{a}$, and note that

$$f'(a) = \lim_{h \to 0} \frac{f(a+h) - f(a)}{h} = \lim_{x \to \pm\infty} \frac{x}{a} \log\left(1 + \frac{1}{x}\right) = \lim_{x \to \pm\infty} \frac{\log\left(\left[1 + \frac{1}{x}\right]^x\right)}{a}$$

if the limits both exist and are equal.

(c) Use V.5.3.5. and the continuity of the logarithm function to conclude that $f'(a)$ exists and

$$f'(a) = \frac{\log e}{a} = \frac{1}{a} \ .$$

(The limits at $+\infty$ and $-\infty$ must also be calculated separately.)

V.5.5.8. Using V.5.5.7. and the Chain Rule, use the following argument from [Gri21] to derive the Product and Quotient Rules. Suppose f and g are differentiable.

(a) Set $h = fg$. From $\log|h| = \log|f| + \log|g|$, conclude that $\frac{h'}{h} = \frac{f'}{f} + \frac{g'}{g}$.

(b) Set $h = f/g$. From $\log|h| = \log|f| - \log|g|$, conclude that $\frac{h'}{h} = \frac{f'}{f} - \frac{g'}{g}$.

(c) Solve each equation for h' to obtain the Product and Quotient Rules.

Is this argument an adequate proof of the rules?

V.5.5.9. Let $f : \mathbb{R} \to \mathbb{R}$ be a continuous function with $f(x+y) = f(x) + f(y)$ for all $x, y \in \mathbb{R}$.

(a) Let $a = f(1)$. Show that $f(n) = an$ for all $n \in \mathbb{Z}$.

(b) Show that $f(r) = ar$ for all $r \in \mathbb{Q}$.

(c) Use continuity to show that $f(x) = ax$ for all $x \in \mathbb{R}$. Thus f is linear.

(d) The continuity hypothesis cannot be removed. (However, the continuity hypothesis can be relaxed to Lebesgue measurability; see **??**.) $\mathbb{R}$ is a vector space over $\mathbb{Q}$ of dimension $2^{\aleph_0}$. Let B be a basis for $\mathbb{R}$ over $\mathbb{Q}$. Then every function from B to $\mathbb{R}$ extends to a $\mathbb{Q}$-linear (hence additive) function from $\mathbb{R}$ to $\mathbb{R}$. There are $2^{2^{\aleph_0}}$ functions from B to $\mathbb{R}$. But there are only $2^{\aleph_0}$ $\mathbb{R}$-linear functions from $\mathbb{R}$ to $\mathbb{R}$. Using the Axiom of Choice, construct a discontinuous example.

V.5.5.10. Let g be a continuous function from $\mathbb{R}$ to $\mathbb{R}$ which is not identically 0 and with the property that $g(x+y) = g(x)g(y)$ for all $x, y \in \mathbb{R}$.
(a) Show that g takes only positive values. [$g(x) = g(x/2)^2$.]
(b) Show using Exercise V.5.5.9. that $g(x) = b^x$ for all x, where $b = g(1) > 0$. So g is an exponential function. [Consider $f(x) = \log g(x)$.]
(c) The continuity hypothesis cannot be removed here either: construct a discontinuous example.
(d) Prove similarly that a continuous function $h : (0, \infty) \to \mathbb{R}$ which is not identically 0 and which has the property that $h(xy) = h(x) + h(y)$ for all $x, y > 0$ must be a logarithm function.

V.5.5.11. Redevelop the entire theory of exponential and logarithm functions by first defining $\log x = \int_1^x \frac{1}{t}\, dt$ for $x > 0$ and then letting $f(x) = e^x$ be the inverse function of $\log x$.

V.5.5.12. Here is an alternate approach to proving differentiability of exponential functions. Let $b > 1$. Then $g_b(x) = b^x$ is continuous on $\mathbb{R}$ (**??**).
(a) If $k \in \mathbb{R}$, $\int_{-k-1}^{-k} b^t\, dt < b^{-k}$. Thus, if $n \in \mathbb{N}$, $\int_{-n}^{0} b^t\, dt < \sum_{k=0}^{n-1} b^{-k} = \frac{1-b^{-n}}{1-b^{-1}}$.
(b) Conclude that the improper integral $\int_{-\infty}^{0} b^t\, dt$ converges, and hence $\int_{-\infty}^{x} b^t\, dt$ converges for any x. For $x \in \mathbb{R}$, set $f_b(x) = \int_{-\infty}^{x} b^t\, dt$. Show that f_b is differentiable and $f_b'(x) = g_b(x) = b^x$ for all x.
(c) By changing variables in the improper integral, show that $f_b(x) = b^x \cdot f_b(0)$ for any x. Thus g_b is infinitely differentiable, and $g_b' = k_b g_b$, where $\frac{1}{k_b} = \int_{-\infty}^{0} b^t\, dt$.
(d) If $a, b > 1$, apply the product rule to $g_{ab} = g_a g_b$ to conclude that $k_{ab} = k_a + k_b$. Prove that $\ell(b) = k_b$ is continuous. Thus ℓ is a logarithm function.

V.6. Trigonometric Functions

There is a dark secret behind the usual (precalculus) development of the theory of trigonometric functions: the entire theory is based on logical quicksand. All of trigonometry is based on the assumption that a circle has a finite "circumference" ("arc length"), which is never really defined; the number π is "defined" to be the ratio of the "circumference" to the diameter, and empirically calculated to be a little more than three. This assumption, while eminently believable and experimentally verifiable, is logically untenable, especially in the absence of a real definition of arc length. The notion of arc length can only be rigorously defined using limits (). See I.6.1.5.ff. for a fuller discussion.

In this section, we will give a rigorous and efficient treatment of trigonometric functions, the properties and identities they satisfy, and their calculus. We will actually define one of the inverse trigonometric functions first, an approach which may seem oddly backwards to readers familiar with the traditional approach, but which has the advantage of being logically impeccable.

V.6.1. Arc Length of a Circle and the Arcsine Function

We will consider the unit circle $\{(x, y) : x^2 + y^2 = 1\}$ in $\mathbb{R}^2$.

V.6.1.1. PROPOSITION. The arc length of the circle is finite.

To prove this, consider the arc from $(0, 1)$ to $(1, 0)$, which is a quarter circle. By symmetry, it is enough to prove that this arc has finite length. We give two arguments.

V.6.1.2. First consider the arc from $(0, 1)$ to $(b, \sqrt{1 - b^2})$ for $0 < b < 1$. This arc is the graph of the continuously differentiable function $y = \sqrt{1 - x^2}$ on $[0, b]$, so by **??** the arc length is finite and given by

$$L(0, b) = \int_0^b \sqrt{1 + \frac{x^2}{1 - x^2}}\, dx = \int_0^b \frac{1}{\sqrt{1 - x^2}}\, dx$$

Thus, for example, the arc from $(0, 1)$ to $(\frac{4}{5}, \frac{3}{5})$ has finite length. Since this arc is congruent to the arc from $(\frac{3}{5}, \frac{4}{5})$ to $(1, 0)$ (via interchanging x and y), this arc also has finite length, and the quarter circle is the union, hence also has finite length which we will call $L(0, 1)$.

V.6.1.3. We give an alternate argument which gives a (rather crude) estimate of the length. As $b \to 1$, $L(0, b) \to L(0, 1)$ (**??**), and $L(0, b)$ is increasing as b increases, so we only need show that $\{L(0, b) : 0 \le b < 1\}$ is bounded. But if $0 < x < 1$, $x^2 < x$, so $\frac{1}{\sqrt{1-x^2}} < \frac{1}{\sqrt{1-x}}$, and

$$L(0, b) = \int_0^b \frac{1}{\sqrt{1 - x^2}}\, dx < \int_0^b \frac{1}{\sqrt{1 - x}}\, dx = -2\sqrt{1 - x}\Big|_0^b = 2 - 2\sqrt{1 - b} < 2$$

for all $b < 1$; thus $L(0, 1)$ is finite and less than 2.

V.6.1.4. To get a lower bound for $L(0, 1)$, since it is the length of an arc from $(0, 1)$ to $(1, 0)$, it must be greater than the straight-line distance between the points, which is $\sqrt{2}$. A better lower bound, for example, is the sum of the distance from $(0, 1)$ to $(\frac{4}{5}, \frac{3}{5})$ and the distance from $(\frac{4}{5}, \frac{3}{5})$ to $(1, 0)$, which is $\sqrt{\frac{4}{5}} + \sqrt{\frac{2}{5}} = 1.52688\cdots$.

V.6.1.5. DEFINITION. The number π is the arc length of half the unit circle.

By symmetry, $\pi = 2L(0,1)$. By the above estimates, we have $2(\sqrt{\frac{4}{5}}+\sqrt{\frac{2}{5}}) = 3.05\cdots < \pi < 4$. Of course, it is well known that the exact value of π is $3.1415926535\cdots$; we will discuss efficient ways to calculate π later (**??**).

V.6.1.6. DEFINITION. If $-1 \le x \le 1$, the *arcsine* of x is the number

$$\arcsin x = \int_0^x \frac{1}{\sqrt{1-t^2}}\,dt$$

(If $x = \pm 1$, this is an improper integral; we can define $\arcsin 1 = L(0,1) = \frac{\pi}{2}$ and $\arcsin(-1) = -L(0,1) = -\frac{\pi}{2}$.)

Thus $\arcsin x$ is the antiderivative of $\frac{1}{\sqrt{1-x^2}}$, i.e. by the Fundamental Theorem of Calculus, $\frac{d}{dx}(\arcsin x) = \frac{1}{\sqrt{1-x^2}}$ for $-1 < x < 1$. Thus $f(x) = \arcsin x$ is continuous on $[-1,1]$ and differentiable on $(-1,1)$, and $f'(x) = \frac{1}{\sqrt{1-x^2}} > 0$ on $(-1,1)$, so $\arcsin x$ is strictly increasing on $[-1,1]$. We have $\arcsin 0 = 0$ and $\arcsin(-x) = -\arcsin x$ for $-1 \le x \le 1$.

V.6.2. The Sine and Cosine Functions

Since $f(x) = \arcsin x$ is continuous and strictly increasing on $[-1,1]$, with range $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$, it has a continuous inverse function $g(x)$ on $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$.

V.6.2.1. DEFINITION. If $x \in \left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$, the *sine* of x is $\sin x = g(x)$, and the *cosine* of x is $\cos x = \sqrt{1-g(x)^2} = \sqrt{1-(\sin x)^2}$.

We usually write $\sin^2 x$ instead of $(\sin x)^2$, i.e. $\cos x = \sqrt{1-\sin^2 x}$ for $-\frac{\pi}{2} \le x \le \frac{\pi}{2}$. Thus $\sin^2 x + \cos^2 x = 1$ for all $x \in \left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$ (of course, $\cos^2 x = (\cos x)^2$.)

V.6.2.2. Since $\arcsin(-x) = -\arcsin(x)$, $\sin x$ has the same property:

$$\sin(-x) = -\sin x$$

$$\cos(-x) = \cos x$$

We have $\sin 0 = 0$, $\cos 0 = 1$, $\sin(\frac{\pi}{2}) = 1$, $\cos(\frac{\pi}{2}) = 0$, $\sin(-\frac{\pi}{2}) = -1$, $\cos(-\frac{\pi}{2}) = 0$.

V.6.2.3. From the Inverse Function Theorem, $g(x) = \sin x$ is differentiable on $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ and

$$g'(x) = \frac{1}{f'(g(x))} = \frac{1}{\frac{1}{\sqrt{1-\sin^2 x}}} = \sqrt{1-\sin^2 x} = \cos x$$

and from the Chain Rule $h(x) = \cos x$ is differentiable on $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ and

$$h'(x) = \frac{d}{dx}\left(\sqrt{1-\sin^2 x}\right) = \frac{1}{2}\left(\sqrt{1-\sin^2 x}\right)^{-1/2}(-2\sin x\cos x)$$

$$= -\frac{\sin x\cos x}{\sqrt{1-\sin^2 x}} = -\frac{\sin x\cos x}{\cos x} = -\sin x$$

and thus we obtain:

V.6.2.4. THEOREM. The functions $\sin x$ and $\cos x$ are infinitely differentiable on $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$, and

$$\frac{d}{dx}(\sin x) = \cos x\,, \quad \frac{d}{dx}(\cos x) = -\sin x$$

for $-\frac{\pi}{2} < x < \frac{\pi}{2}$.

V.6.2.5. By the properties of inverse functions, if $0 \le x \le \frac{\pi}{2}$, $\sin x = b$ means

$$x = \arcsin b = L(0, b) = \int_0^b \frac{1}{\sqrt{1-t^2}}\, dt$$

so the point P on the circle (in the first quadrant) for which the arc from $(0,1)$ to P has length x has first coordinate $\sin x$. The second coordinate is then $\sqrt{1-\sin^2 x} = \cos x$, i.e. $P = (\sin x, \cos x)$. It is more customary to measure arcs of the circle counterclockwise from $(1,0)$, and then the coordinates of the point of arc length x are $(\cos x, \sin x)$ (just apply the transformation interchanging x and y.)

V.6.2.6. We extend the definition of $\sin x$ and $\cos x$ to all real numbers by taking $(\cos x, \sin x)$ to be the coordinates of the point of arc length x traveling counterclockwise around the circle from $(1,0)$ (clockwise a distance $|x|$ if $x < 0$). Since the circumference of the circle is 2π, we obtain that sin and cos are periodic with period 2π: for all x,

$$\sin(x + 2\pi) = \sin x\,, \quad \cos(x + 2\pi) = \cos x$$

It can in fact be easily checked that, for all x,

$$\sin(-x) = -\sin x\,, \quad \cos(-x) = \cos x$$

$$\sin\left(x + \frac{\pi}{2}\right) = \cos x\,, \quad \cos\left(x + \frac{\pi}{2}\right) = -\sin x$$

since when the point (a, b) is rotated a quarter circle counterclockwise, its coordinates become $(-b, a)$. Then replacing x by $x - \frac{\pi}{2}$,

$$\sin\left(x - \frac{\pi}{2}\right) = -\cos x\,, \quad \cos\left(x - \frac{\pi}{2}\right) = \sin x$$

Repeating the process twice, we obtain

$$\sin(x \pm \pi) = -\sin x\,, \quad \cos(x \pm \pi) = -\cos x$$

for all x. Of course, $|\sin x| \le 1$ and $|\cos x| \le 1$ for all x.

V.6.2.7. THEOREM. The functions $\sin x$ and $\cos x$ are infinitely differentiable on all of $\mathbb{R}$, and

$$\frac{d}{dx}(\sin x) = \cos x\,, \quad \frac{d}{dx}(\cos x) = -\sin x$$

for all $x \in \mathbb{R}$.

PROOF: By V.6.2.4., the result holds on $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$. Then, since $\sin x = \cos\left(x - \frac{\pi}{2}\right)$, $\sin x$ is differentiable on $(0, \pi)$, and by the chain rule

$$\frac{d}{dx}(\sin x) = \frac{d}{dx}\left(\cos\left(x - \frac{\pi}{2}\right)\right) = -\sin\left(x - \frac{\pi}{2}\right) = \cos x$$

on $(0, \pi)$, and similarly $\cos x$ is differentiable on $(0, \pi)$ with derivative $-\sin x$. From $\sin x = -\cos\left(x + \frac{\pi}{2}\right)$ we similarly get that $\sin x$ is differentiable on $(-\pi, 0)$ with derivative $\cos x$, and similarly for $\cos x$. Thus the result holds on the interval $(-\pi, \pi)$. Since $\sin(x \pm \pi) = -\sin x$ and $\cos(x \pm \pi) = -\cos x$ for all x, the result holds on $((n-1)\pi, (n+1)\pi)$ for any $n \in \mathbb{Z}$, and hence for the whole real line. 👍

V.6.3. Other Trigonometric Functions

V.6.3.1. DEFINITION. If $x \in \mathbb{R}$, define the *tangent*, *cotangent*, *secant*, and *cosecant* of x, respectively denoted $\tan x$, $\cot x$, $\sec x$, $\csc x$, by

$$\tan x = \frac{\sin x}{\cos x}, \quad \cot x = \frac{\cos x}{\sin x} = \frac{1}{\tan x}$$

$$\sec x = \frac{1}{\cos x}, \quad \csc x = \frac{1}{\sin x}$$

V.6.3.2. These functions are defined wherever the denominators are nonzero. Thus the tangent and secant are defined except at $\pm\frac{\pi}{2} \pm n\pi$, and the cotangent and cosecant are defined except at (integer) multiples of π. We have

$$\lim_{x \to \frac{\pi}{2}-} \tan x = +\infty, \quad \lim_{x \to -\frac{\pi}{2}+} \tan x = -\infty$$

$$\lim_{x \to \frac{\pi}{2}-} \sec x = +\infty, \quad \lim_{x \to -\frac{\pi}{2}+} \sec x = +\infty$$

$$\lim_{x \to \pi-} \cot x = -\infty, \quad \lim_{x \to 0+} \cot x = +\infty$$

$$\lim_{x \to \pi-} \csc x = +\infty, \quad \lim_{x \to 0+} \csc x = +\infty$$

Since $|\sin x|$ and $|\cos x|$ are always ≤ 1, we have $|\sec x| \geq 1$ and $|\csc x| \geq 1$ whenever defined.

The functions $\sec x$ and $\csc x$ are periodic with period 2π. But since $\sin(x+\pi) = -\sin x$ and $\cos(x+\pi) = -\cos x$, the functions $\tan x$ and $\cot x$ are actually periodic with period π.

If $0 \leq x < \frac{\pi}{2}$, the number $\tan x$ is the slope of the line through the origin and the point $(\cos x, \sin x)$ in the first quadrant whose arc length along the unit circle from $(1, 0)$ is x.

V.6.3.3. These functions, where defined, satisfy the identities

$$1 + \tan^2 x = \frac{\cos^2 x}{\cos^2 x} + \frac{\sin^2 x}{\cos^2 x} = \frac{\cos^2 x + \sin^2 x}{\cos^2 x} = \frac{1}{\cos^2 x} = \sec^2 x$$

and similarly $1 + \cot^2 x = \csc^2 x$ (where, as usual, $\tan^2 x = (\tan x)^2$, etc.)

V.6.3.4. These functions are infinitely differentiable on their domains, and their derivatives can be calculated using the quotient rule and power rule:

$$\frac{d}{dx}(\tan x) = \frac{(\cos x)(\cos x) - (\sin x)(-\sin x)}{\cos^2 x} = \frac{1}{\cos^2 x} = \sec^2 x$$

$$\frac{d}{dx}(\cot x) = \frac{(\sin x)(-\sin x) - (\cos x)(\cos x)}{\sin^2 x} = -\frac{1}{\sin^2 x} = -\csc^2 x$$

$$\frac{d}{dx}(\sec x) = \frac{d}{dx}\left((\cos x)^{-1}\right) = (-1)(\cos x)^{-2}(-\sin x) = \frac{\sin x}{\cos^2 x} = \sec x \tan x$$

$$\frac{d}{dx}(\csc x) = \frac{d}{dx}\left((\sin x)^{-1}\right) = (-1)(\sin x)^{-2}(\cos x) = -\frac{\cos x}{\sin^2 x} = -\csc x \cot x$$

V.6.4. The Inverse Trigonometric Functions

We have already defined an inverse function, $\arcsin x$, for $\sin x$. Actually, if we start with the sine function and try to define an inverse, since $\sin x$ is periodic and not one-to-one, we must restrict it to an interval on which it is one-to-one; it is conventional to take the interval $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$. Similarly, for $\cos x$ we conventionally take the interval $[0, \pi]$, which is mapped one-one onto $[-1, 1]$.

V.6.4.1. DEFINITION. The inverse function to $\cos x$ with domain $[-1, 1]$ and range $[0, \pi]$ is called the *arccosine* function, denoted $\arccos x$.

V.6.4.2. Since the function $g(x) = \cos x$ is continuous on $[0, \pi]$ and differentiable on $(0, \pi)$ with nonzero derivative, the function $f(x) = \arccos x$ is continuous on $[-1, 1]$ and differentiable on $(-1, 1)$ with derivative given by the Inverse Function Theorem:

$$\frac{d}{dx}(\arccos x) = f'(x) = \frac{1}{g'(f(x))} = \frac{1}{-\sin(\arccos x)}$$

$$= -\frac{1}{\sqrt{1 - \cos^2(\arccos x)}} = -\frac{1}{\sqrt{1 - x^2}}$$

Actually, from $\sin x = \cos\left(\frac{\pi}{2} - x\right)$ it follows that $\arccos x = \frac{\pi}{2} - \arcsin x$.

V.6.4.3. Now consider $\tan x$. The interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ is one period of the tangent, and $\tan x$ maps this interval one-one onto $(-\infty, \infty)$, so we conventionally take the inverse function for the tangent function to have this range:

V.6.4.4. DEFINITION. The inverse function to $\tan x$ with domain $(-\infty, \infty)$ and range $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ is called the *arctangent* function, denoted $\arctan x$.

Since the function $g(x) = \tan x$ is differentiable on $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ with nonzero derivative, $f(x) = \arctan x$ is differentiable on $(-\infty, \infty)$ with derivative

$$\frac{d}{dx}(\arctan x) = f'(x) = \frac{1}{g'(f(x))} = \frac{1}{\sec^2(\arctan x)} = \frac{1}{1 + \tan^2(\arctan x)} = \frac{1}{1 + x^2}$$

V.6.4.5. We can similarly define an *arccotangent* function with domain $(-\infty, \infty)$, range $(0, \pi)$, and derivative $-\frac{1}{1+x^2}$. Actually, $\operatorname{arccot} x = \frac{\pi}{2} - \arctan x$ since $\cot x = \tan\left(\frac{\pi}{2} - x\right)$.

We could also define arcsecant and arccosecant functions, but these are rarely used.

It is very common to write $\sin^{-1} x$ for $\arcsin x$, etc. This notation is consistent with the usual notation for inverse functions, but incompatible with the convention of writing $\sin^2 x$ for $(\sin x)^2$, etc., and thus can be confusing. (Note that $\sin^{-1} x \neq (\sin x)^{-1}$!)

> "$\sin^2 \phi$ is odious to me, even though Laplace made use of it; should it be feared that $\sin \phi^2$ might become ambiguous, which would perhaps never occur, or at most very rarely when speaking of $\sin(\phi^2)$, well then, let us write $(\sin \phi)^2$, but not $\sin^2 \phi$, which by analogy should signify $\sin(\sin \phi)$."
>
> *C. F. Gauss*[12]

V.6.5. The Area of a Circle

V.6.5.1. We can use trigonometry to calculate the area of a circle. Actually, we should first define what we mean by "area" of a subset of the plane. This is not as easy as it sounds: the general problem is essentially the basic subject matter of measure theory. It would take us too far afield to try to treat this question here (cf. ()), so we will just assume that area is defined for sufficiently well-behaved subsets of the plane, and satisfies

(i) If f is a nonnegative continuous function on a closed bounded interval $[a, b]$, then the region $R = \{(x, y) : a \leq x \leq b, 0 \leq y \leq f(x)\}$ has area $A(R) = \int_a^b f(x)\, dx$.

(ii) If $R \subseteq S$, then $A(R) \leq A(S)$.

(iii) If $R_1, \ldots, R_n$ are nonoverlapping regions ("nonoverlapping" means the intersection of any two is contained in the boundary of both), then

$$A(R_1 \cup \cdots \cup R_n) = A(R_1) + \cdots + A(R_n).$$

(iv) Congruent regions have the same area.

(There is actually a subtle technical problem with (iii), since the boundary of a region can have positive measure, but this will not cause difficulty if we consider only regions bounded by finitely many smooth curves.)

A circle (technically a disk) or any wedge of a circle has a well-defined area under these assumptions. If D is the unit disk, then $A(D) = 2\int_{-1}^{1} \sqrt{1 - x^2}\, dx < 4$. We want to calculate the exact value of $A(D)$.

V.6.5.2. THEOREM. $A(D) = \pi$.

The simplest way to calculate this area is using vector calculus, but we will proceed in an alternate way. We have that $A(D) = \pi p$ for some $p > 0$; we want to show that $p = 1$.

[12] [Mor93, 1886].

V.6.5.3. Define a function $\phi : [0, 2\pi] \to \mathbb{R}$ by setting $\phi(x)$ equal to the area of a wedge of a circle with arc length x. Any two such wedges are congruent, so $\phi(x)$ is well defined, and strictly increasing; we have $\phi(0) = 0$ and $\phi(2\pi) = A(D) = \pi p$. For each $n \in \mathbb{N}$, we have $\phi\left(\frac{2\pi}{n}\right) = \frac{\pi p}{n}$ by (iii), i.e. $\phi(x) = \frac{p}{2}x$ if $x = \frac{2\pi}{n}$ for some n. (Actually this formula holds for all $x \in [0, 2\pi]$, although we will not need this fact for the Proof: it holds for $x = \frac{2\pi m}{n}$ for $m \leq n$ by (iii), and hence for all x since such numbers are dense in $[0, 2\pi]$ and ϕ is strictly increasing.)

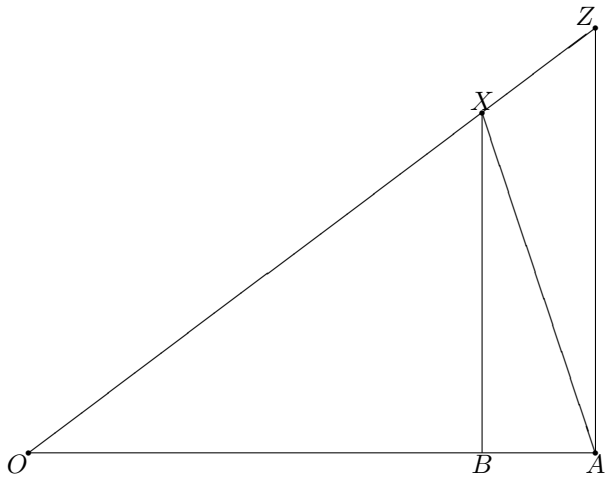

Figure V.8:

If $0 < x < \frac{\pi}{2}$, draw the picture in Figure 1, with $\overline{OA} = 1$, $\overline{OX} = 1$, and $\angle AOX = x$, so $X = (\cos x, \sin x)$. Then $\overline{BX} = \sin x$ and $\overline{AZ} = \tan x$. Let T_1 be the triangle $\triangle AOX$ and T_2 the triangle $\triangle AOZ$. Then $A(T_1) \leq \phi(x) \leq A(T_2)$, so if $x_n = \frac{2\pi}{n}$ for $n > 4$ we have

$$\frac{1}{2}\sin x_n \leq \frac{p}{2}x_n \leq \frac{1}{2}\tan x_n$$

$$\frac{\sin x_n}{x_n} \leq p \leq \frac{\tan x_n}{x_n}$$

Since $\lim_{n\to\infty} \frac{\sin x_n}{x_n} = \lim_{n\to\infty} \frac{\tan x_n}{x_n} = 1$ (), we have $p = 1$. This completes the proof of the theorem.

V.6.5.4. It follows from the argument of the proof that $\phi(x) = \frac{1}{2}x$ for all x, giving an alternate geometric interpretation of the angle x as area rather than arc length. See Exercise () for another derivation of this formula.

V.6.6. The Hyperbolic Functions

The trigonometric functions are sometimes called the *circular functions*, for obvious reasons. We can define analogous functions related to a hyperbola which are formally similar to the circular functions; it turns out that the connections are much more than formal, although these deep connections are beyond the scope of this chapter (cf. XII.1.1.8.).

There are actually two apparently totally different ways the hyperbolic functions can be defined, one using the hyperbola in the way the circle was used for the trigonometric functions, and the other using exponential functions. It is remarkable that the same functions are obtained by the two methods. We will describe both methods in this section.

V.6.6.1. We begin with the unit hyperbola $y^2 - x^2 = 1$. (It is more customary to use the hyperbola $x^2 - y^2 = 1$ with base point $(1, 0)$, but our approach facilitates computations.) Since the upper half of the hyperbola has equation $y = \sqrt{1 + x^2}$, in analogy with the formula defining $\arcsin x$ we define the *hyperbolic arcsine* $\operatorname{arcsinh} x$ by

$$\operatorname{arcsinh} x = \int_0^x \frac{1}{\sqrt{1 + t^2}}\, dt$$

Unfortunately, there is no interpretation of this as arc length in the hyperbolic case. (See Exercise () for a connection with area similar to the one for the trigonometric functions.)

Then $\operatorname{arcsinh} x$ is defined for all x and is differentiable on $(-\infty, \infty)$ with derivative $\frac{1}{\sqrt{1+x^2}}$. We obviously have $\operatorname{arcsinh}(-x) = -\operatorname{arcsinh} x$ for all x.

V.6.6.2. PROPOSITION. The range of $\operatorname{arcsinh} x$ is $(-\infty, \infty)$.

PROOF: Since $\lim_{x\to+\infty} \frac{x}{\sqrt{1+x^2}} = 1$, there is an n such that $\frac{1}{\sqrt{1+x^2}} > \frac{1}{2x}$ for $x > n$. Thus, if $b > n$, we have

$$\int_n^b \frac{1}{\sqrt{1 + x^2}}\, dx > \int_n^b \frac{1}{2x}\, dx = (\ln b - \ln n)$$

which goes to infinity as $b \to +\infty$. So $\operatorname{arcsinh} x$ becomes arbitrarily large as $x \to +\infty$. Since $\operatorname{arcsinh}(-x) = -\operatorname{arcsinh} x$ and the range is an interval, it must be the whole real line. 👍

V.6.6.3. So $f(x) = \operatorname{arcsinh} x$ is strictly increasing and has an inverse function which we call the *hyperbolic sine*, denoted $\sinh x$. By V.6.6.2., the domain of $\sinh x$ is all of $\mathbb{R}$. We then define the *hyperbolic cosine* $\cosh x$ to be $\sqrt{1 + \sinh^2 x}$, so $\cosh^2 x - \sinh^2 x = 1$ for all x. We have $\sinh(-x) = -\sinh x$ and $\cosh(-x) = \cosh x$ for all x, $\sinh 0 = 0$, and $\cosh 0 = 1$.

V.6.6.4. The function $g(x) = \sinh x$ is differentiable on $\mathbb{R}$, with derivative given by

$$\frac{d}{dx}(\sinh x) = g'(x) = \frac{1}{f'(g(x))} = \frac{1}{\frac{1}{\sqrt{1+sinh^2 x}}} = \sqrt{1 + \sinh^2 x} = \cosh x$$

and by the Chain Rule,

$$\begin{aligned}\frac{d}{dx}(\cosh x) = \frac{d}{dx}\left(\sqrt{1 + \sinh^2 x}\right) &= \frac{1}{2}(1 + \sinh^2 x)^{-1/2}(2 \sinh x \cosh x) \\ &= \frac{\sinh x \cosh x}{\sqrt{1 + \sinh^2 x}} = \frac{\sinh x \cosh x}{\cosh x} = \sinh x\end{aligned}$$

and thus $\sinh x$ and $\cosh x$ are infinitely differentiable.

The functions $\sinh x$ and $\cosh x$ thus behave formally in a similar way to $\sin x$ and $\cos x$, with occasional sign differences. The analogy only goes so far, however: $\sinh x$ and $\cosh x$ are not periodic and unbounded. In fact, $\cosh x \geq 1$ for all x.

V.6.6.5. We can define analogs of the other trigonometric functions, called the *hyperbolic tangent, cotangent, secant, and cosecant*:

$$\tanh x = \frac{\sinh x}{\cosh x}\,, \quad \coth x = \frac{\cosh x}{\sinh x} = \frac{1}{\tanh x}$$
$$\operatorname{sech} x = \frac{1}{\cosh x}\,, \quad \operatorname{csch} x = \frac{1}{\sinh x}$$

It is useful to have a one-syllable pronunciation of the names of the hyperbolic functions, since the names "hyperbolic sine," etc., are cumbersome. There is an obvious pronunciation for "cosh", and also for the seldom-used "coth" and "sech". The names "sinh" and "tanh" are normally pronounced "cinch" and "tanch" respectively. Your guess is as good as mine about how to pronounce "csch" (or "csc" for that matter!)

V.6.6.6. The domain of $\tanh x$ and $\operatorname{sech} x$ is all of $\mathbb{R}$; the domain of $\coth x$ and $\operatorname{csch} x$ is $\mathbb{R} \setminus \{0\}$. We have $\tanh 0 = 0$, $\tanh(-x) = -\tanh x$ and $|\tanh x| < 1$ for all x, and $\lim_{x\to+\infty} \tanh x = 1$, $\lim_{x\to-\infty} \tanh x = -1$. Similarly, $\operatorname{sech} 0 = 1$, $\operatorname{sech}(-x) = \operatorname{sech} x$ and $|\operatorname{sech} x| \le 1$ for all x, and $\lim_{x\to+\infty} \operatorname{sech} x = \lim_{x\to-\infty} \operatorname{sech} x = 0$. They satisfy identities similar to the ones for trigonometric functions; for example:

$$1 - \tanh^2 x = 1 - \frac{\sinh x}{\cosh x} = \frac{\cosh^2 x - \sinh^2 x}{\cosh^2 x} = \frac{1}{\cosh^2 x} = \operatorname{sech}^2 x$$

V.6.6.7. These hyperbolic functions are all infinitely differentiable on their domains, with derivatives given by standard rules:

$$\frac{d}{dx}(\tanh x) = \frac{(\cosh x)(\cosh x) - (\sinh x)(\sinh x)}{\cosh^2 x} = \frac{1}{\cosh^2 x} = \operatorname{sech}^2 x$$
$$\frac{d}{dx}(\coth x) = \frac{(\sinh x)(\sinh x) - (\cosh x)(\cosh x)}{\sinh^2 x} = -\frac{1}{\sinh^2 x} = -\operatorname{csch}^2 x$$
$$\frac{d}{dx}(\operatorname{sech} x) = \frac{d}{dx}\left((\cosh x)^{-1}\right) = (-1)(\cosh x)^{-2}(\sinh x) = -\frac{\sinh x}{\cosh^2 x} = -\operatorname{sech} x \tanh x$$
$$\frac{d}{dx}(\operatorname{csch} x) = \frac{d}{dx}\left((\sinh x)^{-1}\right) = (-1)(\sinh x)^{-2}(\cosh x) = -\frac{\cosh x}{\sinh^2 x} = -\operatorname{csch} x \coth x$$

V.6.6.8. Other inverse hyperbolic functions can be defined. For example, the one most often used, the inverse hyperbolic tangent $f(x) = \operatorname{arctanh} x$ is the inverse function of $g(x) = \tanh x$, with domain $(-1, 1)$, range $(-\infty, \infty)$, and derivative

$$\frac{d}{dx}(\operatorname{arctanh} x) = f'(x) = \frac{1}{g'(f(x))} = \frac{1}{\operatorname{sech}^2(\operatorname{arctanh} x)}$$
$$= \frac{1}{1 - \tanh^2(\operatorname{arctanh} x)} = \frac{1}{1 - x^2}$$

Since $\frac{1}{1-x^2} = \frac{1}{2}\frac{1}{1+x} + \frac{1}{2}\frac{1}{1-x}$ by partial fractions, the derivative of $\operatorname{arctanh} x$ is the same as the derivative of $h(x) = \frac{1}{2}\ln(1+x) - \frac{1}{2}\ln(1-x) = \frac{1}{2}\ln\left(\frac{1+x}{1-x}\right)$. Since $h(0) = \operatorname{arctanh} 0 = 0$, we have $h(x) = \operatorname{arctanh} x$ for all x, i.e.

$$\operatorname{arctanh} x = \frac{1}{2}\ln(1+x) - \frac{1}{2}\ln(1-x) = \frac{1}{2}\ln\left(\frac{1+x}{1-x}\right) \quad (-1 < x < 1)$$

There is therefore a close connection between inverse hyperbolic functions and logarithm functions, and hence the hyperbolic functions are actually closely related to exponential functions. Since the connection is not so easy to motivate, we will simply define some new functions and show that they are the same as the hyperbolic functions.

V.6.6.9. DEFINITION. Define $s(x) = \frac{e^x - e^{-x}}{2}$ and $c(x) = \frac{e^x + e^{-x}}{2}$.

V.6.6.10. THEOREM. We have $s(x) = \sinh x$ and $c(x) = \cosh x$ for all x.

To prove this theorem, note that $s(x)$ and $c(x)$ are differentiable on all of $\mathbb{R}$, and that $s'(x) = c(x)$, $c'(x) = s(x)$. Since $c(x) > 0$ for all x, it follows that $s(x)$ is strictly increasing on $\mathbb{R}$. We also have that $s(0) = 0$, $s(-x) = -s(x)$ for all x, and $\lim_{x\to+\infty} s(x) = +\infty$, so it follows that the range of $s(x)$ is all of $\mathbb{R}$. We have, for all x,

$$1 + (s(x))^2 = 1 + \frac{(e^x - e^{-x})^2}{4} = \frac{4 + e^{2x} - 2 + e^{-2x}}{4}$$
$$= \frac{e^{2x} + 2 + e^{-2x}}{4} = \frac{(e^x + e^{-x})^2}{4} = (c(x))^2$$

and thus $c(x) = \sqrt{1 + (s(x))^2}$ for all x.

Thus $s(x)$ has an inverse function $h(x)$, which is defined and differentiable on all of $\mathbb{R}$, with derivative given by the Inverse Function Theorem:

$$h'(x) = \frac{1}{s'(h(x))} = \frac{1}{c(h(x))} = \frac{1}{\sqrt{1 + (s(h(x)))^2}} = \frac{1}{\sqrt{1 + x^2}}$$

so the derivative of $h(x)$ is the same as the derivative of $\operatorname{arcsinh} x$. Since $h(0) = 0 = \operatorname{arcsinh} 0$, we have $h(x) = \operatorname{arcsinh} x$ for all x, and thus the inverse functions are also equal: $s(x) = \sinh x$. The derivatives of these functions are then also equal: $c(x) = \cosh x$. This completes the proof of the theorem.

V.6.6.11. From this, we get formulas for the other hyperbolic functions:

$$\tanh x = \frac{\sinh x}{\cosh x} = \frac{e^x - e^{-x}}{e^x + e^{-x}}, \quad \coth x = \frac{\cosh x}{\sinh x} = \frac{e^x + e^{-x}}{e^x - e^{-x}}$$
$$\operatorname{sech} x = \frac{1}{\cosh x} = \frac{2}{e^x + e^{-x}}, \quad \operatorname{csch} x = \frac{1}{\sinh x} = \frac{2}{e^x - e^{-x}}$$

See Exercise () for a direct algebraic derivation of the formula for $\tanh x$.

V.6.6.12. Actually, the trigonometric functions also have similar formulas in terms of exponential functions, but the formulas involve complex numbers:

$$\cos x = \frac{e^{ix} + e^{-ix}}{2}, \quad \sin x = \frac{e^{ix} - e^{-ix}}{2i}$$

(we will not attempt to explain these formulas here.) The rich and beautiful subject of complex analysis (calculus for functions on the complex numbers) reveals many deep and fascinating connections between trigonometric, hyperbolic, and exponential functions; see XII.1.1.8..

V.6.7. Exercises

V.6.7.1. If $0 \leq x \leq \frac{\pi}{2}$, show that the function $\phi(x)$ of the proof of V.6.5.2. is given by

$$\phi(x) = \frac{1}{2}\cos x \sin x + \int_{\cos x}^{1} \sqrt{1-t^2}\, dt$$

(see Figure ().) Using (), show that $\phi'(x)$ is the constant function $\frac{1}{2}$, so $\phi(x) = \frac{1}{2}x$.

V.6.7.2. If $x \geq 0$, let $\psi(x)$ be the area of the wedge bounded by the hyperbola $x^2 - y^2 = 1$, the line through the origin and $(\cosh x, \sinh x)$, and the x-axis (Figure ().) Show that $\psi(x)$ is given by

$$\psi(x) = \frac{1}{2}\cosh x \sinh x - \int_{1}^{\cosh x} \sqrt{t^2-1}\, dt$$

As in Exercise (), show that $\psi'(x)$ is the constant function $\frac{1}{2}$, so $\psi(x) = \frac{1}{2}x$.

V.6.7.3. Derive the exponential formula for $\tanh x$ from the formula $\operatorname{arctanh} x = \frac{1}{2}\ln\left(\frac{1+x}{1-x}\right)$ by solving the equation

$$2x = \ln\left(\frac{1+y}{1-y}\right)$$

for y.

V.6.7.4. [Bri98] Prove the sum formulas for sine and cosine

$$\sin(\alpha+\beta) = \sin\alpha\cos\beta + \cos\alpha\sin\beta$$

$$\cos(\alpha+\beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta$$

for $\alpha, \beta \in \mathbb{R}$, as follows.

(a) Fix $\beta \in \mathbb{R}$, and replace α by a variable x, and define

$$f(x) = [\sin(x+\beta) - \sin x\cos\beta - \cos x\sin\beta]^2 + [\cos(x+\beta) - \cos x\cos\beta + \sin x\sin\beta]^2 \ .$$

Then f is differentiable on $\mathbb{R}$.

(b) Compute f' using the Chain Rule, and show that f' is identically 0. So f is constant.

(c) Since $f(-\beta) = 0$, f is identically 0. Conclude that the sum formulas hold.

(d) Prove the following identities from the above sum formulas, for every $\alpha, \beta \in \mathbb{R}$ which make sense in the formulas:

$$\sin(\alpha-\beta) = \sin\alpha\cos\beta - \cos\alpha\sin\beta$$

$$\cos(\alpha-\beta) = \cos\alpha\cos\beta + \sin\alpha\sin\beta$$

$$\sin\alpha\cos\beta = \frac{1}{2}[\sin(\alpha+\beta) + \sin(\alpha-\beta)]$$

$$\cos\alpha\cos\beta = \frac{1}{2}[\cos(\alpha+\beta) + \cos(\alpha-\beta)]$$

$$\sin\alpha\sin\beta = \frac{1}{2}\left[\cos(\alpha-\beta) - \cos(\alpha+\beta)\right]$$

$$\sin 2\alpha = 2\sin\alpha\cos\alpha$$

$$\cos 2\alpha = \cos^2\alpha - \sin^2\alpha = 2\cos^2\alpha - 1 = 1 - 2\sin^2\alpha$$

$$\cos^2\frac{\alpha}{2} = \frac{1+\cos\alpha}{2}$$

$$\sin^2\frac{\alpha}{2} = \frac{1-\cos\alpha}{2}$$

$$\tan(\alpha+\beta) = \frac{\tan\alpha + \tan\beta}{1 - \tan\alpha\tan\beta}$$

V.6.7.5. Here is a function which appears in some texts, particularly older ones, and connects trigonometric and hyperbolic functions without the need to use complex numbers.

DEFINITION. The *Gudermannian* is the function

$$gd(x) = \tan^{-1}(\sinh x)\ .$$

(a) Show that the Gudermannian is a strictly increasing differentiable function from $\mathbb{R}$ onto $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$.

(b) Show that $gd'(x) = \operatorname{sech} x$, so, since $gd(0) = 0$, for $x \in \mathbb{R}$,

$$gd(x) = \int_0^x \operatorname{sech} t\, dt\ .$$

(c) The inverse function gd^{-1} is a strictly increasing differentiable function from $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ onto $\mathbb{R}$. Show that it is given by the formulas

$$gd^{-1}(x) = \sinh^{-1}(\tan x) = \log(\sec x + \tan x)$$

for $-\frac{\pi}{2} < x < \frac{\pi}{2}$.

(d) Show that $(gd^{-1})'(x) = \sec x$, so, since $gd^{-1}(0) = 0$, for $x \in \left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$,

$$gd^{-1}(x) = \int_0^x \sec t\, dt\ .$$

V.7. Big-O and Little-o Notation

In this section, we introduce some notation which is commonly used to describe the asymptotic behavior of functions or sequences, the big-O and little-o notation. Although some care must be exercised in using this notation, it is very helpful in simplifying formulas and arguments containing constants whose exact value is unimportant or functions which become negligible as a limit is approached, in addition to giving a clean and precise description of the essential quantitative behavior of limits of functions. Not only does use of this system often simplify arguments in form, but it also sometimes helps conceptually in that the essential ideas of the argument are clarified and highlighted; in addition, arguments written this way are usually closer in spirit to the way the founding fathers of calculus phrased their work (although our arguments have a much higher level of rigor than those of the early days of the subject.) In fact, a version of the little-o notation was used by Newton (it is unclear whether he invented it), who wrote:

> "When I am investigating a truth or the solution to a Probleme I use all sorts of approximations and neglect to write down the letter o, but when I am demonstrating a Proposition I always write down the letter o & proceed exactly by the rules of Geometry."
>
> *Isaac Newton*[13]

Definition. Let a be an extended real number, and f and g functions defined in a deleted neighborhood of a (this does not preclude the possibility that they are also defined at a if $a \in \mathbb{R}$).

(i) If $a \in \mathbb{R}$, then $g(x) = O(f(x))$ as $x \to a$ if there exist constants $M \geq 0$ and $\delta > 0$ such that $|g(x)| \leq M|f(x)|$ whenever $0 < |x - a| < \delta$.

(ii) If $a \in \mathbb{R}$, then $g(x) = o(f(x))$ as $x \to a$ if for every $\epsilon > 0$ there is a $\delta > 0$ such that $|g(x)| \leq \epsilon|f(x)|$ whenever $0 < |x - a| < \delta$.

If $a = \pm\infty$, the δ and $0 < |x - a| < \delta$ must be replaced in the usual way by B and $x > B$ for $a = +\infty$, and by A and $x < A$ if $a = -\infty$.

An analogous definition can be made for one-sided approach if f and g are defined in a deleted one-sided neighborhood of a, and for sequences. Thus we may write "$g(x) = O(f(x))$ as $x \to a+$" or "$y_n = o(x_n)$ as $n \to \infty$."

In the definition of O, we can clearly assume that $M > 0$ since there is no harm in increasing M.

The a is usually fixed throughout an argument and is often understood.

The O and o stand for "order." The expression $g(x) = O(f(x))$ as $x \to a$ roughly means "$|g(x)|$ is of the same order as (or not essentially larger than) $|f(x)|$ for x near a"; $g(x) = o(f(x))$ roughly means "$|g(x)|$ is of smaller order than (or negligibly small compared to) $|f(x)|$ for x near a."

Examples.

(i) $g(x) = O(f(x))$ as $x \to a$ roughly means that "$\frac{g(x)}{f(x)}$ is bounded in a neighborhood of a." In particular, $g(x) = O(1)$ as $x \to a$ exactly means that g is bounded in a neighborhood of a. If $\lim_{x\to a} \frac{g(x)}{f(x)}$ exists, then $g(x) = O(f(x))$ as $x \to a$. But note that $g(x) = O(f(x))$ as $x \to a$ does not imply that $\lim_{x\to a} \frac{g(x)}{f(x)}$ exists; for example, $\sin \frac{1}{x} = O(1)$ as $x \to 0$.

[13] [?, p. 204].

(ii) $g(x) = o(f(x))$ as $x \to a$ roughly means that $\lim_{x\to a} \frac{g(x)}{f(x)} = 0$; if $\lim_{x\to a} \frac{g(x)}{f(x)} = 0$, then $g(x) = o(f(x))$ as $x \to a$, but not quite conversely: $x \sin \frac{1}{x} = o(\sin \frac{1}{x})$ as $x \to 0$. But $g(x) = o(1)$ as $x \to a$ exactly means that $\lim_{x\to a} g(x) = 0$.

(iii) $x^m = O(x^n)$ as $x \to 0$ if and only if $m \geq n$; $x^m = o(x^n)$ as $x \to 0$ if and only if $m > n$. But $x^m = O(x^n)$ as $x \to +\infty$ if and only if $m \leq n$, and $x^m = o(x^n)$ as $x \to +\infty$ if and only if $m < n$.

PROPOSITION. Let a be an extended real number, and f, g, and h real-valued functions defined in a neighborhood of a.

(i) If $g(x) = o(f(x))$ as $x \to a$, then $g(x) = O(f(x))$ as $x \to a$.

(ii) If $g(x) = O(f(x))$ and $h(x) = O(g(x))$ as $x \to a$, then $h(x) = O(f(x))$ as $x \to a$.

(iii) If $g(x) = o(f(x))$ and $h(x) = O(g(x))$ as $x \to a$, then $h(x) = o(f(x))$ as $x \to a$.

(iv) If $g(x) = O(f(x))$ and $h(x) = o(g(x))$ as $x \to a$, then $h(x) = o(f(x))$ as $x \to a$.

In particular, if $g(x) = O(f(x))$ and $f(x) = O(1)$, then $g(x) = O(1)$; if $g(x) = o(f(x))$ and $f(x) = O(1)$, or $g(x) = O(f(x))$ and $f(x) = o(1)$, then $g(x) = o(1)$.

PROOF: (i) is obvious from the definitions.
(ii): By hypothesis, there is an $M > 0$ and $\delta_1 > 0$ such that $|g(x)| \leq M|f(x)|$ for $0 < |x - a| < \delta_1$, and an $N > 0$ and $\delta_2 > 0$ such that $|h(x)| \leq N|g(x)|$ for $0 < |x - a| < \delta_2$. Set $\delta = \min(\delta_1, \delta_2)$. Then, if $0 < |x - a| < \delta$, we have

$$|h(x)| \leq N|g(x)| \leq MN|f(x)| \ .$$

(iii): Let $\epsilon > 0$. By hypothesis, there is an $M > 0$ and $\delta_1 > 0$ such that $|h(x)| \leq M|g(x)|$ for $0 < |x-a| < \delta_1$. There is then a $\delta_2 > 0$ such that $|g(x)| \leq \frac{\epsilon}{M}|f(x)|$ for $0 < |x - a| < \delta_2$. Set $\delta = \min(\delta_1, \delta_2)$. Then, for $0 < |x - a| < \delta$,

$$|h(x)| \leq M|g(x)| \leq M \cdot \frac{\epsilon}{M}|f(x)| = \epsilon|f(x)| \ .$$

(iv) is almost identical to (iii), and is left to the reader. 👍

We often just write "$O(f(x))$" or "$o(f(x))$" (along with "as $x \to a$" if it is not understood from the context) to denote some function $g(x)$ which satisfies $g(x) = O(f(x))$ or $g(x) = o(f(x))$ (as $x \to a$).

Note that the expressions $O(f(x))$ and $o(f(x))$ do not necessarily represent specific functions of x (or, more precisely, different uses of $O(f(x))$ or $o(f(x))$ may represent different specific functions of x). Consequently, these expressions do not necessarily follow the usual algebraic rules. For example, from

$$g(x) + o(f(x)) = h(x) + o(f(x))$$

it cannot be concluded that $g(x) = h(x)$; it only follows that $g(x) = h(x)+o(f(x))$ (i.e. $g(x)-h(x) = o(f(x))$.) Here are some rules that are valid:

PROPOSITION.

(i) If $g_1(x) = O(f(x))$ and $g_2(x) = O(f(x))$ as $x \to a$, then $g_1(x) + g_2(x) = O(f(x))$ as $x \to a$.

(ii) If $g_1(x) = o(f(x))$ and $g_2(x) = o(f(x))$ as $x \to a$, then $g_1(x) + g_2(x) = o(f(x))$ as $x \to a$.

(iii) If $g_1(x) = O(f_1(x))$ and $g_2(x) = O(f_2(x))$ as $x \to a$, then $g_1(x)g_2(x) = O(f_1(x)f_2(x))$ as $x \to a$. In particular, if $g(x) = O(f(x))$ and $h(x) = O(1)$ as $x \to a$, then $g(x)h(x) = O(f(x))$ as $x \to a$.

(iv) If $g_1(x) = o(f_1(x))$ and $g_2(x) = O(f_2(x))$ as $x \to a$, then $g_1(x)g_2(x) = o(f_1(x)f_2(x))$ as $x \to a$. In particular, if $g(x) = o(f(x))$ and $h(x) = O(1)$ as $x \to a$, then $g(x)h(x) = o(f(x))$ as $x \to a$.

These results are often abbreviated: $O(f(x))+O(f(x)) = O(f(x))$, $o(f(x))+o(f(x)) = o(f(x))$, $O(f(x))\cdot O(g(x)) = O(f(x)g(x))$, $o(f(x))\cdot O(g(x)) = o(f(x)g(x))$. One of the simplest and most common applications of the last two results is that $K \cdot O(f(x)) = O(f(x))$ and $K \cdot o(f(x)) = o(f(x))$ for any constant K.

PROOF: We prove only (iv); the other proofs are very similar (but slightly easier). Let $\epsilon > 0$. By hypothesis, there is an $M > 0$ and $\delta_2 > 0$ such that $|g_2(x)| \le M|f_2(x)|$ for $0 < |x - a| < \delta_2$. Then there exists a $\delta_1 > 0$ such that $|g_1(x)| \le \frac{\epsilon}{M}|f_1(x)|$ for $0 < |x - a| < \delta_1$. Set $\delta = \min(\delta_1, \delta_2)$. Then, for $0 < |x - a| < \delta$,

$$|g_1(x)g_2(x)| \le \frac{\epsilon}{M}|f_1(x)| \cdot M|f_2(x)| = \epsilon|f_1(x)f_2(x)| \ .$$

The next result is fairly special, but is useful in dealing with quotients. It is awkward to even state this result without using the o-notation (try it!)

PROPOSITION. Let a be an extended real number, and g, h, and k real-valued functions defined on a deleted neighborhood of a, with $h(x) \neq 0$ for all x in a deleted neighborhood of a. Suppose $g(x) = O(1)$, $\frac{1}{h(x)} = O(1)$, and $k(x) = o(1)$ as $x \to a$ (i.e. g is bounded and h is bounded away from 0 in a deleted neighborhood of a, and $\lim_{x\to a} k(x) = 0$). Then

$$\frac{g(x)}{h(x) + k(x)} = \frac{g(x)}{h(x)} - \frac{g(x)}{[h(x)]^2}k(x) + O([k(x)]^2) \text{ as } x \to a \ .$$

PROOF: The proof uses the algebraic formula

$$\frac{1}{1+t} = 1 - t + \frac{t^2}{1+t}$$

valid for $t \neq -1$, which is easily proved by multiplying both sides by $1 + t$. (This formula is a special case of the formula of ().)

Under the hypotheses, there is an $M > 0$ and $\delta_1 > 0$ such that $|h(x)| \ge M$ for $0 < |x - a| < \delta_1$, and there is a $\delta_2 > 0$ such that $|k(x)| < M/2$ for $0 < |x - a| < \delta_2$. There is also an $N \ge 0$ and $\delta_3 > 0$ such that $|g(x)| \le N$ for $0 < |x - a| < \delta_3$. Set $\delta = \min(\delta_1, \delta_2, \delta_3)$. Then if $0 < |x - a| < \delta$, $|h(x) + k(x)| > M/2$ and in particular is nonzero, so $\frac{g(x)}{h(x)+k(x)}$ is defined in a deleted neighborhood of 0. Also, if $0 < |x - a| < \delta$, $\left|\frac{k(x)}{h(x)}\right| < 1/2$, so $\frac{k(x)}{h(x)} \neq -1$. Thus, for $0 < |x - a| < \delta$, we have

$$\frac{g(x)}{h(x) + k(x)} = \frac{g(x)}{h(x)} \cdot \frac{1}{1 + \frac{k(x)}{h(x)}}$$

$$= \frac{g(x)}{h(x)} \left(1 - \frac{k(x)}{h(x)} + \frac{\left[\frac{k(x)}{h(x)}\right]^2}{1 + \frac{k(x)}{h(x)}} \right)$$

$$= \frac{g(x)}{h(x)} - \frac{g(x)}{[h(x)]^2} k(x) + \frac{g(x)}{[h(x)]^2 (h(x) + k(x))} [k(x)]^2 \ .$$

The last term is $O([k(x)]^2)$ as $x \to a$ since

$$\left| \frac{g(x)}{[h(x)]^2 (h(x) + k(x))} \right| \leq \frac{N}{M^2 \left(\frac{M}{2}\right)} = \frac{2N}{M^3}$$

for $0 < |x - a| < \delta$. 👍

COROLLARY. Let a be an extended real number, and f, g, h, and k real-valued functions defined on a deleted neighborhood of a, with $h(x) \neq 0$ for all x in a deleted neighborhood of a. Suppose $g(x) = O(1)$, $\frac{1}{h(x)} = O(1)$, and $f(x) = o(1)$ as $x \to a$ (i.e. g is bounded and h is bounded away from 0 in a deleted neighborhood of a, and $\lim_{x \to a} f(x) = 0$).

(i) If $k(x) = O(f(x))$ as $x \to a$, then

$$\frac{g(x)}{h(x) + k(x)} = \frac{g(x)}{h(x)} + O(f(x)) \text{ as } x \to a.$$

(ii) If $k(x) = o(f(x))$ as $x \to a$, then

$$\frac{g(x)}{h(x) + k(x)} = \frac{g(x)}{h(x)} + o(f(x)) \text{ as } x \to a.$$

This result is sometimes abbreviated by the following curious algebraic formula: "Under the hypotheses on f, g, and h,

$$\frac{g(x)}{h(x) + o(f(x))} = \frac{g(x)}{h(x)} + o(f(x))"$$

(and similarly for $O(f(x))$.) The explanation of why this expression does not violate the rules of algebra is that the $o(f(x))$'s on the two sides of the equation stand for (usually) different functions of x.

PROOF: First observe that $\frac{g(x)}{[h(x)]^2}$ is bounded in a deleted neighborhood of a. Using the notation of the proof of V.7., it is bounded by $\frac{N}{M^2}$ for $0 < |x - a| < \delta$. Thus the second term is $O(k(x))$, which is $O(f(x))$ if $k(x) = O(f(x))$, and $o(f(x))$ if $k(x) = o(f(x))$. Also, the third term is $O([k(x)]^2) = o(k(x)) = o(f(x))$ in either part since $k(x) = o(1)$. 👍

The o is probably used more than the O, since o denotes a function which becomes negligible and thus is very useful in limit or differentiability arguments (although the O, if used carefully, gives a more precise description of asymptotic behavior). The next result, an almost immediate consequence of the definition of differentiability, is probably the most important example of use of the little-o notation:

PROPOSITION. Let f be a real-valued function defined in a neighborhood of $a \in \mathbb{R}$. Then f is differentiable at a if and only if there is an $m \in \mathbb{R}$ such that

$$f(x) = f(a) + m(x-a) + o(x-a) \text{ as } x \to a$$

(or, more precisely, $f(x) - f(a) - m(x-a) = o(x-a)$ as $x \to a$). Such an m, if it exists, is unique and equals $f'(a)$.

As an example of use of the little-o notation in simplifying arguments, here is a proof of the Product Rule (). Note that this proof shows how the product rule follows naturally from the algebraic rule for multiplying multinomials. In addition, it avoids having to use the trick/technique of adding and subtracting something from an expression which may not be obvious, and also avoids explicitly using the result that a differentiable function is continuous.

PROOF: Let f and g be real-valued functions defined in a neighborhood of $a \in \mathbb{R}$, and differentiable at a. Then $f(x) = f(a) + f'(a)(x-a) + o(x-a)$ and $g(x) = g(a) + g'(a)(x-a) + o(x-a)$ in a neighborhood of a. So, in a neighborhood of a,

$$\begin{aligned} f(x)g(x) &= [f(a) + f'(a)(x-a) + o(x-a)][g(a) + g'(a)(x-a) + o(x-a)] \\ &= f(a)g(a) + f'(a)g(a)(x-a) + g(a)o(x-a) + f(a)g'(a)(x-a) + f'(a)g'(a)(x-a)^2 \\ &\quad + g'(a)(x-a)o(x-a) + f(a)o(x-a) + f'(a)(x-a)o(x-a) + o(x-a)\cdot o(x-a) \\ &= f(a)g(a) + [f'(a)g(a) + f(a)g'(a)](x-a) \\ &\quad + [g(a)o(x-a) + f'(a)g'(a)(x-a)^2 + g'(a)(x-a)o(x-a) \\ &\quad + f(a)o(x-a) + f'(a)(x-a)o(x-a) + o(x-a)\cdot o(x-a)] \end{aligned}$$

The expressions in the last brackets are all $o(x-a)$ since $f(a)$, $g(a)$, $f'(a)g'(a)$, $f'(a)(x-a)$, $g'(a)(x-a)$, and $o(x-a)$ are all $O(1)$ as $x \to a$, and $(x-a)^2 = o(x-a)$ as $x \to a$. Thus

$$f(x)g(x) = f(a)g(a) + [f'(a)g(a) + f(a)g'(a)](x-a) + o(x-a)$$

in a neighborhood of a, and so by V.7., fg is differentiable at a and

$$(fg)'(a) = f'(a)g(a) + f(a)g'(a) \ .$$

We now give a proof of the Quotient Rule using the o-notation. This proof is not as clean or satisfying as the above proof of the Product Rule, but gives a better idea of where the Quotient Rule comes from algebraically than the usual proof, and also avoids the "adding and subtracting" trick/technique. It does, however, use in one place the fact that a differentiable function is continuous.

PROOF: Let f and g be defined in a neighborhood of $a \in \mathbb{R}$ and differentiable at a, with $g(a) \neq 0$. Then, since f and g are continuous at a, there is a $\delta_1 > 0$ such that $|f(x)| < |f(a)| + 1$ for $|x-a| < \delta_1$, and there is $\delta_2 > 0$ such that $|g(x)| > \frac{|g(a)|}{2}$ for $|x-a| < \delta_2$. Thus g is nonzero in a neighborhood of a, so $\frac{f}{g}$ is defined in a neighborhood of a, and f and $\frac{1}{g}$ are bounded in a neighborhood of a. By V.7., we can write $f(x) = f(a) + f'(a)(x-a) + o(x-a)$ and $g(x) = g(a) + g'(a)(x-a) + o(x-a)$ in a neighborhood of a, so

$$\frac{f(x)}{g(x)} = \frac{f(a) + f'(a)(x-a) + o(x-a)}{g(a) + g'(a)(x-a) + o(x-a)} \ .$$

First applying V.7.(ii), and then applying V.7., we obtain

$$\begin{aligned}\frac{f(x)}{g(x)} &= \frac{f(a)+f'(a)(x-a)+o(x-a)}{g(a)+g'(a)(x-a)+o(x-a)}\\ &= \frac{f(a)+f'(a)(x-a)+o(x-a)}{g(a)+g'(a)(x-a)}+o(x-a)\\ &= \frac{f(a)+f'(a)(x-a)+o(x-a)}{g(a)}\\ &\quad -\frac{f(a)+f'(a)(x-a)+o(x-a)}{[g(a)]^2}g'(a)(x-a)+O([x-a]^2)+o(x-a)\\ &= \frac{f(a)+f'(a)(x-a)+o(x-a)}{g(a)}\\ &\quad -\frac{f(a)+f'(a)(x-a)+o(x-a)}{[g(a)]^2}g'(a)(x-a)+o(x-a)\ .\end{aligned}$$

Expanding and rearranging terms, we obtain:

$$\begin{aligned}\frac{f(x)}{g(x)} &= \frac{f(a)}{g(a)}+\frac{f'(a)}{g(a)}(x-a)+\frac{o(x-a)}{g(a)}-\frac{f(a)g'(a)}{[g(a)]^2}(x-a)\\ &\quad -\frac{f'(a)g'(a)}{[g(a)]^2}(x-a)^2-\frac{o(x-a)}{[g(a)]^2}(x-a)+o(x-a)\\ &= \frac{f(a)}{g(a)}+\left[\frac{f'(a)}{g(a)}-\frac{f(a)g'(a)}{[g(a)]^2}\right](x-a)\\ &\quad +\left[\frac{o(x-a)}{g(a)}-\frac{f'(a)g'(a)}{[g(a)]^2}(x-a)^2-\frac{o(x-a)}{[g(a)]^2}(x-a)+o(x-a)\right]\ .\end{aligned}$$

All the terms in the last brackets are $o(x-a)$, so in a neighborhood of a we have

$$\frac{f(x)}{g(x)} = \frac{f(a)}{g(a)}+\left[\frac{f'(a)}{g(a)}-\frac{f(a)g'(a)}{[g(a)]^2}\right](x-a)+o(x-a)\ .$$

Thus by V.7., $\frac{f}{g}$ is differentiable at a and

$$\left(\frac{f}{g}\right)'(a) = \frac{f'(a)}{g(a)}-\frac{f(a)g'(a)}{[g(a)]^2} = \frac{g(a)f'(a)-f(a)g'(a)}{[g(a)]^2}\ .$$

V.7.1. Exercises

1. Give careful definitions of (1) "$g(x) = O(f(x))$ as $x \to +\infty$" (2) "$g(x) = O(f(x))$ as $x \to a+$" (3) "$y_n = O(x_n)$ as $n \to \infty$", and similarly for o, and give versions of all the results of this section for these notions.

V.8. The Mean Value Theorem

> "The Mean Value Theorem is the midwife of calculus – not very important or glamorous by itself, but often helping to deliver other theorems that are of major significance."
>
> *E. Purcell and D. Varberg*[14]

The Mean Value Theorem (MVT) is one of the major theoretical results of calculus. It is the primary tool allowing information about a differentiable function to be obtained from properties of its derivative.

V.8.1. Rolle's Theorem and the Mean Value Theorem

V.8.1.1. THEOREM. [MEAN VALUE THEOREM] Let $a, b \in \mathbb{R}$, $a < b$. Let f be a function which is continuous on $[a, b]$ and differentiable on (a, b). Then there is at least one $c \in (a, b)$ for which

$$f(b) - f(a) = f'(c)(b - a) \ .$$

Alternatively, there is at least one $c \in (a, b)$ with

$$f'(c) = \frac{f(b) - f(a)}{b - a} \ .$$

A geometric interpretation is that there is at least one point on the graph between a and b at which the tangent line is parallel to the secant line between $(a, f(a))$ and $(b, f(b))$ (Figure V.9).

V.8.1.2. The number $f'(c)$ can be interpreted as the instantaneous rate of change of f at c, while the number $\frac{f(b)-f(a)}{b-a}$ is the average rate of change of f between a and b. Thus, for example, if a driver's average speed is 60 MPH over a period of time, there must be at least one instant of time during the period at which his instantaneous speed is exactly 60 MPH.

V.8.1.3. Three important points to note about the conclusion of the MVT:

(i) The c depends on the numbers a and b, as well as on the function f.

(ii) For a given f, a, and b, there may be more than one c, even infinitely many, satisfying the conclusion. (In Figure V.9 there are five, denoted $c_1 - c_5$.) Indeed, in the extreme case where f is linear, every $c \in (a, b)$ works.

(iii) In practice it may be difficult if not impossible to explicitly find a c that works for a given a and b, even for relatively well-behaved f. The MVT is a prime example of a *pure existence theorem*, in which something is shown to exist without any clue as to how to find a specific example. As we will see, however, just the knowledge that such a c exists will be of great importance in obtaining conclusions about the function f.

[14] ?

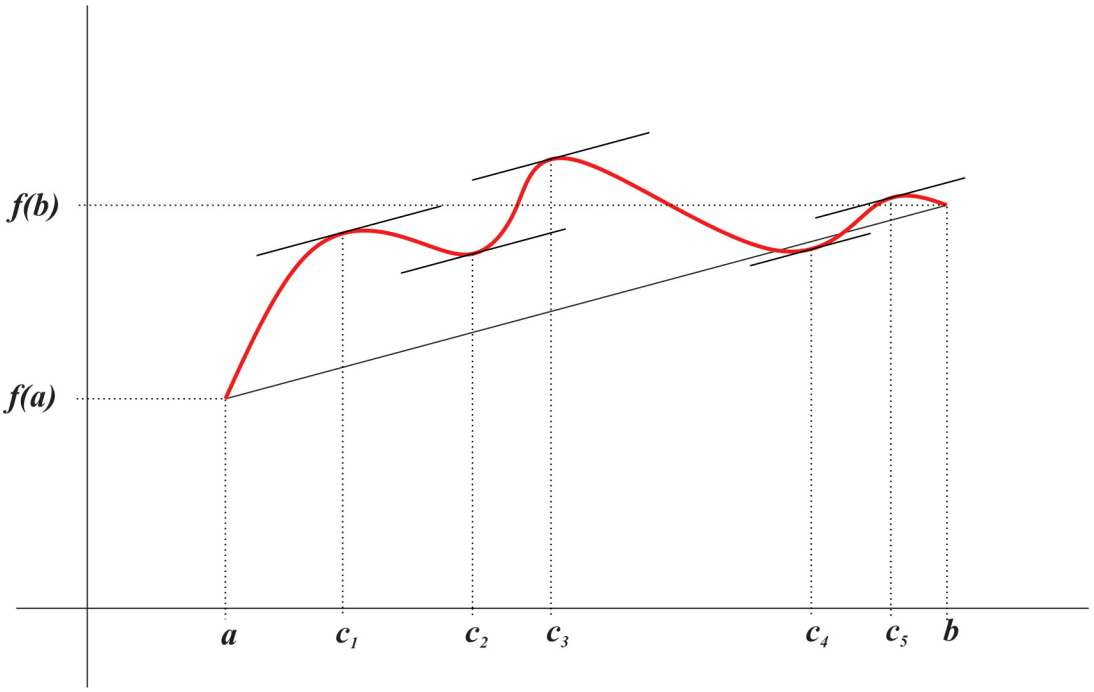

Figure V.9: The Mean Value Theorem

Rolle's Theorem

We will give the standard modern proof of the MVT, due to O. Bonnet in 1868. Cauchy previously gave a more complicated and flawed proof (cf. [Bre07]). The essential step in Bonnet's proof is to prove a special case, which is important enough in its own right to have a standard name:

V.8.1.4. Theorem. [Rolle's Theorem] Let $a, b \in \mathbb{R}$, $a < b$, and let f be continuous on $[a, b]$ and differentiable on (a, b). If $f(a) = f(b)$, then there is at least one $c \in (a, b)$ with $f'(c) = 0$.

It is ironic that a theorem of calculus should be named after Rolle, since according to [Bal60, p. 318], Rolle, a contemporary of Newton and Leibniz, believed that calculus was "nothing but a collection of ingenious fallacies." (It has been suggested that he later changed his mind.) Many references claim that Rolle first stated and proved this theorem; however, Rolle's statement and proof only referred to polynomials and did not use any explicit calculus. It is unclear who first stated the result in its modern form. See the chapter by J. Barrow-Green in [RS09] for the full story. See also Exercise V.8.6.11..

Proof: Since f is continuous on a closed bounded interval, it attains a maximum M and a minimum m on $[a, b]$ (Max-Min Theorem). Then, since $m \leq f(a) \leq M$, at least one of the following is true:

(i) $M > f(a)$.

(ii) $m < f(a)$.

(iii) f is constant on $[a,b]$.

In case (i), there is a $c \in (a,b)$ with $f(c) = M$. Then $f'(c) = 0$ by V.3.6.3..
In case (ii), there is a $c \in (a,b)$ with $f(c) = m$. Again by V.3.6.3. we have $f'(c) = 0$.
And in case (iii), $f'(c) = 0$ for all $c \in (a,b)$. 👍

Before going on to the MVT, we record some simple consequences of Rolle's theorem which are basically just restatements or special cases of the theorem.

V.8.1.5. Corollary. Let $a, b \in \mathbb{R}$, $a < b$, and let f be continuous on $[a,b]$ and differentiable on (a,b). If $f'(x) \neq 0$ for all $x \in (a,b)$, then $f(a) \neq f(b)$.

The next corollary is useful in locating the zeros of a function such as a polynomial:

V.8.1.6. Corollary. Let f be differentiable on an interval I. Then between any two zeros of f in I there is at least one zero of f'.

The Mean Value Theorem

We now turn to the MVT. This theorem was first stated by Lagrange in (). We will actually prove the following more general theorem, due to Cauchy (with a flawed proof) in 1821; the usual MVT is the special case $g(x) = x$.

V.8.1.7. Theorem. [Cauchy Mean Value Theorem] Let $a, b \in \mathbb{R}$, $a < b$. Let f and g be functions which are continuous on $[a,b]$ and differentiable on (a,b). Then there is at least one $c \in (a,b)$ for which

$$g'(c)[f(b) - f(a)] = f'(c)[g(b) - g(a)] \ .$$

Proof: For $x \in [a,b]$, set

$$h(x) = f(x)[g(b) - g(a)] - g(x)[f(b) - f(a)] \ .$$

Then h is continuous on $[a,b]$ and differentiable on (a,b), and $h(a) = h(b)$. By V.8.1.4. there is a $c \in (a,b)$ such that

$$0 = h'(c) = f'(c)[g(b) - g(a)] - g'(c)[f(b) - f(a)] \ .$$

👍

The following special case is commonly stated as Cauchy's Mean Value Theorem:

V.8.1.8. Corollary. Let $a, b \in \mathbb{R}$, $a < b$. Let f and g be functions which are continuous on $[a, b]$ and differentiable on (a, b), such that $g'(x) \neq 0$ for all $x \in (a, b)$. Then $g(a) \neq g(b)$, and there is at least one $c \in (a, b)$ for which

$$\frac{f(b) - f(a)}{g(b) - g(a)} = \frac{f'(c)}{g'(c)} .$$

Proof: The first conclusion follows from V.8.1.5., and then the second conclusion is V.8.1.7.. 👍

V.8.1.9. This corollary has a geometric interpretation. If $\phi(t) = (g(t), f(t))$, then ϕ is the parametrization of a smooth curve in $\mathbb{R}^2$. The slope of the line through the endpoints of the curve is

$$\frac{f(b) - f(a)}{g(b) - g(a)}$$

and the slope of the tangent line at the point $\phi(t)$ is $\frac{f'(t)}{g'(t)}$. Cauchy's MVT says that there is at least one point on the curve where the tangent line is parallel to the line through the two endpoints. (The requirement that $g' \neq 0$ on (a, b) insures that this curve has no vertical tangents, and it turns out to actually be the graph of a differentiable function (cf. V.8.2.14.). The geometric result is true more generally as long as the endpoints are distinct and f' and g' do not simultaneously vanish (Exercise V.8.6.1.).)

V.8.2. Applications of the Mean Value Theorem

There are many important theoretical consequences of the MVT. We begin with a crucial one:

V.8.2.1. Corollary. Let $a, b \in \mathbb{R}$, $a < b$. Let f be a function which is continuous on $[a, b]$ and differentiable on (a, b). If $f'(x) \geq 0$ for all $x \in (a, b)$, then f is nondecreasing on $[a, b]$, and in particular $f(a) \leq f(b)$. If f' is not identically 0 on (a, b), then $f(a) < f(b)$.

Proof: If $a \leq x_1 < x_2 \leq b$, applying the MVT to the interval $[x_1, x_2]$ we have

$$f(x_2) - f(x_1) = f'(c)(x_2 - x_1) \geq 0$$

for some $c \in (x_1, x_2)$. Since f is nondecreasing on $[a, b]$, if $f(a) = f(b)$ we must have f constant on $[a, b]$, and hence f' is identically 0. 👍

Similarly, we have:

V.8.2.2. Corollary. Let $a, b \in \mathbb{R}$, $a < b$. Let f be a function which is continuous on $[a, b]$ and differentiable on (a, b). If $f'(x) \leq 0$ for all $x \in (a, b)$, then f is nonincreasing on $[a, b]$, and in particular $f(a) \geq f(b)$. If f' is not identically 0 on (a, b), then $f(a) > f(b)$.

Putting the last two together, we get a result of basic significance:

V.8.2.3. Corollary. Let $a, b \in \mathbb{R}$, $a < b$. Let f be a function which is continuous on $[a, b]$ and differentiable on (a, b). If $f'(x) = 0$ for all $x \in (a, b)$, then f is constant on $[a, b]$.

V.8.2.4. Corollary. Let $a, b \in \mathbb{R}$, $a < b$. Let f and g be functions which are continuous on $[a, b]$ and differentiable on (a, b). If $f'(x) = g'(x)$ for all $x \in (a, b)$, then f and g differ by a constant.

Proof: Apply V.8.2.3. to $f - g$. 👍

V.8.2.5. Corollary. Let $a, b \in \mathbb{R}$, $a < b$. Let f and g be functions which are continuous on $[a, b]$ and differentiable on (a, b). If $f(a) = g(a)$ and $f'(x) \geq g'(x)$ for all $x \in (a, b)$, then $f(x) \geq g(x)$ for all $x \in [a, b]$, with strict inequality unless $f' = g'$ on (a, x).

Proof: Apply V.8.2.1. to $f - g$. 👍

The First Derivative Test for Local Extrema

One of the standard tests for local extrema is a direct consequence of the MVT:

V.8.2.6. Theorem. [First Derivative Test] Let f be continuous on an interval I, and a an interior point of I. Suppose

(i) There is an $r \in I$, $r < a$, with f differentiable on (r, a) and $f'(x) \geq 0$ for all $x \in (r, a)$.

(ii) There is an $s \in I$, $s > a$, with f differentiable on (a, s) and $f'(x) \leq 0$ for all $x \in (a, s)$.

Then f has a local maximum at a. It is a strict local maximum unless f' is identically zero in an interval to the left or right of a.
Similarly, suppose

(iii) There is an $r \in I$, $r < a$, with f differentiable on (r, a) and $f'(x) \leq 0$ for all $x \in (r, a)$.

(iv) There is an $s \in I$, $s > a$, with f differentiable on (a, s) and $f'(x) \geq 0$ for all $x \in (a, s)$.

Then f has a local minimum at a. It is a strict local minimum unless f' is identically zero in an interval to the left or right of a.

Note that differentiability of f at a is not assumed (if $f'(a)$ exists, it must be 0 as a result of this theorem and V.3.6.3., or from V.8.2.15..)
Proof: In the first case, apply V.8.2.1. to $[r, a]$ and V.8.2.2. to $[a, s]$, and vice versa in the second case. 👍

A one-sided version of this test also applies at endpoints of I; the statement is left to the reader.

Differential Approximation with Error Estimates

We can obtain a variation of differential approximation with error estimates:

V.8.2.7. Corollary. Let $a, b, M \in \mathbb{R}$, $a < b$. Let f be a function which is continuous on $[a, b]$ and differentiable on (a, b). If $f'(x) < M$ for all $x \in (a, b)$, then

$$f(x_2) - f(x_1) < M(x_2 - x_1)$$

for all $x_1, x_2 \in [a, b]$, $x_1 < x_2$. The result also holds if $<$ is replaced by $\leq$ throughout.

Proof: Let $x_1, x_2 \in [a, b]$, $x_1 < x_2$. Then, applying the MVT to $[x_1, x_2]$, for some $c \in (x_1, x_2)$ we have

$$f(x_2) - f(x_1) = f'(c)(x_2 - x_1) < M(x_2 - x_1) \ .$$

Similarly, we have

V.8.2.8. Corollary. Let $a, b, m \in \mathbb{R}$, $a < b$. Let f be a function which is continuous on $[a, b]$ and differentiable on (a, b). If $m < f'(x)$ for all $x \in (a, b)$, then

$$m(x_2 - x_1) < f(x_2) - f(x_1)$$

for all $x_1, x_2 \in [a, b]$, $x_1 < x_2$. The result also holds if $<$ is replaced by $\leq$ throughout.

Combining, we get the two-sided version:

V.8.2.9. Corollary. Let $a, b, m, M \in \mathbb{R}$, $a < b$. Let f be a function which is continuous on $[a, b]$ and differentiable on (a, b). If $m < f'(x) < M$ for all $x \in (a, b)$, then

$$m(x_2 - x_1) < f(x_2) - f(x_1) < M(x_2 - x_1)$$

for all $x_1, x_2 \in [a, b]$, $x_1 < x_2$. The result also holds if $<$ is replaced by $\leq$ throughout.

Taylor's theorem gives a higher-order version of these inequalities ().

V.8.2.10. V.8.2.7. is often called the *Mean Value Inequality*. It is an immediate consequence of the special case V.8.2.1. and linearity of the derivative. There is a direct proof of V.8.2.1. (in the special case where f is differentiable on $[a, b]$) by the Method of Successive Bisections () (Exercise V.8.6.11.). This proof is arguably simpler and more elementary than the proof of the MVT since it only uses the Nested Intervals Theorem and not the Extreme Value Theorem, and several authors, e.g. [**?**, p. 152], [vRS82, p. 93], [Boa95, p. 8], [Kör04, p. 59], argue that the Mean Value Inequality is sufficient for most applications in analysis and that the MVT itself is overrated. I personally do not regard the proof of the MVT as very difficult given the Extreme Value Theorem, which one would want to include anyway in any treatment of real analysis.

Lipschitz Continuity

A similar consequence which will be important later is:

V.8.2.11. Corollary. Let $a, b, M \in \mathbb{R}$, $a < b$, $M \geq 0$. Let f be a function which is continuous on $[a, b]$ and differentiable on (a, b). If $|f'(x)| \leq M$ for all $x \in (a, b)$, then

$$|f(x_2) - f(x_1)| \leq M|x_2 - x_1|$$

for all $x_1, x_2 \in [a, b]$ (i.e. if f' is bounded on (a, b), then f is a *Lipschitz function* () on $[a, b]$).

Proof: Let $x_1, x_2 \in [a, b]$, $x_1 < x_2$. Then, applying the MVT to $[x_1, x_2]$, for some $c \in (x_1, x_2)$ we have

$$|f(x_2) - f(x_1)| = |f'(c)||x_2 - x_1| \leq M|x_2 - x_1| \ .$$

There is also a generalized version whose statement is left to the reader (it is very similar to V.8.4.9.).

The Intermediate Value Property for Derivatives

Although derivatives can be quite discontinuous (cf. V.12.1.), they rather remarkably satisfy the conclusion of the Intermediate Value Theorem.

V.8.2.12. Definition. A function g defined on an interval I has the *Intermediate Value Property*, or *Darboux Property*, if, whenever $a, b \in I$, $a < b$, and r is a number strictly between $g(a)$ and $g(b)$, there is a $c \in (a, b)$ with $g(c) = r$.

A function which has the Intermediate Value Property is sometimes called *Darboux continuous*.

Every continuous function has the Intermediate Value Property by V.2.3.1.. So do derivatives:

V.8.2.13. Theorem. If f is a differentiable function on an interval I, then f' has the Intermediate Value Property on I.

Proof: Let $a, b \in I$, $a < b$, and r a number strictly between $f'(a)$ and $f'(b)$. Set $g(x) = f(x) - rx$; then g is differentiable on I and $g'(x) = f'(x) - r$ for $x \in I$.

If $f'(a) > r > f'(b)$, then $g'(a) > 0$ and $g'(b) < 0$. Since g is continuous on $[a, b]$, it has a maximum on this interval at some $c \in [a, b]$ (V.2.4.1.). The maximum cannot occur at a or b since $g'(a) > 0$ and $g'(b) < 0$ (V.3.6.12.); thus $c \in (a, b)$, and $g'(c) = 0$ by V.3.6.3.. Then $f'(c) = r$.

The case $f'(a) < r < f'(b)$ is nearly identical, considering the minimum of g on $[a, b]$.

V.8.2.14. Corollary. If f is differentiable on an interval I, and $f'(x) \neq 0$ for all $x \in I$, then f' does not change sign on I, i.e. either $f'(x) > 0$ for all $x \in I$ or $f'(x) < 0$ for all $x \in I$. In particular, f is either strictly increasing on I or strictly decreasing on I (V.8.2.1., V.8.2.2.).

Here is another related approximate continuity property of derivatives:

V.8.2.15. THEOREM. Let f be differentiable on an open interval (a,b), and $c \in (a,b)$. Then

$$\liminf_{x\to c+} f'(x) \le f'(c) \le \limsup_{x\to c+} f'(x)$$

$$\liminf_{x\to c-} f'(x) \le f'(c) \le \limsup_{x\to c-} f'(x) \ .$$

In particular, if $\lim_{x\to c+} f'(x)$ exists, it equals $f'(c)$, and similarly for $\lim_{x\to c-} f'(x)$.

PROOF: We prove only the first inequality; the others are virtually identical. If

$$f'(c) < \liminf_{x\to c+} f'(x)$$

there is an $\epsilon > 0$ and a d, $c < d \le b$, such that $f'(x) \ge f'(c) + \epsilon$ for all $x \in (c,d)$. Then, by the MVT, for every $x, y \in (c,d)$, $x \ne y$, we have

$$\frac{f(y) - f(x)}{y - x} \ge f'(c) + \epsilon \ .$$

Fix $y \in (c,d)$; we then get

$$\frac{f(y) - f(c)}{y - c} = \lim_{x\to c+} \frac{f(y) - f(x)}{y - x} \ge f'(c) + \epsilon$$

since f is continuous at c. But then we have

$$f'(c) = \lim_{y\to c+} \frac{f(y) - f(c)}{y - c} \ge f'(c) + \epsilon$$

which is a contradiction. 👍

In fact, every Darboux continuous function has this approximate continuity property (Exercise V.8.6.4.).

See V.9.4.11. for an extension of the last statement. See also V.12.2.5..

V.8.3. Geometric Interpretation of the Second Derivative

Using the MVT, we can now give careful justification of the interpretation of the second derivative of a function in terms of concavity.

V.8.3.1. DEFINITION. Let f be a continuous function on an interval I. Then f is *concave upward* on I if, whenever $a, b, c \in I$ with $a < c < b$, we have

$$f(c) < f(a) + \frac{f(b) - f(a)}{b - a}(c - a) \ .$$

The function f is *concave downward* on I if, whenever $a, b, c \in I$ with $a < c < b$, we have

$$f(c) > f(a) + \frac{f(b) - f(a)}{b - a}(c - a) \ .$$

Geometrically, f is concave upward on I if on every closed bounded subinterval of I, the graph of f on the interior lies strictly below the secant line through the endpoints, and similarly the graph lies strictly above the secant line if f is concave downwards. "Concave upward" is synonymous with "strictly convex" (cf. XIX.3.1.1.).

V.8.3.2. THEOREM. Let f be continuous on $[a,b]$ and differentiable on (a,b). Then f is concave upward on $[a,b]$ if and only if f' is strictly increasing on (a,b), and f is concave downward on $[a,b]$ if and only if f' is strictly decreasing on (a,b).

PROOF: We prove the first statement. Suppose f' is strictly increasing on $[a,b]$. Let $L(x)$ be the linear function

$$L(x) = f(a) + \frac{f(b)-f(a)}{b-a}(x-a)$$

whose graph is the secant line through $(a,f(a))$ and $(b,f(b))$. Suppose there is an $x_0 \in (a,b)$ with $f(x_0) \geq L(x_0)$. Then by the MVT there are $c_1 \in (a,x_0)$ and $c_2 \in (x_0,b)$ with

$$f'(c_1) = \frac{f(x_0)-f(a)}{x_0-a} \geq \frac{L(x_0)-L(a)}{x_0-a} = \frac{f(b)-f(a)}{b-a} \geq \frac{f(b)-f(x_0)}{b-x_0} = f'(c_2)$$

which contradicts that f' is strictly increasing on (a,b) since $a < c_1 < c_2 < b$. The converse is a special case of XIX.3.1.16.. The proof of the second statement is identical with inequalities reversed. 👍

V.8.3.3. COROLLARY. Let f be continuous on $[a,b]$ and twice differentiable on (a,b). If $f''(x) \geq 0$ for all $x \in (a,b)$, and is not identically 0 on any subinterval, then f is concave upward on $[a,b]$. If $f''(x) \leq 0$ for all $x \in (a,b)$, and is not identically 0 on any subinterval, then f is concave downward on $[a,b]$. In particular, if $f'' > 0$ [resp. $f'' < 0$] on an interval I, then f is concave upward [resp. concave downward] on I.

PROOF: If $f'' \geq 0$ on (a,b) and not 0 on any subinterval, then f' is strictly increasing on (a,b) (V.8.2.1.), and similarly if $f'' \leq 0$. 👍

V.8.3.4. A function which is concave upward need not be differentiable everywhere, for example $f(x) = |x| + x^2$ (but it must be differentiable except on a countable set, cf. XIX.3.1.16.). A linear function is twice differentiable, but not concave up or concave down on any interval. And even a nonlinear twice differentiable function need not be either concave upward or concave downward on any interval: consider an antiderivative for the example of ().

There is a pointwise analog:

V.8.3.5. THEOREM. Let I be an interval, f be a function from I to $\mathbb{R}$, and a in the interior of I. Suppose f is twice differentiable at a (which implies that f' exists in a neighborhood of a and is continuous at a). Let L be the linear function whose graph is the tangent line to the graph of f at a, i.e. $L(x) = f(a)+f'(a)(x-a)$.
(i) If $f''(a) > 0$, then there is an $\epsilon > 0$ such that $f(x) > L(x)$ for all x, $0 < |x-a| < \epsilon$.
(ii) If $f''(a) < 0$, then there is an $\epsilon > 0$ such that $f(x) < L(x)$ for all x, $0 < |x-a| < \epsilon$.

Geometrically, if $f''(a) > 0$, the graph of f near a lies strictly above the tangent line at a, and strictly below if $f''(a) < 0$.

PROOF: (i): We have that f' is increasing at a (V.3.6.8.), i.e. there is an $\epsilon > 0$ such that $f'(x) < f'(a)$ if $x \in (a-\epsilon, a)$ and $f'(x) > f'(a)$ if $x \in (a, a+\epsilon)$. If $x \in (a-\epsilon, a)$, then by the MVT there is a $c \in (x, a)$ with

$$\frac{f(x) - f(a)}{x - a} = f'(c) < f'(a) = \frac{L(x) - L(a)}{x - a}$$

and it follows that $f(x) - f(a) > L(x) - L(a) = L(x) - f(a)$ since $x - a < 0$. The argument if $x \in (a, a+\epsilon)$ is essentially identical. The proof of (ii) is the same with inequalities reversed. 👍

A special case is particularly important:

V.8.3.6. COROLLARY. [SECOND DERIVATIVE TEST] Let I be an interval, f be a function from I to $\mathbb{R}$, and a in the interior of I. Suppose f is twice differentiable at a (which implies that f' exists in a neighborhood of a and is continuous at a).

(i) If $f'(a) = 0$ and $f''(a) > 0$, then f has a strict local minimum at a.

(ii) If $f'(a) = 0$ and $f''(a) < 0$, then f has a strict local maximum at a.

PROOF: The function $L(x)$ is the constant function $f(a)$. 👍

V.8.3.7. This result only goes one way. If f has a relative extremum at a, it need not be twice differentiable (or even once differentiable!) at a, and even if it is we can have $f''(a) = 0$ (consider $f(x) = x^4$ at 0). See V.10.7.12. for an extension of the second derivative test.

Points of Inflection

A point of inflection of a function is a place where the function changes concavity:

V.8.3.8. DEFINITION. Let f be continuous on an interval I, and c an interior point of I. Then f has a *point of inflection* at c if there are $a, b \in I$ with $a < c < b$ such that f is concave upward on $[a, c]$ and concave downward on $[c, b]$, or vice versa.

V.8.3.9. If f is differentiable on I, and has a point of inflection at $c \in I$, then by V.8.3.2. and V.8.2.15. f' must have a strict local extremum at c. In particular, if f is twice differentiable at c, then $f''(c) = 0$. However, the converses are not true: if $f(x) = x^4$, then $f''(0) = 0$, but f does not have a point of inflection at 0, and in fact is concave up on all of $\mathbb{R}$. And if g is an antiderivative for the function f of V.3.10.11., then g is twice differentiable everywhere with $g''(0) = 0$, and g' has a strict local minimum at 0, but g does not have a point of inflection at 0: in fact, g is neither concave up or concave down in any interval with endpoint 0. ✋

V.8.4. Refinements of the Mean Value Theorem

We can give a refinement of V.8.2.1.. We do not obtain this as a consequence of the MVT, but give a direct proof in the spirit of the MVT.

V.8.4.1. THEOREM. Let f be a continuous function on $[a,b]$, and A a countable subset of $[a,b]$. Suppose f is differentiable on $[a,b] \setminus A$.

(i) If $f'(x) > 0$ for all $x \in [a,b] \setminus A$, then f is strictly increasing on $[a,b]$.

(ii) If $f'(x) \geq 0$ for all $x \in [a,b] \setminus A$, then f is nondecreasing on $[a,b]$.

(iii) If $f'(x) = 0$ for all $x \in [a,b] \setminus A$, then f is constant on $[a,b]$.

Similar statements to (i) and (ii) hold if $f'(x) < 0$ or $f'(x) \leq 0$ for all $x \in [a,b] \setminus A$.

Of course, this theorem includes the special cases $A = \emptyset$ and $A = \{a,b\}$, which is V.8.2.1..

PROOF: (i): It suffices to show that f is nondecreasing on $[a,b]$, since if f is nondecreasing but not strictly increasing it would be constant on some subinterval, hence have $f' = 0$ on some interval. In fact, it suffices to show that $f(a) \leq f(b)$, since the interval $[a,b]$ can be replaced by any closed subinterval.

So suppose $f(a) > f(b)$. Since $f(A)$ is countable, we can find a number $d \notin f(A)$ with $f(a) > d > f(b)$. Let $B = \{x \in [a,b] : f(x) = d\}$. B is nonempty by the Intermediate Value Theorem. Since f is continuous, B is closed, and thus has a largest element c. We have $a < c < b$ since $f(a) > d > f(b)$, and $c \notin A$ since $f(c) \notin f(A)$. So f is differentiable at c and $f'(c) > 0$. Since $f(b) < d$ and f never takes the value d on (c,b), we must have $f(x) < d$ for all $x \in (c,b)$ by the Intermediate Value Theorem. Hence

$$\lim_{x \to c+} \frac{f(x) - f(c)}{x - c} \leq 0$$

contradicting the assumption that $f'(c) > 0$.

(ii): Let $\epsilon > 0$. Apply (i) to $g(x) = f(x) + \epsilon x$ to conclude that $f(a) \leq f(b) + \epsilon(b-a)$. Since ϵ is arbitrary, $f(a) \leq f(b)$.

(iii): Apply (ii) to f and $-f$. 👍

The differentiability of f on $[a,b] \setminus A$ can be relaxed to the assumption that the upper right Dini derivative of f is positive (nonnegative, zero) on $[a,b] \setminus A$ (the proof of (iii) is a bit more subtle in this case, however; see ()). Hence a more general statement can be proved with the same argument:

V.8.4.2. THEOREM. Let f be a continuous function on an interval $[a,b]$, and let A be a countable subset of $[a,b]$. Then

(i) If $D^+f(x) > 0$ for all $x \in [a,b] \setminus A$, then f is strictly increasing on $[a,b]$.

(ii) If $D^+f(x) \geq 0$ for all $x \in [a,b] \setminus A$, then f is nondecreasing on $[a,b]$.

(iii) If $D^+f(x) = 0$ for all $x \in [a,b] \setminus A$, then f is constant on $[a,b]$.

Similar statements to (i) and (ii) hold if $D_+(x) < 0$ or $D_+(x) \leq 0$ for all $x \in [a,b] \setminus A$.

V.8.4.3. Note that the only property of A needed for the proof of (i) is that $f(A)$ does not contain any interval. However, there is a subtlety in the proof of (ii) (and hence (iii)) if only this assumption is made: if $f(A)$ does not contain any interval, if A is uncountable it is not obvious that $g(A)$ contains no interval if $g(x) = f(x) + \epsilon x$, and in fact this may fail (cf. [vRS82, 21.G]). Thus, to obtain a more general version of V.8.4.2. in this setting, we would have to add a clumsy set of additional hypotheses, although there are situations where a generalization is possible (e.g. XIX.5.1.18.). We can state part (i) in this setting:

V.8.4.4. THEOREM. Let f be a continuous function on an interval $[a,b]$, and let A be a subset of $[a,b]$ such that $f(A)$ contains no interval. Then

(i) If $D^+f(x) > 0$ for all $x \in [a,b] \setminus A$, then f is strictly increasing on $[a,b]$.

(ii) If $D_+f(x) < 0$ for all $x \in [a,b] \setminus A$, then f is strictly decreasing on $[a,b]$.

Perhaps the most general version of V.8.4.2.(ii) which can be stated reasonably simply is:

V.8.4.5. THEOREM. Let f be a continuous function on an interval $[a,b]$. If $D^+f(x) \geq 0$ for all x not in a set A of measure 0, and $B = \{x \in [a,b] : D^+f(x) = -\infty\}$ is at most countable, then f is nondecreasing on $[a,b]$.

(Under the hypotheses, the sets B, and even A, would turn out to be empty, but this need not be assumed. Actually, the result is interesting and useful even in the case $B = \emptyset$.)
PROOF: Let g be a nondecreasing function on $[a,b]$ with $D_+g(x) = +\infty$ for all $x \in A$ (). Fix $\epsilon > 0$ and let $h_\epsilon = f + \epsilon g$. Then $D^+h_\epsilon(x) \geq D^+f(x) \geq 0$ for $x \notin A \cup B$ since g is nondecreasing. If $x \in A \setminus B$, then $D^+f(x) > -\infty$, so $D^+h_\epsilon(x) = +\infty$ by (). Thus $D^+h_\epsilon(x) \geq 0$ for all $x \notin B$, so h_ϵ is nondecreasing by V.8.4.2.(ii). Since $f = \lim_{\epsilon \to 0} h_\epsilon$, f is also nondecreasing. 👍

V.8.4.6. Note that the hypothesis that B be countable cannot be replaced by an assumption that B is a null set: the negative of the Cantor function () is a counterexample.

Using V.8.4.1., we can obtain generalizations of V.8.2.7. and V.8.2.8.. As explained in V.8.4.3., to obtain a clean statement we must assume the conditions hold except on a countable subset.

V.8.4.7. COROLLARY. Let $a, b, M \in \mathbb{R}$, $a < b$. Let f be a function which is continuous on $[a,b]$. Let A be a countable subset of $[a,b]$. If $D_+f(x) < M$ for all $x \in [a,b] \setminus A$, then

$$f(x_2) - f(x_1) < M(x_2 - x_1)$$

for all $x_1, x_2 \in [a,b]$, $x_1 < x_2$. The result also holds if $<$ is replaced by $\leq$ throughout.

PROOF: Apply V.8.4.2. to $h(x) = Mx - f(x)$. 👍

V.8.4.8. COROLLARY. Let $a, b, m \in \mathbb{R}$, $a < b$. Let f be a function which is continuous on $[a,b]$. Let A be a countable subset of $[a,b]$. If $m < D^+f(x)$ for all $x \in [a,b] \setminus A$, then

$$m(x_2 - x_1) < f(x_2) - f(x_1)$$

for all $x_1, x_2 \in [a,b]$, $x_1 < x_2$. The result also holds if $<$ is replaced by $\leq$ throughout.

PROOF: Apply V.8.4.2. to $g(x) = f(x) - mx$. 👍

V.8.4.9. Corollary. Let $a, b, m, M \in \mathbb{R}$, $a < b$. Let f be a function which is continuous on $[a, b]$. Let A be a countable subset of $[a, b]$. If $m < D^+f(x)$ and $D_+f(x) < M$ for all $x \in [a, b] \setminus A$, then

$$m(x_2 - x_1) < f(x_2) - f(x_1) < M(x_2 - x_1)$$

for all $x_1, x_2 \in [a, b]$, $x_1 < x_2$. The result also holds if $<$ is replaced by $\leq$ throughout.

The following special case of V.8.4.2.(iii) is useful:

V.8.4.10. Corollary. Let f and g be continuous functions on an interval I. If there is a countable subset A of I such that $D_Rf(x)$ and $D_Rg(x)$ exist and are equal for all $x \in I \setminus A$, then f and g differ by a constant on I.

Proof: Apply V.8.4.2.(iii) to $f - g$ (on any closed bounded subinterval of I). 👍

V.8.5. Antiderivatives and Primitives

Antiderivatives are usually associated with integration, but we can use the results of the previous subsection to obtain antiderivatives for certain well-behaved functions without discussing integration, at least explicitly.

V.8.5.1. Definition. Let f be a function on an interval I. An *antiderivative* for f on I is a function F on I which is differentiable on I and with $F' = f$ on I.
A *primitive* for f on I is a continuous function F on I such that, for some countable subset A of I, $F'(x)$ exists and equals $f(x)$ for all $x \in I \setminus A$.

V.8.5.2. Since a differentiable function on an interval is continuous, every antiderivative for f on I is a primitive for f on I (with $A = \emptyset$). The terms "antiderivative" and "primitive" are often used as synonyms, but we make a slight technical distinction between them which will be useful.

V.8.5.3. Antiderivatives and primitives are not unique: a constant can be added to any antiderivative (primitive) to obtain another antiderivative (primitive). By V.8.2.5., this is the only change possible for antiderivatives: any two antiderivatives for a function f differ by a constant. This is also true for primitives by V.8.4.10..

Step Functions

Recall () that a *step function* on an interval $[a, b]$ corresponding to a partition

$$\mathcal{P} = \{a = x_0, x_1, \ldots, x_n = b\}$$

is a function which is constant on (x_{k-1}, x_k) for $1 \leq k \leq n$.

V.8.5.4. PROPOSITION. Let f be a step function on $[a,b]$. Then f has a primitive on $[a,b]$.

PROOF: This is quite simple and straightforward, but notationally a bit complicated. The function F will be "piecewise linear" or "polygonal". Suppose f takes the value a_k on (x_{k-1}, x_k). Define f as follows:

For $x_0 \le x \le x_1$, let $F(x) = a_1(x - x_0)$.

For $x_1 < x \le x_2$, let $F(x) = a_1(x_1 - x_0) + a_2(x - x_1)$.

For $x_2 < x \le x_3$, let $F(x) = a_1(x_1 - x_0) + a_2(x_2 - x_1) + a_3(x - x_2)$.

...

For $x_{k-1} < x \le x_k$, let $F(x) = \sum_{j=1}^{k-1} a_j(x_j - x_{j-1}) + a_k(x - x_{k-1})$.

...

It is obvious that F is continuous on $[a,b]$, and that $F'(x) = f(x)$ for $x \in [a,b] \setminus \{x_0, \dots, x_n\}$. 👍

The next theorem is the most important result of this subsection. It will be used for other purposes than the ones of this subsection, such as justifying term-by-term differentiation and integration of infinite series of functions. In many, but not all, applications, the set A in the statement of the theorem will be the empty set. See XIX.5.4.14. for a sophisticated (almost) strengthened version.

V.8.5.5. THEOREM. Let (F_n) and (f_n) be sequences of functions on an interval I, and A a countable subset of I. Suppose

(a) Each F_n is continuous on I.

(b) For every $x \in I \setminus A$, each F_n is differentiable at x and $F_n'(x) = f_n(x)$.

(c) The sequence (f_n) converges u.c. on I to a function f.

(d) There is an $x_0 \in I$ such that the sequence $(F_n(x_0))$ converges.

Then:

(i) The sequence (F_n) converges u.c. on I to a (continuous) function F.

(ii) For each $x \in I \setminus A$, F is differentiable at x and $F'(x) = f(x)$.

PROOF: (i): Let J be a closed bounded subinterval of I. We will show that (F_n) is a uniform Cauchy sequence on J, hence uniformly convergent to a (continuous) limit function F by (). By expanding J, we may assume $x_0 \in J$.

Let $\epsilon > 0$. Choose N such that for all $n, m \ge N$,

$$\sup_{x \in J} |f_n(x) - f_m(x)| < \frac{\epsilon}{2\ell(J)}$$

$$|F_n(x_0) - F_m(x_0)| < \frac{\epsilon}{2} .$$

Then, if $n, m \geq N$ and $x \in J$, by V.8.4.7. we have, since $(F_n - F_m)' = f_n - f_m$ on $J \setminus A$,

$$|[F_n(x) - F_m(x)] - [F_n(x_0) - F_m(x_0)]| < \frac{\epsilon}{2\ell(J)}|x - x_0| \leq \frac{\epsilon}{2}$$

and so

$$\begin{aligned} |F_n(x) - F_m(x)| &= |[F_n(x) - F_n(x_0)] - [F_m(x) - F_m(x_0)] + [F_n(x_0) - F_m(x_0)]| \\ &\leq |[F_n(x) - F_n(x_0)] - [F_m(x) - F_m(x_0)]| + |F_n(x_0) - F_m(x_0)| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon . \end{aligned}$$

(ii): Let J be as above, and $\epsilon > 0$. There is an N such that

$$\sup_{x \in J} |f_n(x) - f(x)| < \frac{\epsilon}{4}$$

for all $n \geq N$. Fix $n \geq N$. For all $m \geq N$, we have

$$\sup_{x \in J} |f_n(x) - f_m(x)| < \frac{\epsilon}{2}$$

and hence by V.8.4.7. we have

$$|[F_m(y) - F_m(x)] - [F_n(y) - F_n(x)]| = |[F_m(y) - F_n(y)] - [F_m(x) - F_n(x)]| < \frac{\epsilon}{2}|y - x|$$

for all $x, y \in J$. Since $F_m \to F$ uniformly on J, letting $m \to \infty$ we have

$$|[F(y) - F(x)] - [F_n(y) - F_n(x)]| \leq \frac{\epsilon}{2}|y - x|$$

for all $x, y \in J$.

Now fix $x \in J \setminus A$. Then there is a $\delta > 0$ such that

$$\left| \frac{F_n(y) - F_n(x)}{y - x} - f_n(x) \right| < \frac{\epsilon}{4}$$

whenever $0 < |y - x| < \delta$. Then, for $0 < |y - x| < \delta$, we have

$$\begin{aligned} \left| \frac{F(y) - F(x)}{y - x} - f(x) \right| &= \left| \frac{[F(y) - F(x)] - [F_n(y) - F_n(x)]}{y - x} + \frac{F_n(y) - F_n(x)}{y - x} - f_n(x) + f_n(x) - f(x) \right| \\ &\leq \left| \frac{[F(y) - F(x)] - [F_n(y) - F_n(x)]}{y - x} \right| + \left| \frac{F_n(y) - F_n(x)}{y - x} - f_n(x) \right| + |f_n(x) - f(x)| < \frac{\epsilon}{2} + \frac{\epsilon}{4} + \frac{\epsilon}{4} = \epsilon \end{aligned}$$

and thus $F'(x) = f(x)$. 👍

V.8.5.6. A simpler proof using the Fundamental Theorem of Calculus can be given in the crucial special case where $A = \emptyset$ and the f_n are continuous (IX.2.9.15.).

V.8.5.7. COROLLARY. Let (f_n) be a sequence of functions on an interval I, converging u.c. on I to a function f.

(i) If each f_n has a primitive on I, then f has a primitive on I.

(ii) If each f_n has an antiderivative on I, then f has an antiderivative on I.

PROOF: Fix $x_0 \in I$. By adjusting by a constant, f_n has a primitive (antiderivative in case (ii)) F_n on I with $F_n(x_0) = 0$. Let A_n be the set of $x \in I$ for which $F_n'(x) = f_n(x)$ does not hold; then A_n is countable, and $A_n = \emptyset$ in case (ii). Set $A = \cup_{n=1}^{\infty} A_n$. Then (f_n), (F_n), A satisfy the hypotheses of V.8.5.5.. 👍

V.8.5.8. PROPOSITION. Let f be a continuous function on an interval I. Then there is a sequence (f_n) of step functions on I converging u.c. to f on I. If A is any dense subset of I, the f_n may be chosen to have discontinuities only in A.

PROOF: This is an almost immediate consequence of (). Let $\{[a_n, b_n]\}$ be an increasing sequence of closed bounded intervals with union I. Then f is uniformly continuous on $[a_n, b_n]$. For each n fix $\delta_n > 0$ such that $x, y \in [a_n, b_n]$, $|x - y| < \delta_n$ implies $|f(x) - f(y)| < \frac{1}{n}$. Then let $\mathcal{P}_n$ be a partition of $[a_n, b_n]$ with interior points in A with mesh $< \delta_n$, and t_k a point in the k'th subinterval of the partition. Let f_n be the step function with value $f(t_k)$ on the k'th subinterval of the partition $\mathcal{P}_n$ (and, say, left continuous at the points of the partition), and extend f_n to I by making it constant to the left and right of $[a_n, b_n]$ if necessary. Then $f_n \to f$ u.c. on I (Exercise V.8.6.6.). 👍

V.8.5.9. THEOREM. Let f be a continuous function on an interval I. Then f has an antiderivative on I.

PROOF: Fix $x_0 \in I$, and let A and B be disjoint countable dense subsets of I (e.g. $A = \mathbb{Q} \cap I$, $B = [\mathbb{Q} + \sqrt{2}] \cap I$). Then there is a sequence (f_n) of step functions on I with discontinuities only in A, converging u.c. to f on I. It follows from V.8.5.5. that f has a primitive F_1 on I satisfying $F_1'(x) = f(x)$ for all $x \in I \setminus A$ and $F_1(x_0) = 0$. Similarly, there is a primitive F_2 of f on I such that $F_2'(x) = f(x)$ for all $x \in I \setminus B$ and $F_2(x_0) = 0$. By V.8.4.10. (applied using the countable set $A \cup B$), F_1 and F_2 differ by a constant. But $F_1(x_0) = F_2(x_0)$, so $F_1 = F_2$. Thus $F_1'(x)$ exists and equals $f(x)$ for all $x \in (I \setminus A) \cup (I \setminus B) = I$. 👍

V.8.5.10. We will give another proof of this theorem in IX.2.9.4.. (Deep down, it is really the same proof.)

Another example where a similar argument applies is monotone functions:

V.8.5.11. PROPOSITION. Let f be a monotone function on an interval I. Then there is a sequence (f_n) of step functions on I converging u.c. to f on I.

V.8.5.12. COROLLARY. Let f be a monotone function on an interval I. Then f has a primitive on I.

V.8.5.13. It can be shown with a little additional work that if f is monotone on I and F is a primitive of f on I, then the (countable) set A of x for which $F'(x) = f(x)$ does not hold is exactly the set of discontinuities of f. See V.8.6.7. for a more general result.

V.8.6. Exercises

V.8.6.1. Let C be a smooth curve from p to q in $\mathbb{R}^2$ (i.e. with a parametrization $(g(t), f(t))_{a \le t \le b}$ with f and g differentiable on $[a, b]$ and f' and g' not simultaneously 0). If $p \neq q$ and r is a point on C of maximum distance from the line L through p and q (why does such a point exist?), show that the tangent line to C at r is parallel to L. Extend to the case where f and g are continuous on $[a, b]$ and differentiable on (a, b).

V.8.6.2. (a) Prove V.8.4.2.(i) and (ii) in the case where the upper right Dini derivative D^+f is positive or nonnegative on $[a, b] \setminus A$. Show why (iii) does not immediately follow from (ii) in this case.

(b) Suppose $D^+f(x) = 0$ for all $x \in [a, b] \setminus A$. Apply (ii) to conclude that f is nondecreasing on $[a, b]$. Thus the lower right Dini derivative D_+f satisfies $D_+f(x) \ge 0$ for all $x \in [a, b]$.

(c) In the situation of (b), conclude that $D_+f(x) = 0$ for all $x \in [a, b] \setminus A$; thus (ii) can be applied to $-f$ to conclude that $-f$ is increasing on $[a, b]$. Thus f is constant on $[a, b]$.

V.8.6.3. Use the Intermediate Value Property for derivatives () to give an alternate proof of (). ?????

V.8.6.4. Let g be a Darboux continuous function on an open interval (a, b), and $c \in (a, b)$. Show that

$$\liminf_{x \to c+} g(x) \le g(c) \le \limsup_{x \to c+} g(x)$$

$$\liminf_{x \to c-} g(x) \le g(c) \le \limsup_{x \to c-} g(x) \ .$$

V.8.6.5. Let f be a continuous function on an open interval I. Set

$$M^+ = \sup\{D^+f(x) : x \in I\}$$

$$m^+ = \inf\{D^+f(x) : x \in I\}$$

(m^+ and/or M^+ may be infinite), and let

$$S = \left\{ \frac{f(y) - f(x)}{y - x} : x, y \in I, x \neq y \right\} \ .$$

(a) Show that $(m^+, M^+) \subseteq S \subseteq [m^+, M^+]$. [To show $(m^+, M^+) \subseteq S$, fix $\lambda \in (m^+, M^+)$ and let $g(x) = f(x) - \lambda x$. Then g has both positive and negative right Dini derivatives on I and hence cannot be one-to-one by (). For $S \subseteq [m^+, M^+]$, let $\lambda \le m^+$ and $\mu \ge M^+$, and apply V.8.4.2.(ii) to $f(x) - \lambda x$ and $\mu x - f(x)$.]

(b) Show that $m^+ \in S$ if and only if f is linear with slope m^+ on a subinterval of I, and similarly for M^+.

(c) Repeat (a) with

$$M_+ = \sup\{D_+f(x) : x \in I\}$$
$$m_+ = \inf\{D_+f(x) : x \in I\}$$

and with M^-, m^- and M_-, m_- defined similarly using D^-f and D_-f. Conclude that

$$m^+ = m_+ = m^- = m_- \text{ and } M^+ = M_+ = M^- = M_- \ .$$

(d) Use (a) to give an alternate proof of the Darboux property for derivatives. [Show that if f is differentiable on an open interval I, then $f'(J)$ is an interval for every open subinterval J of I.]

V.8.6.6. Show that if f is as in V.8.5.8., and (f_n) is the sequence defined in the proof, then $f_n \to f$ u.c. on I.

V.8.6.7. In [**?**, IX, Book IV, Chapter II, §1.3], a function on an interval I is called *regulated* (French *réglée*, also sometimes called *ruled*) on I if it is a u.c. limit of a sequence of step functions on I. Note that every regulated function has a primitive by V.8.5.5. and V.8.5.4.. By V.8.5.8. and V.8.5.11., every continuous function and every monotone function is regulated.

(a) Show that a function on an interval I which has left and right limits at every interior point of I has only countably many discontinuities on I. [Mimic the proof of V.4.2.11..]

(b) Show that a function f on an interval I is regulated if and only if it has left and right limits at every interior point of I and one-sided limits at any endpoints of I which are in I.

(c) Show that if f is regulated on I and F is a primitive for f on I, then the (countable) set A of all $x \in I$ for which $F'(x) = f(x)$ does not hold is precisely the set of discontinuities of f.

(d) Show that a regulated function on an interval I is bounded on every closed bounded subinterval of I. [Step functions are bounded.]

(e) Any (finite) linear combination of regulated functions on an interval I is regulated. Thus every function of bounded variation () on every closed bounded subinterval of I is regulated on I. Not every regulated function (indeed, not every continuous function) has bounded variation, even on closed bounded subintervals of I ().

See IX.2.12.4. for more on regulated functions.

V.8.6.8. (a) Show by direct calculation that every polynomial has an antiderivative on $\mathbb{R}$.

(b) Use V.8.5.5. and XX.10.1.1. to give an alternate proof of V.8.5.9..

V.8.6.9. [**?**, Exercise 7.6.21] (a) Prove the following generalization of Cauchy's Mean Value Theorem:

THEOREM. Let f, g, h be continuous on $[a, b]$ and differentiable on (a, b). Then there is a $c \in (a, b)$ such that

$$0 = Det \begin{bmatrix} f(a) & g(a) & h(a) \\ f(b) & g(b) & h(b) \\ f'(c) & g'(c) & h'(c) \end{bmatrix}$$

$$= f'(c)[g(a)h(b) - g(b)h(a)] - g'(c)[f(a)h(b) - f(b)h(a)] + h'(c)[f(a)g(b) - f(b)g(a)] \ .$$

Cauchy's MVT is the special case where h is the constant function 1. [Consider the function

$$\phi(x) = Det \begin{bmatrix} f(a) & g(a) & h(a) \\ f(b) & g(b) & h(b) \\ f(x) & g(x) & h(x) \end{bmatrix}$$

and apply Rolle's Theorem. Recall that a (square) matrix with two identical rows has determinant 0.]

(b) Extend the result to the case $n > 3$:

THEOREM. Let $n \geq 4$, and let $f_1, \ldots, f_n$ be continuous on $[a, b]$ and differentiable on (a, b). Let

$$\{d_{ij} : 3 \leq i \leq n-1, 1 \leq j \leq n\}$$

be arbitrary constants. Then there is a $c \in (a, b)$ such that

$$0 = Det \begin{bmatrix} f_1(a) & f_2(a) & \cdots & f_n(a) \\ f_1(b) & f_2(b) & \cdots & f_n(b) \\ d_{31} & d_{32} & \cdots & d_{3n} \\ \vdots & \vdots & \ddots & \vdots \\ d_{n-1,1} & d_{n-1,2} & \cdots & d_{n-1,n} \\ f_1'(c) & f_2'(c) & \cdots & f_n'(c) \end{bmatrix}.$$

(c) Here is another version:

THEOREM. Let $n \geq 3$, and let $\mathcal{P} = \{a = x_1, x_2, \ldots, x_{n-1} = b\}$ be a partition of $[a, b]$ into $n-2$ subintervals. Let $f_1, \ldots, f_n$ be continuous on $[a, b]$ and differentiable on $[a, b] \setminus \mathcal{P}$. Then, for each $k \leq n-2$, there is a $c \in (x_k, x_{k+1})$ such that

$$0 = Det \begin{bmatrix} f_1(x_1) & f_2(x_1) & \cdots & f_n(x_1) \\ f_1(x_2) & f_2(x_2) & \cdots & f_n(x_2) \\ \vdots & \vdots & \ddots & \vdots \\ f_1(x_{n-1}) & f_2(x_{n-1}) & \cdots & f_n(x_{n-1}) \\ f_1'(c) & f_2'(c) & \cdots & f_n'(c) \end{bmatrix}.$$

V.8.6.10. The Mean Value Inequality. This problem gives a direct proof of V.8.2.7. (in the case where f is differentiable on all of $[a, b]$) by the Method of Successive Bisections ().

(a) Show that to prove V.8.2.7. it suffices to prove V.8.2.1..

(b) Show that to prove V.8.2.1. it suffices to prove the following. [For each $\epsilon > 0$ set $f_\epsilon(x) = f(x) + \epsilon x$. To show that $f(a) \leq f(b)$, it suffices to show $f_\epsilon(a) \leq f_\epsilon(b)$ for all $\epsilon > 0$.]

PROPOSITION. Let f be differentiable on $[a, b]$. If $f'(x) > 0$ for all $x \in [a, b]$, then $f(a) \leq f(b)$.

(c) To prove this proposition, set $I_1 = [a, b]$, and c the midpoint of I_1. If $f(a) > f(b)$, then either $f(a) > f(c)$ or $f(c) > f(b)$. Let $I_2 = [a, c]$ if the first holds and $I_2 = [c, b]$ otherwise. Repeat the process to obtain a nested sequence (I_n) of intervals, where $I_n = [a_n, b_n]$ with $f(a_n) > f(b_n)$ for all n.

(d) Let $\cap_{n=1}^{\infty} I_n = \{x\}$. Show that $f'(x) \leq 0$, contradicting that $f'(x) > 0$.

V.8.6.11. The aim of this problem is to use a purely algebraic argument, along with the Intermediate Value Theorem for polynomials, to prove Rolle's Theorem for polynomials: between any two real roots of a polynomial p with real coefficients is a root of p'.

(a) Let $p(x)$ be a nonzero polynomial with real coefficients, and a and b consecutive real roots of p. Write

$$p(x) = (x-a)^r(x-b)^s q(x)$$

where $r, s \in \mathbb{N}$ and q is a polynomial with real coefficients with no roots in $[a,b]$, and which therefore does not change sign on $[a,b]$.

(b) Use the product rule to show that

$$p'(x) = (x-a)^{r-1}(x-b)^{s-1}\left[r(x-b)q(x) + s(x-a)q(x) + (x-a)(x-b)q'(x)\right] .$$

(c) Show that the polynomial in brackets in (b) takes values of opposite sign at a and b.

(d) Apply the Intermediate Value Theorem for polynomials to conclude that p' has a root in (a,b).

No actual differential calculus is needed for this problem, since the derivative of a polynomial can be defined and calculated formally, and the product rule for polynomials proved algebraically from the formal definition of derivative; cf. Exercise V.3.10.9.. (Even the Intermediate Value Theorem for polynomials has a purely algebraic proof in real-closed fields; see, for example, [BPR06].) In fact, Rolle did something like this, and it is unclear whether he even realized he was computing derivatives: he generated the sequence of derivatives of the given polynomial p in a somewhat different (algebraic) way and called them the "cascade of polynomials" in using them to locate the (real) roots of p. See the chapter by J. Barrow-Green in [RS09].

V.8.6.12. Let f be differentiable on an interval I, and suppose $f'(x) > 0$ for all $x \in I$. Use V.3.6.8. and the Max-Min Theorem () to prove that f is strictly increasing on I without using the MVT. [If $x_1, x_2 \in I$, $x_1 < x_2$, apply the Max-Min Theorem to $[x_1, x_2]$.]

V.8.6.13. Let f be continuous on an interval I and n-times differentiable on the interior of I. Suppose f has m distinct zeroes in I. Show by repeated application of Rolle's Theorem that for $1 \leq k \leq \min(n,m)$, $f^{(k)}$ has at least $m-k$ distinct zeroes in the interior of I.

V.9. L'Hôpital's Rule

L'Hôpital's Rule is a very useful technique for evaluating limits of indeterminate forms involving quotients. There are a number of variations of the rule, which all fall under the general name "l'Hôpital's Rule."

The rule is named for the French nobleman Marquis Guillaume François Antoine de l'Hôpital (sometimes spelled l'Hospital; his own spelling was apparently Lhospital) and was first published in 1696 in the calculus text *L'Analyse des Infiniment Petits pour l'Intelligence des Lignes Courbes* (the first actual calculus text!) written by l'Hôpital; this name for the rule apparently first appeared in print in [Gou59] in 1902. The rule (or at least one form of it) was actually discovered by Johann (or Jean) Bernoulli, who had taught calculus to l'Hôpital, in 1694; Bernoulli had a business arrangement with l'Hôpital giving l'Hôpital, who was himself a respectable mathematician, the right to publish Bernoulli's results. (See [**?**] for the full story.) L'Hôpital's text, which fairly closely followed lecture notes by Bernoulli, was very influential, and editions remained in print for almost 100 years (a copy is available online at http://www.archive.org/details/infinimentpetits1716lhos00uoft); before this text became available, calculus was known and understood by only a handful of top European mathematicians. L'Hôpital, besides being a gifted expositor (he also wrote a text on conic sections which was the standard for that subject throughout the eighteenth century), seems to have been a considerably more pleasant and genial person than Bernoulli: Bernoulli, although he was a great mathematician and had a reputation as an inspiring teacher (Euler was his prize pupil), was hypercompetitive and was continually embroiled in bitter disputes with other mathematicians, the most vicious of which were with his own brother Jakob (who was himself described as "self-willed, obstinate, aggressive, vindictive, beset by feelings of inferiority and yet firmly convinced of his own abilities.")![15] [Hof71] [Do not confuse the various Bernoullis; there were several outstanding mathematicians in this family, extending over at least three generations, but Johann and Jakob (or Jacques), and Johann's son Daniel, were the best.]

V.9.1. L'Hôpital's Rule, Version 1

The first version we give of l'Hôpital's Rule is an easy consequence of the definition of derivative, and is often not regarded as a form of l'Hôpital's Rule at all, although it is the version stated (imprecisely) by l'Hôpital himself (and, apparently, by Johann Bernoulli).

V.9.1.1. Theorem. [L'Hôpital's Rule, Version 1] Let f and g be functions on an interval I, and a an interior point of I. Suppose

(1) $\lim_{x\to a} f(x) = \lim_{x\to a} g(x) = 0$.

(2) f and g are differentiable at a and $g'(a) \neq 0$.

Then $\lim_{x\to a} \frac{f(x)}{g(x)}$ exists and equals $\frac{f'(a)}{g'(a)}$.

[15] For example, when Johann solved the catenary problem before Jakob, he gloated, "The efforts of my brother were without success; for my part, I was more fortunate, for I found the skill (I say it without boasting, why should I conceal the truth?) to solve it in full." (cf. [Dun90]). He added: "You know the disposition of my brother. He would sooner have taken away from me, if he could have done so honestly, the honor of being the first to solve it, rather than letting me take part by myself, let alone ceding the place, if it had really been his." ([**?**]). Johann was, however, known to try to pass off results of both Jakob and Daniel as his own, and treated Daniel vindictively. Jakob for his part was often petulantly resentful of the mathematical abilities of his younger brother. In [**?**] the Bernoullis were called "the most dysfunctional family in the history of mathematics."

PROOF: First note that since f and g are differentiable at a, they are continuous at a, and thus $f(a) = \lim_{x\to a} f(x) = 0$ and $g(a) = \lim_{x\to a} g(x) = 0$. We have

$$\frac{f'(a)}{g'(a)} = \frac{\lim\limits_{x\to a} \dfrac{f(x)-f(a)}{x-a}}{\lim\limits_{x\to a} \dfrac{g(x)-g(a)}{x-a}}$$

Note that $g(x) = g(x) - g(a) \neq 0$ in a deleted neighborhood of a since

$$g'(a) = \lim_{x\to a} \frac{g(x)-g(a)}{x-a} \neq 0 \ .$$

So, by (),

$$\frac{f'(a)}{g'(a)} = \lim_{x\to a} \left[\frac{\frac{f(x)-f(a)}{x-a}}{\frac{g(x)-g(a)}{x-a}} \right] = \lim_{x\to a} \frac{f(x)-f(a)}{g(x)-g(a)} = \lim_{x\to a} \frac{f(x)}{g(x)} \ .$$

V.9.1.2. This argument has an informal but geometrically appealing interpretation. If x changes from a by Δx, then $f(x)$ changes from $f(a)(= 0)$ by Δf, which by () is approximately $df = f'(a)\,\Delta x$ if Δx is small. Similarly, $g(x)$ changes from $g(a)$ by approximately $dg = g'(a)\,\Delta x$. So, if x is close to a,

$$\frac{f(x)}{g(x)} = \frac{\Delta f}{\Delta g} \approx \frac{df}{dg} = \frac{f'(a)\,\Delta x}{g'(a)\,\Delta x} = \frac{f'(a)}{g'(a)} \ .$$

In fact, it seems likely that BERNOULLI used an argument like this to discover the rule.

Version 1 of the rule is adequate for many of the elementary applications.

V.9.1.3. EXAMPLE. To evaluate

$$\lim_{x\to 0} \frac{e^x - 1}{\sin x}$$

let $f(x) = e^x - 1$, $g(x) = \sin x$, $a = 0$. We have $\lim_{x\to 0} f(x) = \lim_{x\to 0} g(x) = 0$, $f'(0) = g'(0) = 1$, so the hypotheses of Version I are satisfied and

$$\lim_{x\to 0} \frac{e^x - 1}{\sin x} = \frac{f'(0)}{g'(0)} = \frac{1}{1} = 1 \ .$$

(Note that $g(x) \neq 0$ on $(-\pi, \pi) \setminus \{0\}$.)

V.9.2. L'Hôpital's Rule, Version 2

There is another version (the commonly stated version) of l'Hôpital's Rule which is more complicated to prove, but more widely applicable. There are several slight variations of this version, which will collectively be called Version 2 of l'Hôpital's Rule.

V.9.2.4. THEOREM. [L'HÔPITAL'S RULE, VERSION 2A] Let f and g be differentiable functions on an interval (a,b), with g' nonzero on (a,b). Suppose

(1) $\lim_{x\to a+} f(x) = \lim_{x\to a+} g(x) = 0$.

(2) $\lim_{x\to a+} \dfrac{f'(x)}{g'(x)}$ exists in either the usual () or extended () sense.

Then $\lim_{x\to a+} \dfrac{f(x)}{g(x)}$ exists (in the same sense) and equals $\lim_{x\to a+} \dfrac{f'(x)}{g'(x)}$.

Note that it is *not* quite correct to say that if f and g are differentiable on (a,b) with g' nonzero, and $\lim_{x\to a+} f(x) = \lim_{x\to a+} g(x) = 0$, then

$$\lim_{x\to a+} \frac{f(x)}{g(x)} = \lim_{x\to a+} \frac{f'(x)}{g'(x)} \ ;$$

it can happen that $\lim_{x\to a+} \dfrac{f(x)}{g(x)}$ exists but $\lim_{x\to a+} \dfrac{f'(x)}{g'(x)}$ does not exist (Exercise V.9.4.4.), even if f and g are C^∞ and $g(x)$ and $g'(x)$ are nonzero for $x > a$ (Exercise V.9.4.7..)

PROOF: If necessary, extend f and g to be continuous on $[a,b)$ by setting $f(a) = g(a) = 0$. If $x \in (a,b)$, since g is continuous on $[a,x]$ and differentiable on (a,x), by the Mean Value Theorem () we have

$$g(x) - g(a) = g'(d)(x-a)$$

for some $d \in (a,x)$; since $g'(d) \neq 0$, we have $g(x) = g(x) - g(a) \neq 0$. Thus $\frac{f}{g}$ is defined on (a,b).

Set $L = \lim_{x\to a+} \dfrac{f'(x)}{g'(x)} \in \mathbb{R} \cup \{\pm\infty\}$. By the Sequential Criterion (), it suffices to show that if (x_n) is a sequence in (a,b) converging to a, we have $\lim_{n\to\infty} \frac{f(x_n)}{g(x_n)} = L$. By the Cauchy Mean Value Theorem we have, for each n,

$$\frac{f(x_n)}{g(x_n)} = \frac{f(x_n) - f(a)}{g(x_n) - g(a)} = \frac{f'(c_n)}{g'(c_n)}$$

for some $c_n \in (a, x_n)$. Since $a < c_n < x_n$ and $x_n \to a$, we have $c_n \to a$ by the Squeeze Theorem () and hence

$$\frac{f(x_n)}{g(x_n)} = \frac{f'(c_n)}{g'(c_n)} \to L$$

by the Sequential Criterion applied to $\lim_{x\to a+} \dfrac{f'(x)}{g'(x)} = L$.

V.9.2.5. Actually, the hypothesis that g' is nonzero on (a,b) is redundant: it is implicit in the existence of the limit $\lim_{x\to a+} \frac{f'(x)}{g'(x)}$ that $\frac{f'}{g'}$ is defined, i.e. $g' \neq 0$, in an open interval (a,r) for some $r > a$. Thus the hypothesis can be eliminated at the possible price of reducing the b to a smaller number still strictly larger than a. We have left the requirement in the statement of the theorem as a reminder that this hypothesis must be checked when the theorem is applied (cf. Exercise V.9.4.5..)

Note that the hypothesis that $g' \neq 0$ on (a,b) implies that g' does not change sign on (a,b) (V.8.2.14.).

An essentially identical argument shows:

V.9.2.6. THEOREM. [L'HÔPITAL'S RULE, VERSION 2B] Let f and g be differentiable functions on an interval (a, b), with g' nonzero on (a, b). Suppose

(1) $\lim_{x\to b-} f(x) = \lim_{x\to b-} g(x) = 0$.

(2) $\lim_{x\to b-} \dfrac{f'(x)}{g'(x)}$ exists in either the usual or extended sense.

Then $\lim_{x\to b-} \dfrac{f(x)}{g(x)}$ exists (in the same sense) and equals $\lim_{x\to b-} \dfrac{f'(x)}{g'(x)}$.

Combining the two previous versions together, we get:

V.9.2.7. THEOREM. [L'HÔPITAL'S RULE, VERSION 2C] Let f and g be differentiable functions on a deleted neighborhood U of $a \in \mathbb{R}$, with g' nonzero on U. Suppose

(1) $\lim_{x\to a} f(x) = \lim_{x\to a} g(x) = 0$.

(2) $\lim_{x\to a} \dfrac{f'(x)}{g'(x)}$ exists in either the usual or extended sense.

Then $\lim_{x\to a} \dfrac{f(x)}{g(x)}$ exists (in the same sense) and equals $\lim_{x\to a} \dfrac{f'(x)}{g'(x)}$.

There is also a version for limits at ∞:

V.9.2.8. THEOREM. [L'HÔPITAL'S RULE, VERSION 2D] Let f and g be differentiable functions on an interval $(a, +\infty)$, with g' nonzero on $(a, +\infty)$. Suppose

(1) $\lim_{x\to+\infty} f(x) = \lim_{x\to+\infty} g(x) = 0$.

(2) $\lim_{x\to+\infty} \dfrac{f'(x)}{g'(x)}$ exists in either the usual or extended sense.

Then $\lim_{x\to+\infty} \dfrac{f(x)}{g(x)}$ exists (in the same sense) and equals $\lim_{x\to+\infty} \dfrac{f'(x)}{g'(x)}$.
A similar statement holds for limits as $x \to -\infty$ for functions differentiable on an interval $(-\infty, a)$.

PROOF: We may assume $a > 0$. Set $L = \lim_{x\to+\infty} \frac{f'(x)}{g'(x)}$. For $t \in \left(0, \frac{1}{a}\right)$, set $F(t) = f(1/t)$ and $G(t) = g(1/t)$. Then F and G are differentiable on $\left(0, \frac{1}{a}\right)$, $G'(t) = -\frac{1}{t^2} g'(1/t) \neq 0$, and $G(t) \neq 0$. We have

$$\lim_{t\to 0+} \frac{F'(t)}{G'(t)} = \lim_{t\to 0+} \frac{-\frac{1}{t^2} f'(1/t)}{-\frac{1}{t^2} g'(1/t)} = \lim_{t\to 0+} \frac{f'(1/t)}{g'(1/t)} = \lim_{x\to+\infty} \frac{f'(x)}{g'(x)} = L$$

and so, by V.9.2.4.,

$$\lim_{x\to+\infty}\frac{f(x)}{g(x)}=\lim_{t\to0+}\frac{F(t)}{G(t)}=L\ .$$

L'Hôpital's Rule also applies to indeterminate forms of type $\frac{\infty}{\infty}$. The statements are essentially the same, but the proof is a little more complicated. In fact, it is unnecessary to assume the limit of the numerator is $\pm\infty$ (if $\lim\frac{f(x)}{g(x)}\neq0$ and $\lim g(x)=\pm\infty$, it follows automatically that $\lim f(x)=\pm\infty$; this can also be proved directly from $\lim\frac{f'(x)}{g'(x)}\neq0$ without applying l'Hôpital's rule, cf. V.9.4.8.).

V.9.2.9. THEOREM. [L'HÔPITAL'S RULE, VERSION 2A′] Let f and g be differentiable functions on an interval (a,b), with g' nonzero on (a,b). Suppose

(1) $\lim_{x\to a+}g(x)=\pm\infty$.

(2) $\lim_{x\to a+}\frac{f'(x)}{g'(x)}$ exists in either the usual or extended sense.

Then $\lim_{x\to a+}\frac{f(x)}{g(x)}$ exists (in the same sense) and equals $\lim_{x\to a+}\frac{f'(x)}{g'(x)}$.

V.9.2.10. THEOREM. [L'HÔPITAL'S RULE, VERSION 2B′] Let f and g be differentiable functions on an interval (a,b), with g' nonzero on (a,b). Suppose

(1) $\lim_{x\to b-}g(x)=\pm\infty$.

(2) $\lim_{x\to b-}\frac{f'(x)}{g'(x)}$ exists in either the usual or extended sense.

Then $\lim_{x\to b-}\frac{f(x)}{g(x)}$ exists (in the same sense) and equals $\lim_{x\to b-}\frac{f'(x)}{g'(x)}$.

V.9.2.11. THEOREM. [L'HÔPITAL'S RULE, VERSION 2C′] Let f and g be differentiable functions on a deleted neighborhood U of $a\in\mathbb{R}$, with g' nonzero on U. Suppose

(1) $\lim_{x\to a}g(x)=\pm\infty$.

(2) $\lim_{x\to a}\frac{f'(x)}{g'(x)}$ exists in either the usual or extended sense.

Then $\lim_{x\to a}\frac{f(x)}{g(x)}$ exists (in the same sense) and equals $\lim_{x\to a}\frac{f'(x)}{g'(x)}$.

V.9.2.12. THEOREM. [L'HÔPITAL'S RULE, VERSION 2D′] Let f and g be differentiable functions on an interval $(a, +\infty)$, with g' nonzero on $(a, +\infty)$. Suppose

(1) $\lim_{x\to+\infty} g(x) = \pm\infty$.

(2) $\lim_{x\to+\infty} \dfrac{f'(x)}{g'(x)}$ exists in either the usual or extended sense.

Then $\lim_{x\to+\infty} \dfrac{f(x)}{g(x)}$ exists (in the same sense) and equals $\lim_{x\to+\infty} \dfrac{f'(x)}{g'(x)}$.
A similar statement holds for limits as $x \to -\infty$ for functions differentiable on an interval $(-\infty, a)$.

PROOF: We give the proof of Version 2d′ for variety; proofs of the other versions are similar.

We first show that we may assume $g \neq 0$ on (a, ∞). We could give an argument using the Mean Value Theorem (cf. Exercise ()), but there is a simpler argument: since $\lim_{x\to+\infty} g(x) = \pm\infty$, there is automatically an interval $(r, +\infty)$ on which $|g| > 1$, say. Thus by increasing a if necessary we may assume that $g \neq 0$ on (a, ∞).

Let $L = \lim_{x\to+\infty} \dfrac{f'(x)}{g'(x)}$. As before, it suffices to show that if (x_n) is a sequence in $(a, +\infty)$ with $x_n \to +\infty$, then $\lim_{n\to\infty} \dfrac{f(x_n)}{g(x_n)} = L$. We will assume $L \in \mathbb{R}$; the case $L = \pm\infty$ is an easy variation. By Cauchy's Mean Value Theorem, for each m and n for which $x_m \neq x_n$ there is a $d_{m,n}$ between x_m and x_n such that

$$f(x_n) - f(x_m) = \frac{f'(d_{m,n})}{g'(d_{m,n})}[g(x_n) - g(x_m)] \ .$$

We then have

$$\frac{f(x_n)}{g(x_n)} - \frac{f(x_m)}{g(x_n)} = \frac{f(x_n) - f(x_m)}{g(x_n)} = \frac{f'(d_{m,n})}{g'(d_{m,n})}\frac{g(x_n) - g(x_m)}{g(x_n)}$$

$$\frac{f(x_n)}{g(x_n)} - L = \left[\frac{f'(d_{m,n})}{g'(d_{m,n})} - L\right] - \frac{f'(d_{m,n})}{g'(d_{m,n})}\frac{g(x_m)}{g(x_n)} + \frac{f(x_m)}{g(x_n)} \ .$$

Fix $\epsilon > 0$ and let R such that

$$\left|\frac{f'(x)}{g'(x)} - L\right| < \frac{\epsilon}{3}$$

for $x > R$, and fix m_0 such that $x_n > R$ for all $n \geq m_0$. Thus, for $n > m_0$,

$$\left|\frac{f'(d_{m_0,n})}{g'(d_{m_0,n})} - L\right| < \frac{\epsilon}{3} \ .$$

Set $M = |L| + \frac{\epsilon}{3}$. Since $\lim_{x\to+\infty} |g(x)| = +\infty$, choose $N > m_0$ such that $\left|\dfrac{f(x_{m_0})}{g(x_n)}\right| < \dfrac{\epsilon}{3}$ and $\left|\dfrac{g(x_{m_0})}{g(x_n)}\right| < \dfrac{\epsilon}{3M}$ for all $n \geq N$. Then, for $n \geq N$,

$$\left|\frac{f(x_n)}{g(x_n)} - L\right| \leq \left|\frac{f'(d_{m_0,n})}{g'(d_{m_0,n})} - L\right| + \left|\frac{f'(d_{m_0,n})}{g'(d_{m_0,n})}\right|\left|\frac{g(x_{m_0})}{g(x_n)}\right| + \left|\frac{f(x_{m_0})}{g(x_n)}\right| < \epsilon.$$

V.9.2.13. In fact, if g' is never zero and $\lim \dfrac{f'(x)}{g'(x)}$ exists, then $\lim \dfrac{f(x)}{g(x)}$ always exists, but does not necessarily equal $\lim \dfrac{f'(x)}{g'(x)}$ unless $\lim f(x) = \lim g(x) = 0$ or $\lim g(x) = \pm\infty$ (Exercise V.9.4.9.; statements apply to any kind of one-sided limits, but not two-sided).

V.9.2.14. Version 2 of l'Hôpital's Rule (in its various forms) is commonly used even when Version 1 applies. There are also situations where Version 2 can be used although Version 1 does not apply. (The reverse can also happen: there are situations where Version 1 applies but Version 2 does not; cf. Exercise V.9.4.4..)

V.9.3. Applications

V.9.3.1. Examples. (i) As in V.9.1.3., we can apply Version 2c to obtain

$$\lim_{x\to 0} \frac{e^x - 1}{\sin x} = \lim_{x\to 0} \frac{e^x}{\cos x} = 1 \ .$$

(ii) An example of a limit where Version 1 does not apply but Version 2 does is:

$$\lim_{x\to 0+} \frac{\sin x}{\sqrt{x}} \ .$$

Version 2a says that if

$$\lim_{x\to 0+} \frac{\cos x}{\frac{1}{2}x^{-1/2}} = \lim_{x\to 0+} 2\sqrt{x}\cos x$$

exists, the first limit also exists and has the same value. But the second limit is 0 by (); thus

$$\lim_{x\to 0+} \frac{\sin x}{\sqrt{x}} = 0 \ .$$

This limit could have also been evaluated by

$$\lim_{x\to 0+} \frac{\sin x}{\sqrt{x}} = \lim_{x\to 0+} \left[\sqrt{x}\cdot \frac{\sin x}{x}\right] = 0\cdot 1 = 0 \ .$$

(iii) Besides applications of Versions 2d and 2a′–2d′, which have no Version 1 analogues, the most common situation where Version 2 is necessary (i.e. Version 1 does not apply) is illustrated by the following example. Let $f(x) = 1 - \cos x$, $g(x) = x^2$. Then

$$\lim_{x\to 0} \frac{f(x)}{g(x)} = \lim_{x\to 0} \frac{1-\cos x}{x^2}$$

is an indeterminate form of type $\frac{0}{0}$ to which we might try to apply l'Hôpital's Rule. If

$$\lim_{x\to 0} \frac{f'(x)}{g'(x)} = \lim_{x\to 0} \frac{\sin x}{2x}$$

exists, then Version 2c implies that the first limit exists and has the same value. The second limit is also an indeterminate form of type $\frac{0}{0}$, so we may apply Version 2c again to convert it to

$$\lim_{x\to 0} \frac{f''(x)}{g''(x)} = \lim_{x\to 0} \frac{\cos x}{2}$$

i.e. if this limit exists, then the second limit and thus also the first limit exists and has the same value. But the last limit is not an indeterminate form, and equals $\frac{1}{2}$ by direct evaluation. We usually just abbreviate the whole argument as

$$\lim_{x\to 0} \frac{1-\cos x}{x^2} = \lim_{x\to 0} \frac{\sin x}{2x} = \lim_{x\to 0} \frac{\cos x}{2} = \frac{1}{2}$$

where the first two steps are justified by "l'Hôpital's Rule" (specifically, Version 2c); logically, we technically do the second application first and use the result to justify the first application. We could also justify the first step by Version 2c and calculate the second limit directly by Version 1.

(iv) In applying l'Hôpital's Rule, it must be checked that the hypotheses apply. This pitfall is particularly important to watch for when the Rule is used repeatedly as in (iii). For example, one might argue

$$\lim_{x\to 0} \frac{x^2}{x^2+\sin x} = \lim_{x\to 0} \frac{2x}{2x+\cos x} = \lim_{x\to 0} \frac{2}{2-\sin x} = \frac{2}{2} = 1 \ .$$

However, the second limit is not an indeterminate form and the second application of l'Hôpital's Rule is not justified. The second limit can be evaluated directly to be 0, and thus the first limit is also 0.

See Exercise V.9.4.7. for a more subtle example where the hypotheses of l'Hôpital's Rule are not satisfied.

Sometimes some cleverness is required to successfully use l'Hôpital's Rule:

V.9.3.2. Example. Consider

$$\lim_{x\to 0+} \frac{e^{-1/x}}{x} \ .$$

The hypotheses of Version 2a are satisfied with $f(x) = e^{-1/x}$ and $g(x) = x$. Thus the limit can be converted to

$$\lim_{x\to 0+} \frac{e^{-1/x}\frac{1}{x^2}}{1} = \lim_{x\to 0+} \frac{e^{-1/x}}{x^2} \ .$$

But this limit is worse than the one we started with, and repeating l'Hôpital's Rule will make things successively even worse.

Instead, we can rewrite the limit as

$$\lim_{x\to 0+} \frac{1/x}{e^{1/x}}$$

and note that Version 2a′ applies to give

$$\lim_{x\to 0+} \frac{1/x}{e^{1/x}} = \lim_{x\to 0+} \frac{-1/x^2}{-e^{1/x}\frac{1}{x^2}} = \lim_{x\to 0+} e^{-1/x} = 0 \ .$$

We could also make the substitution $u = 1/x$ and use Version 2d′ to give

$$\lim_{x\to 0+} \frac{1/x}{e^{1/x}} = \lim_{u\to+\infty} \frac{u}{e^u} = \lim_{u\to+\infty} \frac{1}{e^u} = 0 \ .$$

Indeterminate forms of other types can often be converted into a form to which l'Hôpital's rule can be applied, by algebraic manipulation or taking logarithms or exponentials:

V.9.3.3. EXAMPLES. (i) $\lim_{x\to+\infty} xe^{-x}$ is an indeterminate form of type $\infty \cdot 0$. It can be converted to $\lim_{x\to+\infty} \frac{x}{e^x}$ and evaluated by Version 2d′. Another similar example is in Exercise ()(d).

(ii) $\lim_{x\to 0} \left[\frac{1}{\sin x} - \frac{1}{x}\right]$ is an indeterminate form of type $\infty - \infty$. It can be converted into a fraction and evaluated by

$$\lim_{x\to 0} \left[\frac{1}{\sin x} - \frac{1}{x}\right] = \lim_{x\to 0} \frac{x - \sin x}{x \sin x}$$

$$= \lim_{x\to 0} \frac{1 - \cos x}{\sin x + x\cos x} = \lim_{x\to 0} \frac{\sin x}{2\cos x - x\sin x} = \frac{0}{2} = 0$$

by two applications of l'Hôpital's Rule. (For the first application, it must be verified that $h(x) = \sin x + x\cos x$ is nonzero in a deleted neighborhood of 0; this follows from the fact that $h'(0) \neq 0$.)

(iii) $\lim_{x\to 0+} x^x$ is an indeterminate form of type 0^0. By taking logarithms we can reduce the problem to computing $\lim_{x\to 0+} x\log x$, which is 0 (Exercise ()). Thus

$$\lim_{x\to 0+} x^x = \lim_{x\to 0+} e^{x\log x} = e^0 = 1$$

by continuity of the exponential function at 0. Similarly,

$$\lim_{x\to+\infty} x^{1/x} = 1$$

(indeterminate form of type ∞^0). See IV.1.12.8. for a direct argument.

(iv) $\lim_{x\to+\infty} \left(1 + \frac{1}{x}\right)^x$ is of the form 1^∞. Taking logarithms, we reduce to evaluating $\lim_{x\to+\infty} x\log\left(1 + \frac{1}{x}\right)$. This is of type $\infty \cdot 0$, so we can convert it to

$$\lim_{x\to+\infty} \frac{\log(1 + 1/x)}{1/x} = \lim_{x\to+\infty} \frac{\frac{1}{1+1/x}(-1/x^2)}{-1/x^2} = \lim_{x\to+\infty} \frac{1}{1 + 1/x} = 1$$

so

$$\lim_{x\to+\infty} \left(1 + \frac{1}{x}\right)^x = e^1 = e$$

again by continuity of the exponential function. (This example is somewhat artificial, since direct evaluation of this limit was used in defining e and the exponential function.)

V.9.4. Exercises

V.9.4.1. Express and justify Version 1 of l'Hôpital's Rule using little-o notation (V.7.) by writing $f(x) = f'(a)(x-a) + o(x-a)$ and $g(x) = g'(a)(x-a) + o(x-a)$.

V.9.4.2. Show that Version 1 and Version 2c of l'Hôpital's Rule are equivalent in the (common) case where f and g are differentiable in a neighborhood of a, f' and g' are continuous at a, $f(a) = g(a) = 0$, and $g'(a) \neq 0$.

V.9.4.3. Let $f(x) = x^2$ for $x \in \mathbb{Q}$ and $f(x) = 0$ for $x \notin \mathbb{Q}$, and let $g(x) = x$ for all x. Then Version 1 of L'Hôpital's Rule applies for $a = 0$. But f is not differentiable, or even continuous, except at 0, so no variant of Version 2 applies.

V.9.4.4. Let $f(x) = x^2 \sin \frac{1}{x^2}$ for $x \neq 0$, and $f(0) = 0$; and let $g(x) = \sin x$. Then f and g are differentiable everywhere, and $f'(0) = 0$ (), $g'(0) = 1$.

(a) Version 1 of L'Hôpital's Rule applies to show that

$$\lim_{x\to 0} \frac{f(x)}{g(x)} = \lim_{x\to 0} \frac{x^2 \sin \frac{1}{x^2}}{\sin x} = \frac{0}{1} = 0 \ .$$

(With a moderate amount of work, this limit can be evaluated directly using the Squeeze Theorem instead of L'Hôpital's Rule.)

(b) $\lim_{x\to 0} f'(x) = \lim_{x\to 0} \left[2x \sin \frac{1}{x^2} - \frac{2}{x} \cos \frac{1}{x^2}\right]$ and $\lim_{x\to 0} \frac{f'(x)}{g'(x)}$ do not exist. In particular, Version 2 of L'Hôpital's rule does not apply.

(c) The existence of $\lim_{x\to a} \frac{f(x)}{g(x)}$ does not imply the existence of $\lim_{x\to a} \frac{f'(x)}{g'(x)}$ even for everywhere differentiable f and g with $g' \neq 0$ in a neighborhood of a. Thus Version 2 is not more general than Version 1 even for functions which are everywhere differentiable.

(d) There are simpler examples for limits at ∞: for example, let $f(x) = x + \sin x$, $g(x) = x$. Then $\lim_{x\to+\infty} f(x) = \lim_{x\to+\infty} g(x) = +\infty$ and $\lim_{x\to+\infty} \frac{f(x)}{g(x)}$ exists (and equals 1), but $\lim_{x\to+\infty} \frac{f'(x)}{g'(x)}$ does not exist.

V.9.4.5. ([**?**]; cf. [Boa86]) What is wrong with the following argument?

(a) Let $f(x) = x + \sin x \cos x$. Show that $f'(x) = 2\cos^2 x$.

(b) Let $g(x) = e^{\sin x} f(x)$. Show that $\lim_{x\to+\infty} f(x) = \lim_{x\to+\infty} g(x) = +\infty$.

(c) We have

$$\lim_{x\to+\infty} \frac{f'(x)}{g'(x)} = \lim_{x\to+\infty} \frac{2\cos^2 x}{e^{\sin x}[f(x)\cos x + 2\cos^2 x]}$$
$$= \lim_{x\to+\infty} \frac{2\cos x}{e^{\sin x}[f(x) + 2\cos x]} = 0$$

since the numerator is bounded and the denominator approaches $+\infty$. Thus, by l'Hôpital's Rule, Version 2d′,

$$\lim_{x\to+\infty} \frac{f(x)}{g(x)} = \lim_{x\to+\infty} e^{-\sin x} = 0 \ .$$

But $e^{-1} \leq e^{-\sin x} \leq e$ for all x, and $\lim_{x\to+\infty} e^{-\sin x}$ does not exist.

V.9.4.6. (a) Using l'Hôpital's Rule, prove that, for every $a > 0$ and $r \in \mathbb{R}$,

$$\lim_{x\to+\infty} \frac{e^{ax}}{x^r} = +\infty \ .$$

[Prove this by induction for $r \in \mathbb{N}$, and use the Squeeze Theorem for other r.]
(b) Using l'Hôpital's Rule, prove that for all $r > 0$,

$$\lim_{x\to+\infty} \frac{\log x}{x^r} = 0 \ .$$

(c) Use (b) to give a proof of (a) not requiring induction.
(d) Using l'Hôpital's Rule, show that for all $r > 0$,

$$\lim_{x\to 0+} x^r \log x = \lim_{x\to 0+} \frac{\log x}{x^{-r}} = 0 \ .$$

For a proof of (a) not using l'Hôpital's Rule, note that, for every x,

$$e^{ax} = \sum_{k=0}^{\infty} \frac{a^k x^k}{k!}$$

and all terms are positive if $a > 0$ and $x > 0$, and hence for any n and m we have

$$e^{ax} > \frac{a^{n+m} x^{n+m}}{(n+m)!}$$

$$\frac{e^{ax}}{x^n} > \frac{a^{n+m}}{(n+m)!} x^m \ .$$

V.9.4.7. [**?**] Let $f(x) = x \sin\left(\frac{1}{x^4}\right) e^{-1/x^2}$ and $g(x) = e^{-1/x^2}$ for $x \neq 0$ and $f(0) = g(0) = 0$.
(a) Show that f and g are C^∞ on $\mathbb{R}$ (), and that $g(x)$ and $g'(x)$ are nonzero for $x \neq 0$.
(b) Show that $\lim_{x\to 0} \frac{f(x)}{g(x)} = 0$.
(c) Show that $\frac{f'(x)}{g'(x)}$ is unbounded in every neighborhood of 0, and that $\lim_{x\to 0} \frac{f'(x)}{g'(x)}$ does not exist.

V.9.4.8. Suppose f and g satisfy the hypotheses Version 2d′ of l'Hôpital's Rule. Recall (V.8.2.14.) that g' does not change sign on $(a, +\infty)$.
(a) Suppose $g' > 0$ on (a, ∞). If $\lim_{x\to+\infty} g(x) = +\infty$ (it cannot be $-\infty$!), and $\lim_{x\to+\infty} \frac{f'(x)}{g'(x)}$ exists and equals L, $0 < L \leq +\infty$, then there is an $M > 0$ such that $f'(x) > Mg'(x)$ for sufficiently large x. Show that this implies $\lim_{x\to+\infty} f(x) = +\infty$ [$f - Mg$ is eventually increasing]. Modify the argument for the case $g' < 0$ on (a, ∞) and/or $-\infty \leq L < 0$.
(b) Modify the argument to apply to Version 2a′, and similarly for Version 2b′ and 2c′.

V.9.4.9. (a) Suppose f and g are differentiable on $(a, +\infty)$ and g' is never zero, and that $\lim_{x\to+\infty} \frac{f'(x)}{g'(x)}$ exists and is finite. If $\lim_{x\to+\infty} g(x) = \pm\infty$ is false, show that $\lim_{x\to+\infty} g(x)$ and $\lim_{x\to+\infty} f(x)$ exist and are finite, and $\lim_{x\to+\infty} \frac{f(x)}{g(x)}$ exists (possibly in the extended sense). [Note that g must be strictly monotone. For some M, $M|g| \pm f$ are eventually increasing.] If $\lim_{x\to+\infty} g(x) \neq 0$, the condition that $\lim_{x\to+\infty} \frac{f'(x)}{g'(x)}$ exists can be relaxed to just a requirement that $\frac{f'(x)}{g'(x)}$ be bounded.

(b) Show that $\lim_{x\to+\infty} \frac{f(x)}{g(x)}$ is not necessarily the same as $\lim_{x\to+\infty} \frac{f'(x)}{g'(x)}$ (which need not even exist if $\lim_{x\to+\infty} g(x) \neq 0$), by considering

$$\lim_{x\to+\infty} \frac{1}{1-\frac{1}{x}} \quad \text{or} \quad \lim_{x\to+\infty} \frac{1-\frac{1}{x^2}}{1-\frac{1}{x}} \quad \text{or} \quad \lim_{x\to+\infty} \frac{1-\frac{\sin x}{x^2}}{1-\frac{1}{x}}$$

or by noting that constants can be added to f and/or g without affecting the hypotheses. In particular, the assumption $\lim_{x\to+\infty} g(x) = \pm\infty$ cannot be eliminated from Version 2d′.

(c) Suppose f and g are differentiable on $(a, +\infty)$ and g' is never zero, and that $\lim_{x\to+\infty} \frac{f'(x)}{g'(x)} = \pm\infty$. If $\lim_{x\to+\infty} g(x) = \pm\infty$ is false, show that $\lim_{x\to+\infty} g(x)$ and $\lim_{x\to+\infty} f(x)$ exist, $\lim_{x\to+\infty} g(x)$ is finite, and $\lim_{x\to+\infty} \frac{f(x)}{g(x)}$ exists (possibly, but not necessarily, in the extended sense).

(d) Obtain versions for $\lim_{x\to-\infty}$ and, for an interval (a, b), for $\lim_{x\to a+}$ and $\lim_{x\to b-}$. (There is no good two-sided version.)

V.9.4.10. Show that hypothesis (1) in Version 2c′ can be relaxed to

(1′) $\lim_{x\to a} |g(x)| = +\infty$.

(The same change can be made in Versions 2a′, 2b′, and 2d′, but this is not an actual change in these cases by V.8.2.14..)

V.9.4.11. Let I be an open interval, $c \in I$, and let f be continuous on I and differentiable on $I \setminus \{c\}$. If $\lim_{x\to c} f'(x)$ exists and equals $L \in \mathbb{R}$, show that f is necessarily differentiable at c and that $f'(c) = L$. [Apply l'Hôpital's Rule Version 2c to $\lim_{x\to c} \frac{f(x)-f(c)}{x-c}$.] Give a similar statement for one-sided limits, and a direct proof using the Mean Value Theorem instead of l'Hôpital's Rule.

Compare with V.8.2.15. and V.12.2.5..

V.9.4.12. Let $x_0 \in \mathbb{R}$, and $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ and $\sum_{k=0}^{\infty} b_k(x-x_0)^k$ be power series () centered at x_0 with positive radius of convergence, defining analytic functions f and g in an open interval around x_0. Let a_m be the first nonzero coefficient in the first series, i.e. $a_m \neq 0$ and $a_k = 0$ for $k < m$. Similarly, let b_n be the first nonzero coefficient in the second series.

(a) Use V.15.3.26. and l'Hôpital's Rule to show that if $m \geq n$, then

$$\lim_{x \to x_0} \frac{f(x)}{g(x)} = \frac{a_n}{b_n}$$

and in particular, the limit always exists (in the usual sense), and is zero if $m > n$ and nonzero if $m = n$.

(b) Obtain the same result from basic limit and power series theorems by first dividing f and g by a suitable power of $x - x_0$, and show additionally that

$$\lim_{x \to x_0} \frac{f(x)}{g(x)}$$

does not exist (in the usual sense) if $m < n$.

(c) Also conclude the result from (), although this argument is less elementary (but shows more).

V.9.4.13. [?, 11.10] Find

$$\lim_{x \to 0} \frac{\sin(\tan(x)) - \tan(\sin(x))}{\arcsin(\arctan(x)) - \arctan(\arcsin(x))} \ .$$

[To apply l'Hôpital's Rule, or Exercise V.9.4.12., try expanding numerator and denominator in Maclaurin series; a computer algebra system can be very helpful.] Does graphing the function near 0 with a computer algebra system help in guessing the answer?

V.9.4.14. [?, 4.4] Let

$$h(x) = \frac{x}{\sqrt{x^2 + 1}}$$

and note that $h(x) > 0$ for $x > 0$. Applying (), (), and l'Hôpital's Rule Version 2d′ to $\lim_{x \to +\infty} h(x)$, the only conclusion that can be drawn is that either the limit is 1 or it does not exist. Use another method to determine which is the case.

V.9.4.15. Let f be a function defined on an open interval around a.

(a) Suppose $f''(a)$ exists. Show that

$$\lim_{h \to 0} \frac{f(a+h) - 2f(a) + f(a-h)}{h^2}$$

exists and equals $f''(a)$.

(b) Show that the limit in (a) can exist even if $f''(a)$ does not exist, and even if f is not continuous at a. [Consider an odd function with $a = 0$.]

V.10. Taylor's Theorem

Taylor's Theorem is one of the most important and useful results in calculus. It can be thought of as a higher-order version of differential approximation or of the Mean Value Theorem, and is crucial in representing functions by power series, which will be discussed later. There are many other applications of both theoretical and practical importance. See III.5.3.8. and V.3.10.9. for purely algebraic versions.

The statement and a "proof" of Taylor's Theorem were first published by Brook Taylor in 1715, although the result was previously known to several mathematicians, and apparently first obtained by Gregory about 1670. Taylor's "proof" fell far short of modern standards of precision and rigor. His statement also did not give error estimates; most modern texts only state later versions of the theorem which include error or remainder formulas. For an account of the history of the result, see [].

V.10.1. Taylor Polynomials

V.10.1.1. Suppose f is a function which is differentiable to some high order near a number x_0. We would like to approximate f near x_0 as closely as possible by a polynomial of fixed degree. It makes intuitive sense that the approximating polynomial should duplicate the values of f and its derivatives at x_0 as closely as possible, since these values should determine the location and shape of the graph of f near x_0. There is a limit to how far this can be done, since if p is a polynomial of degree n, then $p^{(k)}$ is identically 0 for $k > n$; so we can only hope to make the derivatives of a degree n polynomial up through the n'th derivative agree with those of f. In differential approximation, which is the case $n = 1$, we have seen that there is a unique polynomial p_1 of degree ≤ 1 (i.e. linear or affine function) with $p_1(x_0) = f(x_0)$ and $p_1'(x_0) = f'(x_0)$, namely $p_1(x) = f(x_0) + f'(x_0)(x - x_0)$, and p_1 is indeed the polynomial of degree ≤ 1 most closely approximating f near x_0, in the sense that

$$\lim_{x \to x_0} \frac{f(x) - p_1(x)}{x - x_0} = 0$$

and p_1 is the only linear function with this property.

The higher-order case gets its justification from the following result:

V.10.1.2. Theorem. Let g be a real-valued function on an interval I, and x_0 an interior point of I, and $n \geq 1$. Suppose g is n-times differentiable at x_0 (this implies that for all $k < n$, $g^{(k)}$ is defined in a neighborhood of x_0 and is continuous at x_0, and, for $1 \leq r \leq n-1$, $g^{(n-r-1)}$ is r-times differentiable in a neighborhood of x_0). Then

$$\lim_{x \to x_0} \frac{g(x)}{(x - x_0)^n}$$

exists if and only if $g^{(k)}(x_0) = 0$ for $0 \leq k < n$. If the limit exists, it equals $\frac{g^{(n)}(x_0)}{n!}$.

V.10.1.3. Corollary. Let g be a real-valued function on an interval I, and x_0 an interior point of I, and $n \geq 1$. Suppose g is n-times differentiable at x_0 (this implies that for all $k < n$, $g^{(k)}$ is defined in a neighborhood of x_0 and is continuous at x_0, and, for $1 \leq r \leq n-1$, $g^{(n-r-1)}$ is r-times differentiable in a neighborhood of x_0). Then

$$\lim_{x \to x_0} \frac{g(x)}{(x - x_0)^n} = 0$$

if and only if $g(x_0) = g'(x_0) = \cdots = g^{(n)}(x_0) = 0$.

PROOF: By (complete) induction on n. First suppose $n = 1$. By assumption, g is differentiable at x_0 and hence continuous at x_0. If

$$\lim_{x\to x_0} \frac{g(x)}{x - x_0}$$

exists, then $\lim_{x\to x_0} g(x)$ must be 0 since $\lim_{x\to x_0}(x - x_0) = 0$ (). Thus $g(x_0) = 0$. And if $g(x_0) = 0$, then

$$\lim_{x\to x_0} \frac{g(x)}{x - x_0} = \lim_{x\to x_0} \frac{g(x) - g(x_0)}{x - x_0}$$

exists and equals $g'(x_0)$ by definition.

Now let $n > 1$. Assume the result for all k, $1 \le k < n$, and suppose g is n-times differentiable at x_0. Suppose

$$\lim_{x\to x_0} \frac{g(x)}{(x - x_0)^n}$$

exists and equals L. Then, if $0 \le k < n$, we have

$$\lim_{x\to x_0} \frac{g(x)}{(x - x_0)^k} = \left[\lim_{x\to x_0} \frac{g(x)}{(x - x_0)^n}\right] \left[\lim_{x\to x_0} (x - x_0)^{n-k}\right] = L \cdot 0 = 0$$

and thus by the inductive hypothesis $g^{(k)}(x_0) = 0$ (if $k = 0$, we obtain $g(x_0) = 0$ by continuity of g at x_0). Conversely, if $g(x_0) = g'(x_0) = \cdots = g^{(n-1)}(x_0) = 0$, we apply l'Hôpital's rule Version 2c (V.9.2.7.): if

$$\lim_{x\to x_0} \frac{g'(x)}{n(x - x_0)^{n-1}}$$

exists and equals L, then

$$\lim_{x\to x_0} \frac{g(x)}{(x - x_0)^n}$$

also exists and equals L. But the inductive hypothesis applies to g' since it is $(n-1)$-times differentiable at x_0 and $g'(x_0) = (g')'(x_0) = \cdots = (g')^{(n-2)}(x_0) = 0$, so the first limit exists and

$$L = \frac{1}{n} \frac{(g')^{(n-1)}(x_0)}{(n-1)!} = \frac{g^{(n)}(x_0)}{n!} \ .$$

V.10.1.4. In particular, if p is a polynomial of degree $\le n$ and f is n-times differentiable at x_0, then

$$\lim_{x\to x_0} \frac{f(x) - p(x)}{(x - x_0)^n} = 0$$

if and only if $p^{(k)}(x_0) = f^{(k)}(x_0)$ for $0 \le k \le n$. Such a polynomial (if it exists) is unique, and is the "best n'th order polynomial approximation" to f near x_0.

So the problem is to construct a polynomial of degree $\le n$ with specified derivatives at x_0. This is easily done:

V.10.1.5. PROPOSITION. Let $p(x) = a_0 + a_1x + \cdots + a_nx^n$ be a polynomial of degree n. Then, for $0 \leq k \leq n$, $f^{(k)}(0) = k!a_k$.

The proof is a simple calculation. If derivatives at x_0 instead of 0 are desired, a simple trick does the shift: if

$$q(x) = p(x - x_0) = a_0 + a_1(x - x_0) + \cdots + a_n(x - x_0)^n \,,$$

then q is also a polynomial of degree $\leq n$ and $q^{(k)}(x_0) = k!a_k$.

V.10.1.6. Thus, if f is n-times differentiable at x_0 and we want a polynomial p_n of degree $\leq n$ whose derivatives at x_0 up to the n'th are the same as those of f, we may (and must) take

$$p_n(x) = f(x_0) + f'(x_0)(x - x_0) + \frac{f''(x_0)}{2!}(x - x_0)^2 + \cdots + \frac{f^{(n)}(x_0)}{n!}(x - x_0)^n$$

This is the n'th *Taylor Polynomial* of f at x_0 (it will have degree strictly less than n if $f^{(n)}(x_0) = 0$.)

Although our notation does not reflect it, note that p_n depends not only on n (and, of course, f), but also on the choice of x_0, i.e. the function f will generally have different n'th order Taylor polynomials at different points (just as the best linear or affine approximation to f generally varies from point to point.)

We summarize our work in the next theorem (see V.10.1.2. for the last statement):

V.10.1.7. THEOREM. [TAYLOR'S THEOREM] Let f be defined in a neighborhood of x_0, and $n \in \mathbb{N}$. Suppose $f^{(n)}(x_0)$ exists (this implies that for all $k < n$, $f^{(k)}$ is defined in a neighborhood of x_0 and is continuous at x_0, and, for $1 \leq r \leq n-1$, $f^{(n-r-1)}$ is r-times differentiable in a neighborhood of x_0). Then the n'th Taylor polynomial p_n of f at x_0 satisfies

$$\lim_{x \to x_0} \frac{f(x) - p_n(x)}{(x - x_0)^n} = 0$$

and p_n is the unique polynomial of degree $\leq n$ with this property. If f is $(n+1)$-times differentiable at x_0, then

$$\lim_{x \to x_0} \frac{f(x) - p_n(x)}{(x - x_0)^{n+1}} = \frac{f^{(n+1)}(x_0)}{(n+1)!} \,.$$

Note that if $n = 1$, we obtain the differential approximation polynomial p_1. Thus the Taylor polynomials can be regarded as giving "higher-order differential approximation."

V.10.1.8. The Taylor polynomials thus give good approximations to f sufficiently near x_0; rephrasing the limit characterization, for any $\epsilon > 0$ and $n \in \mathbb{N}$ there is a $\delta > 0$ such that

$$|f(x) - p_n(x)| \leq \epsilon |x - x_0|^n \text{ whenever } |x - x_0| < \delta$$

and thus, for x close enough to x_0, the difference between $f(x)$ and $p_n(x)$ is small even compared to the very small number $|x - x_0|^n$.

In general, the δ depends on x_0 and n, as well as on f and ϵ. As a result, for a *fixed* x near x_0 but different from x_0, we should not necessarily expect $p_n(x)$ to be a good approximation to $f(x)$ for any particular n, or

even that $p_n(x)$ becomes a better and better approximation to $f(x)$ as n increases, although fortunately this often happens. In fact, to paraphrase [Act90], the Taylor polynomials give a very, very good approximation close enough to x_0, then get increasingly worse as we move away, and finally (often) explode into complete unusability. These points will be discussed more carefully later.

V.10.2. Vanishing Order

V.10.2.1. DEFINITION. Let f be a function defined in a deleted neighborhood of x_0, and let $\alpha \in [0, \infty)$. Then f *vanishes to order* α *at* x_0 if $f(x) = O(|x - x_0|^\alpha)$ as $x \to x_0$, i.e. there are positive K and δ such that $|f(x)| \le K|x - x_0|^\alpha$ for $0 < |x - x_0| < \delta$.
We say f *vanishes to order* α^+ *at* x_0 if $f(x) = o(|x - x_0|^\alpha)$ as $x \to x_0$, i.e.

$$\lim_{x \to x_0} \frac{f(x)}{|x - x_0|^\alpha} = 0 \ .$$

If f vanishes to order α^+ at x_0, then it vanishes to order α. If it vanishes to order β for some $\beta > \alpha$ at x_0, then it vanishes to order α^+. A function vanishes to order 0^+ at x_0 if and only if it can be extended to be continuous at x_0 by setting $f(x_0) = 0$.

V.10.2.2. EXAMPLES. (i) The function $f(x) = |x - x_0|^\alpha$ vanishes at x_0 to order α but not to order α^+. (ii) The function $f(x) = \frac{|x-x_0|^\alpha}{\log|x-x_0|}$ (with $f(x_0) = 0$) vanishes at x_0 to order α^+, but not to order β for any $\beta > \alpha$.

Taylor's Theorem can be rephrased (the last statement becomes slightly weaker):

V.10.2.3. THEOREM. [TAYLOR'S THEOREM] Let f be n-times differentiable at x_0, and let p_n be the n'th order Taylor polynomial of f at x_0. Then $f - p_n$ vanishes to order n^+ at x_0, and p_n is the unique polynomial of degree $\le n$ with this property. If f is $(n+1)$-times differentiable at x_0, then $f - p_n$ vanishes to order $n + 1$ at x_0.

The special case V.10.1.3. can be similarly rephrased:

V.10.2.4. COROLLARY. Let g be $(n-1)$-times differentiable on an open interval I and n-times differentiable at $x_0 \in I$, with $g(x_0) = g'(x_0) = \cdots = g^{(n)}(x_0) = 0$. Then g vanishes to order n^+ at x_0, and there is a unique function h which is continuous on I (and automatically as differentiable as g on $I \setminus \{x_0\}$), with $h(x_0) = 0$ and $g(x) = (x - x_0)^n h(x)$ for all $x \in I$. If g is $(n+1)$-times differentiable at x_0, then h is differentiable at x_0 and $h'(x_0) = \frac{g^{(n+1)}(x_0)}{(n+1)!}$.

PROOF: Set $h(x) = \frac{g(x)}{(x-x_0)^n}$ for $x \ne x_0$, and $h(x_0) = 0$. The first statement follows immediately from V.10.1.3.. If g is $(n+1)$-times differentiable at x_0, then

$$h'(x_0) = \lim_{x \to x_0} \frac{h(x) - h(x_0)}{x - x_0} = \lim_{x \to x_0} \frac{g(x)}{(x - x_0)^{n+1}}$$

and this limit is $\frac{g^{(n+1)}(x_0)}{(n+1)!}$ by another application of V.10.1.3. with $n+1$ in place of n. 👍

The examples $g(x) = x^n|x|$ and $g(x) = x^{n+1}|x|$ ($x_0 = 0$) show that no higher differentiability of h at x_0 can be concluded in general. But if g is differentiable to order $r > n$ at x_0, then h is differentiable to order $r - n$ at x_0 (V.10.5.4.).

V.10.3. Remainder Formulas

V.10.3.1. It is convenient to think of the situation in terms of the *remainder function* $r_n = f - p_n$. Thus

$$r_n(x) = f(x) - p_n(x) = f(x) - f(x_0) - f'(x_0)(x - x_0) - \cdots - \frac{f^{(n)}(x_0)}{n!}(x - x_0)^n$$

(like p_n, the function r_n depends on x_0 as well as on f and n). The approximation in Taylor's Theorem can be summarized by

$$r_n(x) = o(|x - x_0|^n) \text{ as } x \to x_0 \ (O(|x - x_0|^{n+1}) \text{ if } f^{(n+1)}(x_0) \text{ exists}) .$$

However, for practical applications of Taylor's approximation, as well as for many theoretical applications, it is important to have specific estimates for the size of $r_n(x)$. For example, one might expect that for fixed x near x_0, $r_n(x) \to 0$ as $n \to \infty$, i.e. that the Taylor polynomials for f around x_0 converge to f pointwise near x_0. This turns out to frequently be true, but not always, and has important consequences when it holds. And it goes without saying that when the Taylor polynomials are used to give numerical approximations to function values, it is crucial to have numerical estimates or bounds for the error.

There are many formulas known for $r_n(x)$. The first and still most widely used was found by Joseph Lagrange nearly 100 years after Taylor's work (published 1797). Lagrange's formula and another useful formula due to Cauchy can be derived by the same procedure using the Mean Value Theorem.

Good formulas for the remainder function can only be obtained when f is $(n+1)$-times differentiable in a neighborhood of x_0. Let us assume this, and fix x in such a neighborhood. For specificity we will assume that $x > x_0$, but an essentially identical argument yields the same formulas in the case $x < x_0$.

V.10.3.2. The key trick is to keep x fixed in the formula for r_n, and replace x_0 (which we also regard as fixed) by a variable t. Set

$$\phi(t) = f(x) - f(t) - f'(t)(x - t) - \cdots - \frac{f^{(n)}(t)}{n!}(x - t)^n - r_n(x)\left(\frac{x - t}{x - x_0}\right)^{n+1}$$

for $x_0 \le t \le x$. Then ϕ is differentiable on $[x_0, x]$, $\phi(x_0) = \phi(x) = 0$, and

$$\phi'(t) = -f'(t) - [f''(t)(x-t) - f'(t)] - \cdots - \left[\frac{f^{(n+1)}(t)}{n!}(x - t)^n - \frac{f^{(n)}(t)}{(n-1)!}(x - t)^{n-1}\right] + \frac{r_n(x)}{(x - x_0)^{n+1}}(n+1)(x-t)^n$$

$$= -\frac{f^{(n+1)}(t)}{n!}(x - t)^n + \frac{r_n(x)}{(x - x_0)^{n+1}}(n + 1)(x - t)^n .$$

By Rolle's Theorem, there is a $c \in (x_0, x)$ with $\phi'(c) = 0$. We then have

$$r_n(x) = \frac{(x - x_0)^{n+1}}{(n + 1)(x - c)^n}\frac{f^{(n+1)}(c)}{n!}(x - c)^n = \frac{f^{(n+1)}(c)}{(n + 1)!}(x - x_0)^{n+1} .$$

So we obtain:

V.10.3.3. THEOREM. [TAYLOR'S THEOREM WITH REMAINDER, LAGRANGE'S FORM] Let f be $(n+1)$-times differentiable on an interval I, $x_0 \in I$, p_n the n'th Taylor polynomial for f at x_0, and $x \in I$. Then, for some c between x_0 and x,

$$r_n(x) = f(x) - p_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!}(x - x_0)^{n+1}$$

or, equivalently,

$$f(x) = f(x_0) + f'(x_0)(x - x_0) + \cdots + \frac{f^{(n)}(x_0)}{n!}(x - x_0)^n + \frac{f^{(n+1)}(c)}{(n+1)!}(x - x_0)^{n+1}\,.$$

V.10.3.4. The case $n = 0$ is just the usual Mean Value Theorem. Thus Taylor's Theorem with the Lagrange Remainder Formula can be regarded as a higher-order generalization of the Mean Value Theorem.

V.10.3.5. We can obtain another formula for the remainder by a more straightforward variation of the argument: set

$$\psi(t) = f(x) - f(t) - f'(t)(x - t) - \cdots - \frac{f^{(n)}(t)}{n!}(x - t)^n$$

for $x_0 \le t \le x$. Then ψ is differentiable on $[x_0, x]$, $\psi(x_0) = r_n(x)$, $\psi(x) = 0$, and

$$\psi'(t) = -f'(t) - [f''(t)(x - t) - f'(t)] - \cdots - [\frac{f^{(n+1)}(t)}{n!}(x - t)^n - \frac{f^{(n)}(t)}{(n-1)!}(x - t)^{n-1}]$$

$$= -\frac{f^{(n+1)}(t)}{n!}(x - t)^n\ .$$

We apply the Mean Value Theorem to ψ to obtain a formula for $r_n(x)$:

V.10.3.6. THEOREM. Let f be $(n+1)$-times differentiable on an interval I, $x_0 \in I$, p_n the n'th Taylor polynomial for f at x_0, and $x \in I$. Then, for some c between x_0 and x,

$$r_n(x) = f(x) - p_n(x) = \phi(x_0) - \phi(x) = \phi'(c)(x_0 - x) = \frac{f^{(n+1)}(c)}{n!}(x - c)^n(x - x_0)\,.$$

This formula for the remainder is usually written in a different form. Since c is between x_0 and x, $c = x_0 + \theta(x - x_0)$ for some θ, $0 < \theta < 1$. Then $x - c = x - x_0 - \theta(x - x_0) = (1 - \theta)(x - x_0)$, so

V.10.3.7. COROLLARY. [TAYLOR'S THEOREM WITH REMAINDER, CAUCHY'S FORM] Let f be $(n+1)$-times differentiable on an interval I, $x_0 \in I$, p_n the n'th Taylor polynomial for f at x_0, and $x \in I$. Then, for some θ between 0 and 1,

$$r_n(x) = f(x) - p_n(x) = \frac{f^{(n+1)}(x_0 + \theta(x - x_0))}{n!}(1 - \theta)^n(x - x_0)^{n+1}\,.$$

V.10.3.8. Note that the c is not necessarily unique, and depends on n, as well as on f, x, and x_0, and on which formula (Cauchy or Lagrange) is used. There is usually no reasonable way to explicitly find a c that works in a given example. However, as we will see, mere existence of such a c often gives good error estimates and crucial information about the degree of approximation given by the Taylor polynomials.

V.10.3.9. See V.11.6.7. for a generalization of V.10.3.3. to the case where f is approximated at more than one point.

V.10.4. The Integral Remainder Formula

V.10.4.1. There is another formula (first published by S. Lacroix around 1800) for r_n given by an integral. Let us fix f, x_0 and x. Let J be the closed interval from x_0 to x (x may be greater than or less than x_0). If f is differentiable on J and f' is Riemann integrable on J, then

$$f(x) = f(x_0) + \int_{x_0}^{x} f'(t)\,dt\,.$$

If f'' is defined and Riemann integrable on J, do the integral by parts () the "wrong way" by letting

$$F(t) = f'(t),\ \ G(t) = -(x-t)$$

to obtain

$$f(x) = f(x_0) + [-f'(t)(x-t)]|_{t=x_0}^{t=x} - \int_{x_0}^{x} f''(t)[-(x-t)]\,dt$$

$$f(x) = f(x_0) + f'(x_0)(x-x_0) + \int_{x_0}^{x} f''(t)(x-t)\,dt.$$

If $f'''(t)$ exists and is Riemann integrable on J, do this integral again by parts using

$$F(t) = f''(t),\ \ G(t) = -\frac{1}{2}(x-t)^2$$

and continue in the same fashion n steps if f is $(n+1)$-times differentiable on J and $f^{(n+1)}$ is Riemann integrable on J. The formula for $f(x)$ thus obtained consists of the n'th Taylor polynomial p_n for f at x_0 plus an integral:

$$f(x) = f(x_0) + f'(x_0)(x-x_0) + \cdots + \frac{f^{(n)}(x_0)}{n!}(x-x_0)^n + \frac{1}{n!}\int_{x_0}^{x} f^{(n+1)}(t)(x-t)^n\,dt$$

so we obtain:

V.10.4.2. Theorem. [Taylor's Theorem With Remainder, Integral Form] Let f be $(n+1)$-times differentiable on an interval I and $x, x_0 \in I$. Suppose $f^{(n+1)}$ is Riemann integrable on the interval between x_0 and x. If p_n is the n'th Taylor polynomial of f at x_0, and $r_n = f - p_n$, then

$$r_n(x) = \frac{1}{n!}\int_{x_0}^{x} f^{(n+1)}(t)(x-t)^n\,dt$$

V.10.4.3. Using more advanced integration (XVIII.4.2.1.), the hypothesis that $f^{(n+1)}$ be Riemann integrable can be eliminated, and we alternately need only require that $f^{(n)}$ be absolutely continuous on the interval between x_0 and x (XIX.5.2.1., XIX.5.2.5.) so $f^{(n+1)}$ is not even necessarily defined everywhere (under this hypothesis it will be defined almost everywhere).

V.10.5. The Morse Lemma

The results of this section do not make essential use of Taylor's Theorem, but are closely related in spirit.

V.10.5.1. If f is $(n-1)$-times differentiable on an interval I around x_0 and n-times differentiable at x_0, and $r_{n-1} = f - p_{n-1}$ is the remainder function, then

$$\lim_{x \to x_0} \frac{r_{n-1}(x)}{(x-x_0)^n} = \frac{f^{(n)}(x_0)}{n!}$$

so if we set

$$g_n(x) = \frac{r_{n-1}(x)}{(x-x_0)^n} \ (x \neq x_0), \quad g_n(x_0) = \frac{f^{(n)}(x_0)}{n!}$$

for $x \in I$, then g_n is continuous on I and $(n-1)$-times differentiable on $I \setminus \{x_0\}$, and

$$f(x) = p_{n-1}(x) + (x-x_0)^n g_n(x) = f(x_0) + f'(x_0)(x-x_0) + \cdots + \frac{f^{(n-1)}(x_0)}{(n-1)!}(x-x_0)^{n-1} + (x-x_0)^n g_n(x)$$

for $x \in I$.

V.10.5.2. Proposition. If f is $\mathcal{C}^n$ on I, then for $1 \leq m \leq n$ g_m is $\mathcal{C}^n$ on $I \setminus \{x_0\}$ and continuously $(n-m)$-times differentiable at x_0.

Proof: Since $r_{m-1} = f - p_{m-1}$, hence also g_m, is n-times differentiable on $I \setminus \{x_0\}$, differentiability at x_0 is the only issue. First consider the case $m = 1$. Fix $x \in I$, and set $\phi(t) = f(tx + (1-t)x_0)$ for $0 \leq t \leq 1$. Then $\phi'(t) = f'(tx + (1-t)x_0)(x - x_0)$, so

$$(x-x_0)\int_0^1 f'(tx + (1-t)x_0)\,dt = \int_0^1 \phi'(t)\,dt = \phi(1) - \phi(0) = f(x) - f(x_0) = r_0(x) = (x-x_0)g_1(x)$$

by the Fundamental Theorem of Calculus, so

$$g_1(x) = \int_0^1 f'(tx + (1-t)x_0)\,dt\ .$$

Since f' is continuously $(n-1)$-times differentiable at x_0, by () g_1 is also continuously $(n-1)$-times differentiable at x_0.

Now let $m = 2$ (if $n \geq 2$). We have, for $x \in I$,

$$f(x) = f(x_0) + (x-x_0)g_1(x) = f(x_0) + f'(x_0)(x-x_0) + (x-x_0)^2 g_2(x) = f(x_0) + (x-x_0)[f'(x_0) + (x-x_0)g_2(x)]$$

so

$$g_1(x) = f'(x_0) + (x-x_0)g_2(x) = g_1(x_0) + (x-x_0)g_2(x)$$

for $x \in I$. Thus, by the first part of the proof applied to g_1 in place of f, we obtain that g_2 is continuously $(n-2)$-times differentiable at x_0. Continue inductively. 👍

V.10.5.3. COROLLARY. If f is $\mathcal{C}^\infty$ on I, then g_n is $\mathcal{C}^\infty$ on I for all n.

V.10.5.4. The example $f(x) = x^n|x|$, with $x_0 = 0$, shows that g_m is not $(n-m+1)$-times differentiable at x_0 in general, even if f is $\mathcal{C}^n$ on I and $\mathcal{C}^\infty$ on $I \setminus \{x_0\}$. Note that the conclusion of V.10.5.2. implies that g_m is $\mathcal{C}^{n-m}$ on I.

The hypotheses of V.10.5.2. can be relaxed slightly to only require f to be n-times differentiable at x_0 and $(n-1)$-times differentiable on I, with $f^{(n-1)}$ absolutely continuous on I, but then the conclusion is only that g_m is $(n-1)$-times differentiable on $I \setminus \{x_0\}$ (and n-times differentiable a.e.) and $(n-m)$-times differentiable at x_0.

If f is real analytic, then so are the g_n. The result also holds if f is complex analytic. In these cases, the proofs are simpler, cf. () and ().

The One-Dimensional Morse Lemma

V.10.5.5. If f is more than m-times differentiable at x_0, $f(x_0) = c$, and $f'(x_0) = \cdots = f^{(m-1)}(x_0) = 0$ but $f^{(m)}(x_0) \neq 0$, then $f(x)$ is approximately $p_m(x) = c + d(x-x_0)^m$ for x near x_0, where d is a constant ($d = \frac{f^{(m)}(x_0)}{m!}$). But we can say more: up to a change of coordinates, f is *exactly* of this form, and we can even take $d = \pm 1$.

V.10.5.6. THEOREM. [GENERALIZED ONE-DIMENSIONAL MORSE LEMMA] Let $m, n \in \mathbb{N}$, $m < n$, and let f be $\mathcal{C}^n$ on an interval I around x_0, with $f(x_0) = c$ and $f'(x_0) = \cdots = f^{(m-1)}(x_0) = 0$ but $f^{(m)}(x_0) \neq 0$. Then there is an orientation-preserving diffeomorphism ϕ from an open interval J around 0 onto an open interval $\tilde{I}$ around x_0, with $\phi(0) = x_0$, such that

$$[f \circ \phi](t) = c \pm t^m$$

for all $t \in J$, where the sign is the sign of $f^{(m)}(x_0)$. The function ϕ is $\mathcal{C}^{n-m}$ on J.

PROOF: By V.10.5.2., for $x \in I$ f can be written $f(x) = c + (x-x_0)^m g_m(x)$ with $g_m(x_0) = d \neq 0$. Thus there is an open interval $K \subseteq I$ around x_0 on which g_m is nonzero. For $x \in \tilde{I}$, set

$$\psi(x) = (x - x_0)h(x)$$

where

$$h(x) = |g_m(x)|^{1/m} \ .$$

Then h, hence ψ, is a $\mathcal{C}^{n-m}$ function on K, $\psi(x_0) = 0$, and

$$\psi'(x) = h(x) + (x - x_0)h'(x) \ .$$

Since h' is bounded near x_0 and $h(x_0) > 0$, there is an open interval $\tilde{I}$ around x_0 on which $\psi' > 0$. Thus ψ maps $\tilde{I}$ diffeomorphically onto an open interval J containing 0. Let $\phi : J \to \tilde{I}$ be the inverse function. Then ϕ is also $\mathcal{C}^{n-m}$ by the Inverse Function Theorem (). If $t = \psi(x) \in J$, then

$$[f \circ \phi](t) = f(x) = c + (x-x_0)^m g_m(x) = c \pm [(x-x_0)h(x)]^m = c \pm \psi(x)^m = c \pm t^m \ .$$

The classical one-dimensional Morse Lemma (due to MARSTON MORSE) is the case $m = 2$, and is usually written just for the case f is $\mathcal{C}^\infty$:

V.10.5.7. Corollary. [One-Dimensional Morse Lemma] Let f be $\mathcal{C}^\infty$ on an interval I around x_0, with $f(x_0) = c$ and $f'(x_0) = 0$ but $f''(x_0) \neq 0$. Then there is an orientation-preserving $\mathcal{C}^\infty$-diffeomorphism ϕ from an open interval J around 0 onto an open interval $\tilde{I}$ around x_0, with $\phi(0) = x_0$, such that

$$[f \circ \phi](t) = c \pm t^2$$

for all $t \in J$, where the sign is the sign of $f''(x_0)$.

V.10.5.8. If we allow ϕ to be orientation-reversing, if m is odd we can always take the + sign in the conclusion. But if m is even (in particular, if $m = 2$), the sign does not depend on the orientation of ϕ.

See () for the n-dimensional Morse Lemma. There are also real and complex analytic versions; see V.16.4.4. and XII.6.1.2..

V.10.6. Applications

V.10.7. Exercises

V.10.7.1. In V.10.1.3., the hypothesis that $g^{(n)}(x_0)$ exists is necessary if $n > 1$:

(a) Let $h_n(x) = \begin{cases} x^{n+1} & \text{if} \quad x \in \mathbb{Q} \\ 0 & \text{if} \quad x \notin \mathbb{Q} \end{cases}$. Then $\lim_{x\to 0} \frac{h_n(x)}{x^n} = 0$, but h_n is not even continuous except at 0, so $h_n'', \ldots, h_n^{(n)}$ do not exist at 0 (or anywhere else).

(b) The hypothesis that $g^{(n)}(x_0)$ exists is automatic if $n = 1$: if $g(x_0) = 0$ and $\lim_{x\to 0} \frac{g(x)}{x-x_0} = 0$, then $g'(x_0)$ exists and equals 0.

V.10.7.2. Give an alternate direct proof of Theorem V.10.1.2. not using l'Hôpital's Rule.

V.10.7.3. (a) Mimic the proof of V.10.1.2. to prove the following generalization of V.10.1.3.:

Theorem. [?] Let g be n-times differentiable in an open interval around x_0, with $g^{(n)}$ Hölder continuous () at x_0 with exponent α $(0 < \alpha \leq 1)$ and constant 0, i.e.

$$\lim_{x\to x_0} \frac{g^{(n)}(x) - g^{(n)}(x_0)}{(x - x_0)^\alpha} = 0 \ .$$

Then

$$\lim_{x\to x_0} \frac{g(x)}{(x - x_0)^{n+\alpha}} = 0$$

if and only if $g(x_0) = g'(x_0) = \cdots = g^{(n)}(x_0) = 0$.

(b) Derive V.10.1.3. as a corollary of the case $\alpha = 1$ of (a).

V.10.7.4. Write out the details of the arguments for the Lagrange and Cauchy remainder formulas in the case $x < x_0$.

V.10.7.5. The proof of V.10.3.3. is simple, but requires a nonobvious guess of a function to apply Rolle's theorem to. Phrase the proof in an alternate way not requiring a guess:

(a) Using the hypotheses and the notation of the theorem, show that there is an M such that

$$f(x) = f(x_0) + f'(x_0)(x - x_0) + \frac{f''(x_0)}{2}(x - x_0)^2 + \cdots + \frac{f^{(n)}(x_0)}{n!}(x - x_0)^n + M(x - x_0)^{n+1} \ .$$

(b) For $x_0 \leq t \leq x$ set

$$\phi(t) = f(x) - f(t) - f'(t)(x - t) - \frac{f''(t)}{2}(x - t)^2 - \cdots - \frac{f^{(n)}(t)}{n!}(x - t)^n - M(x - t)^{n+1} \ .$$

(c) Apply Rolle's Theorem to ϕ on $[x_0, x]$ (check that the hypotheses apply) and deduce Lagrange's form of the remainder. (The M will have to be calculated in terms of $r_n(x)$.)

This version of the argument appeared in a Belgian high-school textbook (*Wiskundig Leerpakket*); cf. https://gowers.wordpress.com/2014/02/11/taylors-theorem-with-the-lagrange-form-of-the-remainder/.

V.10.7.6. (a) Prove the following:

THEOREM. Let f be $(n+1)$-times differentiable on an interval I, $x_0 \in I$, p_n the n'th Taylor polynomial for f at x_0, and $x \in I$. Let g be a differentiable function on I such that $g'(t) \neq 0$ for all t in the open interval between x_0 and x. Then there is a c between x_0 and x for which

$$r_n(x) = -\frac{g(x_0) - g(x)}{g'(c)} \frac{f^{(n+1)}(c)}{n!}(x - c)^n$$

[Set

$$\omega(t) = \frac{\psi(t)}{g(t)}$$

where ψ is as in V.10.3.5., and apply the Cauchy Mean Value Theorem.]

(b) Obtain the Lagrange form of the remainder by taking $g(t) = (x - t)^{n+1}$.

V.10.7.7. Prove the following remainder formula:

THEOREM. [TAYLOR'S THEOREM WITH REMAINDER, SCHLÖMILCH'S FORM] Let f be $(n+1)$-times differentiable on an interval I, $x_0 \in I$, p_n the n'th Taylor polynomial for f at x_0, and $x \in I$. Fix $m \in \mathbb{N}$, $1 \leq m \leq n+1$. Then, for some θ between 0 and 1,

$$r_n(x) = f(x) - p_n(x) = \frac{f^{(n+1)}(x_0 + \theta(x - x_0))}{n!m}(1 - \theta)^{n+1-m}(x - x_0)^{n+1} \ .$$

The case $m = 1$ is Cauchy's form, and $m = n + 1$ is Lagrange's form. The θ depends on f, x_0, x, n, and m.

V.10.7.8. Let $f(x) = \begin{cases} e^{-1/x^2} & \text{if} \quad x \neq 0 \\ 0 & \text{if} \quad x = 0 \end{cases}$.

(a) Prove by complete induction that $\lim_{x\to 0} \frac{f(x)}{x^n} = 0$ for all $n \in \mathbb{N} \cup \{0\}$. [Hint: Use l'Hôpital's Rule, but not in the most straightforward way.]

(b) Prove by induction that $f^{(n)}(0)$ exists and equals 0 for all n. Thus f is C^∞ on all of $\mathbb{R}$. [You will need to use part (a) and the definition of the derivative.]

(c) Find the n'th Taylor polynomial p_n for f around 0, and show that $p_n(x)$ does not converge to $f(x)$ for any fixed $x \neq 0$. In fact, although $f(x) > 0$ for all $x \neq 0$, the graph near 0 is so "flat" that the constant function 0 approximates f near zero better than any other polynomial of any degree. See V.17.2.2..

V.10.7.9. Let $f(x) = e^x$, and let p_n be the n'th Taylor polynomial for f around 0. Since $f^{(k)}(x) = e^x$ for all k, $p_n(x) = 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!}$.

(a) Show that for any fixed $x \in \mathbb{R}$, $\lim_{n\to\infty} \frac{x^n}{n!} = 0$. [Consider the ratios of successive terms, and use ().]

(b) What is wrong with the following argument? Fix $x \in \mathbb{R}$. Then by Lagrange's remainder formula there is a c between 0 and x such that

$$f(x) - p_n(x) = \frac{e^c}{(n+1)!} x^{n+1} .$$

Since $\lim_{n\to\infty} e^c \frac{x^{n+1}}{(n+1)!} = 0$, $p_n(x) \to f(x)$ as $n \to \infty$.

(c) Modify the argument of (b) to give a valid proof that $p_n(x) \to f(x)$ for any $x \in \mathbb{R}$.

V.10.7.10. Give an alternate proof of the integral form of the remainder for Taylor's Theorem not requiring integration by parts, by computing the iterated integral

$$\int_{x_0}^{x} \int_{x_0}^{x_n} \cdots \int_{x_0}^{x_1} f^{(n+1)}(t)\, dt\, dx_1 \cdots\ dx_n$$

where $x_1, \ldots, x_n$ are variables ranging over the interval between x_0 and x, by successive applications of the Fundamental Theorem of Calculus. Note that the first integral is not necessarily a Riemann integral unless $f^{(n+1)}$ is well-behaved between x_0 and x, but can be interpreted as a Lebesgue integral or an H-K integral in more general cases. The rest of the integrals are always Riemann integrals.

V.10.7.11. Let f be $\mathcal{C}^n$ $(0 \leq n < \infty)$ on an open interval I, and $x_0 \in I$. Suppose there is a sequence (x_k) in $I \setminus \{x_0\}$ with $x_k \to x_0$ and $f(x_k) = 0$ for all k. Show that

$$f(x_0) = f'(x_0) = \cdots f^{(n)}(x_0) = 0$$

and hence

$$\lim_{x\to x_0} \frac{f(x)}{(x - x_0)^n} = 0 .$$

[Apply Rolle's Theorem to the intervals between x_k and x_{k+1} for each k, and iterate.] Show by example that

$$\lim_{x\to x_0} \frac{f(x)}{(x - x_0)^{n+1}} = 0$$

does not necessarily hold.

V.10.7.12. [Extended Second Derivative Test] Let f be defined in a neighborhood of x_0, and $n \in \mathbb{N}$, $n \geq 2$. Suppose $f^{(n)}(x_0)$ exists, and that $f'(x_0) = \cdots = f^{(n-1)}(x_0) = 0$ and $f^{(n)}(x_0) \neq 0$. Using V.10.5.6. (or just V.10.2.4.), show that

(a) If n is even, then f has a strict local extremum at x_0, a local minimum if $f^{(n)}(x_0) > 0$ and a local maximum if $f^{(n)}(x_0) < 0$.

(b) If n is odd, then f is increasing or decreasing at x_0 in the sense of V.3.6.7., increasing if $f^{(n)}(x_0) > 0$ and decreasing if $f^{(n)}(x_0) < 0$, and f has a point of inflection at x_0.

V.10.7.13. Let f be continuously $(n+1)$-times differentiable on an interval I, and $x_0, x \in I$. Derive the Lagrange form for the remainder V.10.3.3. from the integral form V.10.4.2. using the Mean Value Theorem for Integrals (IX.2.6.10.): There is a c between x_0 and x such that

$$\int_{x_0}^{x} f^{(n+1)}(t)(x-t)^n \, dt = f^{(n+1)}(c) \int_{x_0}^{x} (x-t)^n \, dt \ .$$

(Note that this is slightly less general than V.10.3.3..)

V.10.7.14. Prove the statements in V.10.4.3. (there are some nontrivial technicalities in addition to the results referenced there).

V.11. Interpolation and Extrapolation

In this section, we discuss some topics normally treated only in numerical analysis texts but which are very helpful and relevant to understanding Taylor's Theorem (our exposition is largely based on the nice treatments in [**?**] and http://www.maths.lancs.ac.uk/~jameson/interpol.pdf). No actual calculus is needed for the basic definitions and formulas, but the analysis is closely related in spirit to differential approximation and Taylor's theorem (indeed, TAYLOR obtained his formula as a limiting case of the Gregory-Newton interpolation formula), and results from calculus are needed for error estimates.

The basic problem is as follows. Suppose we have a function f defined on an interval I, which we presume to be suitably nicely behaved, e.g. differentiable to some high order. We know values of f at some points $x_0, \ldots, x_n$ of I (typically forming a partition of I, but not necessarily), and we want to estimate $f(x)$ for a general $x \in I$. This type of approximation is called *interpolation*, especially if x is in the smallest interval containing $x_0, \ldots, x_n$; if x is not in this interval, the approximation is *extrapolation*. (Extrapolation is generally much more difficult and problematic to do with any accuracy.)

One promising way to proceed is to approximate f by the unique polynomial p of degree $\leq n$ whose values at $x_0, \ldots, x_n$ are the same as f, called the *interpolating polynomial* for f with respect to $\{x_0, \ldots, x_n\}$.

V.11.1. The Interpolating Polynomial

We first consider the problem of the existence and uniqueness of the interpolating polynomial and how to find it.

V.11.1.1. The most direct approach is a simple exercise in linear algebra. Given distinct $x_0, \ldots, x_n$ in $\mathbb{R}$ and real numbers $b_0, \ldots, b_n$ (not necessarily distinct), we want a polynomial

$$p(x) = a_0 + a_1 x + \cdots + a_n x^n$$

with real coefficients, of degree $\leq n$ (it could have degree less than n since a_n could be zero), such that $p(x_k) = b_k$ for $0 \leq k \leq n$. Such a polynomial, if it exists, must be unique: if $q(x)$ is another such polynomial, then $p(x) - q(x)$ is a polynomial of degree $\leq n$ with at least $n+1$ roots (at $x_0, \ldots, x_n$), hence must be identically zero.

To show the polynomial exists, we must solve the system

$$\begin{bmatrix} 1 & x_0 & x_0^2 & \cdots & x_0^n \\ 1 & x_1 & x_1^2 & \cdots & x_1^n \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x_n & x_n^2 & \cdots & x_n^n \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_n \end{bmatrix} = \begin{bmatrix} b_0 \\ b_1 \\ \vdots \\ b_n \end{bmatrix}$$

for $\{a_0, \ldots, a_n\}$. The matrix on the left is a *Vandermonde matrix* which is invertible (the determinant is $\prod_{j<k}(x_k - x_j)$; cf. Exercise V.11.8.1.); thus the system has a (unique) solution which can be found by Gaussian elimination. (This works over any field with at least $n+1$ elements.)

V.11.1.2. This procedure for finding p works fine in principle, but is regarded as a poor method in numerical analysis, since it is computationally inefficient and the system is often ill-conditioned, especially if the x_k are close together, leading to large roundoff errors.

V.11.1.3. There is another form of the interpolating polynomial which is more computationally efficient. This form is usually attributed to LAGRANGE and is often called the *Lagrange form* of the interpolation polynomial although it was originally due to E. WARING in 1779.

Fix distinct real numbers $x_0, \dots, x_n$. The polynomial

$$p_k(x) = \frac{(x-x_0)(x-x_1)\cdots(x-x_{k-1})(x-x_{k+1})\cdots(x-x_n)}{(x_k-x_0)(x_k-x_1)\cdots(x_k-x_{k-1})(x_k-x_{k+1})\cdots(x_k-x_n)}$$

of degree n has the property that $p_k(x_j) = \delta_{kj}$ () for $0 \le j \le n$. Thus, if $b_0, \dots, b_n \in \mathbb{R}$, the polynomial p of degree $\le n$ with $p(x_k) = b_k$ for all k is

$$p(x) = \sum_{k=0}^{n} b_k p_k(x) \ .$$

V.11.1.4. There is an even better form of the interpolating polynomial, the Newton form (V.11.3.2.).

V.11.2. Linear Interpolation and Extrapolation

V.11.2.1. If we only know the value of f at one point x_0 of I, the best estimate we can make of $f(x)$ for $x \in I$ is

$$f(x) = f(x_0)$$

i.e. f is constant on I (this is generally a pretty crude estimate, but the best we can do with only one data point, and reasonably accurate for x near x_0 if f is continuous). We will use the notation $f[x_0]$ to denote the number $f(x_0)$; thus we have the 0'th order approximation

$$f(x) = f[x] \approx f[x_0] = f(x_0) \ .$$

Denote by p_0 the constant function with value $f(x_0)$ (we should really write p_{x_0}, but we will think of x_0 as being fixed and adding additional points $x_1, x_2, \dots$ successively).

V.11.2.2. If we know the values of f at two points x_0 and x_1 of I, we can do a little better: we can assume f is linear, with slope

$$f[x_0, x_1] := \frac{f(x_1) - f(x_0)}{x_1 - x_0}$$

(i.e. $f[x_0, x_1]$ is the difference quotient (V.3.1.8.), usually called a *divided difference* in numerical analysis.) We then have the approximation

$$f(x) \approx f(x_0) + f[x_0, x_1](x - x_0) = f[x_0] + (x - x_0)f[x_0, x_1]$$

for $x \in I$ and, of course, the exact formula

$$f(x) = f[x_0] + (x - x_0)f[x_0, x]$$

($x \neq x_0$) which is useless for approximation.

V.11.2.3. The linear function

$$p_{0,1}(x) = f[x_0] + (x - x_0)f[x_0, x_1]$$

is the unique linear function with the same values as f at x_0 and x_1.

V.11.2.4. Linear interpolation and extrapolation can be written in the equivalent form

$$f(\lambda x_0 + (1-\lambda)x_1) \approx \lambda f(x_0) + (1-\lambda)f(x_1)$$

(interpolation if $0 < \lambda < 1$, extrapolation if $\lambda < 0$ or $\lambda > 1$).

V.11.3. Higher-Order Interpolation and Extrapolation

V.11.3.1. Now suppose we know the values of f at x_0, x_1, and x_2 (assumed distinct). We want to find the quadratic polynomial $p_{0,1,2}$ whose values are the same as f at x_0, x_1, and x_2. This can be done as in section V.11.1., but we take a different approach. The polynomial will be of the form

$$p_{0,1,2}(x) = f[x_0] + (x - x_0)f[x_0, x_1] + K(x - x_0)(x - x_1)$$

for some constant K. A little algebra gives

$$K = \frac{f(x_0)}{(x_0 - x_1)(x_0 - x_2)} + \frac{f(x_1)}{(x_1 - x_0)(x_1 - x_2)} + \frac{f(x_2)}{(x_2 - x_0)(x_2 - x_1)} = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0} .$$

We thus define

$$f[x_0, x_1, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$$

so we have, for $x \in I$,

$$f(x) \approx p_{0,1,2}(x) = f[x_0] + (x - x_0)f[x_0, x_1] + (x - x_0)(x - x_1)f[x_0, x_1, x_2]$$

and the exact formula

$$f(x) = f[x_0] + (x - x_0)f[x_0, x_1] + (x - x_0)(x - x_1)f[x_0, x_1, x]$$

(the last expression is not defined if $x = x_0$ or $x = x_1$, but the last term can be taken to be 0 in these cases, which makes the overall formula valid).

V.11.3.2. Continuing inductively in the same manner, if we have $n + 1$ distinct points $x_0, \ldots, x_n \in I$, we have

$$p_{0,1,\ldots,n}(x) = f[x_0] + (x-x_0)f[x_0, x_1] + (x-x_0)(x-x_1)f[x_0, x_1, x_2] + \cdots + (x-x_0)(x-x_1)\cdots(x-x_{n-1})f[x_0, \ldots, x_n]$$

where

$$f[x_0, \ldots, x_n] = \frac{f(x_0)}{(x_0 - x_1)\cdots(x_0 - x_n)} + \cdots + \frac{f(x_k)}{(x_k - x_0)(x_k - x_1)\cdots(x_k - x_{k-1})(x_k - x_{k+1})\cdots(x_k - x_n)} + \cdots + \frac{f(x_n)}{(x_n - x_0)\cdots(x_n - x_{n-1})}$$

are called *higher-order divided differences*. There are many other formulas for these divided differences; see below for some of them.

Thus, for $x \in I$, we have the n'th order approximation

$$f(x) \approx f[x_0] + (x-x_0)f[x_0, x_1] + (x-x_0)(x-x_1)f[x_0, x_1, x_2] + \cdots + (x-x_0)(x-x_1)\cdots(x-x_{n-1})f[x_0, \ldots, x_n]$$

and the exact formula ($x \neq x_0, \ldots, x_{n-1}$)

$$f(x) = f[x_0] + (x-x_0)f[x_0, x_1] + (x-x_0)(x-x_1)f[x_0, x_1, x_2] + \cdots + (x-x_0)(x-x_1)\cdots(x-x_{n-1})f[x_0, \ldots, x_{n-1}, x] .$$

V.11.3.3. Divided differences and the form of the interpolating polynomial in V.11.3.2. are attributed to NEWTON and called the *Newton form*, although they were first obtained by JAMES GREGORY around 1670, at least in the case of evenly-spaced data points.

V.11.3.4. The Newton form of the interpolating polynomial is regarded as the most generally useful and efficient form for numerical analysis purposes. Not only is it computationally efficient, but it also has the nice property that the coefficients do not have to all be recomputed if an additional data point is added.

Properties of Higher-Order Divided Differences

V.11.3.5. In the divided difference $f[x_0, \ldots, x_n]$, the numbers $x_0, \ldots, x_n$ are typically taken in increasing order. However, this is not necessary; in fact, it is obvious from the definition V.11.3.2. that the order in which the x_k are taken is irrelevant: the numerical value is invariant under any permutation of the x_k.

This can be seen in another way. The number $f[x_0, \ldots, x_n]$ is the coefficient of x^n in the interpolating polynomial corresponding to $\{x_0, \ldots, x_n\}$. Since this polynomial obviously depends only on the set $\{x_0, \ldots, x_n\}$ and not on the order of the numbers, so does $f[x_0, \ldots, x_n]$.

V.11.3.6. There is also a recursive formula

$$f[x_0, \ldots, x_n] = \frac{f[x_1, \ldots, x_n] - f[x_0, \ldots, x_{n-1}]}{x_n - x_0}$$

which justifies the name "higher-order divided difference" (Exercise V.11.8.2.). There are many variations obtained by combining this formula with permutations of the x_k (V.11.3.5.).

V.11.4. The Mean Value Theorem for Divided Differences

We now bring some calculus into the picture.

V.11.4.1. The n'th order divided difference $f[x_0, \ldots, x_n]$ can be regarded as a function $f[\cdot, \ldots, \cdot]$ defined on the subset I_d^{n+1} of I^{n+1} consisting of points with all coordinates distinct. The set I_d^{n+1} is a dense open set in I^{n+1}. If f is continuous on I, this n'th order divided difference is clearly continuous on I_d^{n+1}. We will eventually extend it to all of I^{n+1} if f is sufficiently differentiable on I (V.11.5.7.).

The most important calculus result about divided differences is the following version of the MVT:

V.11.4.2. THEOREM. Let f be continuous on $[a, b]$ and n-times differentiable everywhere on (a, b). Let $x_0, \ldots, x_n$ be $n + 1$ distinct points in $[a, b]$. Then there is at least one $c \in (a, b)$ with

$$f[x_0, \ldots, x_n] = \frac{f^{(n)}(c)}{n!} \ .$$

PROOF: We may assume $(x_0, \ldots, x_n)$ is in increasing order. The function

$$g(x) = f(x) - p_{0,1,\ldots,n}(x)$$

has at least $n+1$ distinct zeroes in $[a,b]$ (at $x_0,\dots,x_n$). Applying Rolle's Theorem repeatedly to the intervals between x_{k-1} and x_k, $g'(x)$ has at least n zeroes in (a,b), $g''(x)$ has at least $n-1$ zeroes, $\dots$, $g^{(n)}(x)$ has at least one zero c. But $p_{0,\dots,n}$ is a polynomial of degree $\le n$ whose degree n term is

$$f[x_0,\dots,x_n]x^n$$

so its n'th derivative is the constant function $n!f[x_0,\dots,x_n]$, and thus

$$0 = g^{(n)}(c) = f^{(n)}(c) - p^{(n)}_{0,\dots,n}(c) = f^{(n)}(c) - n!f[x_0,\dots,x_n] \ .$$

V.11.4.3. Note that the case $n=1$ of this theorem is the usual MVT, so this theorem is a generalization of the MVT. But the MVT, or at least the special case of Rolle's Theorem, is used in the proof.

V.11.4.4. We can use this result to calculate the error in using $p_{0,\dots,n}(x)$ to approximate $f(x)$ for $x \in I$. Set

$$E_n(x) = f(x) - p_{0,\dots,n}(x)$$

for $x \in I$. If x is not one of $x_0,\dots,x_n$, then we have from V.11.3.2. that

$$E_n(x) = (x-x_0)(x-x_1)\cdots(x-x_n)f[x_0,\dots,x_n,x]$$

and combining this with V.11.4.2., we obtain:

V.11.4.5. Corollary. Let f be $(n+1)$-times differentiable on I, and $x_0,\dots,x_n$ distinct points of I. Then, for any $x \in I$, there is a c in the interior of the smallest subinterval of I containing $x_0,\dots,x_n,x$ such that

$$E_n(x) = (x-x_0)(x-x_1)\cdots(x-x_n)\frac{f^{(n+1)}(c)}{(n+1)!} \ .$$

Proof: If x is not one of the x_k, the result follows from V.11.4.2., and if x is one of the x_k both sides are zero no matter what c is chosen.

V.11.5. Repeated Points

V.11.5.1. In defining $f[x_0,x_1]$, the x_0 and x_1 must be distinct. But if (and only if) f is differentiable at x_0, we have, for fixed x_0,

$$\lim_{x_1\to x_0} f[x_0,x_1] = \lim_{x_1\to x_0}\frac{f(x_1)-f(x_0)}{x_1-x_0} = f'(x_0)$$

so we may define

$$f[x_0,x_0] = f'(x_0)$$

if f is differentiable at x_0. This definition is especially suitable if f is strictly differentiable at x_0 (), in which case $f[\cdot,\cdot]$ is continuous at (x_0,x_0). In particular, if f is $\mathcal{C}^1$ on I, then $f[\cdot,\cdot]$ is continuous on I^2.

V.11.5.2. We want to extend this to higher-order divided differences. We first consider the case where all the coordinates are the same. Fix n, and for $x_0 \in I$ write $\boldsymbol{x}_0 = (x_0, \ldots, x_0) \in I^{n+1}$. If $\boldsymbol{x} = (y_0, \ldots, y_n) \in I_d^{n+1}$, write $f[\boldsymbol{x}] = f[y_0, \ldots, y_n]$.

V.11.5.3. PROPOSITION. Let f be n-times differentiable on I, and $x_0 \in I$. If $f^{(n)}$ is continuous at x_0, then

$$\lim_{\substack{\boldsymbol{x} \to \boldsymbol{x}_0 \\ \boldsymbol{x} \in I_d^{n+1}}} f[\boldsymbol{x}] = \frac{f^{(n)}(x_0)}{n!} \ .$$

PROOF: Let $\epsilon > 0$. Then there is a $\delta > 0$ such that, for all $y \in I$, $|y - x_0| < \delta$, we have

$$\left| \frac{f^{(n)}(y)}{n!} - \frac{f^{(n)}(x_0)}{n!} \right| < \epsilon \ .$$

Let $J = I \cap (x_0 - \delta, x_0 + \delta)$. If $\boldsymbol{x} = (y_0, \ldots, y_n) \in J_d^{n+1}$, then by V.11.4.2. there is a $c_{\boldsymbol{x}} \in J$ with

$$f[\boldsymbol{x}] = \frac{f^{(n)}(c_{\boldsymbol{x}})}{n!}$$

so

$$\left| f[\boldsymbol{x}] - \frac{f^{(n)}(x_0)}{n!} \right| < \epsilon \ .$$

V.11.5.4. If f is $\mathcal{C}^n$ on I, we can thus extend the n'th order divided difference to points with all coordinates the same by setting

$$f[x_0, \ldots, x_0] = \frac{f^{(n)}(x_0)}{n!}$$

for $x_0 \in I$. The extended function is continuous on the subset of I^{n+1} consisting of points whose coordinates are either all the same or all different.

V.11.5.5. We can extend higher-order divided differences to points where some, but not all, coordinates coincide. Rather than trying to state things in maximum generality (cf. V.11.5.13.), we will just assume f is $\mathcal{C}^n$ on I. The most efficient approach is to prove an integral formula for the higher-order divided differences which is of general interest:

V.11.5.6. THEOREM. Let f be $\mathcal{C}^n$ on an interval I, and $x_0, \ldots, x_n$ distinct points of I. Then

$$f[x_0, \ldots, x_n] = \int_0^1 \int_0^{t_1} \cdots \int_0^{t_{n-1}} f^{(n)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_n(x_n - x_{n-1}))\, dt_n \cdots dt_2\, dt_1 \ .$$

PROOF: By induction on n. The case $n = 1$ is essentially the Fundamental Theorem of Calculus in slight disguise: to evaluate the integral

$$\int_0^1 f'(x_0 + t(x_1 - x_0))\,dt$$

for f $\mathcal{C}^1$, make the substitution

$$u = x_0 + t(x_1 - x_0)$$
$$du = (x_1 - x_0)\,dt$$

to obtain

$$\int_0^1 f'(x_0 + t(x_1 - x_0))\,dt = \frac{1}{x_1 - x_0}\int_{x_0}^{x_1} f'(u)\,du = \frac{f(x_1) - f(x_0)}{x_1 - x_0}\ .$$

Thus $f[x_0, x_1]$ is the average value of f' over the interval $[x_0, x_1]$ (or $[x_1, x_0]$ if $x_1 < x_0$).

Now suppose the formula holds for $n - 1$. Compute the first integral

$$\int_0^{t_{n-1}} f^{(n)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_n(x_n - x_{n-1}))\,dt_n$$

making the substitution

$$u = x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_n(x_n - x_{n-1})$$
$$du = (x_n - x_{n-1})\,dt_n$$

so the first integral evaluates to

$$\frac{1}{x_n - x_{n-1}}[f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_n(x_n - x_{n-1}))]\Big|_0^{t_{n-1}}$$

$$= \frac{1}{x_n - x_{n-1}}[f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}) + t_{n-1}(x_n - x_{n-1}))$$
$$-f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}))]$$

$$= \frac{1}{x_n - x_{n-1}}[f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_n - x_{n-2}))$$
$$-f^{(n-1)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}))]$$

so we have

$$\int_0^1 \int_0^{t_1} \cdots \int_0^{t_{n-1}} f^{(n)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_n(x_n - x_{n-1}))\,dt_n \cdots dt_2\,dt_1$$

$$= \frac{1}{x_n - x_{n-1}}\left[\int_0^1 \int_0^{t_1} \cdots \int_0^{t_{n-2}} f^{(n)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_n - x_{n-2}))\,dt_{n-1} \cdots dt_2\,dt_1\right.$$
$$\left. - \int_0^1 \int_0^{t_1} \cdots \int_0^{t_{n-2}} f^{(n)}(x_0 + t_1(x_1 - x_0) + t_2(x_2 - x_1) + \cdots + t_{n-1}(x_{n-1} - x_{n-2}))\,dt_{n-1} \cdots dt_2\,dt_1\right]$$

$$= \frac{1}{x_n - x_{n-1}}(f[x_0, \ldots, x_{n-2}, x_n] - f[x_0, \ldots, x_{n-2}, x_{n-1}]) = f[x_0, \ldots, x_n]$$

by the inductive hypothesis and V.11.3.6..

V.11.5.7. The formula in V.11.5.6. makes perfect sense even if $x_0, \ldots, x_n$ are not distinct, and clearly gives a continuous function of $(x_0, \ldots, x_n)$ on I^{n+1}. We denote this extended function also by $f[x_0, \ldots, x_n]$. The extended function agrees with the extension given in V.11.5.4. in the case all the coordinates are equal. Thus we obtain

V.11.5.8. COROLLARY. If f is $\mathcal{C}^n$ on an interval I, then $f[\cdot, \ldots, \cdot]$ ($n+1$ arguments), extended as above to points with repeated coordinates, is continuous on I^{n+1}.

V.11.5.9. If f is $\mathcal{C}^n$ on $[a, b]$, then the conclusion of Theorem V.11.4.2. holds also (with $c \in [a, b]$) if not all the x_k are distinct, as can be seen by a straightforward limiting argument using V.11.5.8. and the Bolzano-Weierstrass Theorem (). In particular, if f is $\mathcal{C}^n$, then for any x_0 and any $[a, b]$ containing x_0 there is a $c \in [a, b]$ for which $f[x_0, \ldots, x_0] = \frac{f^{(n)}(c)}{n!}$. Taking the limit as $a, b \to x_0$, we obtain an alternate proof of V.11.5.3..

To extend $f[x_0, \ldots, x_n]$ to points with some repetitions in somewhat greater generality, we use the following result, which is proved inductively using V.11.5.8. and the recursion formula for divided differences with distinct entries:

V.11.5.10. THEOREM. Let f be a function on an interval I, $J_0, \ldots, J_r$ disjoint subintervals of I, and $m_0, \ldots, m_r \in \mathbb{N}$. Suppose f is $\mathcal{C}^{m_k - 1}$ on J_k for each k. Then

$$f[x_{(0,0)}, \ldots, x_{(0,m_0-1)}, x_{(1,0)}, \ldots, x_{(1,m_1-1)}, \ldots, x_{(r,m_r-1)}]$$

extends to a continuous function on $J_0^{m_0} \times \cdots \times J_r^{m_r}$.

V.11.5.11. We can obtain an explicit formula for $f[x_0, \ldots, x_n]$ when the points are not all distinct. Since the function values are independent of the order of the coordinates on a dense set, by continuity this holds everywhere. Thus to evaluate the function we may put the entries in increasing order, with the repeated coordinates grouped together. We write $x_0, \ldots, x_r$ for the distinct values, and suppose x_k occurs m_k times, so $m_0 + \cdots + m_r = n + 1$.

V.11.5.12. THEOREM. Suppose f is $\mathcal{C}^n$ on I. Then $f[x_0, \ldots, x_r]$ is $\mathcal{C}^{n-r}$ on I_d^{r+1}, and

$$f[x_0, \ldots, x_0, x_1, \ldots, x_1, \ldots, x_r] = \frac{1}{(m_0 - 1)!(m_1 - 1)! \cdots (m_r - 1)!} \frac{\partial^{n-r}}{\partial x_0^{m_0-1} \partial x_1^{m_1-1} \cdots \partial x_r^{m_r-1}} (f[x_0, \ldots, x_r])$$

where x_k occurs m_k times on the left and once on the right.

V.11.5.13. Actually, for this formula to hold and define $f[x_0, \ldots, x_0, x_1, \ldots, x_1, \ldots, x_r]$ continuously at $(x_0, \ldots, x_0, x_1, \ldots, x_1, \ldots, x_r)$, it suffices that f be $\mathcal{C}^{m_k - 1}$ in an interval around x_k for each k (although the $\mathcal{C}^{n-r}$ statement does not hold in general). See [**?**, p. 72-73] for an outline of the proof. Note that the formula agrees with the previous cases where $r = n$ (all $m_k = 1$) or $r = 0$ ($m_0 = n + 1$).

V.11.6. Osculating Polynomials

V.11.6.1. We want to extend the notion of interpolating polynomial to the case where the points $x_0, \dots, x_n$ are not all distinct. The first thing we must decide is what this should mean: if x_0 is repeated m times, how should the approximating polynomial p agree with f at x_0?

The approximation should be of "order m" in the sense that $f - p$ should have a zero of "order m" at x_0. The broadest sense in which this can be interpreted is to demand that

$$f(x) - p(x) = o(|x - x_0|^{m-1})$$

as $x \to x_0$ in I. By V.10.1.3., if f is $(m-1)$-times differentiable at x_0, this will happen if and only if

$$p(x_0) = f(x_0), p'(x_0) = f'(x_0), \dots, p^{(m-1)}(x_0) = f^{(m-1)}(x_0) \ .$$

So, if f is differentiable to high enough order, we need to find a polynomial with specified values and derivatives up to a certain level at each of the points. This is possible because of the following extension of V.11.1.1.:

V.11.6.2. THEOREM. Let $n \in \mathbb{N}$, $x_0, \dots, x_r$ distinct real numbers, $m_0, \dots, m_r \in \mathbb{N}$ with $m_0 + \cdots + m_r = n + 1$ (so necessarily $r \le n$), and

$$b_0^{(0)}, b_0^{(1)}, \dots, b_0^{(m_0-1)}, b_1^{(0)}, \dots, b_r^{(m_r-1)}$$

real numbers (not necessarily distinct). Then there is a unique polynomial p with real coefficients, of degree $\le n$, for which $p^{(j)}(x_k) = b_k^{(j)}$ for $0 \le k \le r$, $0 \le j \le m_k - 1$.

PROOF: To find

$$p(x) = a_0 + a_1 x + \cdots + a_n x^n$$

we need to solve the system

$$\begin{bmatrix} 1 & x_0 & x_0^2 & x_0^3 & \cdots & x_0^n \\ 0 & 1 & 2x_0 & 3x_0^2 & \cdots & nx_0^{n-1} \\ 0 & 0 & 2 & 6x_0 & \cdots & n(n-1)x_0^{n-2} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x_1 & x_1^2 & x_1^3 & \cdots & x_1^n \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & n(n-1)\cdots(n-m_r+2)x_r^{n-m_r+1} \end{bmatrix} \begin{bmatrix} a_0 \\ \vdots \\ \vdots \\ \vdots \\ \vdots \\ a_n \end{bmatrix} = \begin{bmatrix} b_0^{(0)} \\ b_0^{(1)} \\ b_0^{(2)} \\ \vdots \\ b_1^{(0)} \\ \vdots \\ b_r^{(m_r-1)} \end{bmatrix}$$

where there are m_k rows for each x_k. It can be shown (Exercise V.11.8.1.) that the matrix on the left is invertible if the x_k are distinct, so the system has a unique solution. 👍

V.11.6.3. COROLLARY. Let f be a function on an interval I. Let $n \in \mathbb{N}$, $x_0, \dots, x_r$ distinct numbers in I, and $m_0, \dots, m_r \in \mathbb{N}$ with $m_0 + \cdots + m_r = n + 1$ (so necessarily $r \le n$). Suppose f is $(m_k - 1)$-times differentiable at x_k for each k. Then there is a unique polynomial p of degree $\le n$, with real coefficients, such that $p^{(j)}(x_k) = f^{(j)}(x_k)$ for $0 \le k \le r$, $0 \le j \le m_k - 1$.

V.11.6.4. DEFINITION. The polynomial p is called the *osculating polynomial* of f with respect to $(x_0, \dots, x_r; m_0, \dots, m_r)$.

V.11.6.5. The osculating polynomial generalizes both the interpolating polynomial (the case $r = n$ and all $m_k = 1$) and the Taylor polynomial (the case $r = 0$, $m_0 = n + 1$). If f is sufficiently differentiable, the osculating polynomial is a limiting case of interpolation polynomials for distinct points approaching the repeated points (this is essentially how TAYLOR found the Taylor polynomials).

V.11.6.6. In fact, there is a formula for the osculating polynomial using the extended definitions of higher-order divided differences which is just an extension of the Newton form of the interpolation polynomial:

$$p(x) = f[x_0] + (x - x_0)f[x_0, x_0] + \cdots + (x - x_0)^{m_0-1} f[x_0, \dots, x_0] + (x - x_0)^{m_0} f[x_0, \dots, x_0, x_1]$$

$$+(x-x_0)^{m_0}(x-x_1)f[x_0, \dots, x_0, x_1, x_1]+\cdots+(x-x_0)^{m_0}(x-x_1)^{m_1}\cdots(x-x_r)^{m_r-1}f[x_0, \dots, x_0, x_1, \dots, x_1, \dots, x_r]$$

where x_{k+1} starts appearing when x_k has been repeated m_k times. There is also an exact formula

$$f(x) = f[x_0] + (x - x_0)f[x_0, x_0] + \cdots + (x - x_0)^{m_0-1} f[x_0, \dots, x_0] + (x - x_0)^{m_0} f[x_0, \dots, x_0, x_1]$$

$$+(x-x_0)^{m_0}(x-x_1)f[x_0, \dots, x_0, x_1, x_1]+\cdots+(x-x_0)^{m_0}(x-x_1)^{m_1}\cdots(x-x_r)^{m_r}f[x_0, \dots, x_0, x_1, \dots, x_1, \dots, x_r, x]$$

where x_k is repeated m_k times, which is valid for $x \neq x_0, \dots, x_r$, and even also for $x = x_k$ if f is m_k-times differentiable at x_k.

We thus get a formula for the error from approximation by the osculating polynomial: if $E(x) = f(x) - p(x)$, we have

$$E(x) = (x - x_0)^{m_0}(x - x_1)^{m_1} \cdots (x - x_r)^{m_r} f[x_0, \dots, x_0, x_1, \dots, x_1, \dots, x_r, x]$$

and, combining this with V.11.5.9., we obtain:

V.11.6.7. COROLLARY. Let f be $(n + 1)$-times differentiable on I, $x_0, \dots, x_r$ distinct points of I, and $m_0, \dots, m_r \in \mathbb{N}$ with $m_0 + \cdots + m_r = n + 1$ (so necessarily $r \leq n$). Let p be the osculating polynomial of f with respect to $(x_0, \dots, x_r; m_0, \dots, m_r)$. Then, for any $x \in I$, there is a c in the smallest subinterval of I containing $x_0, \dots, x_r, x$ such that

$$f(x) - p(x) = (x - x_0)^{m_0}(x - x_1)^{m_1} \cdots (x - x_r)^{m_r} \frac{f^{(n+1)}(c)}{(n + 1)!} .$$

Note that both V.11.4.5. and the Lagrange form of the error in Taylor's Theorem (V.10.3.3.) are special cases.

V.11.6.8. An osculating polynomial where all m_k are 2 (n is then necessarily odd) is called a *Hermite polynomial*, and approximation by such a polynomial is called *Hermite interpolation*. (Approximation with general $m_k \geq 2$ is also sometimes called Hermite interpolation.)

V.11.6.9. In practical approximation problems, it can happen, although it is somewhat unusual, that one has data allowing approximation of an unknown function by an osculating polynomial, especially a Hermite polynomial. Such an approximation, when possible, will generally (but not always) be more accurate than approximation by the interpolation polynomial for the same data points.

V.11.7. How Good are the Approximations?

It is beyond the scope of this book to give a comprehensive discussion of the accuracy (not to mention the efficiency) of the various ways to approximate functions by polynomials. But we will briefly survey some of the aspects of accuracy in this section. Almost any book on numerical analysis contains a much more thorough treatment. The article http://people.maths.ox.ac.uk/trefethen/mythspaper.pdf has some important observations about polynomial approximation. See also [**?**].

Approximation With Evenly-Spaced Nodes

V.11.7.1. If $I = [a, b]$, the most obvious choice of $x_0, \dots, x_n$ is as a partition of I into n subintervals of equal length $h = \frac{b-a}{n}$, i.e. $x_k = x_0 + kh$. In this case, the denominators in the recursive formula (V.11.3.6.) for the divided differences are all equal to h, so we may instead consider just the ordinary differences

$$\Delta f(x_j) = \Delta^1 f(x_j) = f(x_{j+1}) - f(x_j)$$

$$\Delta^{k+1} f(x_j) = \Delta^k f(x_{j+1}) - \Delta^k f(x_j)$$

(these are usually called *forward differences*), giving the formula (easily proved by induction)

$$f[x_0, \dots, x_k] = \frac{1}{k! h^k} \Delta^k f(x_0) \ .$$

We also use the notation

$$\pi_k(t) = t(t-1)\cdots(t-k+1)$$

for $k \geq 1$ (we may set $\pi_0(t) = 1$; π_k is called the k'th *factorial polynomial*); cf. V.3.11.14.. The Newton formula for the interpolation polynomial then becomes, for $0 \leq t \leq n$,

$$p_{0,\dots,n}(x_0 + th) = f(x_0) + \sum_{k=1}^{n} \frac{\pi_k(t)}{k!} \Delta^k f(x_0) = \sum_{k=0}^{n} \frac{\pi_k(t)}{k!} \Delta^k f(x_0)$$

if we set $\Delta^0 f(x_0) = f(x_0)$. This is the *Gregory-Newton interpolation formula*. We may further rewrite this using the generalized binomial coefficient

$$\binom{t}{k} = \frac{\pi_k(t)}{k!}$$

(cf. V.12.5.1.), so

$$p_{0,\dots,n}(x_0 + th) = \sum_{k=0}^{n} \binom{t}{k} \Delta^k f(x_0) \ .$$

We may get similar formulas for backward differences or centered differences; see books on numerical analysis for details.

V.11.7.2. If f is continuous on $[a,b]$ and $(n+1)$-times differentiable on (a,b), we get a corresponding formula for the error term for $0 \le t \le n$:

$$E_n(x_0+th) = \pi_n(t)h^{n+1}\frac{f^{(n+1)}(c)}{(n+1)!}$$

for some $c \in (a,b)$.

V.11.7.3. We also get a formula for the Lagrange form of the interpolation formula using evenly-spaced nodes. Using the same notation as above, we have

$$p_{0,\dots,n}(x_0+th) = \frac{\pi_n(t)}{n!}\sum_{k=0}^{n}(-1)^{n-k}\binom{n}{k}\frac{f(x_k)}{t-k} \ .$$

The Runge Phenomenon

V.11.7.4. Suppose f is a function on $[a,b]$. One might expect that as $n \to \infty$, the interpolation polynomials $p_{0,\dots,n}$ for f corresponding to a subdivision of $[a,b]$ into n subintervals of equal length should converge to f pointwise or even uniformly on $[a,b]$ if f is sufficiently smooth. But this fails dramatically in general, even if f is analytic. This phenomenon was found by C. Runge in 1901, although related work had previously been done by C. Meray.

V.11.7.5. Runge's classic example is the innocent-looking function

$$g(x) = \frac{1}{x^2+1}$$

on the interval $[-5,5]$, or equivalently by rescaling

$$f(x) = \frac{1}{25x^2+1}$$

on $[-1,1]$. These functions are real-analytic on all of $\mathbb{R}$, and complex-analytic on $\mathbb{C}$ except for two poles. Figure V.10 (from http://www.math.utk.edu/~ccollins/M471/runge.jpg) shows some approximants of small order, which suggest there is an approximation problem near the ends of the interval.

V.11.7.6. In fact, the approximants for g converge pointwise for

$$|x| < x_c \approx 3.63$$

and u.c. on $(-x_c, x_c)$, but diverge pointwise for $x_c < |x| < 5$. The demonstration http://demonstrations.wolfram.com/RungesPhenomenon shows just how wildly the approximations diverge near the endpoints.

V.11.7.7. It should not be too surprising that there are problems near the endpoints, since interpolation near the endpoints is almost extrapolation, for which one would expect problems. In fact, the polynomial π_n has large values near the ends of the interval $[0,n]$, so the error in V.11.7.2. might tend to blow up (and often does) toward the ends of the interval as n increases.

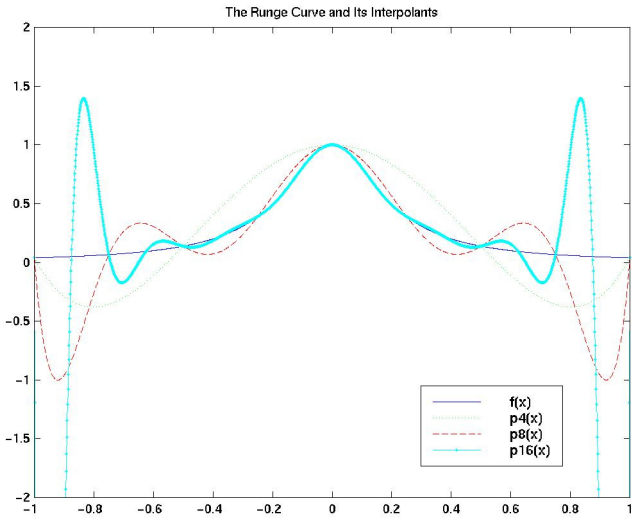

Figure V.10: The Runge Phenomenon

V.11.7.8. The real "explanation" of why approximation fails in this example is that the poles of the function in $\mathbb{C}$ are too close to the interval of approximation (cf. Exercise V.11.8.10.). A detailed discussion can be found in [**?**], (), ().

V.11.7.9. A nice discussion of the Runge phenomenon can be found in http://www.maa.org/sites/default/files/images/upload_library/22/Ford/Epperson329-341.pdf.

Chebyshev Nodes

V.11.7.10. It would appear that one gets a better approximation using nodes which are not evenly spaced, but are more concentrated near the endpoints. This is true in reasonable cases. We will work on the interval $[-1, 1]$ for simplicity; other intervals can be handled via an affine transformation.

V.11.7.11. If f is smooth, the error in approximating by $p_{0,\dots,n}$ for $\{x_0, \dots, x_n\}$ is given by

$$(x - x_0)(x - x_1) \cdots (x - x_n) \frac{f^{(n+1)}(c)}{(n+1)!}$$

for some $c \in (-1, 1)$. To try to minimize this, we can choose the x_k so that the polynomial

$$q(x) = (x - x_0)(x - x_1) \cdots (x - x_n)$$

is uniformly as small as possible on $[-1, 1]$. Chebyshev showed that the minimum occurs when

$$x_k = \cos\left(\frac{2k+1}{2(n+1)}\pi\right) .$$

These are called the *Chebyshev nodes* (note that they do not form a partition of $[-1,1]$; the endpoints are not nodes). If the x_k are the Chebyshev nodes, the maximum value of $q(x)$ is 2^{-n}, so the error in the approximation can be bounded:

$$|f(x) - p_{0,\dots,n}(x)| \leq \frac{1}{2^n(n+1)!} \sup_{-1<c<1} |f^{(n+1)}(c)|$$

for $x \in [-1,1]$.

V.11.7.12. In fact, the Chebyshev approximations converge uniformly to f if f is Hölder continuous, and in particular if f is $\mathcal{C}^1$ or even Lipschitz (the minimal requirement to insure convergence is somewhat weaker than Hölder continuity; cf. ()). They converge rapidly if f is differentiable to high order. There are, however, examples of continuous f where the Chebyshev approximations do not converge even pointwise. In fact, for any scheme of choosing interpolation points an example of a continuous f can be concocted for which the scheme does not converge (Faber's theorem).

Extrapolation

V.11.7.13. Because the polynomial

$$q(x) = (x - x_0)(x - x_1)\cdots(x - x_n)$$

grows rapidly outside the smallest interval containing $x_0, \dots, x_n$, the error estimate from V.11.4.5. or V.11.6.6. quickly blows up outside this interval. In fact, extrapolation using an interpolating or osculating polynomial is not generally too accurate outside the interval of nodes.

V.11.7.14. Using a Taylor polynomial for f at x_0 to approximate $f(x)$ for $x \neq x_0$ is really always extrapolation, so it is not surprising that the Taylor polynomials do not always give good approximations to $f(x)$ for a fixed $x \neq x_0$. It is actually more surprising (from the interpolation-extrapolation point of view) that they really do give good approximations in so many important cases.

Other Types of Approximation

V.11.7.15. The Chebyshev polynomials are not usually the best uniform approximants to a smooth function f. It can be shown that for any f which is continuous on $[a,b]$, there is a unique polynomial p of degree $\leq n$ which approximates f uniformly most closely on $[-1,1]$ (*minimax approximation*), i.e. for which $\|f - p\|_\infty$ is minimum [existence of a minimizing polynomial is a simple compactness argument, but uniqueness is not so obvious since $\|\cdot\|_\infty$ is not strictly convex], and p is an interpolation polynomial for f for some choice of $x_0, \dots, x_n$ (*Chebyshev's equioscillation theorem*, cf. Exercise V.11.8.9.). But there is no reasonable procedure for finding the best $x_0, \dots, x_n$ in general, even if f is smooth, although there is an iterative procedure (the *Remez algorithm*) which converges rapidly in good cases. In reasonable cases, the Chebyshev polynomials come close to realizing the minimum. See [May06] for a nice discussion of Chebyshev's equioscillation theorem with illustrative applets.

V.11.7.16. Another way of uniformly approximating a continuous f is by Bernstein polynomials (XX.10.1.2.). These are not interpolation polynomials and converge uniformly to f relatively slowly even if f is smooth, but they are guaranteed to converge uniformly to f for any continuous f.

V.11.7.17. One can also try for approximation of f in other norms besides the uniform norm. One alternative which can be efficiently computed is using the 2-norm (*least-square approximation*). See ().

V.11.7.18. One can also use other functions besides polynomials to approximate, e.g. rational functions or trigonometric functions. There is an extensive theory of such approximations, discussed in numerical analysis texts.

V.11.8. Exercises

V.11.8.1. (a) Verify the formula for the determinant of the Vandermonde matrix (V.11.1.1.). [Regard $x_0, \dots, x_n$ successively as variables. The determinant is a polynomial in these variables which vanishes when $x_k = x_j$ for $j \neq k$, so $x_k - x_j$ is a factor.]
(b) Similarly compute the determinant of the matrix in the proof of V.11.6.2. and show it is nonzero. [Experiments with small-size examples using a computer algebra system can be helpful in guessing the correct formula.]
(c) Give an alternate proof that the system of V.11.6.2. (and the special case V.11.1.1.) always has a unique solution without computing determinants, as follows. First show that the homogeneous system (all $b_k^{(j)} = 0$) has a unique solution [a solution q is a polynomial of degree $\leq n$ with at least $n+1$ roots, counted with multiplicity]. This implies that the matrix is invertible, so the system is uniquely solvable for any $b_k^{(j)}$'s.

V.11.8.2. (a) Verify the formula for K in V.11.3.1. and the formula in V.11.3.2..
(b) Verify the recursive formula for $f[x_0, \dots, x_n]$ in V.11.3.6.. [Use that

$$f[x_0] + (x - x_0)f[x_0, x_1] + (x - x_0)(x - x_1)f[x_0, x_1, x_2] + \cdots + (x - x_0)(x - x_1)\cdots(x - x_{n-1})f[x_0, \dots, x_n]$$

$$= f[x_n] + (x - x_n)f[x_n, x_{n-1}] + (x - x_n)(x - x_{n-1})f[x_n, x_{n-1}, x_{n-2}] + \cdots + (x - x_n)(x - x_{n-1})\cdots(x - x_1)f[x_n, \dots, x_0]$$

(both are the interpolating polynomial) and equate the coefficients of x^{n-1}.]

V.11.8.3. Suppose f is $\mathcal{C}^r$ on an interval I ($r \geq 1$), and $x_0 \in I$. Set

$$g(x) = \begin{cases} f[x_0, x] & \text{if} \quad x \neq x_0 \\ f'(x_0) & \text{if} \quad x = x_0 \end{cases} .$$

Show that g is $\mathcal{C}^{r-1}$ on I.

V.11.8.4. (a) Suppose f is a function on an interval I, and $x_0, \dots, x_n$ are distinct points of I. Show that, for $x \in I$, x not equal to any x_k,

$$f[x_0, \dots, x_n, x] = \sum_{k=0}^{n} \frac{f[x_k, x]}{\prod_{j \neq k}(x_k - x_j)} .$$

(b) Suppose f is $\mathcal{C}^r$ on I ($r \geq 1$). Set

$$g(x) = f[x_0, \dots, x_n, x] = \sum_{k=0}^{n} \frac{f[x_k, x]}{\prod_{j \neq k}(x_k - x_j)}$$

where $f[x_k, x]$ is extended to $x = x_k$ as in V.11.8.3.. Show that g is $\mathcal{C}^{r-1}$ on I.

V.11.8.5. Write out the details of the proof of V.11.5.10. and V.11.5.13..

V.11.8.6. Show that the formula in V.11.6.6. gives the osculating polynomial.

V.11.8.7. Derive the formula for $p_{0,\dots,n}$ in V.11.7.1. from V.11.3.2., and the Lagrange form in V.11.7.3. from V.11.1.3..

V.11.8.8. For $n \geq 0$, define

$$T_{n+1}(x) = (x - x_0)(x - x_1) \cdots (x - x_n)$$

where $x_0, \dots, x_n$ are the Chebyshev nodes (V.11.7.11.). T_{n+1} is called the $(n+1)$'st *monic Chebyshev polynomial of the first kind*. (References differ on whether to multiply by a conventional factor of 2^n, which is why we use the term "monic Chebyshev polynomial." We will not discuss Chebyshev polynomials of other kinds.)

(a) Show that

$$T_n(x) = 2^{-n+1} \cos(n \cos^{-1} x)$$

for $n \geq 1$ and $-1 \leq x \leq 1$. (This formula can also be used to define T_n for $n = 0$.)

(b) Show that $\max\limits_{|x| \leq 1} |T_n(x)| = 2^{-n+1}$, and that the maximum occurs precisely at the $n+1$ points $\cos \frac{k}{n}$, $0 \leq k \leq n$.

(c) Show that T_n $(n \geq 1)$ has the smallest uniform norm of all monic polynomials of degree $\leq n$, with real coefficients, with n roots in $[-1, 1]$ counted with multiplicity.

(d) Prove the recurrence formula $T_{n+1}(x) = xT_n(x) - \frac{1}{4}T_{n-1}(x)$ for $n \geq 1$.

(d) Show that T_n is a solution to the differential equation

$$(1 - x^2)y'' = xy' - n^2 y \ .$$

(e) Show that

$$T_n(x) = \frac{1}{2}\left[(x + \sqrt{x^2 - 1})^n + (x - \sqrt{x^2 - 1})^n\right] \ .$$

The Chebyshev polynomials also arise in least-squares approximation ().

V.11.8.9. Let f be a continuous function on a closed bounded interval $[a, b]$, and $n \in \mathbb{N}$.

(a) Prove using the Heine-Borel theorem that there is a polynomial p of degree $\leq n$ for which $\|f - p\|_\infty$ is minimum among all polynomials of degree $\leq n$.

(b) If p is a polynomial of degree $\leq n$ and there are $n+2$ distinct points $y_0, \dots, y_{n+1}$ in $[a, b]$ (in increasing order) such that

$$f(y_k) - p(y_k) = \pm \|f - p\|_\infty$$

with alternating signs, then $\|f - p\|_\infty$ is minimum among all polynomials of degree $\leq n$. [If q is a polynomial of degree $\leq n$ with $\|f - q\|_\infty < \|f - p\|_\infty$, then $q(y_k)$ is alternately greater than and less than $p(y_k)$. Thus $p - q$ is a nonzero polynomial of degree $\leq n$ with at least $n+1$ roots by the Intermediate Value Theorem.]

(c) Chebyshev's Equioscillation Theorem states the converse to (b): a polynomial p for which $\|f - p\|_\infty$ is minimum among all polynomials of degree $\leq n$ has the equioscillation property of (b).

(d) Show that the result of (c) implies that the polynomial of degree $\leq n$ of minimum uniform distance from f is unique. [If p and q minimize distance from f, then so does $\phi = \frac{1}{2}(p + q)$, and thus ϕ has the equioscillation property.]

(e) Show by the Intermediate Value Theorem that the closest approximant p is an interpolation polynomial for f with nodes $x_0, \ldots, x_n$ with $y_k < x_k < y_{k+1}$ for all k.

V.11.8.10. Let $f(x) = \frac{1}{x^2+1}$. Sketch the graphs of the Taylor polynomials of f around 0. On what interval do they converge to f? What is the radius of convergence of the Taylor series of f around 0? What about the Taylor series around a general $x_0 \in \mathbb{R}$? Justify this geometrically by considering f as an analytic function with poles on $\mathbb{C}$. This suggests some connection between complex poles and the Runge phenomenon; one would expect interpolating polynomials to approximate somewhat better over an interval than Taylor polynomials, but perhaps not to an unlimited extent.

V.12. Miscellaneous Topics in Calculus

V.12.1. How Discontinuous Can a Derivative Be?

If f is a differentiable function (on an interval, or all of $\mathbb{R}$), what can be said about the properties of the function f'?

V.12.1.1. EXAMPLE. If f is differentiable, the function f' need not itself be differentiable everywhere. For perhaps the simplest example, let

$$f(x) = \begin{cases} x^2 & \text{if } x \geq 0 \\ -x^2 & \text{if } x < 0 \end{cases} .$$

Then we have

$$f'(x) = \begin{cases} 2x & \text{if } x \geq 0 \\ -2x & \text{if } x < 0 \end{cases} .$$

(It must be shown directly from the definition of derivative that $f'(0)$ exists and equals 0.) Thus f is differentiable everywhere, but f' is not differentiable at 0.

V.12.1.2. In this example, f' is continuous. In fact, every continuous function occurs as the derivative of a differentiable function: if g is continuous on an interval I, and $x_0 \in I$, for $x \in I$ define

$$f(x) = \int_{x_0}^{x} g(t)\,dt .$$

Then, by the Fundamental Theorem of Calculus (), $f'(x) = g(x)$.

However, a derivative need not even be continuous:

V.12.1.3. EXAMPLE. Let $f(x) = x^2 \sin \frac{1}{x}$ for $x \neq 0$, and $f(0) = 0$. Then, for $x \neq 0$,

$$f'(x) = 2x \sin \frac{1}{x} - \cos \frac{1}{x} .$$

It can be checked from the definition (Exercise ()) that $f'(0)$ exists and equals 0. Thus f is differentiable everywhere, but f' is not continuous at 0 since $\lim_{x\to 0} f'(x)$ does not exist.

In this example, although f' is not continuous, it is bounded on bounded intervals, and measurable, hence Lebesgue integrable on any bounded interval, and f can be recovered from f' by

$$f(x) = \int_{0}^{x} f'(t)\,dt$$

where the integral is a Lebesgue integral. (In fact, since f' is bounded and continuous except at one point, it is Riemann integrable on any bounded interval, so the integral can even be taken to be a Riemann integral in this case.)

But f' need not be even locally Lebesgue integrable:

V.12.1.4. EXAMPLE. Let $f(x) = x^2 \sin \frac{1}{x^2}$ for $x \neq 0$, and $f(0) = 0$. Then, for $x \neq 0$,

$$f'(x) = 2x \sin \frac{1}{x^2} - \frac{2}{x} \cos \frac{1}{x^2} \ .$$

It can again be checked from the definition (Exercise ()) that $f'(0)$ exists and equals 0, so f is differentiable, but f' is unbounded and not Lebesgue integrable in any neighborhood of 0.

V.12.1.5. However, if f is any differentiable function, then f' is always locally H-K integrable to f (). In fact, the function f' of V.12.1.4. is one of the standard examples of a function which is H-K integrable but not Lebesgue integrable.

V.12.1.6. The above examples of derivatives are continuous except at one point. A differentiable function can be easily constructed whose derivative has a dense set of discontinuities (Exercise V.12.4.2.). Much more extreme examples can be constructed; see Exercise V.12.4.3. for an example of a differentiable function whose derivative is discontinuous almost everywhere. One of the most extreme examples is Example () of KATZNELSON and STROMBERG ([KS74]; cf. [vRS82, 13.2]):

V.12.1.7. EXAMPLE. There is a differentiable function f with the following properties:

(i) $|f'(x)| \leq 1$ for all x.

(ii) Each of the following sets is dense in $\mathbb{R}$:

$$A = \{x : f'(x) > 0\}$$
$$B = \{x : f'(x) = 0\}$$
$$C = \{x : f'(x) < 0\}$$

(iii) f is not monotone on any interval.

In fact, "many" differentiable functions satisfy (ii) and (iii) (XIII.12.5.7., XIII.12.5.8.). It follows from (ii) that the discontinuities of f' are dense; in fact, f' must be discontinuous wherever it is nonzero.

By (), f' is not Riemann integrable on any interval, hence f' is not continuous a.e. on any interval (). In fact, the sets A and C both have positive Lebesgue measure.

But the next result, combined with (), shows that the derivative of a differentiable function cannot be "too discontinuous."

V.12.1.8. PROPOSITION. If f is differentiable, then f' is of Baire Class 1 (), and in particular must be Lebesgue measurable, and continuous except on a meager set (which may, however, have positive Lebesgue measure (V.12.1.7., V.12.4.3.)).

PROOF: Define

$$g_n(x) = \frac{f\left(x + \frac{1}{n}\right) - f(x)}{1/n} = n\left[f\left(x + \frac{1}{n}\right) - f(x)\right]$$

(The definition may need slight modification if working on a closed interval; see Exercise V.12.4.1.). Then each g_n is continuous, and $g_n \to f'$ pointwise. 👍

V.12.2. Other Properties of Derivatives

V.12.2.1. Derivatives have another property characteristic of continuous functions: they have the *Intermediate Value Property*, or *Darboux Property*, i.e. they satisfy the conclusion of the Intermediate Value Theorem (V.8.2.13.).

V.12.2.2. So which functions are derivatives, i.e. if g is a function on an interval I, when is there a differentiable function f on I with $f' = g$? This is a difficult question, and no reasonable necessary and sufficient conditions are known. It is *sufficient* that g be continuous, but not necessary. And it is *necessary* that g be a Baire Class 1 function with the Intermediate Value Property, but this is not sufficient either:

V.12.2.3. EXAMPLE. Let $g_t(x) = 2x \sin \frac{1}{x} - \cos \frac{1}{x}$ for $x \neq 0$, and $g_t(0) = t$ (cf. V.12.1.3.). Then g_t is Baire Class 1 for any t (), and has the Intermediate Value Property if $-1 \leq t \leq 1$. But g_t is a derivative if and only if $t = 0$. (The only differentiable function f with $f(0) = 0$ for which f' could be g_t is $f(x) = x^2 \sin \frac{1}{x}$; the derivative of this f is g_0.)

V.12.2.4. A derivative must also be H-K integrable over every closed bounded subinterval of I, which is a quite mild restriction, although not automatic for a Baire Class 1 function with the Intermediate Value Property (e.g. the function $g(x) = \frac{1}{x} \sin^2 \frac{1}{x}$, $g(0) = 0$.)

V.12.2.5. One *can* give one necessary and sufficient condition: we must have that

$$\lim_{h \to 0+} \frac{1}{h} \int_{x_0}^{x_0+h} g(t)\, dt \quad \text{and} \quad \lim_{h \to 0+} \frac{1}{h} \int_{x_0-h}^{x_0} g(t)\, dt$$

must both exist and be equal, for every x_0, and the value of g at x_0 must be equal to this common value, i.e. for every x_0, the value of g at x_0 must be approximately equal to the average value of g over short intervals to the left and right of x_0. However, this condition is not a useful one to check in most cases. Compare with V.8.2.15. and V.9.4.11..

V.12.2.6. EXAMPLE. Let $g(t) = 1$ for $t > 0$ except for thin "spikes" down to 0 around $1/n$, and $g(-t) = -g(t)$ for $t > 0$. (See Fig. ().) Then g is bounded, continuous except at 0 (hence Riemann-integrable over every interval), but $\frac{1}{h} \int_0^h g(t)\, dt$ is approximately 1 and $\frac{1}{h} \int_{-h}^0 g(t)\, dt$ is approximately -1 if the spikes are thin enough. So g is not a derivative no matter how $g(0)$ is defined, i.e. g is not equal a.e. to the derivative of an everywhere differentiable function. If $-1 \leq g(0) \leq 1$, then g has the Intermediate Value Property.

See the article [] for more information on which functions are derivatives.

V.12.3. Analysis on $\mathbb{Q}$

In understanding the crucial role of completeness in real analysis, it is instructive to consider what happens if we just use $\mathbb{Q}$ (or a similar ordered field) as our number system. In this section (up to V.12.3.6.), "number" will always mean "rational number," and we will pretend we don't know about anything else. In fact, when Calculus was first developed, and up to the nineteenth century, completeness was not really understood or used, except sometimes implicitly and somewhat vaguely in assumptions that certain numbers (e.g. sums of certain infinite series) existed.

V.12.3.1. In our rational world, we can develop Calculus mechanically in the usual way: the definitions of limits of sequences and functions can be made identically to the ones in IV.1.3.6. and V.1.1.3., and the properties described in IV.1.3.21. and () hold, including the Sequential Criterion. Continuity can also be defined in the usual way, and the usual functions are continuous, although not many standard functions besides polynomials and rational functions are defined on entire intervals (cf. V.12.3.6.). We can define differentiability and the derivative as in V.3.1.9., and all the usual rules of differentiation hold, and in particular polynomials and rational functions are differentiable everywhere with their usual derivatives. Some properties of derivatives such as V.3.6.3. persist. We can also define Riemann integrability and the Riemann integral using Definitions 1A (IX.2.3.1.) or Definition 1B (IX.2.3.2.), which are equivalent (but not equivalent to the other definitions! And many standard functions are not Riemann-integrable on many intervals.) To verify these facts, note that the proofs do not use any form of completeness and are equally valid in our restricted number system.

V.12.3.2. However, almost all of the basic theorems of Calculus fail to hold. Most obviously, the Completeness Axiom fails, as do the Monotone Sequence Theorem (), the Cauchy Criterion (), and *a fortiori* the Bolzano-Weierstrass Theorem (). For example, the sequence

$$3, 3.1, 3.14, 3.141, 3.1415, 3.14159, 3.141492, 3.1415926, \ldots$$

is a bounded strictly increasing sequence which is a Cauchy sequence, but does not converge and does not even have a convergent subsequence (note that it is still true that a Cauchy sequence with a convergent subsequence must converge ()).

V.12.3.3. The Nested Intervals Property also does not hold. For example, the sequence

$$[3, 4], [3.1, 3.2], [3.14, 3.15], [3.141, 3.142], [3.1415, 3.1416], [3.14159, 3.1416], \ldots$$

is a decreasing sequence of closed bounded intervals whose intersection is empty.

V.12.3.4. In fact, it is a little ambiguous what a "closed bounded interval" should be. Should it be an interval of the form $[a, b]$, or should it be a bounded interval which is topologically closed? Specifically, is the interval

$$\{x : x^2 < 2\}$$

closed, open, both, or neither? Is it even an interval? (It is by the definition in III.1.9.12., and is topologically both open and closed.) Note that although this interval is bounded, it does not have a length.

V.12.3.5. The following functions provide counterexamples to other basic theorems of Calculus.

EXAMPLES. (i) Let

$$f(x) = \frac{1}{x^2 - 2} \ .$$

Then f is defined everywhere [on $\mathbb{Q}$!], and is continuous and even differentiable everywhere. But f is not bounded above or below on $[1, 2]$, and is not uniformly continuous on $[1, 2]$ (cf. ()). It is also not Riemann integrable on $[1, 2]$, in contrast to ().

(ii) Let

$$f(x) = \begin{cases} x & \text{if} \quad x^2 < 2 \\ 0 & \text{if} \quad x^2 > 2 \end{cases} \ .$$

Then f is defined everywhere, and is continuous and even differentiable everywhere. And f is bounded on $[1, 2]$, but does not attain a maximum on this interval.

By (i) and (ii), both conclusions of the Extreme Value Theorem fail to hold.

(iii) Let

$$f(x) = \begin{cases} x & \text{if} \quad x^2 < 2 \\ 3 - x & \text{if} \quad x^2 > 2 \end{cases} \ .$$

Then f is defined everywhere, and is continuous and even differentiable everywhere. We have $f(1) = f(2) = 1$, but there is no $c \in (1, 2)$ with $f'(c) = 0$. Thus Rolle's Theorem, and *a fortiori* the Mean Value Theorem, fail to hold on $[1, 2]$.

(iv) Let

$$f(x) = \begin{cases} 1 & \text{if} \quad x^2 < 2 \\ 0 & \text{if} \quad x^2 > 2 \end{cases} \ .$$

Then f is defined everywhere, and is continuous and even differentiable everywhere, and $f'(x) = 0$ for all x. But f is not constant, contradicting V.8.2.3. in our setting. And f does not satisfy the Intermediate Value Theorem on $[1, 2]$. The Fundamental Theorem of Calculus, Version 2 also does not hold for this f: f' is Riemann integrable on $[1, 2]$, but

$$\int_1^2 f'(x)\, dx \neq f(2) - f(1) \ .$$

Note that f itself is not Riemann integrable on $[1, 2]$, in contrast to IX.2.8.5..

One can do much worse. Let X be a closed subset of $\mathbb{R}$ contained in $\mathbb{J}$ (for example, there is a Cantor set contained in $\mathbb{J}$ (XIII.10.6.9.)). Then $U = \mathbb{R} \setminus X$ is an open set containing $\mathbb{Q}$. U is a finite or countable disjoint union $\cup I_n$ of open intervals; we may let f be constant on each $I_n \cap \mathbb{Q}$, with the constant values chosen arbitrarily (in $\mathbb{Q}$) and independently on the intervals. Such an f is differentiable everywhere and f' is identically 0. Thus a function with an antiderivative has a huge number of antiderivatives, which do not differ by constants.

Perhaps we cheated in the *construction* of these functions since we had to go outside $\mathbb{Q}$, but the *existence* of these functions is an incontestable fact. The underlying reason these pathological functions exist, and the other examples too, is that $\mathbb{Q}$ is totally disconnected (zero-dimensional) as a topological space (XIII.13.6.1.).

V.12.3.6. Using $\mathbb{Q}$ as our number system has other inadequacies independent of the completeness problem: many functions we would like to define have no reasonable definition. For example, e^x makes no sense (cf. III.9.3.5.), and $\cos x$ and $\sin x$ are defined only for $x = 0$ (III.9.3.6.). Even $\sqrt{x}$ has a small domain (although the domain is dense). And the definite integrals of even some rational functions over some intervals, such as

$$\int_1^2 \frac{1}{x}\,dx \quad \text{or} \quad \int_0^1 \frac{1}{1+x^2}\,dx$$

are not defined. [Note that a limited version of the Fundamental Theorem of Calculus, Version 1 holds: if f is a continuous function and *if*

$$A(x) = \int_a^x f(t)\,dt$$

exists (i.e. is in $\mathbb{Q}$) for all $x \in [a, b]$, then A is differentiable on $[a, b]$ and $A' = f$.]

But these inadequacies can be remedied without completeness. It is routine (using Countable AC) to construct a countable subfield $\mathbb{F}$ of $\mathbb{R}$ (necessarily containing $\mathbb{Q}$) such that

> $\mathbb{F}$ is real-closed (), and in particular contains all real algebraic numbers.
>
> $\mathbb{F}$ contains e, π, and all other standard mathematical constants.
>
> If $x, y \in \mathbb{F}$ and $y > 0$, then $\cos x$ (hence $\sin x = \pm\sqrt{1 - \cos^2 x}$, $\tan x$, etc.), $\log y$, y^x, $\Gamma(y)$, $\tan^{-1} x$, and (if $-1 \le x \le 1$) $\sin^{-1} x$ are all in $\mathbb{F}$.
>
> More generally, if $\{f_n : n \in \mathbb{N}\}$ is a countable collection of functions from $\mathbb{R}$ to $\mathbb{R}$, then $f_n(x) \in \mathbb{F}$ for all n and all $x \in \mathbb{F}$ for which $f_n(x)$ is defined. If each f_n is smooth, we may take $\{f_n\}$ to be closed under derivatives and antiderivatives of arbitrary order. We may also obtain that
>
> $$\int_a^b f_n(x)\,dx \in \mathbb{F}$$
>
> for every n and every $a, b \in \mathbb{F}$ for which f_n is defined on $[a, b]$.

If $\mathbb{F}$ is such a field, then all mechanical parts of Calculus involving standard functions can be carried out in $\mathbb{F}$, and existence of antiderivatives and definite integrals, at least of standard functions, is assured (we apparently cannot construct $\mathbb{F}$ so that every continuous function has an antiderivative; we cannot have such an $\mathbb{F}$ so that even indicator functions of clopen intervals have definite integrals over larger intervals, cf. V.12.3.5.(iv)). But counterexamples to most of the theorems of Calculus can be constructed as in V.12.3.5., although it is more delicate to describe them explicitly; one way to do it is to fix a bounded increasing sequence (c_n) in $\mathbb{F}$ with no limit in $\mathbb{F}$ [i.e. whose limit is in $\mathbb{R} \setminus \mathbb{F}$], and define functions like

$$f(x) = \begin{cases} 1 & \text{if } x < c_n \text{ for some } n \\ 0 & \text{otherwise} \end{cases} .$$

V.12.4. Exercises

V.12.4.1. Let f be a differentiable function on a closed bounded interval $[a, b]$. Find a sequence of continuous functions on $[a, b]$ converging pointwise to f'. [Modify the functions g_n in the proof of V.12.1.8. on $[b - \frac{1}{n}, b]$.]

V.12.4.2. Let $\phi(x) = x^2 \sin\left(\frac{1}{x}\right)$ for $x \neq 0$ and $\phi(0) = 0$. Then ϕ is differentiable everywhere ().

(a) Show that $|\phi(x)| \leq 1$ and $|\phi'(x)| \leq 3$ for $x \in [-1, 1]$.

(b) Let (q_k) be an enumeration of the rationals in $[0, 1]$, and for each k set $f_k(x) = 2^{-k}\phi(x - q_k)$. Then f_k is differentiable everywhere, $|f_k(x)| \leq \frac{1}{2^k}$ and $|f'(x)| \leq \frac{3}{2^k}$ for $x \in [0, 1]$.

(c) $\sum_{k=1}^{\infty} f_k$ and $\sum_{k=1}^{\infty} f_k'$ converge uniformly on $[0, 1]$ to functions f and g respectively. Apply V.8.5.5. (the hypotheses are more than fulfilled by the partial sums) to show that f is differentiable on $[0, 1]$ and that $g = f'$.

(d) Show that f' is discontinuous at each q_n (and only at these numbers). [For each n, write $f = f_n + \tilde{f}_n$, where $\tilde{f}_n = \sum_{k \neq n} f_k$; repeat the earlier arguments to show that $\tilde{f}_n$ is differentiable on $[0, 1]$ and that $\tilde{f}_n' = \sum_{k \neq n} f_k'$. Since each f_k' for $k \neq n$ is continuous at q_n, $\tilde{f}_n'$ is continuous at q_n. But f_n' is discontinuous at q_n.]

V.12.4.3. [vRS82, 14.3–14.5] If $I = [a, b]$ is a closed bounded interval, let g_I be the function with graph as in Figure (), with $L_I = \frac{b-a}{4}$.

(a) Let f_I be an antiderivative of g_I with $f_I(a) = 0$. Show that $f(b) = 0$ and $0 \leq f(x) \leq L_I^2$ for all $x \in [a, b]$.

(b) Let K be a Cantor set of positive measure in $[0, 1]$, and (I_n) an enumeration of the closures of the open intervals in $[0, 1] \setminus K$. Let f be the function on $[0, 1]$ which is 0 on K and f_{I_n} on I_n, and similarly g the function which is 0 on K and g_{I_n} on I_n. Show that f is differentiable on $[0, 1]$ and $f' = g$. [It is only necessary to show that $f'(a) = 0$ for $a \in K$. If $f(x) \neq 0$, then $x \in I_n$ for some n, so

$$\left|\frac{f(x) - f(a)}{x - a}\right| = \frac{f_{I_n}(x)}{|x - a|} \leq \frac{L_{I_n}^2}{|x - a|} \leq |x - a|$$

since $|x - a| \geq L_{I_n}$.]

(c) Show that for $a \in K$, $\limsup_{x \to a} g(x) = 1$, so g is discontinuous at each point of K, i.e. f' is discontinuous on a set of positive measure.

(d) Show that for $a \in K$, $\liminf_{x \to a} g(x) = 0$, so g is lower semicontinuous.

(e) Let K_n be a Cantor set in $[0, 1]$ of measure $1 - \frac{1}{n}$, and h_n the g constructed as above for K_n. Set $h = \sum_{n=1}^{\infty} 2^{-n} h_n$. Then h has an antiderivative ϕ on $[0, 1]$ ().

(f) Since each h_n is lower semicontinuous, h is discontinuous wherever one of the h_n is discontinuous (). Thus h is discontinuous at all points of $\cup K_n$, i.e. ϕ' is discontinuous a.e.

V.12.4.4. [vRS82, 14.J] Let g be a Darboux continuous function on an interval I which is of Baire Class 1 (e.g. $g = f'$ for a differentiable function f on I). Show that the graph of g is connected.

When is a function f from $\mathbb{R}$ (or $[a,b]$) to $\mathbb{R}$ the derivative of an everywhere differentiable function? Necessary conditions:

(1) f is Baire class 1, i.e. a pointwise limit of a sequence of continuous functions [if $f = F'$, set $f_n(t) = n[F(t+1/n) - F(t)]$; then f_n is continuous and $f_n \to f$.] This implies:

  (a) f is Lebesgue measurable.

  (b) f is continuous except on a set of first category [**?**].

(2) f is Henstock-Kurzweil integrable on every bounded interval [**?**].

(3) f has the Intermediate Value Property.

These properties are not sufficient:

EXAMPLES.

(i) Let $f(t) = \sin(1/t)$ for $t \neq 0$. For any α, $-1 \leq \alpha \leq 1$, define $f(0) = \alpha$. Then f has the above properties, but is a derivative if and only if $\alpha = 0$.

(ii) Let $f(t) = 1$ for $t > 0$ except for thin "spikes" down to 0 around $1/n$, and $f(-t) = -f(t)$ for $t > 0$, $f(0) = 0$. Then f has the above properties, is bounded, continuous except at 0, but not equal a.e. to the derivative of an everywhere differentiable function.

V.12.5. The Binomial Theorem

The Binomial Theorem in algebra gives a formula for positive integral powers of a sum of two numbers. The Binomial Theorem can be extended to apply also to negative and nonintegral powers, but the extended version involves infinite series and there are convergence questions which must be addressed.

Recall that the *binomial coefficients* are defined by the following formula:

V.12.5.1. DEFINITION. If $n \in \mathbb{N}$, $0 \leq k \leq n$, then

$$\binom{n}{k} = \frac{n!}{k!(n-k)!} = \frac{n(n-1)(n-2)\cdots(n-k+1)}{k!}$$

V.12.5.2. The last expression makes sense for any $n \in \mathbb{R}$ if $k \in \mathbb{N}$, and hence we can define the generalized binomial coefficient

$$\binom{\alpha}{k} = \frac{\alpha(\alpha-1)(\alpha-2)\cdots(\alpha-k+1)}{k!}$$

for $\alpha \in \mathbb{R}$, $k \in \mathbb{N}$. We set $\binom{\alpha}{0} = 1$ for all α (even $\alpha = 0$). Note that if $n \in \mathbb{N} \cup \{0\}$, then $\binom{n}{k} = 0$ for $k > n$; but if $\alpha \notin \mathbb{N} \cup \{0\}$, then $\binom{\alpha}{k} \neq 0$ for all k. $\binom{\alpha}{k}$ is read "α choose k," since if $n \in \mathbb{N}$, $\binom{n}{k}$ is just the number of ways of choosing k elements out of an n-element set.

Here is the standard Binomial Theorem of algebra:

V.12.5.3. THEOREM. Let $x, y \in \mathbb{C}$, $n \in \mathbb{N}$. Then

$$(x+y)^n = \sum_{k=0}^{n} \binom{n}{k} x^k y^{n-k}$$

(with the convention that $t^0 = 1$ for all t, even $t = 0$.) The formula actually holds (suitably interpreted) in any commutative ring.

This theorem can easily be proved by induction on n using the following relation among binomial coefficients, which can be proved by induction on k:

V.12.5.4. PROPOSITION. Let $\alpha, \beta \in \mathbb{R}$, $k \in \mathbb{N} \cup \{0\}$. Then

$$\binom{\alpha+\beta}{k} = \sum_{j=0}^{k} \binom{\alpha}{k-j}\binom{\beta}{j}$$

In particular, if $k \in \mathbb{N}$,

$$\binom{\alpha+1}{k} = \binom{\alpha}{k} + \binom{\alpha}{k-1}$$

The fact that the binomial coefficient $\binom{n}{k}$ is always a natural number if n and k are natural numbers with $k \leq n$ has an interesting consequence in number theory, which is not entirely obvious:

V.12.5.5. COROLLARY. If $k \in \mathbb{N}$, then the product of any k consecutive integers is divisible by $k!$.

PROOF: Let n be the largest number in the sequence. Then $n \geq k$, and

$$\frac{n(n-1)(n-2)\cdots(n-k+1)}{k!} = \binom{n}{k} \in \mathbb{N} .$$

V.12.5.6. COROLLARY. Let g be a polynomial with integer coefficients, and $k \in \mathbb{N}$. Then all coefficients of the k'th derivative $g^{(k)}$ are divisible by $k!$.

PROOF: It suffices to prove this for $g(x) = x^n$. If $n \geq k$, then $g^{(k)}(x) = n(n-1)(n-2)\cdots(n-k+1)x^{n-k}$, and $g^{(k)}$ is identically 0 if $k > n$.

This result is also an easy corollary of Taylor's Theorem.

V.12.5.7. To prove a version of the Binomial Theorem when n is not a positive integer, we restrict to the case where $y = 1$ and regard $(1+x)^n$ as a function of x. This is not an essential restriction, since if $y \neq 0$ we have $(x+y)^n = y^n \left(\frac{x}{y} + 1\right)^n$.

Fix $\alpha \in \mathbb{R}$ and consider the function $f(x) = (1+x)^\alpha$. This function is infinitely differentiable on $(-1, \infty)$ and extends to a continuous function on $[-1, \infty)$ if $\alpha \geq 0$. For certain special α it also extends to numbers less than -1.

V.12.5.8. PROPOSITION. For any $k \in \mathbb{N} \cup \{0\}$,

$$\frac{f^{(k)}(0)}{k!} = \binom{\alpha}{k} .$$

Thus the Taylor series for f around 0 is

$$\sum_{k=0}^{\infty} \binom{\alpha}{k} x^k .$$

The proof of the first formula is an easy calculation, and the second formula follows immediately.

V.12.5.9. THEOREM. [BINOMIAL THEOREM] For any $\alpha \in \mathbb{R}$, the series

$$\sum_{k=0}^{\infty} \binom{\alpha}{k} x^k$$

converges on $(-1, 1)$ to $(1+x)^\alpha$. If $\alpha \geq 0$, the series converges uniformly on $[-1, 1]$ to $(1+x)^\alpha$.

PROOF: The proof has three steps. (i) Show that the series converges on $(-1,1)$. (ii) Show that the series represents the function on $(-1,1)$. (iii) If $\alpha \geq 0$, show the series converges uniformly on $[-1,1]$. Since the results are obvious when $\alpha \in \mathbb{N} \cup \{0\}$ (since then the sum is finite), we will assume $\alpha \notin \mathbb{N} \cup \{0\}$. We set $a_k = \left|\binom{\alpha}{k}\right|$; then $a_k > 0$ for all k.
(i) Using the Ratio Test, the radius of convergence of the series is

$$\lim_{k\to\infty} \frac{a_k}{a_{k+1}} = \lim_{k\to\infty} \frac{k+1}{k-\alpha} = 1$$

so the series converges for $|x| < 1$.
(ii) For $x \in (-1,1)$, let $f(x) = \sum_{k=0}^{\infty} \binom{\alpha}{k} x^k$. Then f is differentiable on $(-1,1)$, and

$$f'(x) = \sum_{k=1}^{\infty} k\binom{\alpha}{k} x^{k-1} = \sum_{k=0}^{\infty} (k+1)\binom{\alpha}{k+1} x^k$$

on $(-1,1)$. We have

$$(1+x)f'(x) = \sum_{k=0}^{\infty} \left[(k+1)\binom{\alpha}{k+1} + k\binom{\alpha}{k}\right] x^k \ .$$

Since

$$(k+1)\binom{\alpha}{k+1} = \frac{\alpha(\alpha-1)\cdots(\alpha-k)}{k!} = (\alpha-k)\binom{\alpha}{k}$$

we have

$$(k+1)\binom{\alpha}{k+1} + k\binom{\alpha}{k} = \alpha\binom{\alpha}{k}$$

for any k and hence, since $\alpha \neq 0$,

$$f(x) = \frac{1}{\alpha}(1+x)f'(x) \ .$$

Since $g(x) = (1+x)^{-\alpha}$ is differentiable on $(-1,\infty)$ and $g'(x) = -\alpha(1+x)^{-\alpha-1}$ (), by the product rule

$$\frac{d}{dx}\left((1+x)^{-\alpha} f(x)\right) = (1+x)^{-\alpha} f'(x) - \alpha(1+x)^{-\alpha-1} f(x) = 0 \ .$$

Thus $(1+x)^{-\alpha} f(x)$ is constant, so $f(x) = C(1+x)^{\alpha}$ for some C. Since $f(0) = 1$, $C = 1$.
(iii) Suppose $\alpha > 0$. We will show that $\sum_{k=0}^{\infty} a_k$ converges. If $k > \alpha$, then $\frac{a_{k+1}}{a_k} = \frac{k-\alpha}{k+1}$, so $(k+1)a_{k+1} = (k-\alpha)a_k$, $ka_k - (k+1)a_{k+1} = \alpha a_k > 0$. Thus the sequence (ka_k) is nonnegative and decreasing for $k > \alpha$, and hence $\lambda = \lim_{k\to\infty} ka_k$ exists. We have

$$\sum_{k=0}^{n} (ka_k - (k+1)a_{k+1}) = -(n+1)a_{n+1} \to -\lambda$$

so $\sum_{k=0}^{\infty}(ka_k - (k+1)a_{k+1})$ converges. Since $a_k = \alpha^{-1}(ka_k - (k+1)a_{k+1})$ for $k > \alpha$, $\sum_{k=0}^{\infty} a_k$ converges. Thus, by the Weierstrass M-test, $\sum_{k=0}^{\infty} \binom{\alpha}{k} x^k$ converges absolutely and uniformly on $[-1,1]$. Since by (ii) the series represents $(1+x)^{\alpha}$ on $(-1,1)$, it represents $(1+x)^{\alpha}$ on $[-1,1]$ by continuity. 👍

V.12.6. Exercises

V.12.6.1. (a) Prove the second formula in V.12.5.4. by induction on k. [Hint: show using the inductive step that

$$\binom{\alpha+1}{k+1} = \binom{\alpha}{k}\left[\frac{\alpha-k}{k+1} + \frac{1}{k+1}\right] + \binom{\alpha}{k-1}\frac{\alpha-k+1}{k+1}$$

and consider three terms by multiplying. Show that the first term is $\binom{\alpha}{k+1}$ and the last is $\frac{k}{k+1}\binom{\alpha}{k}$.]

(b) Give a combinatorial argument for this formula if $\alpha \in \mathbb{N}$, interpreting $\binom{n}{k}$ as the number of ways of choosing k elements from an n-element set.

(c) Use this formula to prove V.12.5.3. by induction on n.

(d) Generalize the argument in (a) to prove the first formula in V.12.5.4..

V.12.6.2. Here is an alternate proof of V.12.5.9.(ii) (this was essentially CAUCHY'S original argument). Fix x with $|x| < 1$. Set $F_n(\alpha) = \sum_{k=0}^{n}\binom{\alpha}{k}x^k$.

(a) Mimic the proof of the Ratio test to show that the infinite series $\sum_{k=0}^{\infty}\binom{\alpha}{k}x^k$ converges absolutely and uniformly on $\mathbb{R}$ to a function $F(\alpha)$, i.e. $F_n(\alpha) \to F(\alpha)$ uniformly in α. Thus $F(\alpha)$ is continuous in α.

(b) For fixed $\alpha, \beta \in \mathbb{R}$, use the product formula for power series () to show that

$$F(\alpha)F(\beta) = \sum_{k=0}^{\infty}\left[\sum_{j=0}^{k}\binom{\alpha}{k-j}\binom{\beta}{j}\right]x^k \ .$$

(c) Conclude from V.12.5.4. that $F(\alpha)F(\beta) = F(\alpha+\beta)$.

(d) Apply () to conclude that $F(\alpha) = b^\alpha$ for some $b > 0$. Since $F(1) = 1 + x$, $b = 1 + x$.

V.12.6.3. (a) Show that for any $n \in \mathbb{N}$ and $x \in \mathbb{R}$,

$$(1-x)(1+x+x^2+\cdots+x^n) = 1 - x^{n+1} \ .$$

(b) Show that for all $x \in \mathbb{R}$, $x \neq -1$,

$$\frac{1}{1+x} = 1 - x + x^2 - \cdots + (-1)^n x^n + \frac{(-1)^{n+1}x^{n+1}}{1+x} \ .$$

(c) Show from (b) that if $|x| < 1$, then the series $\sum_{n=0}^{\infty}(-1)^n x^n$ converges to $\frac{1}{1+x}$. Compare with the Binomial Theorem for $\alpha = -1$.

V.12.6.4. Here is yet another proof of V.12.5.9.(ii), based on the Cauchy Remainder Formula for Taylor's Theorem (V.10.7.7.).

(a) Fix x with $|x| < 1$. By the Cauchy remainder formula, for any n there is a $\theta = \theta_n$, $0 < \theta < 1$, such that

$$R_n(x) = (1+x)^\alpha - \sum_{k=0}^{n}\binom{\alpha}{k}x^k = \frac{f^{(n+1)}(\theta x)}{n!}(1-\theta)^n x^{n+1}$$

$$= \frac{\alpha(\alpha-1)\cdots(\alpha-n)(1+\theta x)^{\alpha-n-1}}{n!}(1-\theta)^n x^{n+1}$$
$$= \left[\frac{(\alpha-1)(\alpha-2)\cdots(\alpha-n)}{n!}x^n\right]\left[\alpha x(1+\theta x)^{\alpha-1}\left(\frac{1-\theta}{1+\theta x}\right)^n\right]$$

(b) If $M = \max((1+x)^{\alpha-1}, (1-x)^{\alpha-1})$, the second factor is bounded in absolute value by $M|\alpha x|$ independent of n since $\left|\frac{1-\theta}{1+\theta x}\right| < 1$.

(c) The first factor is $\binom{\alpha-1}{n}x^n$ which goes to 0 as $n \to \infty$ since $\sum \binom{\alpha-1}{n}x^n$ converges by V.12.5.9.(i).

(d) Thus $R_n(x) \to 0$ as $n \to \infty$ and the series converges to $(1+x)^\alpha$.

V.13. The Gamma Function

The Gamma function, while not as well known as trigonometric, exponential, and logarithm functions, is of comparable importance in both theoretical and applied mathematics, and notably in probability and statistics. In this section, we will only develop the most basic aspects of the theory of this function.

The origin of the Gamma function was an attempt to find an analytic expression for the factorial function and extend its definition from $\mathbb{N}$ to $\mathbb{R}$. EULER found both infinite product and improper integral formulas for $n!$, both of which also make sense for nonintegral n:

$$n! = \prod_{k=1}^{\infty} \frac{\left(1+\frac{1}{k}\right)^n}{1+\frac{n}{k}} = \int_0^1 (-\log s)^n \, ds \ .$$

V.13.1. Definition of the Gamma Function

LEGENDRE (1811) used the integral expression of EULER, modified by the substitution $t = -\log s$, to give the first formal definition of the Gamma function:

V.13.1.5. DEFINITION. If $x > 0$, define

$$\Gamma(x) = \int_0^{\infty} t^{x-1} e^{-t} \, dt \ .$$

Note that LEGENDRE'S definition, for unknown reasons, has a shift of 1 in the argument, so that $\Gamma(n) = (n-1)!$ for $n \in \mathbb{N}$. It has remained the convention in mathematics to this day to include this shift, although it has dubious practical merit.

V.13.1.6. PROPOSITION. The improper Riemann integral $\displaystyle\int_0^{\infty} t^{x-1} e^{-t} \, dt$ converges for $x > 0$ (and only for $x > 0$).

PROOF: The integrand is continuous and positive on $(0, \infty)$, hence the Riemann integral over any closed bounded subinterval is defined. The integral $\int_0^{\infty}$ converges if and only if $I_1 = \int_0^1$ and $I_2 = \int_1^{\infty}$ both converge. For I_1, note that $t^{x-1}e^{-t} < t^{x-1}$ for $0 < t \leq 1$, and $\int_0^1 t^{x-1} \, dt$ converges for $x > 0$. (For the parenthetical assertion, $t^{x-1}e^{-t} \geq e^{-1}t^{x-1}$ for $0 < t \leq 1$, and $\int_0^1 t^{x-1} \, dt$ diverges for $x \leq 0$.)

For I_2, note that, for any $x \in \mathbb{R}$,

$$\lim_{t \to +\infty} \frac{t^{x-1}}{e^{t/2}} = 0$$

by (), and hence $t^{x-1}e^{-t} < e^{-t/2}$ for all sufficiently large t. Since $\int_1^{\infty} e^{-t/2} \, dt$ converges, so does I_2 for any $x \in \mathbb{R}$. 👍

The next result gives a crucial factorial-like recurrence property of the Gamma function.

V.13.1.7. PROPOSITION. If $x > 0$, then $\Gamma(x+1) = x\Gamma(x)$.

PROOF: Let $0 < a < b < \infty$. Compute the integral $\displaystyle\int_a^b t^x e^{-t}\,dt$ by parts:

$$\int_a^b t^x e^{-t}\,dt = \left[-t^x e^{-t}\right]_a^b - \int_a^b xt^{x-1}(-e^{-t})\,dt$$

$$= -a^x e^{-a} + b^x e^{-b} + x\int_a^b t^{x-1}e^{-t}\,dt\ .$$

As $a \to 0$ and $b \to +\infty$, the original integral approaches $\Gamma(x+1)$ and the final expression approaches $x\Gamma(x)$. 👍

V.13.1.8. COROLLARY. If $n \in \mathbb{N} \cup \{0\}$, then $\Gamma(n+1) = n!$. [Recall that $0! = 1$ by definition.]

PROOF: This is an easy proof by induction using the recurrence formula and the direct computation

$$\Gamma(1) = \int_0^\infty e^{-t}\,dt = \lim_{b\to+\infty}\int_0^b e^{-t}\,dt = \lim_{b\to+\infty}[-e^{-t}]_0^b = \lim_{b\to+\infty}[-e^{-b}+1] = 1 = 0!\ .$$

👍

So the Gamma function extends the (shifted) factorial function to $(0,\infty)$. This extension has the desired analytic property:

V.13.1.9. THEOREM. The Gamma function is real analytic () (and in particular C^∞) on $(0,\infty)$, and

$$\Gamma^{(n)}(x) = \int_0^\infty t^{x-1}e^{-t}(\log t)^n\,dt\ .$$

This is a special case of the general result () concerning differentiation under the integral sign. It is routine to show that the integral giving $\Gamma^{(n)}(x)$ converges for $x > 0$, and this follows anyway from the general theory.

V.13.1.10. Not many values of $\Gamma(x)$ for noninteger x can be computed exactly (of course, modern computers can easily calculate values to great numerical accuracy). One important value which can be computed () is

$$\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}\ .$$

V.13.2. Log-Convexity and a Characterization of the Gamma Function

V.13.2.11. The Gamma function is far from the only function on $(0,\infty)$ extending the (shifted) factorial: an extension can be defined arbitrarily for nonintegers. Γ is not even the only real-analytic function extending the factorial: if f is any real-analytic function vanishing at the positive integers, e.g. $f(x) = \sin \pi x$, then $\Gamma + f$ is an extension.

Satisfying the functional equation $g(x+1) = xg(x)$ for all $x > 0$ is only slightly more difficult to achieve. In fact, if a function g is defined arbitrarily on $(0,1)$, set $g(1) = 1$ and extend g by repeatedly applying the functional equation. It is not even hard to find another real-analytic extension satisfying the functional equation, e.g. $g(x) = \Gamma(x)(1 + \sin 2\pi x)$ ($1 + \sin 2\pi x$ can be replaced by any periodic real-analytic function f with period 1 and $f(1) = 1$).

V.13.2.12. However, Γ seems to be the "simplest" and/or "most natural" extension, due to the multitude of formulas for it and its appearance in many contexts. Many leading mathematicians over almost a 200-year period tried to make this precise with a natural characterization, with varied success. The best characterization (to date) was obtained in 1922 by H. Bohr and J. Mollerup using the notion of log-convexity.

V.13.2.13. It is immediate from V.13.1.9. that $\Gamma''(x) > 0$ for $x \in (0,\infty)$, and thus that Γ is a convex function on $(0,\infty)$. But more is true.

V.13.2.14. Definition. If I is an interval, a function $g : I \to (0,\infty)$ is *log-convex* on I if $\log g$ is convex on I.

V.13.2.15. Alternatively, a positive function g on an interval I is log-convex on I if, for all $a, b \in I$, $0 \le \lambda \le 1$,

$$g(\lambda a + (1-\lambda)b) \le g(a)^{\lambda} g(b)^{1-\lambda} .$$

The right-hand side is a sort of weighted geometric mean of $g(a)$ and $g(b)$. If g is continuous, then by () g is log-convex if and only if, for every $a, b \in I$,

$$g\left(\frac{a+b}{2}\right) \le \sqrt{g(a)g(b)} .$$

V.13.2.16. Proposition. A log-convex function is convex.

Proof: Let g be log-convex on I, and let $a, b \in I$, and $0 \le \lambda \le 1$. Since the log function is concave, we have

$$\log(\lambda g(a) + (1-\lambda)g(b)) \ge \lambda \log g(a) + (1-\lambda) \log g(b) .$$

On the other hand, since g is log-convex, we have

$$\log g(\lambda a + (1-\lambda)b) \le \lambda \log g(a) + (1-\lambda) \log g(b) .$$

Combining these, we get

$$\log g(\lambda a + (1-\lambda)b) \le \log(\lambda g(a) + (1-\lambda)g(b))$$

and it follows that $g(\lambda a + (1-\lambda)b) \le \lambda g(a) + (1-\lambda)g(b)$ since the log function is increasing. 👍

V.13.2.17. The converse is false. $g(x) = x^2$ is convex on $(0, \infty)$, but not log-convex on any subinterval. In fact, an increasing log-convex function on an interval (a, ∞) must grow at least exponentially as $x \to +\infty$.

V.13.2.18. Since a sum of convex functions is convex, it is obvious that a product of log-convex functions is log-convex. It is also clear that a positive scalar multiple of a log-convex function is log-convex. It is less obvious, but true, that a sum of log-convex functions is log-convex (XIX.3.5.7.).

V.13.2.19. LEMMA. Let $a_1, a_2, b_1, b_2, c_1, c_2$ be positive real numbers. If $a_1c_1 - b_1^2 \geq 0$ and $a_2c_2 - b_2^2 \geq 0$, then

$$(a_1 + a_2)(c_1 + c_2) - (b_1 + b_2)^2 \geq 0 \ .$$

PROOF: If a, b, c are positive real numbers, then the polynomial $f(x) = ax^2 + 2bx + c$ takes only nonnegative real values (for x real) if and only if $ac - b^2 \geq 0$. By assumption, the polynomials $f_1(x) = a_1x^2 + 2b_1x + c_1$ and $f_2(x) = a_2x^2 + 2b_2x + c_2$ take only nonnegative real values, and hence

$$f_1(x) + f_2(x) = (a_1 + a_2)x^2 + 2(b_1 + b_2)x + (c_1 + c_2)$$

also takes only nonnegative real values. 👍

V.13.2.20. PROPOSITION. A sum of log-convex functions on an interval I is log-convex on I.

PROOF: Since log-convex functions are continuous, by XIX.3.5.2. it suffices to show that if f and g are log-convex on I and $x, y \in I$, then

$$\left[f\left(\frac{x+y}{2}\right) + g\left(\frac{x+y}{2}\right)\right]^2 \leq (f(x) + g(x))(f(y) + g(y)) \ .$$

Apply XIX.3.5.6. with $a_1 = f(x)$, $a_2 = g(x)$, $b_1 = f\left(\frac{x+y}{2}\right)$, $b_2 = g\left(\frac{x+y}{2}\right)$, $c_1 = f(y)$, $c_2 = g(y)$. 👍

V.13.2.21. The conclusion of XIX.3.5.7. extends to arbitrary finite sums. Since a positive pointwise limit of log-convex functions is obviously log-convex, it also extends to a positive pointwise limit of finite sums of log-convex functions, e.g. a pointwise-convergent infinite series. By approximating the integrals by Riemann sums, we also obtain:

V.13.2.22. PROPOSITION. Let f be a function on $I \times [a, b]$ for some interval I and $a, b \in \mathbb{R}$, $a < b$. If $f(x, t)$ is log-convex on I for each fixed t, and $f(x, t)$ is continuous on $[a, b]$ for each fixed x, then

$$g(x) = \int_a^b f(x, t)\, dt$$

is log-convex on I.

PROOF: Let $n \in \mathbb{N}$ and $h = \frac{b-a}{n}$. Then $g_n(x) = h(f(x, a) + f(x, a+h) + \cdots + f(x, a+(n-1)h)$ is log-convex, and $g_n \to g$ pointwise. Since f is strictly positive, it is obvious that g is also strictly positive. 👍

This result extends to improper integrals:

V.13.2.23. Corollary. Let f be a function on $I \times (a,b)$ for some interval I and $a, b \in [-\infty, \infty]$, $a < b$. If $f(x,t)$ is log-convex on I for each fixed t, $f(x,t)$ is continuous on (a,b) for each fixed x, and the improper Riemann integral $\int_a^b f(x,t)\,dt$ converges for all $x \in I$, then

$$g(x) = \int_a^b f(x,t)\,dt$$

is log-convex on I.

Proof: Let (a_n) be a decreasing sequence with $a_n \to a$, (b_n) an increasing sequence with $b_n \to b$, $a_n < b_n$ for all n. Set

$$g_n(x) = \int_{a_n}^{b_n} f(x,t)\,dt\ .$$

Then g_n is log-convex on I for all n by XIX.3.5.9., and $g_n \to g$ pointwise on I. It is also clear that g is strictly positive. 👍

V.13.2.24. Theorem. The Gamma function is log-convex on $(0,\infty)$.

Proof: We have that $\Gamma(x) \in (0,\infty)$ for $x > 0$. Let $a, b > 0$ and $0 \le \lambda \le 1$.

$$\log\Gamma(\lambda a + (1-\lambda)b) = \log\int_0^\infty e^{-t}t^{\lambda a+(1-\lambda)b-1}\,dt = \log\int_0^\infty (e^{-t}t^{a-1})^\lambda (e^{-t}t^{b-1})^{1-\lambda}\,dt\ .$$

Apply Hölder's inequality () with $p = \frac{1}{\lambda}$ and $q = \frac{1}{1-\lambda}$ to obtain

$$\log\int_0^\infty (e^{-t}t^{a-1})^\lambda (e^{-t}t^{b-1})^{1-\lambda}\,dt \le \log\left[\left(\int_0^\infty e^{-t}t^{a-1}\,dt\right)^\lambda \left(\int_0^\infty e^{-t}t^{b-1}\,dt\right)^{1-\lambda}\right]$$

$$= \lambda\log\Gamma(a) + (1-\lambda)\log\Gamma(b)\ .$$

👍

The next theorem is the main result of this section. Our proof is adapted from the Planet Math website http://planetmath.org/?op=getobj&from=objects&id=3808.

V.13.2.25. Theorem. [Bohr-Mollerup] The Gamma function is the unique function g on $(0,\infty)$ which is log-convex and satisfies $g(1) = 1$ and $g(x+1) = xg(x)$ for all $x > 0$.

Proof: Since Γ satisfies the conditions, we need only prove uniqueness. In fact, it suffices to show that the conditions uniquely determine a function on $(0,1)$, since the rest of the values are then uniquely determined by the recurrence formula.

So let g be a function satisfying the conditions, $0 < x < 1$, and $n \in \mathbb{N}$. Using $n + x = (1-x)n + x(n+1)$, we have

$$g(n+x) \le g(n)^{1-x}g(n+1)^x = g(n)^{1-x}g(n)^x n^x = (n-1)!n^x\ .$$

Similarly, $n+1 = x(n+x) + (1-x)(n+1+x)$, so $n! \le g(n+x)(n+x)^{1-x}$.

Combining these two we get

$$n!(n+x)^{x-1} \le g(n+x) \le (n-1)!n^x$$

and by using the recurrence relation to obtain $g(n+x) = x(x+1)(x+2)\cdots(x+n-1)$,

$$a_n := \frac{n!(n+x)^{x-1}}{x(x+1)\cdots(x+n-1)} \le g(x) \le \frac{(n-1)!n^x}{x(x+1)\cdots(x+n-1)} =: b_n \ .$$

These inequalities hold for every positive integer n. We have

$$\lim_{n\to\infty} \frac{b_n}{a_n} = \lim_{n\to\infty} \left(\frac{n}{n+x}\right)^{x-1} = 1$$

so

$$1 \le \frac{g(x)}{a_n} \le \frac{b_n}{a_n} \to 1$$

and thus $g(x) = \lim_{n\to\infty} a_n$, so g is uniquely determined. 👍

As a corollary of the proof, we get a formula for the unique solution, which must be Γ. This formula is due to Gauss, and is equivalent to Euler's infinite product formula from the introduction to the section.

V.13.2.26. Corollary. For $0 < x \le 1$,

$$\Gamma(x) = \lim_{n\to\infty} \frac{n!n^x}{x(x+1)\cdots(x+n)} \ .$$

V.13.3. Miscellaneous Additional Results

We give only a few additional sample results about the Gamma function. More are pursued in the Exercises.

V.13.3.27. The integral definition of $\Gamma(x)$ makes sense if x is a complex number with positive real part, and defines a complex analytic function on the right half of the complex plane. This function can be analytically continued to the entire complex plane, with simple poles at the nonpositive integers. In fact, Gauss's formula (V.13.2.26.) holds for any complex number x which is not a nonpositive integer. It turns out that this complex Γ has no zeros, so the reciprocal is an entire function.

V.13.3.28. Unlike the trigonometric, exponential, and logarithm functions, the Gamma function does not satisfy any *algebraic differential equation* (roughly, a differential equation whose coefficient functions are algebraic functions). This theorem was proved by Hölder in 1887. In particular, there is no formula for the derivative or antiderivative of the Gamma function in terms of standard functions, including the Gamma function itself.

V.13.3.29. There is an almost bewildering array of other formulas, identities, and applications related to the Gamma function. There are entire books (e.g. [Art64]) written on the subject. See [Dav59] for a good survey of the history and importance of this function. In DAVIS'S words, "[E]ach generation has found something of interest about the gamma function. Perhaps the next generation will also."

V.13.4. Exercises

V.13.4.1. (a) Use Gauss's formula V.13.2.26. to prove the product formula

$$\Gamma(x) = \frac{1}{x} \prod_{k=1}^{\infty} \frac{\left(1 + \frac{1}{k}\right)^x}{1 + \frac{x}{k}}$$

if x is not a nonpositive integer. Discuss convergence of the infinite product.

(b) Derive from this WEIERSTRASS'S product formula

$$\frac{1}{\Gamma(x)} = x e^{\gamma x} \prod_{k=1}^{\infty} \left[\left(1 + \frac{x}{k}\right) e^{x/k} \right]$$

where γ is the Euler-Mascheroni constant (IV.2.16.26.). Show that the product converges for all x, and the convergence is u.c.

(c) Deduce from (b) that Γ has simple poles at the nonpositive integers.

V.13.4.2. (a) Use the product formula to prove that if x is not an integer, then

$$\Gamma(x)\Gamma(1-x) = \frac{\pi}{\sin \pi x} \ .$$

(b) Use this to give an alternate proof that $\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$.

V.13.4.3. Show that $\Gamma'(1) = -\gamma$, where γ is the Euler-Mascheroni constant (IV.2.16.26.).

V.13.5. Stirling's Formula

In this section, we establish an important and useful approximation to the factorial and gamma functions, attributed to James Stirling (1730), but primarily due to A. de Moivre.

V.13.5.1. Theorem. [Stirling's Formula] For any $n \in \mathbb{N}$, we have

$$\sqrt{2\pi n}\, n^n e^{-n} < n! < \sqrt{2\pi n}\, n^n e^{-n} e^{\frac{1}{12n}} \ .$$

In particular,

$$\lim_{n\to\infty} \frac{n!}{\sqrt{2\pi n}\, n^n e^{-n}} = 1 \ .$$

More generally,

$$\lim_{x\to+\infty} \frac{\Gamma(x)}{\sqrt{\frac{2\pi}{x}}\, x^x e^{-x}} = 1 \ .$$

Informally, we have the approximation

$$n! \approx \sqrt{2\pi n}\, n^n e^{-n} = \sqrt{2\pi n} \left(\frac{n}{e}\right)^n$$

$$\Gamma(x) \approx \sqrt{\frac{2\pi}{x}}\, x^x e^{-x} = \sqrt{\frac{2\pi}{x}} \left(\frac{x}{e}\right)^x$$

for $n \in \mathbb{N}$, $x > 0$. The theorem gives precise error estimates. Better error estimates can be obtained by making more careful estimates along the way in the proof; see Exercise ().

V.13.5.2. Stirling's formula can be written as

$$n\log n - n + \frac{1}{2}\log(2\pi n) < \log(n!) < n\log n - n + \frac{1}{2}\log(2\pi n) + \frac{1}{12n} \ .$$

A crude version of this formula can be obtained by approximating

$$\log(n!) = \sum_{k=1}^{n} \log k = \sum_{k=2}^{n} \log k$$

by integrals. We have

$$n\log n - n + 1 = \int_1^n \log x\, dx < \log(n!)$$

$$< \int_2^{n+1} \log x\, dx = (n+1)\log(n+1) - (n+1) - (2\log 2 - 2) = n\log(n+1) - n + \log(n+1) + (1 - 2\log 2) \ .$$

This gives

$$e\left(\frac{n}{e}\right)^n = n^n e^{-n+1} \ < \ n! \ < \ \frac{e}{4}(n+1)^{n+1} e^{-n} = \frac{e(n+1)}{4}\left(\frac{n+1}{e}\right)^n \ .$$

Better approximations can be made using the Euler-Maclaurin formula () to compute the difference between $\log(n!)$ and $\displaystyle\int_1^n \log x\,dx$, and the theorem can be proved this way. See ().

We will proceed differently. The proof we give consists of a sequence of calculations, some of which yield other formulas of interest.

V.13.5.3. Recall that if $|x| < 1$, we have

$$\log(1+x) = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k} x^k \ .$$

Thus, we have, for $|x| < 1$, combining terms and using some reindexing,

$$\log\left(\frac{1+x}{1-x}\right) = \log(1+x) - \log(1-x) = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k} x^k - \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k} (-x)^k$$

$$= \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k} x^k + \sum_{k=1}^{\infty} \frac{1}{k} x^k = \sum_{k=0}^{\infty} \frac{2}{2k+1} x^{2k+1} = 2x \sum_{k=0}^{\infty} \frac{1}{2k+1} x^{2k} \ .$$

This is in itself a useful formula.

V.13.5.4. Now set $x = \frac{1}{2n+1}$ for $n \in \mathbb{N}$. Then $\frac{1+x}{1-x} = \frac{n+1}{n} = 1 + \frac{1}{n}$, so we obtain

$$\log\left(1 + \frac{1}{n}\right) = \frac{2}{2n+1} \sum_{k=0}^{\infty} \frac{1}{2k+1} \frac{1}{(2n+1)^{2k}}$$

$$\left(n + \frac{1}{2}\right) \log\left(1 + \frac{1}{n}\right) = \sum_{k=0}^{\infty} \frac{1}{2k+1} \frac{1}{(2n+1)^{2k}} \ .$$

Therefore

$$\left(n + \frac{1}{2}\right) \log\left(1 + \frac{1}{n}\right) < 1 + \frac{1}{3} \sum_{k=1}^{\infty} \frac{1}{(2n+1)^{2k}}$$

and the last sum is a geometric series with sum

$$\frac{\frac{1}{(2n+1)^2}}{1 - \frac{1}{(2n+1)^2}} = \frac{1}{(2n+1)^2 - 1} = \frac{1}{4n(n+1)}$$

so we obtain the estimates

$$1 < \left(n + \frac{1}{2}\right) \log\left(1 + \frac{1}{n}\right) < 1 + \frac{1}{12n(n+1)}$$

$$e < \left(1 + \frac{1}{n}\right)^{n+\frac{1}{2}} < e^{1 + \frac{1}{12n(n+1)}}$$

$$1 < \frac{1}{e} \left(1 + \frac{1}{n}\right)^{n+\frac{1}{2}} < e^{\frac{1}{12n(n+1)}}$$

for $n \in \mathbb{N}$.

V.13.5.5. Now set

$$a_n = n!e^n n^{-n-\frac{1}{2}} \ , \quad y_n = e^{-\frac{1}{12n}} \ .$$

We have

$$1 < \frac{a_n}{a_{n+1}} = \frac{1}{e}\left(1+\frac{1}{n}\right)^{n+\frac{1}{2}} < e^{\frac{1}{12n(n+1)}} = \frac{y_{n+1}}{y_n} \ .$$

Thus the sequence (a_n) is nonnegative and decreasing, hence converges to a limit a. The sequence $(a_n y_n)$ is increasing, and since $y_n \to 1$, $a_n y_n \to a$, and $a_n y_n < a < a_n$ for all n. Thus

$$a < a_n < a e^{\frac{1}{12n}}$$

for all n. Since

$$n! = a_n \sqrt{n}\, n^n e^{-n}$$

we obtain that

$$a\sqrt{n}\, n^n e^{-n} < n! < a\sqrt{n}\, n^n e^{-n} e^{\frac{1}{12n}}$$

for $n \in \mathbb{N}$. (This version is due to DE MOIVRE.)

It remains to show that $a = \sqrt{2\pi}$ (this was STIRLING'S contribution to the formula). We first derive WALLIS'S beautiful infinite product formula for π:

V.13.5.6. THEOREM.

$$\lim_{n\to\infty}\left[\frac{1}{2}\cdot\frac{3}{2}\cdot\frac{3}{4}\cdot\frac{5}{4}\cdot\frac{5}{6}\cdot\frac{7}{6}\cdots\frac{2n-1}{2n}\cdot\frac{2n+1}{2n}\right] = \frac{2}{\pi} \ .$$

PROOF: We will prove the equivalent statement

$$\lim_{n\to\infty}\left[\frac{2}{1}\cdot\frac{2}{3}\cdot\frac{4}{3}\cdot\frac{4}{5}\cdot\frac{6}{5}\cdot\frac{6}{7}\cdots\frac{2n}{2n-1}\cdot\frac{2n}{2n+1}\right] = \frac{\pi}{2} \ .$$

Use the formula obtained by integration by parts:

$$\int \sin^n x\, dx = \int \sin^{n-1} x \sin x\, dx = -\sin^{n-1} x \cos x + (n-1)\int \sin^{n-2} x \cos^2 x\, dx$$

$$= -sin^{n-1}x\cos x + (n-1)\int \sin^{n-2} x(1-\sin^2 x)\, dx = -sin^{n-1}x\cos x + (n-1)\int \sin^{n-2} x\, dx - (n-1)\int \sin^n x\, dx$$

$$\int \sin^n x\, dx = -\frac{1}{n}\sin^{n-1} x\cos x + \frac{n-1}{n}\int \sin^{n-2} x\, dx$$

$$\int_0^{\pi/2} \sin^n x\, dx = \frac{n-1}{n}\int_0^{\pi/2} \sin^{n-2} x\, dx \ .$$

Iterating, we obtain

$$\int_0^{\pi/2} \sin^{2n} x\, dx = \frac{2n-1}{2n}\cdot\frac{2n-3}{2n-2}\cdots\frac{1}{2}\cdot\int_0^{\pi/2} dx = \frac{2n-1}{2n}\cdot\frac{2n-3}{2n-2}\cdots\frac{1}{2}\cdot\frac{\pi}{2}$$

$$\int_0^{\pi/2} \sin^{2n+1} x\,dx = \frac{2n}{2n+1}\cdot\frac{2n-2}{2n-1}\cdots\frac{2}{3}\cdot\int_0^{\pi/2}\sin x\,dx = \frac{2n}{2n+1}\cdot\frac{2n-2}{2n-1}\cdots\frac{2}{3}\ .$$

We thus obtain, for any n,

$$\frac{\pi}{2} = \frac{2\cdot 2}{1\cdot 3}\cdot\frac{4\cdot 4}{3\cdot 5}\cdot\frac{6\cdot 6}{5\cdot 7}\cdots\frac{(2n)^2}{(2n-1)(2n+1)}\cdot\frac{\int_0^{\pi/2}\sin^{2n} x\,dx}{\int_0^{\pi/2}\sin^{2n+1} x\,dx}\ .$$

Thus to prove the formula it suffices to show

$$\lim_{n\to\infty}\frac{\int_0^{\pi/2}\sin^{2n} x\,dx}{\int_0^{\pi/2}\sin^{2n+1} x\,dx} = 1\ .$$

We have

$$0 \le \sin^{2n+1} x \le \sin^{2n} x \le \sin^{2n-1} x$$

for $0 \le x \le \frac{\pi}{2}$ and thus

$$1 \le \frac{\int_0^{\pi/2}\sin^{2n} x\,dx}{\int_0^{\pi/2}\sin^{2n+1} x\,dx} \le \frac{\int_0^{\pi/2}\sin^{2n-1} x\,dx}{\int_0^{\pi/2}\sin^{2n+1} x\,dx} = \frac{2n+1}{2n}$$

so the result follows from the Squeeze Theorem ().

V.13.5.7. Corollary.

$$\lim_{n\to\infty}\frac{(n!)^2\cdot 2^{2n}}{(2n)!\cdot\sqrt{n}} = \sqrt{\pi}\ .$$

Proof: We have

$$\frac{\pi}{2} = \lim_{n\to\infty}\left[\frac{2^2\cdot 4^2\cdot 6^2\cdots(2n-2)^2}{3^2\cdot 5^2\cdot 7^2\cdots(2n-1)^2}\cdot\frac{(2n)^2}{2n+1}\right] = \lim_{n\to\infty}\left[\frac{2^2\cdot 4^2\cdot 6^2\cdots(2n-2)^2}{3^2\cdot 5^2\cdot 7^2\cdots(2n-1)^2}\cdot 2n\right]$$

since $\lim_{n\to\infty}\frac{2n}{2n+1} = 1$. Thus, taking the square root and multiplying numerator and denominator by $2\cdot 4\cdot 6\cdots(2n-2)$, we have

$$\sqrt{\frac{\pi}{2}} = \lim_{n\to\infty}\left[\frac{2^2\cdot 4^2\cdot 6^2\cdots(2n-2)^2}{(2n-1)!}\cdot\sqrt{2n}\right] = \lim_{n\to\infty}\left[\frac{2^2\cdot 4^2\cdot 6^2\cdots(2n)^2}{(2n)!}\cdot\frac{\sqrt{2n}}{2n}\right]\ .$$

V.13.5.8. To calculate a, note that that

$$\sqrt{\pi} = \lim_{n\to\infty}\left[\frac{(n!)^2\cdot 2^{2n}}{(2n)!\cdot\sqrt{n}}\right] = \lim_{n\to\infty}\left[\frac{(a_n e^{-n} n^{n+1/2})^2\cdot 2^{2n}}{a_{2n}e^{-2n}(2n)^{2n+1/2}\cdot\sqrt{n}}\right] = \lim_{n\to\infty}\frac{(a_n)^2}{a_{2n}\sqrt{2}} = \frac{a}{\sqrt{2}}\ .$$

This completes the proof of Stirling's Formula.

V.13.5.9. To obtain the formula for the Gamma function, note that

$$\lim_{n\to\infty} \frac{n\Gamma(n)}{\sqrt{2\pi n}\, n^n e^{-n}} = \lim_{n\to\infty} \frac{n!}{\sqrt{2\pi n}\, n^n e^{-n}} = 1$$

$$\lim_{n\to\infty} \frac{\Gamma(n)}{\sqrt{\frac{2\pi}{n}}\, n^n e^{-n}} = 1 \ .$$

To transition to the limit as $x \to +\infty$ through positive real numbers, use XIX.3.7.10. and log convexity of the Gamma function:

The proof using the Euler-Maclaurin formula works directly for the Gamma function for $x > 0$ (and even for complex numbers away from the negative real axis). See, for example, [Str81, p. 468].

V.13.5.10. There is a more precise series giving an approximation to the factorial and the gamma function:

$$n! \approx \sqrt{2\pi n}\, n^n e^{-n} \left[1 + \frac{1}{12n} + \frac{1}{288n^2} - \frac{139}{51840n^3} - \frac{571}{2488320n^4} + \cdots\right]$$

$$\Gamma(x) \approx \sqrt{\frac{2\pi}{x}}\, x^x e^{-x} \left[1 + \frac{1}{12x} + \frac{1}{288x^2} - \frac{139}{51840x^3} - \frac{571}{2488320x^4} + \cdots\right]$$

(the coefficients have a closed formula which is complicated; see e.g. http://mathworld.wolfram.com/StirlingsSeries.html.)

This is an asymptotic expansion () and not a convergent series: for fixed n or x adding more terms eventually gives a worse approximation. The relative error after taking finitely many terms is always smaller than the next term.

V.13.5.11. By approximating the terms in the asymptotic expansion, we obtain a better asymptotic formula for $n!$:

$$n! \approx \sqrt{\left(2n + \frac{1}{3}\right)\pi} \left(\frac{n}{e}\right)^n \ .$$

This approximation is due to R. W. Gosper.

V.13.5.12. Another numerically efficient approximation, due to G. Nemes [**?**], is

$$\Gamma(x) \approx \sqrt{\frac{2\pi}{x}} \left[\frac{1}{e}\left(x + \frac{1}{12x - \frac{1}{10x}}\right)\right]^x \ .$$

V.13.6. Exercises

V.14. The Volume of the Unit Ball in $\mathbb{R}^n$

Throughout this section, we will use the Euclidean norm

$$\|(x_1, \ldots, x_n)\| = \sqrt{x_1^2 + \cdots + x_n^2} \ .$$

Recall that the closed unit ball and unit sphere in $\mathbb{R}^n$ are

$$B^n = \{\mathbf{x} \in \mathbb{R}^n : \|\mathbf{x}\| \leq 1\}$$

$$S^{n-1} = \{\mathbf{x} \in \mathbb{R}^n : \|\mathbf{x}\| = 1\} \ .$$

Our objective in this section is to compute the Lebesgue measure $\beta_n = \lambda^{(n)}(B^n)$ of the unit ball in $\mathbb{R}^n$. These numbers will be needed for a number of purposes, such as the development of Hausdorff measure, and are intimately tied up with the measure theory of hypersurfaces and other subsets of Euclidean space (such as the $(n-1)$-dimensional "hypersurface area" of S^{n-1}).

V.14.0.1. We can compute β_n for small values of n by elementary or calculus methods:

We have $\beta_1 = \lambda([-1, 1]) = 2$.

We have that β_2 is the area of the unit disk in $\mathbb{R}^2$. This can be computed as in () or () to obtain $\beta_2 = \pi$.

Using spherical coordinates (), we may obtain $\beta_3 = \frac{4}{3}\pi$.

Actually, β_n can be calculated for any n just using calculus, either directly (Exercise V.14.4.1.) or using "hyperspherical" coordinates (Exercise V.14.4.2.). However, the formula obtained in this way becomes increasingly complicated for large n. (Try to guess the right formula!)

Instead, we will use some machinery from measure theory to rather painlessly compute a simple formula for β_n. This argument is adapted from [Fol99, 2.7].

V.14.1. Radial Borel Sets and Functions

Fix an n. We will examine radially symmetric sets in $\mathbb{R}^n$.

V.14.1.2. Definition. A subset S of $\mathbb{R}^n$ is *radially symmetric* if $\mathbf{x} \in S$, $\|\mathbf{y}\| = \|\mathbf{x}\|$ imply $\mathbf{y} \in S$.
B^n and S^{n-1} are radially symmetric sets in $\mathbb{R}^n$. A set is radially symmetric if and only if it is a union of spheres of various radii around the origin.

V.14.1.3. If $A \subseteq [0, \infty)$, the *symmetrization* of A in $\mathbb{R}^n$ is

$$s_n(A) = \{\mathbf{x} \in \mathbb{R}^n : \|\mathbf{x}\| \in A\} \ .$$

It is clear that $s_n(A)$ is radially symmetric. Conversely, identify $[0, \infty)$ with the ray

$$R_+^{(n)} = \{(t, 0, \ldots, 0) : t \in [0, \infty)\} \subseteq \mathbb{R}^n \ .$$

If $S \subseteq \mathbb{R}^n$ is radially symmetric, set $A = S \cap R_+^{(n)}$; then $S = s_n(A)$.

V.14.1.4. If A is a subset of $[0,\infty)$, then $s_n(A) = f^{-1}(A)$, where $f : \mathbb{R}^n \to \mathbb{R}$ is the norm function $f(\mathbf{x}) = \|\mathbf{x}\|$. Since f is continuous, if $B \subseteq [0,\infty)$ is a Borel set, then $s_n(B)$ is a Borel set in $\mathbb{R}^n$. Conversely, if S is a radially symmetric Borel set in $\mathbb{R}^n$, then $B = S \cap R_+^{(n)}$ is a Borel set in $[0,\infty)$ with $S = s_n(B)$.

V.14.1.5. DEFINITION. A *radial Borel set* is a radially symmetric Borel subset of $\mathbb{R}^n$. Let $\mathcal{R}^{(n)}$ be the set of all radial Borel sets in $\mathbb{R}^n$.

The next proposition is obvious, since the collection of radially symmetric subsets of $\mathbb{R}^n$ is closed under unions, intersections, and complements.

V.14.1.6. PROPOSITION. $\mathcal{R}^{(n)}$ is a sub-σ-algebra of $\mathcal{B}^{(n)}$.

V.14.1.7. DEFINITION. A function $f : \mathbb{R}^n \to \mathbb{R}$ is *radially symmetric* if $\|\mathbf{x}\| = \|\mathbf{y}\|$ implies $f(\mathbf{x}) = f(\mathbf{y})$. If $g : [0,\infty) \to \mathbb{R}$, the *symmetrization* $s_n(g)$ is defined by $[s_n(g)](\mathbf{x}) = g(\|x\|)$. Then $s_n(g)$ is radially symmetric, and every radially symmetric function is of this form.

V.14.1.8. PROPOSITION. (i) A function $f : \mathbb{R}^n \to \mathbb{R}$ is $\mathcal{R}^{(n)}$-measurable if and only if it is Borel measurable and radially symmetric.
(ii) If $g : [0,\infty) \to \mathbb{R}$, then $s_n(g)$ is $\mathcal{R}^{(n)}$-measurable if and only if g is Borel measurable.

PROOF: If f is $\mathcal{R}^{(n)}$-measurable, then f is Borel measurable since $\mathcal{R}^{(n)} \subseteq \mathcal{B}^{(n)}$, and $\{\mathbf{x} : f(\mathbf{x}) = \alpha\} \in \mathcal{R}^{(n)}$ for any $\alpha \in \mathbb{R}$, so f is radially symmetric. The converse and (ii) are obvious from the fact that $\mathcal{R}^{(n)}$ consists precisely of the radially symmetric Borel sets, the symmetrizations of Borel sets in $[0,\infty)$. 👍

The main result of this subsection is:

V.14.1.9. THEOREM. Let g be a nonnegative Borel measurable function on $[0,\infty)$. Then

$$\int_{\mathbb{R}^n} s_n(g)\, d\lambda^{(n)} = n\beta_n \int_0^\infty r^{n-1} g(r)\, d\lambda(r) \ .$$

PROOF: We first prove the result for "annuli." Let $S = s_n((a,b])$, where $0 \le a < b < \infty$. Then S is a set-theoretic difference of two closed balls around the origin, so by the scaling invariance of $\lambda^{(n)}$ we have

$$\int_{\mathbb{R}^n} \chi_S\, d\lambda^{(n)} = \lambda^{(n)}(S) = \beta_n(b^n - a^n) = n\beta_n \int_0^\infty r^{n-1} \chi_{(a,b]}(r)\, d\lambda(r) \ .$$

Now let $\mathcal{S}$ be the collection of all subsets of $\mathbb{R}^n$ of the form $s_n((a,b])$ as above. Then $\mathcal{S}$ is a semialgebra, and the σ-algebra generated by $\mathcal{S}$ is $\mathcal{R}^{(n)}$. Let μ be the measure on $(\mathbb{R}^n, \mathcal{R}^{(n)})$ given by

$$\mu(s_n(B)) = n\beta_n \int_B r^{n-1}\, d\lambda(r) \ .$$

Since we have shown that $\mu|_{\mathcal{S}} = \lambda^{(n)}|_{\mathcal{S}}$, we have $\mu = \lambda^{(n)}|_{\mathcal{R}^{(n)}}$ by (). Thus the formula in the theorem holds for radially symmetric characteristic functions, and hence for radially symmetric simple functions by linearity.

Finally, let (f_k) be an increasing sequence of nonnegative simple functions on $[0,\infty)$ converging pointwise to g. Then $(s_n(f_k))$ is an increasing sequence of radially symmetric simple functions increasing pointwise to $s_n(g)$, so by two applications of the Monotone Convergence Theorem we get

$$\int_{\mathbb{R}^n} s_n(g)\,d\lambda^{(n)} = \lim_{k\to\infty}\int_{\mathbb{R}^n} s_n(f_k)\,d\lambda^{(n)} = \lim_{k\to\infty} n\beta_n\int_0^\infty r^{n-1}f_k(r)\,d\lambda(r) = n\beta_n\int_0^\infty r^{n-1}g(r)\,d\lambda(r)\ .$$

The proof of this theorem is somewhat simpler and more elementary if g is continuous, since the second step can be bypassed by using an improper Riemann integral on the right side. This is actually the only case we will use in the calculation of β_n.

V.14.2. Calculation of β_n

V.14.2.10. The trick we will use to calculate β_n is to consider the function $f_n : \mathbb{R}^n \to \mathbb{R}$ given for $\mathbf{x} = (x_1,\dots,x_n)$ by

$$f_n(\mathbf{x}) = e^{-\|\mathbf{x}\|^2} = e^{-x_1^2-\cdots-x_n^2} = e^{-x_1^2}e^{-x_2^2}\cdots e^{-x_n^2}\ .$$

This function is nonnegative, continuous, and radially symmetric, and is also a product of functions of each coordinate separately; moreover, the integrals can be computed in two separate ways.

V.14.2.11. On the one hand, from V.14.1.9. we have

$$I_n := \int_{\mathbb{R}^n} f_n\,d\lambda^{(n)} = n\beta_n\int_0^\infty r^{n-1}e^{-r^2}\,dr$$

(the last integral may be regarded as an improper Riemann integral).

V.14.2.12. On the other hand, since $f_n(x_1,\dots,x_n) = f_1(x_1)f_1(x_2)\cdots f_1(x_n)$, by Tonelli's theorem (the vector calculus version () suffices) we have

$$\begin{aligned} I_n = \int_{\mathbb{R}^n} f_n\,d\lambda^{(n)} &= \int_{\mathbb{R}} f_1(x_1)\left[\int_{\mathbb{R}} f_1(x_2)\left[\cdots\left[\int_{\mathbb{R}} f_1(x_n)\,d\lambda(x_n)\right]\cdots\right]d\lambda(x_2)\right]d\lambda(x_1)\\ &= \left[\int_{\mathbb{R}} f_1(x)\,d\lambda(x)\right]^n = (I_1)^n\ . \end{aligned}$$

V.14.2.13. The integral which can be computed by elementary means is I_2. Since $\beta_2 = \pi$ (V.14.0.1.), we have

$$I_2 = 2\pi\int_0^\infty re^{-r^2}\,dr = 2\pi\lim_{b\to+\infty}\left[-\frac{1}{2}e^{-r^2}\right]_0^b = \pi$$

and so $I_1 = \sqrt{\pi}$.

V.14.2.14. So we have

$$(I_1)^n = \pi^{n/2} = I_n = n\beta_n \int_0^\infty r^{n-1} e^{-r^2}\, dr\ .$$

Making the substitution $u = r^2$, we have

$$\pi^{n/2} = \frac{n\beta_n}{2} \int_0^\infty u^{\frac{n}{2}-1} e^{-u}\, du = \frac{n\beta_n}{2}\Gamma\left(\frac{n}{2}\right)$$

where Γ is the Gamma function (). Solving for β_n and using $\Gamma(\frac{n}{2}+1) = \frac{n}{2}\Gamma(\frac{n}{2})$, we get the final result:

V.14.2.15. THEOREM.

$$\beta_n = \frac{\pi^{n/2}}{\Gamma(\frac{n}{2}+1)}\ .$$

So if $n = 2m$ is even, we have $\beta_n = \frac{\pi^m}{m!}$.

V.14.2.16. Using $\beta_1 = 2$, we can obtain $\Gamma(\frac{3}{2}) = \frac{\sqrt{\pi}}{2} = \frac{1}{2}\Gamma(\frac{1}{2})$, so $\Gamma(\frac{1}{2}) = \sqrt{\pi}$. Thus, if $n = 2m+1$ is odd, we have

$$\Gamma\left(\frac{n}{2}+1\right) = \frac{1}{2}\cdot\frac{3}{2}\cdot\frac{5}{2}\cdots\frac{n}{2}\sqrt{\pi} = \frac{1\cdot 3\cdot 5\cdots n}{2^{m+1}}\sqrt{\pi}$$

so we obtain

$$\beta_n = \frac{2^{m+1}\pi^m}{1\cdot 3\cdot 5\cdots n}\ .$$

V.14.2.17. Thus $\beta_4 = \frac{\pi^2}{2}$, $\beta_5 = \frac{8\pi^2}{15}$, etc. Note that each time n increases by 2, one more factor of π appears. The power of π that occurs in the final formulas is always an integer.

V.14.2.18. We can also define β_s for any $s \in [0,\infty)$ by the formula

$$\beta_s = \frac{\pi^{s/2}}{\Gamma(\frac{s}{2}+1)}\ .$$

This is the theoretical s-dimensional "measure of the closed unit ball in $\mathbb{R}^s$." This definition will be used in the construction of Hausdorff measure.

V.14.3. Surface Area of a Sphere

V.14.3.19. The arguments of this section can be taken much farther. Fix n. We can define "spherical coordinates" (ρ, Θ) in $\mathbb{R}^n \setminus \{\mathbf{0}\}$ by setting

$$\rho(\mathbf{x}) = \|x\|, \qquad \Theta(\mathbf{x}) = \frac{\mathbf{x}}{\|\mathbf{x}\|}\ .$$

Then $\rho(\mathbf{x}) \in (0,\infty)$ and $\Theta(\mathbf{x}) \in S^{n-1}$, and $\Phi = (\rho, \Theta)$ is a homeomorphism from $\mathbb{R}^n \setminus \{\mathbf{0}\}$ to $(0,\infty) \times S^{n-1}$; the inverse function Φ^{-1} is given by $\Phi^{-1}(r, \mathbf{x}) = r\mathbf{x}$. Since these functions are homeomorphisms, they send Borel sets to Borel sets.

V.14.3.20. We can also transfer Lebesgue measure $\lambda^{(n)}$ to the product space $(0,\infty)\times S^{n-1}$ via Φ; call the image measure μ. Thus, if E is a Borel subset of $(0,\infty)\times S^{n-1}$, we have $\mu(E)=\lambda^{(n)}(\Phi^{-1}(E))$. Theorem V.14.1.9. can be rephrased to say that if A is a Borel subset of $(0,\infty)$, then

$$\mu(A\times S^{n-1})=n\beta_n\int_A r^{n-1}\,d\lambda(r)\ .$$

Define a measure ν on $(0,\infty)$ by $\nu(A)=\int_A r^{n-1}\,d\lambda(r)$. We will show that there is a finite Borel measure σ on S^{n-1}, with $\sigma(S^{n-1})=n\beta_n$, such that $\mu=\nu\times\sigma$.

V.14.3.21. If B is a Borel subset of S^{n-1} (in either the abstract sense regarding S^{n-1} as a topological space, or a subset of S^{n-1} which is a Borel set in $\mathbb{R}^n$; since S^{n-1} is a closed, hence Borel, subset of $\mathbb{R}^{n-1}$, the two notions are equivalent), then $\Phi^{-1}((0,1]\times B)$ is a Borel subset of $\mathbb{R}^n$. Define

$$\sigma(B)=n\lambda^{(n)}((0,1]\times B)\ .$$

It is almost immediate that σ is a Borel measure on S^{n-1}. The main result is:

V.14.3.22. THEOREM. The measures μ and $\nu\times\sigma$ coincide on the Borel sets in $(0,\infty)\times S^{n-1}$.

PROOF: In a manner almost identical to the proof of V.14.1.9., for a fixed B we have $\mu(A\times B)=\nu(A)\sigma(B)$ for every Borel subset A of $(0,\infty)$ (first show this for $A=(a,b]$ by homogeneity, and then bootstrap to all Borel sets). Thus, if $\mathcal{A}$ is the σ-algebra of Borel sets in $(0,\infty)$ and $\mathcal{B}$ the Borel sets in S^{n-1}, we have $\mu=\nu\times\sigma$ on $\mathcal{A}\times\mathcal{B}$. So by () μ and $\nu\times\sigma$ agree on $\mathcal{A}\otimes\mathcal{B}$, which is the σ-algebra of Borel sets in $(0,\infty)\times S^{n-1}$. 👍

V.14.3.23. The measure σ is called the *surface measure* of S^{n-1}. In the cases $n=2$ and $n=3$ this surface measure represents arc length and surface area respectively. This measure can be defined in several other ways: it is the restriction of $(n-1)$-dimensional Hausdorff measure () on $\mathbb{R}^n$ to S^{n-1}, it is the Riemannian measure on S^{n-1} as a smooth submanifold of $\mathbb{R}^n$ (), and it can be defined via a parametrization ().

V.14.3.24. The total surface measure $\sigma(S^{n-1})$ is just $n\beta_n$. Thus $\sigma(S^1)=2\pi$, the circumference of the unit circle, and $\sigma(S^2)=4\pi$, the surface area of the unit sphere in $\mathbb{R}^3$. By scaling, the surface measure of the sphere of radius r in $\mathbb{R}^n$ is $r^{n-1}\sigma(S^{n-1})$. This is the derivative of the function $V(r)=\beta_n r^n$ giving the Lebesgue measure of a ball in $\mathbb{R}^n$ of radius r. An interpretation of this is: if S_h is the spherical shell of inside radius 1 and outside radius $1+h$ in $\mathbb{R}^n$, we have:

$$\sigma(S^{n-1})=\lim_{h\to 0}\frac{\lambda^{(n)}(S_h)}{h}\ .$$

A similar formula holds for any Borel subset of S^{n-1}.

V.14.4. Exercises

V.14.4.1. Let $n \geq 2$. Use iterated integration to compute β_n as follows.

(a) Write $\beta_n = \displaystyle\int_{x_1^2+\cdots+x_n^2\leq 1} 1\, d(x_1,\ldots,x_n) = \int_{-1}^{1} \left[\int_{x_2^2+\cdots+x_n^2\leq 1-x_1^2} 1\, d(x_2,\ldots,x_n) \right] dx_1$.

(b) The quantity in brackets is the $(n-1)$-dimensional measure of a ball of radius $\sqrt{1-x_1^2}$ in $\mathbb{R}^{n-1}$. By scaling invariance, this integral equals $\beta_{n-1}(1-x_1^2)^{\frac{n-1}{2}}$.

(c) Obtain a recurrence formula $\beta_n = \beta_{n-1} \displaystyle\int_{-1}^{1} (1-x^2)^{\frac{n-1}{2}}\, dx = 2\beta_{n-1} \int_0^1 (1-x^2)^{\frac{n-1}{2}}\, dx$.

(d) Make the change of variables $x = \cos\theta$ to convert the recurrence formula to

$$\beta_n = \beta_{n-1} \int_0^{\pi} \sin^n\theta\, d\theta = 2\beta_{n-1} \int_0^{\pi/2} \sin^n\theta\, d\theta \ .$$

(e) Evaluate the integral using () and obtain the formula of V.14.2.15. using $\beta_1 = 2$.

V.14.4.2. Let $n \geq 3$. Compute the n-dimensional Lebesgue measure of the ball $B_r^{(n)}$ of radius r around the origin in $\mathbb{R}^n$ as follows.

(a) Introduce "hyperspherical" coordinates $(\rho, \theta_1, \ldots, \theta_{n-1})$ in $\mathbb{R}^n$, where

$$\begin{aligned} x_1 &= \rho\cos\theta_1 \\ x_2 &= \rho\sin\theta_1\cos\theta_2 \\ &\cdots \\ x_{n-1} &= \rho\sin\theta_1\cdots\sin\theta_{n-2}\cos\theta_{n-1} \\ x_n &= \rho\sin\theta_1\cdots\sin\theta_{n-2}\sin\theta_{n-1} \end{aligned}$$

(for $n = 3$, the usual spherical coordinates (ρ, ϕ, θ) have $\theta_1 = \phi$, $\theta_2 = \theta$, and the coordinates come out in the order (z, x, y)).

(b) Show that the n-dimensional volume $\lambda^{(n)}(B_r^{(n)})$ is given by

$$\begin{aligned} &\int_0^r \int_0^{\pi} \cdots \int_0^{\pi} \int_0^{2\pi} \rho^{n-1} \sin^{n-2}\theta_1 \sin^{n-3}\theta_2 \cdots \sin\theta_{n-2}\, d\theta_1\, d\theta_2 \cdots d\theta_{n-1}\, d\rho \\ &= \left(\int_0^r \rho^{n-1}\, d\rho \right) \left(\int_0^{2\pi} d\theta_{n-1} \right) \prod_{k=1}^{n-2} \left(\int_0^{\pi} \sin^k\theta_{n-k-1}\, d\theta_{n-k-1} \right) \\ &= \frac{2\pi}{n} r^n \prod_{k=1}^{n-2} \left(\int_0^{\pi} \sin^k\theta\, d\theta \right) \ . \end{aligned}$$

(This formula also holds with a simplified argument if $n = 2$ if the last product is taken to be the "empty product" 1.)

(c) Conclude that if $n \geq 2$, then

$$\beta_n = \frac{2\pi}{n} \prod_{k=1}^{n-2} \left(\int_0^{\pi} \sin^k \theta \, d\theta \right)$$

(with the last product equal to 1 if $n = 2$). Show that this formula coincides with the formula of V.14.2.15. (cf. ()).

V.14.4.3. (a) Find for which $n \in \mathbb{N}$ we have β_n maximum.

(b) Find for which $s \in [0, \infty)$ we have β_s maximum.

(c) Show that $\lim_{s \to +\infty} \beta_s = 0$.

V.14.4.4. [BB92] Show that

$$\left(10^{-5} \sum_{-\infty}^{\infty} e^{-\frac{n^2}{10^{10}}} \right)^2$$

agrees with π to at least 42 billion decimal places, but the numbers are not equal. Which is larger? [Show that

$$\pi = \left(10^{-5} \int_{-\infty}^{\infty} e^{-\frac{x^2}{10^{10}}} \, dx \right)^2$$

(cf. V.14.2.13.).]

V.15. Infinite Series of Functions

V.15.1. Infinite Series of Functions

Pointwise, Uniform, and Absolute Convergence of Series

Normal Convergence of Series and the Weierstrass M-Test

The most useful basic result about convergence of series of functions is the following test, due to Weierstrass, a version of IV.2.5.2.:

V.15.1.1. Theorem. [Weierstrass M-Test] Let

$$\sum_{k=1}^{\infty} f_k$$

be an infinite series of real- or complex-valued functions on a set X. Suppose there is a sequence (M_k) of nonnegative real numbers such that $|f_k(x)| \leq M_k$ for all k and all $x \in X$, and that

$$\sum_{k=1}^{\infty} M_k$$

converges. Then the series of functions converges absolutely and uniformly on X.

Proof: Let

$$s_n = \sum_{k=1}^{n} f_k$$

be the n'th partial sum of the function series. Fix $\epsilon > 0$. There is then an $N \in \mathbb{N}$ such that

$$\sum_{k=n+1}^{m} M_k < \epsilon$$

for $N \leq n < m$. Then, by the triangle inequality, we have, for $N \leq n < m$,

$$|s_m(x) - s_n(x)| = \left| \sum_{k=n+1}^{m} f_k(x) \right| \leq \sum_{k=n+1}^{m} |f_k(x)| \leq \sum_{k=n+1}^{m} M_k < \epsilon$$

for all $x \in X$. Thus the sequence (s_n) is a uniform Cauchy sequence, hence converges () uniformly on X. And, for each $x \in X$,

$$\sum_{k=1}^{\infty} |f_k(x)|$$

converges by comparison with $\sum_{k=1}^{\infty} M_k$, so $\sum_{k=1}^{\infty} f_k(x)$ converges absolutely. 👍

There is an alternate phrasing of this result.

V.15.1.2. Definition. Let X be a set, and f a bounded real-or-complex-valued function on X. Set

$$\|f\|_\infty = \sup_{x\in X} |f(x)| \ .$$

Then $\|f\|$ is called the *supremum norm* of f on X.

This norm is indeed a norm () on the set of bounded functions on X, and is complete ().

V.15.1.3. Corollary. Let X be a set, and (f_k) a sequence of bounded real- or complex-valued functions on X. If

$$\sum_{k=1}^{\infty} \|f_k\|_\infty$$

converges, then the infinite series

$$\sum_{k=1}^{\infty} f_k$$

converges absolutely and uniformly on X.

V.15.1.4. An infinite series of bounded functions for which

$$\sum_{k=1}^{\infty} \|f_k\|_\infty$$

converges is said to *converge normally*. By V.15.1.3. an infinite series of functions which converges normally converges absolutely and uniformly. Note, though, that normal convergence of an infinite series is not the same thing as normal (i.e. u.c.) convergence of the sequence of partial sums in the sense of IV.3.2.2., an unfortunate ambiguity in established terminology. Normal convergence generalizes to Banach spaces ().

Term-by-Term Differentiation

V.15.1.5. It is important to understand that even a uniformly convergent infinite series of differentiable functions cannot be differentiated term-by-term in general. For a simple example, the infinite series

$$\sum_{k=1}^{\infty} 2^{-k} \sin 2^k x$$

converges uniformly on $\mathbb{R}$ to a (continuous) function f. But the series of term-by-term derivatives

$$\sum_{k=1}^{\infty} \cos 2^k x$$

does not even converge pointwise at 0 or most other points. (In fact, f is not even differentiable at most places.) See I.6.1.18. for a heuristic explanation.

We do have the following series version of V.8.5.5.:

V.15.1.6. THEOREM. Let (F_n) and (f_n) be sequences of functions on an interval I, and A a countable subset of I. Suppose

(a) Each F_n is continuous on I.

(b) For every $x \in I \setminus A$, each F_n is differentiable at x and $F_n'(x) = f_n(x)$.

(c) The series $\sum_{n=1}^{\infty} f_n$ converges u.c. on I to a function f.

(d) There is an $x_0 \in I$ such that the series $\sum_{n=1}^{\infty} F_n(x_0)$ converges.

Then:

(i) The series $\sum_{n=1}^{\infty} F_n$ converges u.c. on I to a (continuous) function F.

(ii) For each $x \in I \setminus A$, F is differentiable at x and $F'(x) = f(x)$.

As usual, the proof is just an application of V.8.5.5. to the sequence of partial sums.

V.15.1.7. The important special case where $A = \emptyset$ and each f_n is continuous follows from IX.2.9.15..

V.15.2. Exercises

V.15.2.1. (a) Prove the *sophomore's dream*:

$$\int_0^1 x^{-x}\,dx = \int_0^1 \frac{1}{x^x}\,dx = \sum_{k=1}^{\infty} \frac{1}{k^k} \quad \text{and} \quad \int_0^1 x^x\,dx = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k^k}\ .$$

[Write $x^x = e^{x \log x}$, expand in an infinite series using the Maclaurin series for e^x, and integrate term-by-term.]

The name "sophomore's dream" was coined in [BBG04].

(b) Another sophomore's dream:

$$\int_0^{\infty} \frac{x}{x^3+1}\,dx = \int_0^{\infty} \frac{1}{x^3+1}\,dx\ .$$

V.15.2.2. Does the iterated integral

$$\int_0^8 \int_0^{\sqrt{4-x}} 2y\,dy\,dx$$

exist? If so, what is its value? Interpret the integral geometrically.

V.15.2.3. Define

$$f(x) = \sum_{k=0}^{\infty} \frac{x^2}{(1+x^2)^k} \ .$$

(a) Show that the series converges (absolutely) for all $x \in \mathbb{R}$. [For each x, it is a multiple of a geometric series.]

(b) Show that the series does not converge uniformly on any interval containing 0.

(c) Show that $f(0) = 0$ and $f(x) = 1 + x^2$ for $x \neq 0$. Thus f is not continuous at 0.

V.15.3. Power Series

Power series are probably the most important kinds of infinite series of functions (although trigonometric series are also very important). A great many of the most important functions can be represented as power series, and power series have some special properties which make them relatively easy to use and work with.

> "Mathematicians of the 18th century mostly regarded power series as infinite polynomials. To a large extent, polynomials and power series behave in calculations in the same way. It would have appeared artificial to regard them as essentially different entities."
>
> *Hans Niels Jahnke*[16]

This attitude is largely justifiable (although the justifications are nontrivial!), *provided* one carefully stays within the open interval of convergence (or disk in the complex case), and persists to this day:

> "A power series is, after all, a rather long polynomial."
>
> *Forman S. Acton*[17]

V.15.3.1. DEFINITION. Let x_0 be a real number. A *(real) power series centered at* x_0 is an expression of the form

$$\sum_{k=0}^{\infty} a_k (x - x_0)^k$$

where the a_k are real numbers. Complex power series can be defined similarly: if z_0 is a complex number, a *complex power series centered at* z_0 is an expression of the form

$$\sum_{k=0}^{\infty} a_k (z - z_0)^k$$

where the a_k are complex numbers.

While we will (except in Chapter XII) generally only consider real power series, the theory of power series is most naturally done for complex power series as part of complex analysis, and there are places in the real theory where the complex point of view is very helpful. Any real power series can, of course, be regarded as a complex power series by replacing x by z.

V.15.3.2. A power series is regarded as an infinite series of functions. It is conventional when working with power series to regard $(x - x_0)^0 = 1$ no matter how $x - x_0$ is interpreted; thus the $k = 0$ term of the power series is just the constant function a_0. The same convention holds for complex power series.

V.15.3.3. A power series is, at first, only a formal expression, but it can be regarded as defining a function f of x, whose domain is the set of all x for which the series converges. Because of our convention, x_0 is always in the domain of the defined function f, with $f(x_0) = a_0$. It can happen that the domain of f consists only of $\{x_0\}$ (such power series are not very interesting as functions).

The most important basic property of power series is V.15.3.5., which says that the domain of the defined function is an interval, or degenerate interval, centered at x_0.

[16] [Jah03, p. 108].
[17] [Act90, p. 13-14].

V.15.3.4. DEFINITION. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series, and define

$$L = \limsup_{k\to\infty} |a_k|^{1/k} = \limsup_{k\to\infty} \sqrt[k]{|a_k|}$$

and let $R = \frac{1}{L}$ if $0 < L < +\infty$, $R = 0$ if $L = +\infty$, and $R = +\infty$ if $L = 0$. R is called the *radius of convergence* of the power series.

An identical definition can be made for complex power series. Note that the radius of convergence of a power series depends only on the coefficients a_k, not on the center x_0, of the power series. The slower the coefficients grow in size, or the faster they approach zero, the larger the radius of convergence.

The term "radius of convergence" is justified by the next result:

V.15.3.5. THEOREM. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series, with radius of convergence R. Then

(i) If $x \in \mathbb{R}$ and $|x-x_0| < R$, then the series $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ converges absolutely.

(ii) If $x \in \mathbb{R}$ and $|x-x_0| > R$, then the series $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ diverges.

(iii) If $r \in \mathbb{R}$ and $0 < r < R$, then the series $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ converges uniformly on the interval $[x_0-r, x_0+r]$.

(Of course, (i) and (iii) are vacuous if $R = 0$ and (ii) is vacuous if $R = +\infty$.)

PROOF: In cases (i) and (ii), apply the Root Test () to the series $\sum_{k=0}^{\infty} |a_k(x-x_0)^k|$. We have

$$\limsup |a_k(x-x_0)^k|^{1/k} = |x-x_0| \limsup |a_k|^{1/k} = \frac{|x-x_0|}{R}$$

(it is $+\infty$ if $x \neq x_0$ and $R = 0$, and 0 if $R = +\infty$ or $x = x_0$). Thus the series converges absolutely if $|x-x_0| < R$ or $x = x_0$ and diverges since the terms do not go to zero if $|x-x_0| > R$.
For (iii), use the Weierstrass M-test (). Set $M_k = |a_k|r^k$. Then $|a_k(x-x_0)^k| \leq M_k$ for all k and for all x, $|x-x_0| \leq r$. We have

$$\limsup M_k^{1/k} = r \limsup |a_k|^{1/k} = \frac{r}{R} < 1$$

if $0 < R < \infty$, and $\limsup M_k^{1/k} = 0$ if $R = +\infty$. Thus $\sum_{k=0}^{\infty} M_k$ converges by the Root Test. ☝

The statement and proof of the theorem work identically for complex power series (the uniform convergence in (iii) is on the closed disk of radius r centered at x_0).

V.15.3.6. Corollary. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series, with radius of convergence $R>0$. Then the series converges u.c. on the open interval (x_0-R, x_0+R), and the sum is continuous on this interval.

Proof: If $[a,b] \subseteq (x_0-R, x_0+R)$, then $[a,b] \subseteq [x_0-r, x_0+r]$ for some $r<R$. Continuity of the sum follows from ().

The sum is actually far more than just continuous on this open interval ().

V.15.3.7. Thus the set on which a power series centered at x_0 converges is an interval centered at x_0, possibly of length zero, i.e. the degenerate interval $\{x_0\}$, or of infinite length, i.e. all of $\mathbb{R}$, possibly including one or both endpoints, called the *interval of convergence* of the power series. (If $0<R<\infty$, the theorem has nothing to say about behavior at the points where $x-x_0=\pm R$, the endpoints of the interval of convergence; endpoint behavior will be discussed below.) Similarly, the set on which a complex power series centered at z_0 converges is a disk in $\mathbb{C}$ centered at z_0, possibly degenerate or all of $\mathbb{C}$, and possibly including some or all points on the boundary circle of the disk.

V.15.3.8. The radius of convergence of a power series $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ can always be computed as

$$R = \frac{1}{\limsup |a_k|^{1/k}}$$

(with the usual conventions if the lim sup is 0 or $+\infty$), but it is not always easy to evaluate this expression. Sometimes the radius of convergence can be computed more simply by the following:

V.15.3.9. Proposition. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series, with all a_k nonzero. If

$$\lim_{k\to\infty} \left| \frac{a_k}{a_{k+1}} \right|$$

exists (in the usual or extended sense), it equals the radius of convergence of the power series.

Proof: Let S be this limit. Apply the Ratio Test () to show that $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ converges absolutely if $|x-x_0|<S$ and diverges if $|x-x_0|>S$. Thus S must be exactly the radius of convergence.

Note that in the limit of V.15.3.9., the a_k and a_{k+1} are reversed from the way they appear in the Ratio Test ().

Another convenient characterization of the radius of convergence is the following:

V.15.3.10. PROPOSITION. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series. The power series has radius of convergence $R>0$ if and only if, for all r, $0<r<R$, there is a constant M such that $|a_k| \le \frac{M}{r^k}$ for all k, and there is no such M if $r>R$.

PROOF: Suppose the series has radius of convergence $R>0$, and $0<r<R$. Then

$$\limsup |a_k|^{1/k} < \frac{1}{r}$$

so there is a k_0 such that $|a_k| < \frac{1}{r^k}$ for all $k \ge k_0$. There is an $M \ge 1$ such that $|a_k| \le \frac{M}{r^k}$ for $0 \le k < k_0$. This M works for all k.

Conversely, if the condition holds for all r with $0<r<R$ and no $r>R$, we have, for each such r with $0<r<R$,

$$\limsup |a_k|^{1/k} \le \limsup \frac{M^{1/k}}{r} = \frac{1}{r}$$

for some constant M, so the radius of convergence R' is $\ge R$. If $R'>R$, choose r so that $R<r<R'$; then the condition holds for r by the first half of the proof, a contradiction. 👍

V.15.3.11. EXAMPLES. (i) Let $c \in \mathbb{R}$, $c \ne 0$. The power series $\sum_{k=0}^{\infty} c^k(x-x_0)^k$ has radius of convergence $\frac{1}{|c|}$, and interval of convergence $\left(x_0 - \frac{1}{|c|}, x_0 + \frac{1}{|c|}\right)$.

(ii) The power series $\sum_{k=0}^{\infty} \frac{1}{k!}(x-x_0)^k$ has radius of convergence $+\infty$ and interval of convergence $\mathbb{R}$.

(iii) The power series $\sum_{k=0}^{\infty} k!(x-x_0)^k$ has radius of convergence 0 and (degenerate) interval of convergence $\{x_0\}$.

V.15.3.12. The convergence behavior of an infinite series does not depend on x_0, and if x_0 is changed, leaving the a_k the same, the function defined is simply changed by a translation. In particular, if f is the function defined by $\sum_{k=0}^{\infty} a_k x^k$ on its interval of convergence I, then the function defined by $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ is simply the function $g(x) = f(x-x_0)$ on $x_0 + I$. Thus in analyzing behavior of functions defined by power series, we generally may (and often will) take $x_0 = 0$ to simplify notation.

Endpoint Behavior

Almost any kind of behavior can occur at endpoints of the interval of convergence, as the following examples show.

V.15.3.13. EXAMPLES. (i) The power series $\sum_{k=0}^{\infty} x^k$ has radius of convergence 1. The series diverges if $x = \pm 1$ since the terms do not go to zero, so the interval of convergence is $(-1, 1)$.

(ii) The power series $\sum_{k=1}^{\infty} \frac{1}{k} x^k$ (a power series with constant term 0) has radius of convergence 1. The series diverges if $x = 1$ (harmonic series), but converges conditionally if $x = -1$, so the interval of convergence is $[-1, 1)$. The power series $\sum_{k=1}^{\infty} \frac{(-1)^k}{k} x^k$ has interval of convergence $(-1, 1]$.

(iii) The power series $\sum_{k=1}^{\infty} \frac{1}{k^2} x^k$ has radius of convergence 1. The series converges absolutely if $x = \pm 1$, so the interval of convergence is $[-1, 1]$.

(iv) The series $\sum_{k=1}^{\infty} \frac{(-1)^k}{k} x^{2k}$ (this is a power series with odd coefficients 0) has radius of convergence 1. The series converges conditionally if $x = \pm 1$, so the interval of convergence is $[-1, 1]$.

V.15.3.14. If a power series converges absolutely at one endpoint, it converges absolutely at the other endpoint too, since the absolute series $\sum_{k=0}^{\infty} |a_k (x - x_0)^k|$ is the same at both endpoints. This is the only restriction on endpoint behavior for real infinite series.

V.15.3.15. Convergence behavior of a complex series on the boundary circle of the disk of convergence is much more subtle. The series can diverge everywhere on this circle (e.g. $\sum_{k=0}^{\infty} (z - z_0)^k$) or it can converge absolutely at all points of the circle (e.g. $\sum_{k=1}^{\infty} \frac{1}{k^2} (z - z_0)^k$), or it can converge conditionally on some subset S of the boundary circle. But S cannot be an arbitrary subset of the circle (it must be an $F_{\sigma\delta}$ (), and not even all of these occur; see [Kör83]). The study of boundary behavior of analytic functions is a big topic in complex analysis, with important applications.

We will primarily be interested in using power series on open intervals. But we note one important result about the behavior of a power series near an endpoint or boundary point where it converges:

V.15.3.16. THEOREM. [ABEL'S THEOREM] Let $\sum_{k=0}^{\infty} a_k (x - x_0)^k$ be a power series. If $[a, b]$ is a closed bounded interval contained in the interval of convergence of the series, then the series converges uniformly on $[a, b]$. (In other words, the series converges u.c. on its entire interval of convergence.)

If $[a, b]$ is contained in the interior of the interval of convergence, the result follows immediately from V.15.3.6., so Abel's Theorem only gives additional information in the case where $[a, b]$ contains one or both endpoints of the interval of convergence, and this is the case it is designed for.

V.15.3.17. COROLLARY. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series, with interval of convergence I. Then the function on I defined by the series is continuous on I, including at any endpoints of I.

PROOF: Combine V.15.3.16. with (). 👍

V.15.3.18. Abel's Theorem also has a complex version, which we do not state precisely. But even the real version is enough to almost immediately show that if $\sum_{k=0}^{\infty} a_k(z-z_0)^k$ is a complex power series, and it converges at some z_1 on the boundary circle of the disk of convergence, then the value at z_1 is the radial limit of the value at z as $z \to z_1$ along the ray from z_0 to z_1. See Exercise ().

We now give the proof of Abel's Theorem.

PROOF: By applying V.15.3.6. to expand the interval if necessary, we may assume $a \leq x_0 \leq b$. We prove that the series converges uniformly on $[x_0, b]$; the proof that it converges uniformly on $[a, x_0]$ is essentially identical.

Let $\epsilon > 0$. Since $\sum_{k=1}^{\infty} a_k(b-x_0)^k$ converges, by () there is an N such that

$$\left| \sum_{k=n+1}^{n+m} a_k(b-x_0)^k \right| < \epsilon$$

whenever $n \geq N$ and $m \in \mathbb{N}$. If $x \in [x_0, b]$, set

$$c_k = \left(\frac{x-x_0}{b-x_0} \right)^k .$$

Then by Abel's Partial Summation Formula (IV.2.7.5.) with $r = n$ we have, for any $n \geq N$ and $m \in \mathbb{N}$,

$$\sum_{k=n+1}^{n+m} a_k(x-x_0)^k = \sum_{k=n+1}^{n+m} c_k a_k(b-x_0)^k = \sum_{k=n+1}^{n+m} (c_k - c_{k+1}) s_{k,n} + c_{n+m+1} s_{n+m,n}$$

where $s_{k,n} = \sum_{j=n+1}^{k} a_j(b-x_0)^j$. Since $|s_{k,n}| < \epsilon$ for all $k \geq n$, and $0 \leq c_{k+1} \leq c_k \leq 1$ for all k, we have

$$\left| \sum_{k=n+1}^{n+m} a_k(x-x_0)^k \right| \leq \sum_{k=n+1}^{n+m} (c_k - c_{k+1})|s_{k,n}| + c_{n+m+1}|s_{n+m,n}|$$

$$\leq \epsilon \left[\sum_{k=n+1}^{n+m} (c_k - c_{k+1}) + c_{n+m+1} \right] = (c_{n+1} - c_{n+m+1})\epsilon \leq \epsilon$$

and so the series converges uniformly on $[x_0, b]$. 👍

Term-by-Term Integration

Because of the u.c. convergence of a power series on its interval of convergence I, we can apply () to integrate a power series term-by-term on any closed bounded interval contained in I:

V.15.3.19. COROLLARY. Let $\sum_{k=0}^{\infty} c_k(x-x_0)^k$ be a power series with interval of convergence I, and $[a,b]$ a closed bounded subinterval of I. Then the function f defined by the power series is integrable on $[a,b]$, and

$$\int_a^b f(x)\,dx = \int_a^b \left[\sum_{k=0}^{\infty} c_k(x-x_0)^k\right] dx = \sum_{k=0}^{\infty}\left[\int_a^b c_k(x-x_0)^k\,dx\right]$$

$$= \sum_{k=0}^{\infty} \frac{c_k}{k+1}\left[(b-x_0)^{k+1} - (a-x_0)^{k+1}\right] = \sum_{k=0}^{\infty} \frac{c_k}{k+1}(b-x_0)^{k+1} - \sum_{k=0}^{\infty} \frac{c_k}{k+1}(a-x_0)^{k+1}\ .$$

In particular, the series on the last line converge. This result is a consequence of V.15.3.6. if $[a,b]$ is contained in the open interval of convergence, but requires Abel's Theorem if a or b is an endpoint of the interval of convergence. If $[a,b]$ is contained in the open interval of convergence, the series in the last expression will automatically converge absolutely by comparison to the power series evaluated at a and b (which converge absolutely by V.15.3.5.(i)). If a or b is an endpoint of the interval of convergence, the original series evaluated at a or b may not converge absolutely, but the next result shows that the integrated series still converge in this case.

V.15.3.20. PROPOSITION. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series. If this power series converges for $x = x_1$, then the integrated series $\sum_{k=0}^{\infty} \frac{a_k}{k+1}(x-x_0)^{k+1}$ also converges for $x = x_1$.

PROOF: Apply Abel's Test (IV.2.7.7.) with $c_k = \frac{x_1-x_0}{k+1}$. 👍

Term-by-Term Differentiation

Term-by-term differentiation of a power series is a dicier matter. One of the beautiful and crucial properties of power series is that they can in fact be differentiated term-by-term, in contrast to more general series of functions.

The key fact making this possible is the next result. Note that if $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ is a power series, the series $\sum_{k=1}^{\infty} ka_k(x-x_0)^{k-1}$ of term-by-term derivatives is also a power series.

V.15.3.21. PROPOSITION. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series, with radius of convergence R. Then the radius of convergence of the series $\sum_{k=1}^{\infty} ka_k(x-x_0)^{k-1}$ of term-by-term derivatives is also exactly R.

PROOF: First note that the series $\sum_{k=1}^{\infty} ka_k(x-x_0)^{k-1}$ and $\sum_{k=1}^{\infty} ka_k(x-x_0)^k$ converge for exactly the same x's: both converge for $x = x_0$, and for $x \neq x_0$ each series is a constant scalar multiple of the other. Thus it suffices to show that the radius of convergence R' of the series $\sum_{k=1}^{\infty} ka_k(x-x_0)^k$ is equal to R.

Let $L = \limsup |a_k|^{1/k}$. Then $R = \frac{1}{L}$ (with the usual conventions if L is 0 or ∞). Similarly, $R' = \frac{1}{L'}$, where $L' = \limsup |ka_k|^{1/k}$. So it suffices to show that $L' = L$. But $\lim_{k\to\infty} k^{1/k} = 1$ (V.9.3.3.(iii)), so by ()

$$L' = \limsup_{k\to\infty} |ka_k|^{1/k} = \left(\lim_{k\to\infty} k^{1/k}\right)\left(\limsup_{k\to\infty} |a_k|^{1/k}\right) = 1 \cdot L = L \ .$$

This result and proof are also valid for complex power series.

V.15.3.22. Note that this result does not say that the *interval* of convergence of the derived series is the same as the interval of convergence of the original series; in fact, endpoint behavior can be different. In examples V.15.3.13.(ii)–(iv), the interval of convergence of the derived series is strictly smaller than that of the original series; it cannot be larger (cf. V.15.3.20.).

We now apply () to get the main result:

V.15.3.23. THEOREM. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series, with radius of convergence $R > 0$. Then the function f defined by the power series is differentiable on $(x_0 - R, x_0 + R)$, and

$$f'(x) = \sum_{k=1}^{\infty} ka_k(x-x_0)^{k-1}$$

for all $x \in (x_0 - R, x_0 + R)$.

V.15.3.24. But why stop there? The power series representing f' can also be differentiated term-by-term, and the theorem applies to show that f' is also differentiable on $(x_0 - R, x_0 + R)$, i.e. f has a second derivative on this interval given by taking term-by-term derivatives twice. This argument can be iterated arbitrarily many times. Thus we obtain:

V.15.3.25. Corollary. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series, with radius of convergence $R>0$. Then the function f defined by the power series is C^∞ on (x_0-R, x_0+R), and

$$f^{(n)}(x) = \sum_{k=n}^{\infty} k(k-1)\cdots(k-n+1)a_k(x-x_0)^{k-n} = \sum_{k=n}^{\infty} \frac{k!}{(k-n)!}a_k(x-x_0)^{k-n}$$

for every n and every $x \in (x_0-R, x_0+R)$.

Note that V.15.3.23. and hence V.15.3.26. apply also on any open subinterval of the interval of convergence. Thus we can rephrase:

V.15.3.26. Corollary. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series which converges to a function f on an open interval I. Then f is C^∞ on I, and

$$f^{(n)}(x) = \sum_{k=n}^{\infty} k(k-1)\cdots(k-n+1)a_k(x-x_0)^{k-n} = \sum_{k=n}^{\infty} \frac{k!}{(k-n)!}a_k(x-x_0)^{k-n} = \sum_{k=0}^{\infty} \frac{(k+n)!}{k!}a_{k+n}(x-x_0)^k$$

for every n and every $x \in I$ (in particular, this series converges for all n and all $x \in I$).

Uniqueness of Power Series Representations

V.15.3.27. V.15.3.26. has another important consequence: if $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ is a power series with positive radius of convergence, then the coefficients a_k can be recovered from the function f defined by the power series. We have that f is infinitely differentiable in an interval around x_0, and $f^{(n)}$ is given by the n'th derived power series. In particular, $f^{(n)}(x_0)$ is the constant term of the n'th derived power series, which is $n!a_n$. Thus we obtain:

V.15.3.28. Corollary. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series with positive radius of convergence, and f the function defined by the series on its open interval of convergence. Then

$$a_n = \frac{f^{(n)}(x_0)}{n!}$$

for each n. In particular, the given power series is the only possible power series centered at x_0 that can represent f on an open interval containing x_0. Thus a function can be represented near x_0 by at most one power series centered at x_0.

V.15.3.29. DEFINITION. Let f be C^∞ on an interval around $x_0 \in \mathbb{R}$. The *Taylor series* for f around x_0 is the infinite series

$$\sum_{k=0}^{\infty} \frac{f^{(k)}(x_0)}{k!}(x - x_0)^k \ .$$

Note that the partial sums of the Taylor series for f around x_0 are exactly the Taylor polynomials (V.10.1.6.) of f around x_0. The corollary can be rephrased:

V.15.3.30. COROLLARY. Let f be C^∞ on an interval around $x_0 \in \mathbb{R}$. Then the only power series centered at x_0 which can converge to f in any open neighborhood of x_0 is the Taylor series for f around x_0.

V.15.3.31. Note two important things about the corollary:

(i) The result only applies to power series centered at x_0. It does not imply that f cannot be represented near x_0 by a different power series centered at some $x_1 \neq x_0$. In fact, if f can be represented in some interval by a power series centered at x_0, there will be such a power series centered at any x_1 sufficiently close to x_0 ().

(ii) The result says nothing about *whether* a function defined near x_0 can in fact be represented by a power series centered at x_0, only that *if* it can, the series is unique and is the Taylor series for f around x_0. An obvious necessary condition for f to be representable is that it be C^∞ in an interval around x_0, but this is far from sufficient. The question of which functions can be represented by power series is a substantial one which will be discussed in the next section.

V.16. Analytic Functions

Functions which can be locally represented by their Taylor series, called *analytic functions*, are particularly well-behaved. It turns out that most standard functions, and many of the functions naturally encountered in mathematics, are analytic.

V.16.1. Definitions and Basic Properties

V.16.1.1. DEFINITION. (i) Let U be an open set in $\mathbb{R}$. A function $f : U \to \mathbb{R}$ is *real analytic* on U if for every $x_0 \in U$, f is represented in some neighborhood of x_0 by a (real) power series centered at x_0.

(ii) Let V be an open set in $\mathbb{C}$. A function $f : V \to \mathbb{C}$ is *complex analytic* on V if for every $z_0 \in V$, f is represented in some neighborhood of z_0 by a complex power series centered at z_0.

In mathematics it is most common to use the term *analytic* to mean "complex analytic." However, in this book, except in Chapter XII, it will normally mean "real analytic" or occasionally "real or complex analytic."

V.16.1.2. Some remarks on the definition:

(i) The phrase "represented in some neighborhood of x_0 by a (real) power series centered at x_0" means that there is some $\epsilon > 0$ and some (real) power series centered at x_0 which converges to $f(x)$ for all $x \in (x_0 - \epsilon, x_0 + \epsilon)$. The meaning in (ii) is analogous.

(ii) If f is analytic (in either the real or complex sense), then f is C^∞ and the (unique) power series centered at x_0 representing f in a neighborhood of x_0 is the Taylor series of f around x_0 (V.15.3.29.).

(iii) Since the partial sums of the Taylor series for f around x_0 are the Taylor polynomials (V.10.1.6.) of f around x_0, f is analytic on U if and only if, for each $x_0 \in U$, the Taylor polynomials for f around x_0 converge to f in a neighborhood of x_0, i.e. the remainder terms r_n converge to zero on a neighborhood of x_0 (cf. V.10.1.8.).

(iv) It is important to note that if f is analytic on U and $x_0 \in U$, then the Taylor series of f around x_0 does not converge to f on all of U in general; it only converges to f in *some* open interval around x_0. Thus the property of being analytic on U is strictly a local property. If $f : U \to \mathbb{R}$ is a function, and for every $x \in U$ there is a neighborhood of x in U on which f is analytic, then f is analytic on U. In particular, if f is analytic on every open subinterval of U, then f is analytic on U; thus for convenience we often just work with open intervals when dealing with analytic functions.

A similar comment applies in the complex analytic case. See ().

V.16.1.3. One of the important theorems of complex analysis is a strong form of the converse to V.16.1.2.(ii): if V is an open subset of $\mathbb{C}$ and $f : V \to \mathbb{C}$ is differentiable in the complex sense at every point of V, then f is complex analytic on V. There is nothing resembling an analog of this result for real analytic functions, and this is one of the most fundamental differences in nature between real analysis and complex analysis. More specifically:

> If f is differentiable on I, then f' need not even be continuous on I (), much less differentiable. In particular, a differentiable real function is "usually" not even C^1, much less C^∞.
>
> Even most C^∞ functions are not real analytic; see section () for details.

V.16.1.4. **Notation:** The set of real analytic functions on an open set U is denoted $C^\omega(U)$.

V.16.1.5. EXAMPLES. (i) Let f be a polynomial of degree n. Then, for any $x_0 \in \mathbb{R}$, by Taylor's Theorem the n'th order Taylor polynomial for f around x_0 is f itself, i.e. the Taylor series for f around x_0 (which has only finitely many nonzero terms) represents f on all of $\mathbb{R}$. Thus f is analytic on $\mathbb{R}$.

(ii) Let $f(x) = \sin x$. Then f is C^∞ on $\mathbb{R}$, and $|f^{(k)}(x)| \leq 1$ for all k and x. Fix $x_0 \in \mathbb{R}$, and let p_n be the n'th order Taylor polynomial for f around x_0, and $r_n = f - p_n$. Then, for any $x \in \mathbb{R}$, we have

$$r_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!}(x - x_0)^{n+1}$$

for some c between x_0 and x, and thus

$$|r_n(x)| \leq \frac{|x - x_0|^{n+1}}{(n+1)!} \to 0$$

as $n \to \infty$, so the Taylor series for f around x_0 converges to $f(x)$ for all x and f is analytic on $\mathbb{R}$. An identical argument shows that $g(x) = \cos x$ is analytic on $\mathbb{R}$.

(iii) Let $f(x) = e^x$. Then f is C^∞ on $\mathbb{R}$, and $f^{(k)}(x) = e^x$ for all k and x. Fix $x_0 \in \mathbb{R}$ and $s > 0$, and let $m = e^{x_0+s}$. Then $|f^{(k)}(x)| < m$ if $|x - x_0| < s$. Let p_n be the n'th order Taylor polynomial for f around x_0, and $r_n = f - p_n$. Then, for any x with $|x - x_0| < s$, we have

$$r_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!}(x - x_0)^{n+1}$$

for some c between x_0 and x, and thus

$$|r_n(x)| \leq \frac{m|x - x_0|^{n+1}}{(n+1)!} \to 0$$

as $n \to \infty$, so the Taylor series for f around x_0 converges to $f(x)$ for all x, $|x - x_0| < s$. Since s is arbitrary, the Taylor series converges to $f(x)$ for all $x \in \mathbb{R}$. Thus f is analytic on $\mathbb{R}$.

Analyticity of Functions Defined by Power Series

The definition of an analytic function is hard to check directly: to show that f is analytic on U, one must show for *every* $x_0 \in U$ that the Taylor series for f around x_0 converges to f in an interval around x_0, an (uncountably) infinite number of conditions since there is a different Taylor series at each point. The following theorem is one of the most important facts about analytic functions, and saves an enormous amount of work in checking that specific functions are analytic since only one x_0 must be considered.

V.16.1.6. THEOREM. Let $\sum_{k=0}^{\infty} a_k(x - x_0)^k$ be a power series with radius of convergence $R > 0$, and let f be the function defined on $I = (x_0 - R, x_0 + R)$ defined by the power series. Then f is analytic on I.

In fact, the following more precise result holds:

V.16.1.7. THEOREM. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series with radius of convergence $R > 0$, and let f be the function defined on $I = (x_0 - R, x_0 + R)$ defined by the power series. Let $x_1 \in I$, and set $S = R - |x_1 - x_0|$. Then the Taylor series for f around x_1 has radius of convergence at least S and converges to f on $(x_1 - S, x_1 + S)$.

See Figure (). Note that f is C^∞ on I (), so the Taylor series for f around x_1 is defined.

To prove these theorems, we first need a lemma which will also be used later.

V.16.1.8. LEMMA. Let $\sum_{k=0}^{\infty} a_k(x-x_0)^k$ be a power series with radius of convergence $R > 0$, and let f be the function defined on $I = (x_0 - R, x_0 + R)$ defined by the power series. Fix r, $0 < r < R$, and s, $0 < s < R - r$. Then there is a constant m such that

$$|f^{(k)}(x)| \leq \frac{m \cdot k!}{s^k}$$

for all $k \geq 0$ and all x with $|x - x_0| \leq r$.

PROOF: First note that the power series $\sum_{j=0}^{\infty} x^j$ converges to $f(x) = \frac{1}{1-x}$ on $(-1, 1)$, and thus the k'th derived series

$$\sum_{j=k}^{\infty} j(j-1)\cdots(j-k)x^{j-k}$$

converges on $(-1, 1)$ to $f^{(k)}(x) = \frac{k!}{(1-x)^{k+1}}$ for any k ().

Let r and s be as in the statement. Since $r + s < R$, by () there is an M such that $|a_k| \leq \frac{M}{(r+s)^k}$ for all k. If $|x - x_0| \leq r$, then we have, for any k,

$$f^{(k)}(x) = \sum_{j=k}^{\infty} j(j-1)\cdots(j-k)a_j(x-x_0)^{j-k}$$

$$|f^{(k)}(x)| \leq \sum_{j=k}^{\infty} j(j-1)\cdots(j-k)\frac{M}{(r+s)^j}r^{j-k} = \frac{M}{(r+s)^k}\sum_{j=k}^{\infty} j(j-1)\cdots(j-k)\left(\frac{r}{r+s}\right)^{j-k}$$

$$= \frac{M}{(r+s)^k}\frac{k!}{\left(1-\frac{r}{r+s}\right)^{k+1}} = \frac{M}{(r+s)^k}\frac{k!(r+s)^{k+1}}{s^{k+1}} = \frac{m \cdot k!}{s^k}$$

where $m = \frac{M(r+s)}{s}$. 👍

We now give the proof of Theorem V.16.1.6. and most of Theorem V.16.1.7..

PROOF: Let $\sum_{k=0}^{\infty} b_k(x-x_1)^k$ be the Taylor series for f around x_1. We will show that for every r, $|x_1 - x_0| < r < R$, and s, $0 < s < R - r$, this Taylor series has radius of convergence at least s and converges to $f(x)$ whenever $|x - x_1| < \min(s, r - |x_1 - x_0|)$. This will show that this Taylor series has radius of convergence at least S and that it converges to f in a neighborhood of x_1; it follows that f is analytic on I.

Fix such an r and s. By Lemma V.16.1.8., there is an m such that $|f^{(k)}(x)| \leq \frac{m \cdot k!}{s^k}$ for all $k \geq 0$ whenever $|x - x_0| \leq r$. In particular, we have

$$|b_k| = \frac{|f^{(k)}(x_1)|}{k!} \leq \frac{m}{s^k}$$

for all k, so the radius of convergence of $\sum_{k=0}^{\infty} b_k(x-x_1)^k$ is

$$\frac{1}{\limsup |b_k|^{1/k}} \geq \frac{1}{\limsup \left(\frac{m}{s^k}\right)^{1/k}} = s \ .$$

Since s can be made arbitrarily close to S by choosing r close enough to $|x_1 - x_0|$, the radius of convergence is at least S.

Let g be the function on $J = (x_1 - S, x_1 + S)$ defined by $\sum_{k=0}^{\infty} b_k(x-x_1)^k$, and let

$$g_n(x) = \sum_{k=0}^{n} b_k(x-x_1)^k$$

for $n \in \mathbb{N}$. Then $g_n \to g$ on J. Set $\phi_n = f - g_n$. Then ϕ_n is C^∞ on I, $\phi_n^{(k)}(x_1) = 0$ for $0 \leq k \leq n$, and $\phi_n^{(k)} = f^{(k)}$ on I for $k > n$ since g_n is a polynomial of degree $\leq n$.

Set $t = \min(s, r - |x_1 - x_0|)$, and let x satisfy $|x - x_1| < t$. By the Lagrange Remainder Formula (), we have

$$\phi_n(x) = \frac{\phi_n^{(n+1)}(c_n)}{(n+1)!}(x-x_1)^{n+1} = \frac{f^{(n+1)}(c_n)}{(n+1)!}(x-x_1)^{n+1}$$

for some c_n between x_1 and x; since $|c_n - x_0| \leq r$ we have

$$|\phi_n(x)| \leq \frac{m}{s^{n+1}}|x-x_1|^{n+1} = m\left(\frac{|x-x_1|}{s}\right)^{n+1} \ .$$

Since $|x - x_1| < s$, $\phi_n(x) \to 0$, $g_n(x) \to f(x)$, and thus $f = g$ on $(x_1 - t, x_1 + t)$. 👍

V.16.1.9. We have now proved V.16.1.6., and all that remains to finish the proof of V.16.1.7. is to show that $f = g$ on all of J. We have that f and g are both analytic on J by V.16.1.6., and $f = g$ on a neighborhood of x_1. The conclusion then follows by an application of V.16.2.2..

V.16.1.10. An analogous theorem holds for complex analytic functions: if f is defined by a complex power series around z_0 on an open disk D of radius $R > 0$, $z_1 \in D$, and $S = R - |z_1 - z_0|$, then the Taylor series for f around z_1 has radius of convergence at least S and converges to f on the open disk of radius S around z_1. This can be proved by an identical proof to the one above, but there is a simpler proof using other theorems of complex analysis.

Growth of Derivatives of Analytic Functions

We can obtain a closely related characterization of analytic functions: they are exactly the C^∞ functions whose derivatives "do not grow too rapidly" locally. Precisely:

V.16.1.11. THEOREM. Let f be a real-valued function on an open set U in $\mathbb{R}$. Then f is analytic on U if and only if f is C^∞ on U and, for each $x_0 \in U$, there is an open interval J containing x_0 and natural numbers m and n such that

$$|f^{(k)}(x)| \leq m \cdot k! \cdot n^k$$

for all $k \geq 0$ and all $x \in J$.

PROOF: Suppose f is analytic on U and $x_0 \in U$. Then the Taylor series for f around x_0 has positive radius of convergence R, and there is an r, $0 < r < R$, such that this Taylor series represents f on $J = (x_0 - r, x_0 + r)$. Fix s with $0 < S < R - r$. Then by Lemma V.16.1.8., there is an m such that, for any $k \geq 0$ and $x \in J$, $|f^{(k)}(x)| \leq \frac{m \cdot k!}{s^k}$. We may assume $m \in \mathbb{N}$, and we may take n any natural number $\geq \frac{1}{s}$.

Conversely, suppose f is C^∞ on U and the growth condition is satisfied. Fix $x_0 \in U$, and let $\sum_{k=0}^{\infty} a_k(x - x_0)^k$ be the Taylor series of f around x_0. Let J, m, and n be as in the statement, and set $s = \frac{1}{n}$. Then there is an r, $0 < r < s$, such that $(x_0 - r, x_0 + r) \subseteq J$. For each k, let p_k be the k'th Taylor polynomial for f around x_0, and $r_k = f - p_k$ the k'th remainder. If $|x - x_0| < r$, then we have

$$r_k(x) = \frac{f^{(k+1)}(c_k)}{(k+1)!}(x - x_0)^{k+1}$$

for some c_k between x_0 and x; since $c_k \in (x_0 - r, x_0 + r)$ we have

$$|r_k(x)| \leq m \cdot n^{k+1} r^{k+1} = m \left(\frac{r}{s}\right)^{k+1} \to 0$$

as $k \to \infty$; thus the Taylor series for f around x_0 converges to f on $(x_0 - r, x_0 + r)$ and f is analytic on U. 👍

V.16.2. Rigidity of Analytic Functions

One of the remarkable properties of an analytic function f on an open interval I is that the values of f on a small part of I (e.g. a small subinterval of I) completely determine the values of f on all of I. In particular, if an analytic function f on an interval I is identically 0 on a small subinterval of I, then f is identically 0 on all of I, and in fact the zeroes of a nonzero analytic function are (relatively) isolated in I.

V.16.2.1. THEOREM. Let f and g be analytic on an open interval I, and (x_n) a sequence of distinct points in I converging to $x_0 \in I$. If $f(x_n) = g(x_n)$ for all n, then $f(x) = g(x)$ for all $x \in I$.

V.16.2.2. Corollary. Let f and g be analytic on an open interval I, and J a (nondegenerate) subinterval of I. If $f(x) = g(x)$ for all $x \in J$, then $f(x) = g(x)$ for all $x \in I$.

V.16.2.3. Corollary. Let f be analytic and not identically 0 on an open interval I. Then the zeros of f in I are isolated in I: if $x_0 \in I$ and $f(x_0) = 0$, then there is a deleted neighborhood U of x_0 in I such that $f(x) \neq 0$ for all $x \in U$.

V.16.2.4. **Caution:** Two analytic functions on an interval I can agree at a sequence of points in I without being identical, so long as the sequence has no cluster points in I. For example, $f(x) = \sin x$ takes the same values as the constant function 0 at $n\pi$ for all n. The sequence where f and g agree can even have a limit which is not in I: $f(x) = \sin\left(\frac{1}{x}\right)$ is analytic on $(0, +\infty)$ and agrees with the constant function 0 at a sequence of points $\left(\frac{1}{n\pi}\right)$ converging to 0.

To prove Theorem V.16.2.1., we need a lemma which is of independent interest:

V.16.2.5. Lemma. Let f be C^∞ on an open interval I, and (x_n) a sequence of distinct points in I converging to $x_0 \in I$. If $f(x_n) = 0$ for all n, then $f^{(k)}(x_0) = 0$ for all k.

Proof: We have $f(x_0) = \lim_{n\to\infty} f(x_n) = 0$ by continuity, and

$$f'(x_0) = \lim_{n\to\infty} \frac{f(x_n) - f(x_0)}{x_n - x_0} = 0 \ .$$

Suppose $f(x_0) = f'(x_0) = \cdots = f^{(k-1)}(x_0) = 0$ and $f^{(k)}(x_0) \neq 0$, and set $a = \frac{f^{(k)}(x_0)}{k!}$. Then by Taylor's Theorem () we have

$$f(x) = a(x - x_0)^k + o((x - x_0)^k)$$

for all $x \in I$. Thus there is a $\delta > 0$ such that

$$|f(x) - a(x - x_0)^k| < \frac{|a|}{2}|x - x_0|^k$$

$$|f(x)| > \frac{|a|}{2}|x - x_0|^k > 0$$

whenever $0 < |x - x_0| < \delta$. But there is an n with $0 < |x_n - x_0| < \delta$, a contradiction. Thus there is no such k.

See V.10.7.11. for an alternate argument. We now give the proof of Theorem V.16.2.1..

Proof: First suppose g is identically 0, i.e. $f(x_n) = 0$ for all n. Then by V.16.2.5. the Taylor series for f around x_0 is identically 0, i.e. f is identically 0 in a neighborhood of x_0 in I. Let E be the set of all $x \in I$ such that f is identically 0 in a neighborhood of x in I. Then E is nonempty since $x_0 \in E$, and it is obviously open in I. If $c \in I$ is in the closure of E, another application of V.16.2.5. shows that $f^{(k)}(c) = 0$ for all k, and hence f is identically 0 in a neighborhood of c in I, i.e. $c \in E$. Thus E is relatively closed in I. Since I is connected, $E = I$.

Now consider the case of general g. We have that $f - g$ is analytic on I and vanishes at each x_n, so $f - g$ is identically 0 on I.

V.16.2.6. There are (nonanalytic) C^∞ functions on I satisfying the hypotheses of Lemma V.16.2.5. which are not identically zero (V.17.2.2.). Thus C^∞ functions do not generally have the same rigidity properties as analytic functions. In fact, the difference is dramatic; see V.17.2.9..

There are many important consequences of V.16.2.1., for example:

V.16.2.7. COROLLARY. Let f be an analytic function on an open interval I, and $x_0 \in I$. Let J be the interval of convergence of the Taylor series for f around x_0. Then the Taylor series for f around x_0 represents f on all of $I \cap J$, and f extends uniquely to an analytic function on $I \cup J^o$.

PROOF: Let g be the function defined on J by the Taylor series for f around x_0. Then g is analytic on J^o. The functions f and g are analytic on $I \cap J^o$, and agree in a neighborhood of x_0 by V.16.1.7., so they agree on all of $I \cap J^o$ by V.16.2.2.. If x is an endpoint of J contained in I, then x is in the closure of $I \cap J^0$ and both f and g are continuous at x (V.15.3.17.), so $f(x) = g(x)$.

For the last statement, define $h(x) = f(x)$ if $x \in I$ and $h(x) = g(x)$ if $x \in J^o$. Then h is well defined by the first part of the proof, and is obviously analytic on $I \cup J^o$. Since $I \cup J^o$ is an interval, and any extension of f to $I \cup J^o$ agrees with f on I, uniqueness follows from V.16.2.2.. 👍

V.16.2.8. EXAMPLE. Note that the interval I cannot be replaced by an open set U in this result: let $U = \mathbb{R} \setminus \{0\}$, and let $f(x) = 0$ for $x < 0$ and $f(x) = 1$ for $x > 0$. Then f is analytic on U, but V.16.2.7. fails for any $x_0 \in U$.

V.16.2.9. The exact complex analog of V.16.2.1. holds, with essentially identical proof: if f and g are complex analytic on a connected open set V, (z_n) is a sequence in V converging to $z_0 \in V$, and $f(z_n) = g(z_n)$ for all n, then $f(z) = g(z)$ for all $z \in V$. V.16.2.7. also extends to the complex case, with "interval" replaced by "disk." (There are topological obstructions to extending this result to connected open sets in $\mathbb{C}$, even simply connected open sets, but it does extend to convex open sets.)

This is needed to prove the following important fact:

V.16.2.10. THEOREM. Let f be a real analytic function on an open set U in $\mathbb{R}$. Then there is an open set V in $\mathbb{C}$ with $V \cap \mathbb{R} = U$, and a complex analytic function g on V, such that $g|_U = f$.

PROOF: For each $x_0 \in U$, the Taylor series for f around x_0, regarded as a complex power series, defines a complex analytic function g_{x_0} on an open disk in $\mathbb{C}$ centered at x_0 whose intersection with the real axis is contained in U, and on which g_{x_0} agrees with f. It is only necessary to show that these functions agree on the overlaps of their domains; then g can be defined on the union of these disks. But any two of these functions agree on the part of the overlap of their domain disks contained in U (which is an open interval in $\mathbb{R}$), and the overlap is connected, so they agree on the entire overlap. 👍

V.16.3. Combinations of Analytic Functions

In this section, we show that all usual ways of manufacturing new functions out of old preserve analyticity. Specifically:

(i) Linear combinations of analytic functions are analytic.

(ii) Derivatives and antiderivatives of analytic functions are analytic (V.15.3.20., V.15.3.23.).

(iii) Products of analytic functions are analytic.

(iv) Quotients of analytic functions are analytic if the denominator is nonzero.

(v) Compositions of analytic functions are analytic.

(vi) Inverse functions of analytic functions with nonzero derivatives are analytic.

These results, among other things, provide a large supply of standard analytic functions. The direct proofs range from very easy (i) to easy consequences of previous results ((ii)–(iii)) to moderately involved ((iv)–(v)) to quite difficult (vi). The "easy" way to prove (iii)–(vi) is to use V.16.2.10. and theorems from complex analysis, but we will describe direct proofs not using complex analysis.

Linear Combinations of Analytic Functions

V.16.3.1. Proposition. Let f and g be analytic on an open set U, and α a scalar. Then $f+g$ and αf are analytic on U.

Proof: The conclusions are immediate consequences of IV.2.1.16. and IV.2.1.18. respectively (plus the observation that linear combinations of power series centered at the same place are also power series). 👍

Unordered Power Series

V.16.3.2. Definition. An *unordered power series* is an unordered sum (IV.2.9.2.)

$$\sum_{j\in J} a_j X^{n_j}$$

where J is an index set, a_j is a scalar, X is an indeterminate symbol, and $n_j \in \mathbb{N}\cup\{0\}$ for each j. (Thus we may have unordered real power series or unordered complex power series).

The differences between an unordered power series and an ordinary formal power series are:

(i) The order of the terms is not specified.

(ii) There may be many terms, even infinitely many, with the same power of X.

V.16.3.3. An unordered power series $\sum_{j\in J} a_j X^{n_j}$ with coefficients in $\mathbb{F}$ ($= \mathbb{R}$ or $\mathbb{C}$) defines a function by setting

$$f(x) = \sum_{j\in J} a_j x^{n_j}$$

whose domain is the set of x for which the unordered sum converges (i.e. converges absolutely by IV.2.9.9.). The domain may be empty (we adhere to the convention that $x^0 = 1$ even if $x = 0$). We may more generally fix an x_0 and consider the function

$$f(x) = \sum_{j\in J} a_j (x - x_0)^{n_j} \ .$$

V.16.3.4. While the index set J can in principle be uncountable, if it is not countable, or at least if $\{j : a_j \neq 0\}$ is uncountable (terms with $a_j = 0$ can be effectively ignored in the sum), the unordered sum cannot converge for any $x \neq 0$ by IV.2.9.6.. Thus in examining such series expansions of functions there is no essential loss of generality in considering only countable index sets. So from now on we will restrict to the case where J is countable.

V.16.3.5. We can formally rearrange an unordered power series into an ordinary power series. To do this, for each $k \in \mathbb{N} \cup \{0\}$ set $J_k = \{j : n_j = k\}$ (i.e. the set of indices for which the power of X in the term is k). We can then form the ordinary infinite series

$$\sum_{k=0}^{\infty} \left[\left(\sum_{j\in J_k} a_j \right) x^k \right]$$

provided the unordered sum $\sum_{j\in J_k} a_j$ converges for each k. This power series is called the *standard revision* of the unordered power series.

V.16.3.6. THEOREM. Let

$$\sum_{j\in J} a_j X^{n_j}$$

be an unordered power series, and x_0 a scalar. Suppose the unordered sum

$$\sum_{j\in J} a_j (x_1 - x_0)^{n_j}$$

converges for some $x_1 \neq x_0$. Then

(i) The unordered sum

$$f(x) = \sum_{j\in J} a_j (x - x_0)^{n_j}$$

converges for all x, $|x - x_0| \leq |x_1 - x_0|$.

(ii) The unordered sum

$$\sum_{j\in J_k} a_j$$

converges for each k.

(iii) The standard revision

$$\sum_{k=0}^{\infty}\left[\left(\sum_{j\in J_k} a_j\right)(x-x_0)^k\right]$$

of the unordered power series converges absolutely to $f(x)$ for all x, $|x-x_0|\le|x_1-x_0|$. (In particular, this power series has radius of convergence at least $|x_1-x_0|$.)

(If $x_1=x_0$, (i) and (iii) still hold, and (ii) holds for $k=0$, but the result has little content in this case.)

Proof: By IV.2.9.9.,

$$\sum_{j\in J}|a_j(x_1-x_0)^{n_j}|$$

converges, and thus for $|x-x_0|\le|x_1-x_0|$ the unordered sum

$$\sum_{j\in J}|a_j(x-x_0)^{n_j}|$$

converges by comparison, hence $\sum_{j\in J} a_j(x-x_0)^{n_j}$ converges. (Technically we should convert the unordered sums to ordinary infinite series by taking the terms in some order; the order is irrelevant.) Also, for any k, the unordered sum

$$\sum_{j\in J_k}|a_j(x_1-x_0)^{n_j}| = |(x_1-x_0)^k|\sum_{j\in J_k}|a_j|$$

converges since it is a subsum of a convergent nonnegative unordered sum. Thus, since $x_1\ne x_0$,

$$\sum_{j\in J_k} a_j$$

converges for each k. Finally, for any x with $|x-x_0|\le|x_1-x_0|$ the standard revision

$$\sum_{k=0}^{\infty}\left[\left(\sum_{j\in J_k} a_j\right)(x-x_0)^k\right]$$

(with the terms from each J_k ordered in some arbitrary way) is a drastic revision (IV.2.10.14.) of the unordered sum

$$f(x)=\sum_{j\in J} a_j(x-x_0)^{n_j}$$

(with terms ordered in some way). Since the unordered sum converges (absolutely), the standard revision converges to the same sum by IV.2.10.16.. 👍

V.16.3.7. Conversely, any ordinary power series can be regarded as an unordered power series. The unordered power series converges exactly whenever the original power series converges absolutely, i.e. either on the interval (or disk) of convergence or the open interval (or disk) of convergence of the power series.

V.16.3.8. Corollary. Let

$$\sum_{j\in J} a_j X^{n_j}$$

be an unordered power series. If the unordered series

$$\sum_{j\in J} a_j x^{n_j}$$

converges for some $x \neq 0$, then for any x_0 the function

$$f(x) = \sum_{j\in J} a_j (x - x_0)^{n_j}$$

is analytic on an interval (or disk) around x_0. The Taylor series for f around x_0 is the standard revision of the unordered power series.

V.16.3.9. This result can be used to justify many formal manipulations with power series. The rough general principle is:

> If f and g are functions defined by infinite summations, and the summations can be formally manipulated into the same sum, *and the summations converge absolutely in an appropriate sense*, then the functions are equal.

We give several specific examples below (V.16.3.12.,).

Products of Analytic Functions

V.16.3.10. Theorem. Let f and g be analytic functions on an open set U. Then fg is analytic on U.

Proof: Fix $x_0 \in U$, and let

$$f(x) = \sum_{k=0}^{\infty} a_k (x - x_0)^k \quad \text{and} \quad \sum_{k=0}^{\infty} b_k (x - x_0)^k$$

be the Taylor series for f and g, converging to f and g on $\{x : |x - x_0| < R\} \subseteq U$. If $|x - x_0| < R$, then the above series converge absolutely, so the product series

$$\sum_{n=0}^{\infty} \left[\left(\sum_{k=0}^{n} a_k b_{n-k} \right) (x - x_0)^k \right]$$

converges (absolutely) to $f(x)g(x)$ by IV.2.11.8.. 👍

V.16.3.11. It can be readily checked by repeated applications of the Product Rule that if f and g are infinitely differentiable at x_0, then so is fg, and that the Taylor series for fg around x_0 is the product of the Taylor series for f and g around x_0 (i.e. the Taylor series for fg around x_0 is the standard revision of the unordered power series obtained by multiplying the two Taylor series termwise). This observation is not needed for the proof of V.16.3.10., but it and V.16.3.10. give additional motivation for why the definition (IV.2.11.5.) of the product of two infinite series is the "right" one.

Compositions of Analytic Functions

V.16.3.12. THEOREM. Let f be analytic on an open set U, g analytic on an open set V, and $f(U) \subseteq V$. Then $g \circ f$ is analytic on U.

PROOF: We may proceed formally as follows, ignoring convergence questions for the moment. Let $x_0 \in U$, and $y_0 = f(x_0) \in V$. Let

$$f(x) = \sum_{k=0}^{\infty} a_k (x - x_0)^k \quad \text{and} \quad g(y) = \sum_{k=0}^{\infty} b_k (y - y_0)^k$$

be the Taylor series for f around x_0 and for g around y_0. Then we can expand

$$g(f(x)) = \sum_{k=0}^{\infty} b_k (f(x) - y_0)^k = \sum_{k=0}^{\infty} b_k \left(\sum_{j=1}^{\infty} a_j (x - x_0)^j \right)^k .$$

If we expand the k'th power series

$$\left(\sum_{j=1}^{\infty} a_j (x - x_0)^j \right)^k$$

into a product series

$$\sum_{n=0}^{\infty} c_{kn} (x - x_0)^n$$

for each k (cf. IV.2.11.11.), we have a drastic revision

$$\sum_{k=0}^{\infty} b_k \left(\sum_{n=1}^{\infty} c_{kn} (x - x_0)^n \right) \tag{V.1}$$

of an unordered power series

$$\sum_{(n,k)} b_k c_{kn} (x - x_0)^n \ . \tag{V.2}$$

The drastic revision V.1 converges to $g(f(x))$ if x is sufficiently close to x_0; so if the unordered series V.2 converges for some $x \neq x_0$, we can conclude from V.16.3.8. that its sum (which is $g \circ f$ by IV.2.10.16.) is analytic on a neighborhood of x_0. Since $x_0 \in U$ is arbitrary, the result follows.

The two power series

$$\sum_{k=1}^{\infty} |a_k| x^k \quad \text{and} \quad \sum_{k=0}^{\infty} |b_k| y^k$$

have a positive radius of convergence, hence define analytic functions F and G near 0. Thus, if t is a sufficiently small positive number, we can write

$$G(F(t)) = \sum_{k=0}^{\infty} |b_k| F(t)^k = \sum_{k=0}^{\infty} |b_k| \left(\sum_{j=1}^{\infty} |a_j| t^j \right)^k \tag{V.3}$$

where all the series converge (absolutely). Expanding the k'th power series

$$\left(\sum_{j=1}^{\infty} |a_j| t^j \right)^k = \sum_{n=0}^{\infty} d_{kn} t^n$$

for each k (note that $d_{kn} \geq 0$ for all k and n) and converting V.3 to an unordered series

$$\sum_{(n,k)} |b_k| d_{kn} t^n$$

we obtain a convergent nonnegative unordered series which converges to $G(F(t))$.

If we compare the series

$$\left(\sum_{j=1}^{\infty} a_j (x - x_0)^j \right)^k = \sum_{n=0}^{\infty} c_{kn} (x - x_0)^n$$

$$\left(\sum_{j=1}^{\infty} |a_j| t^j \right)^k = \sum_{n=0}^{\infty} d_{kn} t^n$$

we obtain easily from the triangle inequality that $|c_{kn}| \leq d_{kn}$ for all k and n. Thus the unordered series

$$\sum_{(n,k)} b_k c_{kn} t^n$$

converges absolutely by comparison, which was what needed to be shown to complete the proof (taking $x = x_0 + t$). 👍

V.16.3.13. Remarks. Here are some remarks about the theorem and its proof.

(i) In most of the proof we work with $\sum_{k=1}^{\infty} a_k (x - x_0)^k$, not $\sum_{k=0}^{\infty} a_k (x - x_0)^k$. This is because we necessarily have $a_0 = f(x_0) = y_0$ and we are working with $f(x) - y_0$.

(ii) The k'th power sum

$$\left(\sum_{j=1}^{\infty} a_j (x - x_0)^j \right)^k$$

when converted into the product series

$$\sum_{n=0}^{\infty} c_{kn}(x-x_0)^n$$

has summation starting at k, i.e. $c_{kn}=0$ for $n<k$. Thus the standard revision of the unordered series

$$\sum_{(n,k)} b_k c_{kn}(x-x_0)^n$$

representing $g\circ f$ is an ordinary revision, not a drastic revision:

$$\sum_{n=0}^{\infty}\left[\left(\sum_{k=0}^{n} b_k c_{kn}\right)(x-x_0)^n\right] \tag{V.4}$$

which must be the Taylor series for $g\circ f$ around x_0.

(iii) If f is $\mathcal{C}^\infty$ on U, g is $\mathcal{C}^\infty$ on V, and $f(U)\subseteq V$, then $g\circ f$ is $\mathcal{C}^\infty$ on U by the Chain Rule. If $x_0\in U$ and the Taylor series for $g\circ f$ around x_0 is calculated using Faà di Bruno's formula (V.3.7.8.), the same power series as in V.4 is obtained, as can be verified by unpleasant direct calculation. In fact, the derivation of this Taylor series in the proof of V.16.3.12. is a good way to derive (but not prove!) Faà di Bruno's formula.

Quotients of Analytic Functions

The next result is an immediate corollary of V.16.3.12., since $g(x)=\frac{1}{x}$ is analytic on $\{x : x\neq 0\}$:

V.16.3.14. Corollary. Let f be analytic on an open set U, with $f(x)\neq 0$ for all $x\in U$. Then $\frac{1}{f}$ is analytic on U.

Combining this with V.16.3.10., we obtain:

V.16.3.15. Theorem. Let f and g be analytic on an open set U, with $g(x)\neq 0$ for all $x\in U$. Then $\frac{f}{g}$ is analytic on U.

Bernstein's Theorem

We prove a theorem obtained by S. Bernstein in 1912, which is at least interesting if not too useful. (Bernstein only stated (ii), but the more precise statements of (i) and (iii) follow easily from his proof.)

V.16.3.16. Theorem. Let $I=(a,b)$ be an open interval in $\mathbb{R}$ (where $a\in\mathbb{R}\cup\{-\infty\}$ and $b\in\mathbb{R}\cup\{+\infty\}$), and let f be a C^∞ function on I. If $f^{(k)}(x)\geq 0$ for all $k\geq 0$ and all $x\in I$, then:

(i) If $x_0\in I$ and $R=b-x_0$ ($R=+\infty$ if $b=+\infty$), then the Taylor series for f around x_0 converges to $f(x)$ for all $x\in I$ with $|x-x_0|<R$. (In particular, the radius of convergence of this Taylor series is at least R.)

(ii) f is analytic on I.

(iii) If $\ell = b - a$ ($\ell = +\infty$ if $b = +\infty$ or $a = -\infty$), then f extends uniquely to an analytic function on $(a - \ell, b)$ (all of $\mathbb{R}$ if $b = +\infty$).

Note, however, that the extension in (iii) does not necessarily have $f^{(k)}(x) \geq 0$ for all k and x: consider $f(x) = x^3$ on $(0, \infty)$.

PROOF: (i): Fix $x_0 \in I$, and fix $x > x_0$. Let $c \in I$ with $c > x$. Let p_n be the n'th Taylor polynomial for f around x_0. We have $p_n(x) \geq 0$ since all the terms in the Taylor series are nonnegative. By the Integral Form of the Remainder (V.10.4.2.), we have

$$R_n(x) = f(x) - p_n(x) = \frac{1}{n!} \int_{x_0}^{x} f^{(n+1)}(t)(x - t)^n \, dt \ .$$

Using two changes of variable ($u = t - x_0$ and $s = \frac{u}{x - x_0}$), we obtain

$$R_n(x) = \frac{1}{n!} \int_0^{x - x_0} f^{(n+1)}(u + x_0)(x - x_0 - u)^n \, du = \frac{(x - x_0)^{n+1}}{n!} \int_0^1 f^{(n+1)}((x - x_0)s + x_0)(1 - s)^n \, ds$$

and, since $f^{(n+1)}$ is nonnegative and nondecreasing ($f^{(n+2)}$ is also nonnegative), we have

$$0 \leq R_n(x) \leq \left(\frac{x - x_0}{c - x_0} \right)^{n+1} \frac{(c - x_0)^{n+1}}{n!} \int_0^1 f^{(n+1)}((c - x_0)s + x_0)(1 - s)^n \, ds = \left(\frac{x - x_0}{c - x_0} \right)^{n+1} R_n(c) \ .$$

We have $R_n(c) = f(c) - p_n(c) \leq f(c)$ since $p_n(c) \geq 0$, so we have

$$0 \leq R_n(x) \leq \left(\frac{x - x_0}{c - x_0} \right)^{n+1} f(c)$$

and thus $R_n(x) \to 0$ as $n \to \infty$, i.e. the Taylor series for f around x_0 converges to $f(x)$.

Now suppose $x \in I$, $x < x_0$, $|x - x_0| < R$. Set $y = x_0 + |x - x_0|$, i.e. $y > x_0$ and $|y - x_0| = |x - x_0|$. By comparison of integrals we have $|R_n(x)| \leq R_n(y)$ since $f^{(n+1)}$ is nondecreasing, so $R_n(x) \to 0$ as $n \to \infty$.

(ii): Immediate from (i).

(iii): If $x_0 > a$ and $R = b - x_0$, then by (i) the Taylor series for f around x_0 defines an analytic function on $(x_0 - R, x_0 + R)$ which agrees with f on I. Let $x_0 \to a+$. (All the extensions defined this way must coincide on the intersections of their domains by V.16.2.1., which also gives the uniqueness of the extension.) 👍

Formal Manipulation of Power Series

V.16.3.17. The results of this section can be used to justify the formal manipulation of power series. For example, suppose we are given analytic functions f and h taking the same value at 0 and we want to find an analytic function g satisfying $g(0) = 0$ and $h = f \circ g$ (we stick to analytic functions around 0 for notational simplicity; more generally, we may take power series centered at other points than 0). Temporarily ignoring questions of convergence, we can proceed formally: write

$$f(x) = \sum_{k=0}^{\infty} a_k x^k$$

$$h(x) = \sum_{k=0}^{\infty} c_k x^k$$

with $a_0 = c_0$. The unknown function

$$g(x) = \sum_{k=1}^{\infty} b_k x^k$$

can be "found" by manipulation of the power series:

$$f(g(x)) = a_0 + a_1(b_1 x + b_2 x^2 + \cdots) + a_2(b_1 x + b_2 x^2 + \cdots)^2 + \cdots$$

We can formally multiply out the last expression to get

$$(b_1 x + b_2 x^2 + \cdots)^2 = b_1^2 x^2 + 2b_1 b_2 x^3 + \cdots$$

and similarly for higher powers. Collecting together like powers of x, we get

$$f(g(x)) = a_0 + a_1 b_1 x + (a_1 b_2 + a_2 b_1^2) x^2 + \cdots$$

and for this to be equal to $h(x)$, we get the equations

$$c_0 = a_0$$

$$c_1 = a_1 b_1$$

$$c_2 = a_1 b_2 + a_2 b_1^2$$

etc., which must be solved for the b_k. It is easy to see exactly when this can be done recursively, and what the (necessarily unique) solution is when it exists.

To justify the formal manipulations, the theorems of this section can be used. In fact, using (), we can show:

V.16.3.18. THEOREM. If the system is solvable for the b_k, and if the power series

$$\sum_{k=1}^{\infty} b_k x^k$$

has a positive radius of convergence, then the function g defined by the series satisfies $h = f \circ g$ in a neighborhood of 0. Conversely, if g is an analytic function in a neighborhood of 0 satisfying $g(0) = 0$ and $h = f \circ g$ in a neighborhood of 0, and

$$g(x) = \sum_{k=1}^{\infty} b_k x^k$$

is its Taylor series around 0, then the b_k satisfy the equations. In particular, g is the unique analytic function with these properties.

V.16.3.19. It is a more delicate matter to find or estimate *how large* a neighborhood of 0 the formula is valid in. In fact, it is valid in the largest open disk around 0 mapped by g into the open disk of convergence of the Taylor series for f around 0.

V.16.4. The Analytic Morse Lemma

V.16.4.1. If f is analytic on an interval I around x_0, and $r_{n-1} = f - p_{n-1}$ is the remainder function, then

$$\lim_{x\to x_0} \frac{r_{n-1}(x)}{(x-x_0)^n} = \frac{f^{(n)}(x_0)}{n!}$$

so if we set

$$g_n(x) = \frac{r_{n-1}(x)}{(x-x_0)^n}\ (x \neq x_0), \quad g_n(x_0) = \frac{f^{(n)}(x_0)}{n!}$$

for $x \in I$, then g_n is continuous on I and analytic on $I \setminus \{x_0\}$, and

$$f(x) = p_{n-1}(x) + (x-x_0)^n g_n(x) = f(x_0) + f'(x_0)(x-x_0) + \cdots + \frac{f^{(n-1)}(x_0)}{(n-1)!}(x-x_0)^{n-1} + (x-x_0)^n g_n(x)$$

for $x \in I$.

V.16.4.2. Proposition. If f is analytic on I, then for each $n \in \mathbb{N}$ g_n is analytic on I.

Proof: Since $r_{n-1} = f - p_{n-1}$, hence also g_n, is analytic on $I \setminus \{x_0\}$, analyticity near x_0 is the only issue. The Taylor series for f around x_0 converges u.c. to f on an open interval $I_0 \subseteq I$, i.e.

$$f(x) = f(x_0) + f'(x_0)(x-x_0) + \cdots + \frac{f^{(n-1)}(x_0)}{(n-1)!}(x-x_0)^{n-1} + \sum_{k=n}^{\infty} \frac{f^{(k)}(x_0)}{k!}(x-x_0)^k$$

for $x \in I_0$, so if we set

$$g_n(x) = \sum_{k=n}^{\infty} \frac{f^{(k)}(x_0)}{k!}(x-x_0)^{k-n}$$

for $x \in I_0$ (the power series converges u.c. to an analytic function on I_0), then

$$f(x) = f(x_0) + f'(x_0)(x-x_0) + \cdots + \frac{f^{(n-1)}(x_0)}{(n-1)!}(x-x_0)^{n-1} + (x-x_0)^n g_n(x)$$

for $x \in I_0$, and g_n is analytic on I_0. 👍

The Analytic One-Dimensional Morse Lemma

V.16.4.3. If f is analytic in an interval around x_0, $f(x_0) = c$, and $f'(x_0) = \cdots = f^{(m-1)}(x_0) = 0$ but $f^{(m)}(x_0) \neq 0$, then $f(x)$ is approximately $p_m(x) = c + d(x-x_0)^m$ for x near x_0, where d is a constant ($d = \frac{f^{(m)}(x_0)}{m!}$). But we can say more: up to an analytic change of coordinates, f is *exactly* of this form, and we can even take $d = \pm 1$.

V.16.4.4. Theorem. [Analytic Generalized One-Dimensional Morse Lemma] Let $m \in \mathbb{N}$, and let f be analytic on an interval I around x_0, with $f(x_0) = c$ and $f'(x_0) = \cdots = f^{(m-1)}(x_0) = 0$ but $f^{(m)}(x_0) \neq 0$. Then there is an analytic order-preserving diffeomorphism ϕ from an open interval J around 0 onto an open interval $\tilde{I}$ around x_0, with $\phi(0) = x_0$, such that

$$[f \circ \phi](t) = c \pm t^m$$

for all $t \in J$, where the sign is the sign of $f^{(m)}(x_0)$.

Proof: By V.16.4.2., for $x \in I$ f can be written $f(x) = c + (x - x_0)^m g_m(x)$ with $g_m(x_0) = d \neq 0$. Thus there is an open interval $K \subseteq I$ around x_0 on which g_m is nonzero. For $x \in \tilde{I}$, set

$$\psi(x) = (x - x_0)h(x)$$

where

$$h(x) = |g_m(x)|^{1/m} .$$

Then h, hence ψ, is an analytic function on K since $\rho(x) = |x|^{1/m}$ is analytic on $\mathbb{R} \setminus \{0\}$, $\psi(x_0) = 0$, and

$$\psi'(x) = h(x) + (x - x_0)h'(x) .$$

Since h' is bounded near x_0 and $h(x_0) > 0$, there is an open interval $\tilde{I}$ around x_0 on which $\psi' > 0$. Thus ψ maps $\tilde{I}$ diffeomorphically onto an open interval J containing 0. Let $\phi : J \to \tilde{I}$ be the inverse function. Then ϕ is also analytic by the Inverse Function Theorem (). If $t = \psi(x) \in J$, then

$$[f \circ \phi](t) = f(x) = c + (x - x_0)^m g_m(x) = c \pm [(x - x_0)h(x)]^m = c \pm \psi(x)^m = c \pm t^m .$$

The classical one-dimensional Morse Lemma (due to Marston Morse) is the case $m = 2$:

V.16.4.5. Corollary. [Analytic One-Dimensional Morse Lemma] Let f be analytic on an interval I around x_0, with $f(x_0) = c$ and $f'(x_0) = 0$ but $f''(x_0) \neq 0$. Then there is an analytic order-preserving diffeomorphism ϕ from an open interval J around 0 onto an open interval $\tilde{I}$ around x_0, with $\phi(0) = x_0$, such that

$$[f \circ \phi](t) = c \pm t^2$$

for all $t \in J$, where the sign is the sign of $f''(x_0)$.

V.16.4.6. If we allow ϕ to be orientation-reversing, if m is odd we can always take the + sign in the conclusion. But if m is even (in particular, if $m = 2$), the sign does not depend on the orientation of ϕ.

V.17. Smooth Non-Analytic Functions

A striking and important phenomenon is that a smooth (C^∞) function on an interval I need not be analytic on I; in fact, it can be "completely nonanalytic" on I. In this section we describe various ways in which a smooth function can be nonanalytic.

This is a topic in which the fairly extensive work over a rather long period of time does not seem to be widely known in the mathematical community (e.g. the author only rather recently became aware of it). It is remarkable how often the basic results and examples (with slight variations) have been rediscovered, reproved, and republished. Only variations of Cauchy's original example, and Borel's Theorem, have apparently become standard knowledge among mathematicians. For an extensive survey of the work done in this area, see http://mathforum.org/kb/message.jspa?messageID=387148 .

V.17.1. Analyticity at a Point

The definition of an analytic function (V.16.1.1.) only defines analyticity on an open interval in $\mathbb{R}$ (or an open set in $\mathbb{C}$). It is useful to make the following definition of "analyticity at a point."

V.17.1.1. Definition. Let I be an interval in $\mathbb{R}$, and $x_0 \in I$. A real-valued C^∞ function f on I is *analytic at* x_0 if the Taylor series of f around x_0 converges to f in some relatively open subinterval of I containing x_0 (an open interval if x_0 is an interior point of I). A point where f is not analytic is called a *singular point* of f.

The next result, an immediate corollary of V.16.1.6., is fundamental:

V.17.1.2. Proposition. Let $f \in C^\infty(I)$. The set

$$A_f = \{x_0 \in I : f \text{ is analytic at } x_0\}$$

is relatively open in I.

Thus the set of singular points of f is a relatively closed subset of I. (It is not yet clear that this set can be nonempty.)

Types of Singular Points

V.17.1.3. If f is C^∞ on I and $x_0 \in I$, there are two potential ways f can fail to be analytic at x_0:

(i) The Taylor series of f around x_0 has radius of convergence zero. Such a point is sometimes called a *divergence point* of f. In [Zah47], such points are called *points of type (P)*, or *(P)-points* (for Pringsheim).

(ii) The Taylor series of f around x_0 has positive radius of convergence, but does not represent the function on any interval around x_0. Such a point is sometimes called a *false convergence point* of f. The name from [Zah47] is *point of type (C)*, or *(C)-point* (for Cauchy).

V.17.1.4. Thus, if f is C^∞ on I, I decomposes as the disjoint union of the set A_f of points where f is analytic, the set P_f of the (P)-points of f, and the set C_f of the (C)-points of f. A_f is (relatively) open by V.17.1.2., so $P_f \cup C_f$ is (relatively) closed.

V.17.2. (C)-Points and Smooth Partitions

V.17.2.1. The first example of a (C)-point, the best-known example in this subject, was given by Cauchy in 1823.

V.17.2.2. Example. Let

$$f(x) = \begin{cases} e^{-1/x^2} & \text{if} \quad x \neq 0 \\ 0 & \text{if} \quad x = 0 \end{cases} .$$

Then f is clearly analytic on $\mathbb{R} \setminus \{0\}$. On $\mathbb{R} \setminus \{0\}$, it can easily be shown by induction on k () that $f^{(k)}(x)$ is a finite sum of terms of the form $c\frac{e^{-1/x^2}}{x^m}$ for $c \in \mathbb{R}$, $m \in \mathbb{N} \cup \{0\}$. Thus, since $f(0) = 0$, we have by induction that $f^{(k)}(0)$ exists and is 0 for all k (cf. V.10.7.8.).

So f is infinitely differentiable also at 0, thus C^∞ on $\mathbb{R}$. The Taylor series at 0 (Maclaurin series) for f has all terms zero, and thus has infinite radius of convergence. But it does not converge to $f(x)$ for any $x \neq 0$ since $f(x) > 0$ for $x \neq 0$. Thus 0 is a (C)-point of f and f is not analytic at 0. See Figure (). See XII.5.2.17.(ii) for an "explanation" of why the function is not analytic at 0.

V.17.2.3. This example is usually presented with an exponent of $-\frac{1}{x^2}$, but this is just somewhat a matter of taste. Identical arguments show that each of the following functions has the same properties:

$$f_2(x) = \begin{cases} e^{-1/|x|} & \text{if} \quad x \neq 0 \\ 0 & \text{if} \quad x = 0 \end{cases}$$

$$f_3(x) = \begin{cases} e^{-1/x} & \text{if} \quad x > 0 \\ 0 & \text{if} \quad x \leq 0 \end{cases}$$

$$f_4(x) = \begin{cases} e^{-1/x^2} & \text{if} \quad x > 0 \\ 0 & \text{if} \quad x \leq 0 \end{cases}$$

i.e. each of these is C^∞ on $\mathbb{R}$, analytic on $\mathbb{R} \setminus \{0\}$, and has a (C)-point at 0 where its Taylor series is identically 0. Any of these can be called "Cauchy's example." The last two have the interesting property that they are identically zero on the negative real axis. Note that all these examples take values in $[0, 1)$, and are in particular bounded.

Smooth Bump Functions

We can combine translates of these functions to make smooth "bump functions" which are identically zero outside a specified interval:

V.17.2.4. Example. Let $a, b \in \mathbb{R}$, $a < b$. Define

$$g_{a,b}(x) = f_3(x-a)f_3(b-x) = \begin{cases} e^{-\frac{b-a}{(x-a)(b-x)}} & \text{if} \quad a < x < b \\ 0 & \text{if} \quad x \leq a \text{ or } x \geq b \end{cases} .$$

Then g is C^∞ on $\mathbb{R}$, analytic on $\mathbb{R} \setminus \{a, b\}$, has (C)-points at a and b where its Taylor series is identically zero, and is positive on (a, b) and identically zero on $\mathbb{R} \setminus (a, b)$. See Figure ().

Smooth Heaviside Functions

V.17.2.5. The function

$$\phi(x) = \int_a^x g_{a,b}(t)\,dt$$

is C^∞ on $\mathbb{R}$, analytic on $\mathbb{R} \setminus \{a, b\}$, identically 0 for $x \leq a$, takes a constant positive value for $x \geq b$, and is strictly increasing on $[a, b]$. A suitable scalar multiple $h_{a,b}$ has the same properties and is identically 1 for $x \geq b$. This can be regarded as a smooth version of the Heaviside function $\chi_{[b,\infty)}$. See Figure ().

Smooth Mesa Functions

V.17.2.6. Let $a < b < c < d$, and let f be the function

$$f(x) = h_{a,b}(x)(1 - h_{c,d}(x)) \ .$$

Then f is C^∞ on $\mathbb{R}$, analytic on $\mathbb{R} \setminus \{a, b, c, d\}$, identically 0 on $(-\infty, a]$ and on $[d, +\infty)$, identically 1 on $[b, c]$, strictly increasing on $[a, b]$, and strictly decreasing on $[c, d]$. See Figure ().

Smooth Partitions of Unity

Recall the definition of partition of unity (). We will show that on $\mathbb{R}$, smooth partitions of unity exist:

V.17.2.7. THEOREM. Let $\mathcal{U}$ be an open cover of $\mathbb{R}$. Then there is a countable partition of unity $\{f_n\}$ subordinate to $\mathcal{U}$ consisting of C^∞ functions of compact support.

PROOF: This is an easy consequence of (). There is a collection $\mathcal{V} = \{(a_n, b_n) : n \in \mathbb{Z}\}$ of bounded open intervals refining $\mathcal{U}$ such that $a_n < b_{n-1} < a_{n+1} < b_n$ for all n. Take f_n to be the smooth mesa function

$$f_n = h_{a_n,b_{n-1}}(1 - h_{a_{n+1},b_n})$$

defined in V.17.2.6. and V.17.2.5.. 👍

Smooth Functions With Prescribed Zero Sets

V.17.2.8. If f is a continuous function, then its *zero set*

$$Z_f = \{x : f(x) = 0\}$$

is always closed. We now show that every closed subset of $\mathbb{R}$ is the zero set of a smooth function. This is in stark contrast to the situation for analytic functions, where the zero set is either discrete or all of $\mathbb{R}$ (). For a simple example of a $\mathcal{C}^\infty$ function with a nonisolated zero, see Exercise V.17.5.1..

V.17.2.9. THEOREM. Let E be a closed subset of $\mathbb{R}$. Then there is a nonnegative bounded $\mathcal{C}^\infty$ function θ on $\mathbb{R}$ for which $Z_\theta = E$ and θ is analytic on $\mathbb{R} \setminus E$.

PROOF: There is a simple and appealing argument that almost works to prove this result, which can be adapted to give a real proof. The open set $U = \mathbb{R} \setminus E$ is a countable disjoint union of open intervals I_n. For each n, we can take a smooth bump function f_n which is nonzero exactly on I_n (if I_n is unbounded, take a translation of the f_3 of V.17.2.3. or its reflection instead of a bump function). Define θ to be f_n on I_n and 0 on E. Alternately, define $\theta = \sum_{n=1}^{\infty} f_n$; the series converges for each x since at most one term is nonzero.

However, there is a problem with this approach. Since the set of endpoints of the I_n is not closed and discrete in general (e.g. consider the case where E is the Cantor set), the sum of the series will not even be continuous in general unless the heights of the bumps are controlled.

We can do this as follows. The complement of E consists of at most a countable number of bounded open intervals $I_n = (a_n, b_n)$, plus possibly one or two unbounded open intervals we will deal with separately at the end of the argument. We may assume there are infinitely many I_n since otherwise a finite sum of bump functions works for f. Let $g = g_{0,1}$ be the smooth bump function of V.17.2.4., normalized so that $\max(g(x)) = 1$, and for each $k \geq 0$ let $M_k = \max |g^{(k)}|$. Let g_n be g translated to I_n, i.e.

$$g_n(x) = g\left(\frac{x - a_n}{b_n - a_n}\right)$$

for $x \in \mathbb{R}$. Set $f_n = c_n g_n$, where

$$c_n = \frac{\min(1, (b_n - a_n)^n)}{2^n \left(\max_{0 \leq k \leq n} M_k\right)} .$$

Then f_n is $\mathcal{C}^\infty$ on $\mathbb{R}$, and $|f_n^{(k)}(x)| \leq 2^{-n}$ for $0 \leq k \leq n$ and all $x \in \mathbb{R}$. Thus

$$\sum_{n=1}^{\infty} f_n^{(k)}$$

converges uniformly on $\mathbb{R}$ for each k. If $\theta = \sum_{n=1}^{\infty} f_n$, then by V.15.1.6. (the simpler version suffices), θ is $\mathcal{C}^\infty$ on $\mathbb{R}$ and $\theta^{(k)} = \sum_{n=1}^{\infty} f_n^{(k)}$ for all k. The function θ takes values in $[0, 1]$, and is clearly zero precisely on E and any unbounded intervals in E^c. There will be such an unbounded interval if and only if E has a minimum element a and/or a maximal element b. If there is such a b, adding to f a translated version of Cauchy's example f_3 makes θ positive on $(b, +\infty)$. A similar correction can be made on $(-\infty, a)$ if a exists. Since, for each $x \in E^c$, θ is equal to f_n for some n (or a translated Cauchy function) on a neighborhood of x, θ is analytic at x. 👍

The Smooth Urysohn Lemma

With somewhat more work along the same lines, we can get a smooth version of Urysohn's Lemma () for $\mathbb{R}$:

V.17.2.10. THEOREM. [SMOOTH URYSOHN LEMMA FOR $\mathbb{R}$] Let A be a closed subset of $\mathbb{R}$ and U an open set in $\mathbb{R}$ containing A. Then there is a C^∞ function ϕ from $\mathbb{R}$ to $[0, 1]$ such that $\phi \equiv 1$ on A and $\phi \equiv 0$ on $\mathbb{R} \setminus U$. We may choose ϕ so that $\phi^{-1}(\{1\}) = A$ and $\phi^{-1}(\{0\}) = \mathbb{R} \setminus U$.

Alternatively, if E and F are disjoint closed subsets of $\mathbb{R}$, there is a smooth function $\phi : \mathbb{R} \to [0,1]$ such that $\phi^{-1}(\{1\}) = E$ and $\phi^{-1}(\{0\}) = F$ (set $A = E$ and $U = \mathbb{R} \setminus F$).

PROOF: We prove the alternative form. Let E and F be disjoint closed subsets of $\mathbb{R}$. Then the open set $V = \mathbb{R} \setminus (E \cup F)$ is a countable disjoint union of open intervals, at most two of which are unbounded. Let $\{(a_i, b_i) : i \in I\}$ be the set of bounded intervals in this union such that $a_i \in E$ and $b_i \in F$, and let $\{(c_j, d_j) : j \in J\}$ be the set of bounded intervals in the collection with $c_j \in F$ and $d_j \in E$. Then I and J are countable. Between any two a_i there must be at least one of the intervals (c_j, d_j), and similarly for the other combinations.

Let $L_E = \{a_i : i \in I\}$, $L_F = \{c_j : j \in J\}$, $R_E = \{d_j : j \in J\}$, $R_F = \{b_i : i \in I\}$. L_E is countable; we claim it is closed and discrete in $\mathbb{R}$. If not, there is a sequence (a_{i_n}) in L_E of distinct points converging to some $x \in \mathbb{R}$, and passing to a subsequence we may assume that the sequence is strictly monotone (). Since each $a_{i_n} \in E$, $x \in E$. If (a_{i_n}) is strictly monotone, we also have $b_{i_n} \to x$ since b_{i_n} is between $a_{i_{n-1}}$ and $a_{i_{n+1}}$, so $x \in F$, contradicting that E and F are disjoint. Thus L_E is closed and discrete. By similar arguments, L_F, R_E, R_F are all closed and discrete in $\mathbb{R}$. Thus $L_E \cup L_F \cup R_E \cup R_F$ is also closed and discrete, i.e. there are only finitely many points in any bounded interval.

Thus the endpoints of the intervals can be reindexed $\{(a_k, b_k), (c_k, d_k) : k \in \mathbb{Z}\}$, where

$$a_k < b_k < c_k < d_k < a_{k+1}$$

for all k. If V contains an unbounded interval on either side, the indexing on that side will be finite. Define ϕ separately on each of the subintervals of $\mathbb{R}$ so defined. On $[b_k, a_{k+1}]$, let ϕ be the smooth Heaviside function h_{c_k,d_k} (V.17.2.5.), and on $[d_{k-1}, c_k]$ let ϕ be $1 - h_{a_k,b_k}$. Note that these definitions coincide on the overlaps of the intervals. If there is an unbounded interval to $+\infty$ in V, let ϕ be h_{c_k,d_k} on $[b_k, +\infty)$ if (c_k, d_k) is the last bounded interval, and $1 - h_{a_k,b_k}$ on $[d_{k-1}, +\infty)$ if (a_k, b_k) is the last bounded interval; define ϕ analogously if V has an unbounded interval to $-\infty$. Since the endpoints of the intervals form a closed discrete set, the ϕ so defined is a C^∞ function from $\mathbb{R}$ to $[0,1]$ which is identically 1 on E and 0 on F.

This ϕ, however, does not necessarily have the property that $\phi^{-1}(\{1\}) = E$ and $\phi^{-1}(\{0\}) = F$. We can obtain this property by a trick. Let θ be a C^∞ function from $\mathbb{R}$ to $[0,1)$ such that $\theta = 0$ precisely on $E \cup F$ (V.17.2.9.). Then $\psi_1 = \phi(1 - \theta)$ is a C^∞ function from $\mathbb{R}$ to $[0,1]$ which is 0 on F and which is 1 precisely on E. Similarly, $\psi_2 = 1 - (1 - \phi)(1 - \theta)$ is a C^∞ function from $\mathbb{R}$ to $[0,1]$ which is 1 on E and 0 precisely on F. Then $\psi = \frac{1}{2}(\psi_1 + \psi_2)$ is a C^∞ function from $\mathbb{R}$ to $[0,1]$ which is 1 precisely on E and 0 precisely on F. 👍

Multivariable Versions

V.17.2.11. There are versions of all these examples and results for real-valued functions on $\mathbb{R}^n$ (VIII.4.2.).

V.17.3. (P)-Points and Borel's Theorem

The first example of a (P)-point was apparently obtained by CELLÈRIER in the early 1860's, only published posthumously in 1890 (Exercise ()). The first published example was by DU BOIS-REYMOND in 1876 (Exercise ()).

Some specific examples of (P)-points will be given in (). In this subsection we will be primarily concerned with a striking theorem of E. BOREL from 1895, which provides (P)-points in profusion. The theorem can be stated in two equivalent ways.

V.17.3.1. THEOREM. Let $(a_k)_{k\geq 0}$ be any sequence of real numbers. Then there is a C^∞ function on $\mathbb{R}$ whose Taylor series around 0 (Maclaurin series) is

$$\sum_{k=0}^{\infty} a_k x^k \ .$$

V.17.3.2. COROLLARY. Let $(b_k)_{k\geq 0}$ be any sequence of real numbers. Then there is a C^∞ function f on $\mathbb{R}$ such that $f^{(k)}(0) = b_k$ for all k.

The two statements are equivalent by setting $b_k = k!a_k$.

We first give a simple proof from [Mir56] (the same proof works in the multidimensional case ()). Then we will give another argument giving an example with additional analyticity properties.

PROOF: Fix a smooth mesa function g such that g is supported on $(-1, 1)$, and for each n let M_n be a bound on $g^{(n)}$. Note that $g^{(n)}(0) = 0$ for all $n > 0$ since g is constant on an interval around 0. For $k \geq 0$ define

$$f_k(x) = a_k x^k g(c_k x)$$

where (a_k) is the given sequence and (c_k) is a sequence of natural numbers to be chosen later. Then f_k is C^∞ on $\mathbb{R}$, and by the higher product rule () and the chain rule for the g factors,

$$f_k^{(n)}(x) = \sum_{m=0}^{n} \binom{n}{m} k(k-1)\cdots(k-n+m+1) a_k c_k^m x^{k-n+m} g^{(m)}(c_k x)$$

for all n (the product $k(k-1)\cdots(k-n+m+1)$ is 1 if $m = n$). In particular, we have

$$f_k^{(k)}(0) = \sum_{m=0}^{k} \binom{k}{m} k(k-1)\cdots(m+1) a_k c_k^m 0^m g^{(m)}(0) = k!a_k = b_k$$

and $f_k^{(n)}(0) = 0$ if $n \neq k$ (for $n > k$, note that $f_k^{(n)}$ is identically 0 in a neighborhood of 0). Since $f_k(x) = 0$ for all x with $|x| \geq \frac{1}{c_k}$, we have

$$|f_k^{(n)}(x)| \leq \sum_{m=0}^{n} \binom{n}{m} k(k-1)\cdots(k-n+m+1) a_k c_k^m c_k^{-k+n-m} M_m$$

$$\leq \frac{1}{c_k} \sum_{m=0}^{n} \binom{n}{m} k(k-1)\cdots(k-n+m+1) a_k M_m$$

for $0 \leq n < k$ and all x, and thus by choosing c_k sufficiently large we obtain that

$$|f_k^{(n)}(x)| \leq 2^{-k}$$

for $0 \le n < k$ and all x. Thus the series

$$\sum_{k=0}^{\infty} f_k^{(n)}$$

converges uniformly on $\mathbb{R}$ for every $n \ge 0$ by the M-test. So the function

$$f = \sum_{k=0}^{\infty} f_k$$

is C^∞ on $\mathbb{R}$ and

$$f^{(n)} = \sum_{k=0}^{\infty} f_k^{(n)}$$

for every n by (). In particular, $f^{(n)}(0) = b_n$ for all n. 👍

V.17.3.3. To obtain an example of a smooth function with a (P)-point, apply the theorem with a sequence $a_k \to +\infty$ rapidly, e.g. $a_k = k!$.

V.17.3.4. Note that the example constructed in the above proof is analytic except on a countable set; in fact, if $x_0 \neq 0$ and U is an open neighborhood of x_0 bounded away from 0, then all but finitely many of the terms in the series are identically zero on U. Thus this theorem is strictly a single-point result.

We can in fact improve this result to make f analytic on all of $\mathbb{R} \setminus \{0\}$. This result is due to Besicovitch [Bes24].

V.17.3.5. Theorem. Let (b_k) be an arbitrary sequence of real numbers. Then there is a real-valued function f, C^∞ on $[0, +\infty)$ and analytic on $(0, +\infty)$, with $f^{(k)}(0) = b_k$ for all k (these are one-sided derivatives).

Proof: [KP02b, Lemma 2.2.4] Define

$$f_0(x) = \frac{1}{\sqrt{c_0 + x}}$$

and for each $k \ge 1$, define

$$f_k(x) = \int_0^x \int_0^{t_{k-1}} \cdots \int_0^{t_1} \frac{1}{\sqrt{c_k + t}}\, dt\, dt_1 \cdots dt_{k-1}$$

where the c_k are positive real numbers which will be chosen later, i.e. f_k is the unique function such that $f_k^{(k)}(x) = \frac{1}{\sqrt{c_k + x}}$ and $f_k^{(n)}(0) = 0$ for $0 \le n < k$. For each k, f_k is C^∞ on $(-c_k, +\infty)$.

Fix $N > 1$. If $0 \le x \le N$, we have, for $0 \le n < k$,

$$0 \le f_k^{(n)}(x) \le \int_0^N \int_0^{t_{k-n-1}} \cdots \int_0^{t_1} \frac{1}{\sqrt{t}}\, dt\, dt_1 \cdots dt_{k-n-1} = \frac{N^{k-n-1/2}}{\frac{1}{2}\frac{3}{2}\cdots\frac{2(k-n)-1}{2}} < \frac{2N^{k-n}}{(k-n-1)!}$$

and so the series

$$\sum_{k=0}^{\infty} \sigma_k f_k^{(n)}$$

converges uniformly on $[0, N]$ for every $n \geq 0$ and any choice of $\sigma_k = -1, 0, 1$ by the M-test. Thus, for any such choice of σ_k, we have that

$$f = \sum_{k=0}^{\infty} \sigma_k f_k$$

is C^∞ on $[0, \infty)$ and for each n,

$$f^{(n)} = \sum_{k=0}^{\infty} \sigma_k f_k^{(n)}$$

by (). We also have, for $\epsilon > 0$,

$$|f^{(n)}(x)| \leq \sum_{k=0}^{n} \frac{2}{(c_k + \epsilon)^{k+1/2}} + \sum_{k=n+1}^{\infty} \frac{2N^{k-n}}{(k-n-1)!} \leq 2(n+1)\left(\frac{1}{\epsilon}\right)^{n+1} + 2e^N$$

for $\epsilon \leq x \leq N$, so by () f is analytic on $(0, \infty)$.

The above results hold for any choice of c_k and σ_k. We need only show that these can be chosen so that $f^{(k)}(0) = b_k$ for all k. Since $f_k^{(n)}(0) = 0$ if $0 \leq n < k$, we must solve the equations

$$b_0 = \sigma_0 \frac{1}{c_0^{1/2}}$$

$$b_1 = -\frac{1}{2}\sigma_0 \frac{1}{c_0^{3/2}} + \sigma_1 \frac{1}{c_1^{1/2}}$$

$$b_2 = \frac{1}{2} \cdot \frac{3}{2}\sigma_0 \frac{1}{c_0^{5/2}} - \frac{1}{2}\sigma_1 \frac{1}{c_1^{3/2}} + \sigma_2 \frac{1}{c_2^{1/2}}$$

$$\cdots$$

We may solve these successively. If $b_0 = 0$, set $\sigma_0 = 0$ and $c_0 = 1$; otherwise, set $\sigma_0 = \frac{b_0}{|b_0|}$ and $c_0 = |b_0|^{-2}$. Then set σ_1 equal to $1, -1, 0$ depending whether

$$b_1 + \frac{1}{2}\sigma_0 \frac{1}{c_0^{3/2}}$$

is positive, negative, or 0, and then c_1 is determined from the previous choices. This process can clearly be continued indefinitely. 👍

As a corollary, we get a two-sided version which improves Borel's result:

V.17.3.6. Corollary. Let (b_k) be an arbitrary sequence of real numbers. Then there is a real-valued function f, C^∞ on $\mathbb{R}$ and analytic on $\mathbb{R} \setminus \{0\}$, with $f^{(k)}(0) = b_k$ for all k.

Proof: Let f be as in the Theorem for the sequence (b_k), and g as in the theorem for the sequence $((-1)^k b_k)$. Extend f to $\mathbb{R}$ by setting $f(x) = g(-x)$ for $x < 0$. The extended f is C^∞ at 0. 👍

We now obtain the main result of [Bes24], that the derivatives of a C^∞ function can be independently specified at two points with the function analytic in between:

V.17.3.7. Theorem. Let (a_k) and (b_k) be arbitrary sequences of real numbers. Then there is a real-valued function f, C^∞ on $\mathbb{R}$ and analytic on $\mathbb{R} \setminus \{0, 1\}$, such that $f^{(k)}(0) = a_k$ and $f^{(k)}(1) = b_k$ for all k.

Proof: Let $h(x) = h_{0,1}$ be the smooth Heaviside function from V.17.2.5.. Let g_0 and g_1 be functions as in V.17.3.6. for the sequences (a_k) and (b_k) respectively, and set

$$f_0(x) = g_0(x)(1 - h(x))$$
$$f_1(x) = g_1(x - 1)h(x)$$

and $f = f_0 + f_1$. Then f_0, f_1, f are C^∞ on $\mathbb{R}$ and analytic on $\mathbb{R} \setminus \{0, 1\}$. We have that $f_0^{(k)}(0) = a_k$ and $f_0^{(k)}(1) = 0$ for all k, and $f_1^{(k)}(0) = 0$ and $f_1^{(k)}(1) = b_k$ for all k. Thus f is the desired function. 👍

V.17.4. Everywhere Nonanalytic Functions

There are smooth functions on an interval I which are not analytic anywhere. By V.17.1.2., these are precisely the functions f for which the set $C_f \cup P_f = I$. Since $C_f \cup P_f$ is closed in I, to find examples it suffices to find f's for which C_f or P_f is dense in I. (It turns out that for any such example, P_f must be dense in I (V.17.4.10.), but this is often not easy to explicitly verify.)

V.17.4.1. There are two standard methods for constructing smooth functions which are not analytic anywhere, both involving infinite series. The first is to take a smooth function g which is not analytic at one, or a few, points, such as Cauchy's example, and form a sum of the form

$$f(x) = \sum_{n=1}^{\infty} c_n g(x - r_n)$$

where the r_n form a dense sequence (e.g. an enumeration of $\mathbb{Q}$) and $c_n \to 0$ rapidly, or some variation of this involving translation and scaling of g. This method is called the method of *condensation of singularities*.

The other method is to consider an infinite sum of the form

$$\sum_{n=1}^{\infty} c_n \cos(\lambda_n x)$$

(sin can be used instead of cos) where $c_n \to 0$ rapidly, $\lambda_n \to \infty$ rapidly, and there are appropriate relations between the c_n and λ_n. The first example of a function with a dense set of (P)-points was a function of this second kind due to Cellèrier in the 1860's (Exercise ()). We give a nice example of this sort in V.17.4.3.. (Caution: there is an example of this kind on Wikipedia which is not correct.) ✋

The Fabius Function

V.17.4.2. EXAMPLE. Perhaps the nicest example of a C^∞ function which is not analytic anywhere is the *Fabius function* [Fab66], which has a dense set of (C)-points. Although there is no closed form formula or even simple infinite series of functions which defines this function, there are at least two nice characterizations.

FABIUS defined the function probabilistically. Let (ξ_n) be a sequence of independent nonnegative uniformly distributed random variables on $[0,1]$ with range $[0,1]$. Then the Fabius function $F(t)$ is the distribution function for the random variable

$$\sum_{n=1}^{\infty} 2^{-n}\xi_n \ .$$

This can be described as the process of choosing a number x_1 randomly in $\left[0,\frac{1}{2}\right]$, a number $x_2 \in \left[0,\frac{1}{4}\right]$, ..., $x_n \in [0,2^{-n}]$, ..., then adding them up; $F(t)$ is the probability that $\sum_{n=1}^{\infty} x_n \le t$.

See e.g. http://www.math.osu.edu/~edgar/selfdiff/ for the graph of F.

This function can be shown to have the following properties, which give an alternate characterization:

(i) $0 \le F(t) \le 1$ for $0 \le t \le 1$; $F(0) = 0$, $F(1) = 1$, and F is strictly increasing on $[0,1]$.

(ii) $F(1-t) = 1 - F(t)$ for $0 \le t \le 1$.

(iii) F is differentiable on $[0,1]$ and $F'(t) = 2F(2t)$ for $0 \le t \le \frac{1}{2}$.

It then follows from (ii) that $F'(t) = F'(1-t) = 2F(2-2t)$ for $\frac{1}{2} \le t \le 1$.

We can then extend F to $[1,2]$ by setting $F(t) = F(2-t)$ for $1 \le t \le 2$. Extension beyond $[0,2]$ can be done by iterating, with or without reflection across the x-axis. It is customary to extend F to $[2,4]$ by setting $F(t) = -F(t-2)$ for $2 \le t \le 4$. We then successively extend F to $[0,+\infty)$ by setting $F(t) = -F(t-2^n)$ for $2^n \le t \le 2^{n+1}$. We have that $F(t) = \frac{1}{2}F'\left(\frac{t}{2}\right)$ for $0 \le t \le 2$; in particular, the extended F is differentiable at 0, 1, and 2 and $F'(0) = F'(1) = F'(2) = 0$. So F is differentiable everywhere and $F'(t) = 2F(2t)$ for all $t \in [0,+\infty)$. It follows that F is C^∞ on $[0,+\infty)$ and $F^{(n)}(t) = 2^{\sigma(n)}F(2^n t)$ for all n and t, where

$$\sigma(n) = \sum_{k=1}^{n} k = \frac{n(n+1)}{2} \ .$$

F can be extended to be C^∞ on all of $\mathbb{R}$ by setting $F(-t) = F(t)$ or $F(-t) = -F(t)$ (there seems to be no convention). Thus the graph of $F^{(n)}$ is similar to the graph of F, stretched vertically by a factor of $2^{\sigma(n)}$ and compressed horizontally by a factor of 2^n. See Figure () for the graph of F'.

However, F is not analytic anywhere. For if $t_0 = \frac{k}{2^m}$ is a dyadic rational number, it follows that $2^m t_0 \in \mathbb{Z}$, so $F^{(n)}(t_0) = 0$ for $n > m$. Thus the Taylor series for $F^{(n)}$ around t_0 has all terms zero except possibly the constant term. This series therefore has infinite radius of convergence, but represents $F^{(n)}$ only for $t = t_0$ since $F^{(n)}$ is not constant on any interval by (i). So by working backwards, the Taylor series for F around t_0 has infinite radius of convergence (it is a polynomial), but represents F only at t_0. So every dyadic rational is a (C)-point for F, i.e. F has a dense set of (C)-points..

Smooth Functions With Only (P)-Points

The following example of a smooth function with only (P)-points is from http://mathoverflow.net/questions/43462/existence-of-a-smooth-function-with-nowhere-converging-taylor-series-at-every-poi/81465#81465. This is a specific instance of a general class of examples from [SZ55]. The first example of this kind was given by H. Cartan in 1940 [Car40].

V.17.4.3. Example. Let

$$f_n = (n!)^{-3n+2}\cos((n!)^3 x)$$

which has the following properties:

(i) $|f_n^{(k)}(x)| \le \frac{1}{n!}$ for all x if $0 \le k \le n-1$.

(ii) $[f_n^{(n)}(x)]^2 + [f_n^{(n+1)}(x)]^2 \ge (n!)^4$ for all x; hence $\max(|f_n^n(x)|, |f_n^{(n+1)}(x)|) \ge \frac{1}{2}(n!)^2$ for all x (a better constant can be obtained, but this is sufficient for the argument).

We will inductively choose a sequence (n_m) so that, if $f = \sum_{m=1}^{\infty} f_{n_m}$, f is C^∞ and the Taylor series of f around any x_0 has radius of convergence zero. We need to insure that at least some of the derivatives of f increase rapidly in size at every x.

First note that however the n_m are chosen (strictly increasing), the resulting f will be C^∞ and its derivatives will be given by successive term-by-term differentiation. For the k'th term-by-term derived series is dominated by the series

$$\sum_{n=1}^{\infty}(n!)^{-3n+2+3k}$$

which obviously converges for each k, so the k'th derived series converges uniformly on $\mathbb{R}$ by the M-test, and we can apply (). Also note that if $r > k$, we have, for all x,

$$\sum_{n=r}^{\infty}|f_n^{(k)}(x)| \le \sum_{n=r}^{\infty}\frac{1}{n!}$$

which is a tail sum for the Maclaurin series for e^1, so by Taylor's Theorem we have, for some $c < 1$,

$$\sum_{n=r}^{\infty}|f_n^{(k)}(x)| \le \frac{e^c}{r!} < \frac{e}{r!}\ .$$

Let $n_1 = 1$. Suppose $n_1, \ldots, n_r$ have been chosen. Let $g(x) = \sum_{m=1}^{r} f_{n_m}(x)$. Then the Maclaurin series for g converges to g on all of $\mathbb{R}$, and g is periodic, so there is a constant C such that $|g^{(k)}(x)| \le C(k+1)!$ for all k and all $x \in \mathbb{R}$ (). Choose $n \ge n_r + 2$ large enough that $C(n+2)! < \frac{1}{4}(n!)^2$, and set $n_{r+1} = n$. This completes the inductive construction of the n_m.

Fix r and let $k = n_r$. Set $g = \sum_{m=1}^{r-1} f_{n_m}$ and $h = \sum_{m=r+1}^{\infty} f_{n_m}$. Then $f = f_k + g + h$. We have

$$\max(|f^{(k)}(x)|, |f^{(k+1)}(x)|) \ge \max(|f_k^{(k)}(x)|, |f_k^{(k+1)}(x)|) - \max(|g^{(k)}(x)|, |g^{(k+1)}(x)|) - \max(|h^{(k)}(x)|, |h^{(k+1)}(x)|)$$

$$\geq \frac{1}{2}(k!)^2 - C(k+2)! - \frac{1}{k!} \geq \frac{1}{5}(k!)^2$$

for any x, and so it follows that, for any x_0,

$$\limsup_{k\to\infty} \left| \frac{f^{(k)}(x_0)}{k!} \right|^{1/k} \geq \lim_{k\to\infty} \left[\frac{(k!)^2}{5(k+1)!} \right]^{1/k} = \lim_{k\to\infty} \frac{(k!)^{1/k}}{5^{1/k}(k+1)^{1/k}} = +\infty$$

(Stirling's formula () is helpful in evaluating this limit.) Thus the Taylor series for f around x_0 has radius of convergence 0.

Most Smooth Functions are Nowhere Analytic

We can use the Baire Category Theorem to show that "most" C^∞ functions on an interval have only (P)-points and are thus nowhere analytic. This result was first proved by D. MORGENSTERN [Mor54a]. The result has been reproved and republished several times, sometimes in the weaker form of Corollary V.17.4.5..

V.17.4.4. THEOREM. Let I be an interval in $\mathbb{R}$. The set of all smooth functions on I for which every point of I is a (P)-point is a residual subset of $C^\infty(I)$ with its usual topology. Thus the set of smooth functions which have a Taylor series at at least one point which has a positive radius of convergence is a meager set in $C^\infty(I)$.

PROOF: We will prove the result for I closed and bounded; the proof can be adapted to the general case.

Let $\mathcal{P}$ be the set of all g in $C^\infty(I)$ such that $P_g = I$. First note that $\mathcal{P}$ is dense in $C^\infty(I)$: since the polynomials are dense in $C^\infty(I)$ (), the functions $f+\phi$, where f is the function of Example V.17.4.3. and ϕ is a polynomial, are dense in $C^\infty(I)$. But addition of a polynomial to f does not change the radius of convergence of any Taylor series of f since only finitely many terms are changed; in particular, $P_{f+\phi} = P_f = I$, so $f+\phi \in \mathcal{P}$ for any polynomial ϕ.

So we need only show that $\mathcal{P}$ is a G_δ, i.e. that $\mathcal{P}^c$ is an F_σ. Let $E_{m,n}$ be the set of all $f \in C^\infty(I)$ such that there is an $x \in I$ with

$$|f^{(k)}(x)| \leq k! \cdot m \cdot n^k$$

for all $k \in \mathbb{N}$. We show that $E_{m,n}$ is closed for each m and n and $\cup_{m,n} E_{m,n} = \mathcal{P}^c$.

To show that $E_{m,n}$ is closed, suppose $f_n \in E_{m,n}$ and $f_n \to f$ in $C^\infty(I)$. For each n there is an x_n such that $|f_n^{(k)}(x_n)| \leq k! \cdot m \cdot n^k$. Passing to a subsequence, we may assume $x_n \to x$ for some $x \in I$ since I is compact (recall that the topology of $C^\infty(I)$ is metrizable). Then $f_n^{(k)}(x_n) \to f^{(k)}(x)$ for all k, since $f_n^{(k)} \to f^{(k)}$ uniformly on I for each k (). Thus

$$|f^{(k)}(x)| = \lim_{n\to\infty} |f_n^{(k)}(x_n)| \leq k! \cdot m \cdot n^k$$

for all k, i.e. $f \in E_{m,n}$.

Now suppose $f \in E_{m,n}$. Then there is an $x_0 \in I$ such that

$$\left| \frac{f^{(k)}(x_0)}{k!} \right|^{1/k} \leq m^{1/k} n$$

for all k, so we have

$$\limsup_{k\to\infty}\left|\frac{f^{(k)}(x_0)}{k!}\right|^{1/k} \leq n$$

so the radius of convergence of the Taylor series for f around x_0 is at least $\frac{1}{n}$, and $f \notin \mathcal{P}$. Conversely, suppose $f \notin \mathcal{P}$, i.e. there is an $x_0 \in I$ where the Taylor series has positive radius of convergence. Thus there is an $n \in \mathbb{N}$ such that

$$\limsup_{k\to\infty}\left|\frac{f^{(k)}(x_0)}{k!}\right|^{1/k} < n$$

so there is a k_0 such that

$$\left|\frac{f^{(k)}(x_0)}{k!}\right|^{1/k} < n$$

for all $k > k_0$, i.e. $|f^{(k)}(x_0)| < k! \cdot n^k$ for $k \geq k_0$.

Let $m \in \mathbb{N}$, $m \geq \max(|f(x_0)|, |f'(x_0)|, \ldots, |f^{(k_0)}(x_0)|)$. Then $|f^{(k)}(x_0)| < k! \cdot m \cdot n^k$ for all k, i.e. $f \in E_{m,n}$. 👍

V.17.4.5. Corollary. Let I be an interval in $\mathbb{R}$. The set of all smooth functions on I which are nowhere analytic is a residual subset of $C^\infty(I)$ with its usual topology. Thus the set of smooth functions which are analytic at at least one point is a meager set in $C^\infty(I)$.

Can a Smooth Function Have Only (C)-Points?

V.17.4.6. We can similarly apply the Baire Category Theorem to the question of whether a nowhere analytic smooth function f on an interval I can have a Taylor series around each $x_0 \in I$ with a positive radius of convergence, i.e. whether we can have $C_f = I$. For $m, n \in \mathbb{N}$, define

$$E_{m,n}(f) = \{x_0 \in I : |f^{(k)}(x_0)| \leq k! \cdot m \cdot n^k \text{ for all } k \geq 0\} .$$

V.17.4.7. Proposition. Let $f \in C^\infty(I)$. Then each $E_{m,n}(f)$ is relatively closed in I, and $\cup_{m,n} E_{m,n}(f) = I \setminus P_f$. Thus C_f is an F_σ and P_f is a G_δ.

Proof: The proof of the first statement is a simplified form of the argument in the proof of V.17.4.4., and is left to the reader. For the second statement, note that each of the following subsets of $\mathbb{R}$ is both an F_σ and a G_δ:

I, an interval ().

A_f, a relatively open subset of I.

$C_f \cup P_f = I \setminus A_f$, a relatively closed subset of I.

$E_{m,n}(f)$, a relatively closed subset of I.

So by the first statement $I \setminus P_f$ is an F_σ, and thus $C_f = (C_f \cup P_f) \cap (I \setminus P_f)$ is an F_σ, and $P_f = I \setminus (I \setminus P_f)$ is a G_δ. 👍

Each $E_{m,n}(f)$ is contained in $A_f \cup C_f$. The key fact is that interior points of $E_{m,n}(f)$ are in A_f:

V.17.4.8. PROPOSITION. If x_0 is an interior point of $E_{m,n}(f)$ for some (m,n), then f is analytic in a neighborhood of x_0.

PROOF: Let J be an open interval around x_0 contained in $E_{m,n}(x_0)$, and let $x \in J$ with $|x - x_0| = r < \frac{1}{n}$. If p_k is the k'th Taylor polynomial of f around x_0, we have, by Taylor's Theorem,

$$f(x) - p_k(x) = \frac{f^{(k+1)}(c)}{(k+1)!}(x - x_0)^{k+1}$$

for some $c \in J$, and so we have

$$|f(x) - p_k(x)| \leq \frac{(k+1)! \cdot m \cdot n^{k+1}}{(k+1)!}|x - x_0|^{k+1} = m(nr)^{k+1} \to 0$$

and so the Taylor series for f around x_0 converges to f on $J \cap \left(x_0 - \frac{1}{n}, x_0 + \frac{1}{n}\right)$. 👍

V.17.4.9. THEOREM. Let $f \in C^\infty(I)$. Then the set C_f is a meager subset of I, and in particular has empty interior.

PROOF: We have that $C_f = \cup_{m,n}[C_f \cap E_{m,n}(f)]$, and by V.17.4.8. $C_f \cap E_{m,n}(f)$ is nowhere dense (note that $C_f \cap E_{m,n}(f) = A_f^c \cap E_{m,n}(f)$ is relatively closed in I). 👍

V.17.4.10. COROLLARY. Let $f \in C^\infty(I)$.

(i) If $P_f = \emptyset$, i.e. if the Taylor series for f around x_0 has positive radius of convergence for every $x_0 \in I$, then f is analytic on a dense open subset of I.

(ii) If f is not analytic at any point of I, then P_f is dense in I.

Note that a function satisfying (i) is not necessarily analytic everywhere: CAUCHY'S example is a counterexample. But there is a companion result to (i), first stated by PRINGSHEIM in 1893 with a faulty proof and proved by R. BOAS in 1935 in the same paper [BJ35] where V.17.4.9. was first proved:

V.17.4.11. THEOREM. Let $f \in C^\infty(I)$. If there is an $r > 0$ such the Taylor series for f around x_0 has radius of convergence at least r, for every $x_0 \in I$, then f is analytic at every point of I (i.e. analytic on I if I is open).

V.17.4.12. We give only a partial argument; for the full proof see (). Since P_f is empty, it follows from V.17.4.10. that C_f is a nowhere dense relatively closed subset of I. We only show that C_f has no isolated points. If x_0 is an isolated point of C_f, i.e. f is analytic on a deleted open interval J around x_0, and $r > 0$ is as in the statement, take $x_1 \in J$ with $x_0 < x_1 < x_0 + r$. The Taylor series for f around x_1 defines an analytic function g on $(x_1 - r, x_1 + r)$, and g agrees with f on (x_0, x_1) by V.16.2.2., since they agree on an interval around x_1. By continuity of all derivatives of f and g, the Taylor series for g around x_0 agrees with the Taylor series for f around x_0, so the Taylor series for f around x_0 converges to f on $[x_0, x_1)$ by V.16.2.7. (applied to g). A similar argument shows that the Taylor series for f around x_0 converges to f on an interval $(x_2, x_0]$ for some $x_2 < x_0$. Thus f is analytic at x_0, contradicting that $x_0 \in C_f$.

This argument does not rule out that C_f could look like a Cantor set. Showing that this is impossible requires a more delicate argument involving application of the Baire Category Theorem to the set C_f, which is a locally compact metrizable space.

Zahorski's Theorem

In 1947 Z. Zahorski [Zah47] gave a complete characterization of which subsets of I occur as C_f and P_f for a smooth function f on an interval I. We have shown that these sets have the following properties:

C_f is a meager F_σ.

P_f is a G_δ disjoint from C_f.

$C_f \cup P_f$ is relatively closed in I.

Zahorski's Theorem asserts that these conditions are sufficient as well as necessary:

V.17.4.13. Theorem. [Zahorski's Theorem] Let I be an interval in $\mathbb{R}$, and let C and P be subsets of I such that

C is a meager F_σ.

P is a G_δ disjoint from C.

$C \cup P$ is relatively closed in I.

Then there is an $f \in C^\infty(I)$ such that $C_f = C$ and $P_f = P$.

See [SZ55] for a proof which is somewhat simpler than Zahorski's, but still complicated.

V.17.4.14. Thus, although C_f is always a meager set, it can be large in a measure-theoretic sense. For example, there is a smooth function f on $\mathbb{R}$ for which P_f is the set of Liouville numbers and C_f the complement. This f is not analytic anywhere, and C_f is a set whose complement has Lebesgue measure zero, and in fact Hausdorff dimension zero (III.8.2.37.).

V.17.4.15. There is a multidimensional version of Zahorski's Theorem [**?**].

V.17.5. Exercises

V.17.5.1. Let

$$f(x) = \begin{cases} e^{-1/x^2} \sin \frac{1}{x} & \text{if} \quad x \neq 0 \\ 0 & \text{if} \quad x = 0 \end{cases} .$$

Show that f is $\mathcal{C}^\infty$ on all of $\mathbb{R}$, and has a nonisolated zero at 0.

V.17.5.2. [?, p. 69] Let

$$f(x) = \sum_{k=1}^{\infty} \frac{\cos(k!x)}{(k!)^k} .$$

(a) Show that this series and the series of term-by-term n'th derivatives converge uniformly on $\mathbb{R}$ for every n. In particular, $f(x)$ is defined for all $x \in \mathbb{R}$, and f is periodic with period 2π.

(b) Use V.15.1.6. inductively to conclude that f is $\mathcal{C}^\infty$ on $\mathbb{R}$, and that n-fold term-by-term differentiation is justified for every n.

(c) Show that 0 is a (P)-point of f.

(d) Show that for any $p \in \mathbb{Z}$ and $q \in \mathbb{N}$, $f\left(x + \frac{\pi p}{q}\right) - f(x)$ is analytic on $\mathbb{R}$ [the infinite series differ in only finitely many terms], and that $\frac{\pi p}{q}$ is a (P)-point of f. Thus f has a dense set of (P)-points. Conclude from V.17.1.2. that f is not analytic anywhere.

(e) Is every $x \in \mathbb{R}$ a (P)-point of f?

Chapter VI

The Topology of $\mathbb{R}$, $\mathbb{R}^n$, and Metric Spaces

In this chapter we discuss the basic notions of open and closed sets, closure of a set, interior and boundary of a set, and some of the elementary results about them, beginning with the real numbers, then moving on to $\mathbb{R}^n$ and general metric spaces. This chapter should be considered a parallel thread to Chapter () on sequences and series; there is much interplay between the two chapters.

The general theory of topology and more detailed results along the lines of this chapter are the subject of Chapter ().

VI.1. The Topology of $\mathbb{R}$

We begin with the real numbers. Recall the definition of an interval in $\mathbb{R}$ (III.1.9.12.). The open intervals and the closed intervals are most important for this section. The open intervals are the intervals of the form (a, b), where $a \in \mathbb{R} \cup \{-\infty\}$, $b \in \mathbb{R} \cup \{+\infty\}$, and $a < b$. The closed intervals are of the form $[a, b]$ with $a, b \in \mathbb{R}$, $a < b$, or $[a, +\infty)$, $(-\infty, b]$, or all of $\mathbb{R}$. We generalize both open intervals and closed intervals into open sets and closed sets respectively.

VI.1.1. Open and Closed Sets in $\mathbb{R}$

VI.1.1.1. Definition. (i) A subset U of $\mathbb{R}$ is an *open set* if, whenever $x \in U$, there is an open interval I with $x \in I$ and $I \subseteq U$.

(ii) A subset E of $\mathbb{R}$ is a *closed set* if $E^c = \mathbb{R} \setminus E$ is an open set.

A slight rephrasing of the definition gives:

VI.1.1.2. Proposition. A subset of $\mathbb{R}$ is an open set if and only if it is a union of open intervals.

VI.1.1.3. An open set is, roughly, a set which locally looks like an open interval. Any open interval is an open set. The empty set vacuously satisfies the definition of open set, hence is also an open set (it is an "empty union" of open intervals). The complement of a closed interval is either one open interval, the disjoint union of two open intervals, or the empty set, hence open; thus a closed interval is a closed set, so the terminology is consistent. The complement of the empty set is $\mathbb{R}$, which is open, so $\emptyset$ is closed as well as open. There are many nonempty closed sets which look nothing like closed intervals: for example, any finite set is closed since its complement is a union of open intervals; similarly $\mathbb{Z}$ is a closed set. There are much more complicated examples; see e.g. (), ().

A half-open interval of the form $[a, b)$ for $a < b$ is not an open set since it does not contain an open interval around a; similarly, its complement is not open, so $[a, b)$ is not a closed set either. $\mathbb{Q}$ is also neither open nor closed, since every open interval contains both rational and irrational numbers. In fact, "most" subsets of $\mathbb{R}$ are neither open nor closed.

The only subsets of $\mathbb{R}$ which are both open and closed are $\emptyset$ and $\mathbb{R}$ ().

Here is a useful rephrasing of the definition of open set:

VI.1.1.4. PROPOSITION. Let U be a subset of $\mathbb{R}$. Then U is an open set if and only if, for every $x \in U$, there is an $\epsilon > 0$ such that the open interval $(x - \epsilon, x + \epsilon) = \{y \in \mathbb{R} : |y - x| < \epsilon\}$ is contained in U. (The ϵ can depend on x.)

PROOF: Any such set is obviously open, since $(x - \epsilon, x + \epsilon)$ is an open interval. Conversely, if U is open and $x \in U$, and I is an open interval with $x \in I$ and $I \subseteq U$, then there is a smaller open interval J centered at x contained in I (and hence in U); J will be of the form $(x - \epsilon, x + \epsilon)$ for some $\epsilon > 0$. 👍

Unions and Intersections

VI.1.1.5. PROPOSITION. (i) An arbitrary union of open sets is open. A *finite* intersection of open sets is open.

(ii) An arbitrary intersection of closed sets is closed. A *finite* union of closed sets is closed.

PROOF: (i): It is obvious from VI.1.1.2. (or just straight from the definition) that a union of any collection of open sets is open. For a finite intersection, we use VI.1.1.4.. Let $U_1, \ldots, U_n$ be a finite collection of open sets, and $U = U_1 \cap \cdots \cap U_n$. Let $x \in U$. Then $x \in U_j$ for each j, so for each j there is an $\epsilon_j > 0$ such that $(x - \epsilon_j, x + \epsilon_j) \subseteq U_j$. Set $\epsilon = \min\{\epsilon_1, \ldots, \epsilon_n\}$. Then $\epsilon > 0$, and $(x - \epsilon, x + \epsilon) \subseteq U$. Since this can be done for any $x \in U$, U is open.

(ii) follows from (i) by taking complements and using de Morgan's Laws (). 👍

VI.1.1.6. The intersection of an infinite number of open sets is not open in general. For example, $\cap_{n=1}^{\infty} \left(x - \frac{1}{n}, x + \frac{1}{n}\right) = \{x\}$, which is not open (in fact it is closed). Similarly, an infinite union of closed sets is not closed in general. In fact, every subset of $\mathbb{R}$ is a union of singleton sets, each of which is closed.

VI.1.1.7. COROLLARY. Let U be an open set and E a closed set. Then $U \setminus E$ is open and $E \setminus U$ is closed.

PROOF: $U \setminus E = U \cap E^c$ and $E \setminus U = E \cap U^c$. 👍

Neighborhoods and Deleted Neighborhoods

VI.1.1.8. Let x be a real number. An open interval containing x, or more generally an open set containing x, is often called a *neighborhood*, or *open neighborhood*, of x. In topology, a neighborhood of x is generally thought of as a set of points "close to x"; this is literally true if the neighborhood is something like $(x-\epsilon, x+\epsilon)$ for a small positive ϵ, but may be somewhat of a stretch for general neighborhoods. Nonetheless, the notion of neighborhood is a useful one, as we will see. An open set is an open neighborhood of each of its points.

Sometimes we use the term "neighborhood" to mean a not necessarily open set: a neighborhood of x is a set containing an open neighborhood of x. For example, it is sometimes useful to consider closed neighborhoods (e.g. ()).

VI.1.1.9. It is also often useful to consider deleted neighborhoods of a point. If $x \in \mathbb{R}$, a *deleted neighborhood* of x is a subset of $\mathbb{R}$ of the form $U \setminus \{x\}$, where U is a neighborhood of x. Deleted neighborhoods are usually taken to be open, but not necessarily.

The most commonly used deleted neighborhoods of an $x \in \mathbb{R}$ are sets of the form

$$(x-\epsilon, x) \cup (x, x+\epsilon) = \{y \in \mathbb{R} : 0 < |y-x| < \epsilon\}$$

for some (typically "small") $\epsilon > 0$. Every deleted neighborhood of x contains a deleted neighborhood of this form.

VI.1.2. Limit Points and Closures

There is an alternate way to view closed sets, via the notions of limit points and closures, which we now describe.

VI.1.2.1. DEFINITION. Let A be a subset of $\mathbb{R}$, and $x \in \mathbb{R}$. Then x is a *limit point* of A if every open neighborhood of x contains at least one point of A.

The word "open" may be deleted from the definition without effect.

VI.1.2.2. Any point of A is a limit point of A: if $x \in A$, then any neighborhood of x contains at least one point of A, namely x itself. But the importance of the definition is that there may be real numbers which are not in A but are limit points of A. For example, $0 \notin (0,1)$, but 0 is a limit point of $(0,1)$ since every neighborhood of 0 contains small positive numbers. For a more dramatic example, every real number is a limit point of $\mathbb{Q}$, since every nonempty open set in $\mathbb{R}$ contains rational numbers.

Some authors define "limit point" to mean what is more commonly called an *accumulation point* of A. The number x is an accumulation point of A if every neighborhood of x contains a point of A other than x, i.e. every deleted neighborhood of x contains a point of A. Not every element of A is necessarily an accumulation point of A; those which are not are called *isolated points* of A. We will not need to make much use of the notion of accumulation point; limit points are more important for most purposes.

As with open sets, the notion of limit point can be phrased in terms of ϵ's:

VI.1.2.3. Proposition. Let $A \subseteq \mathbb{R}$, $x \in \mathbb{R}$. Then x is a limit point of A if and only if, for every $\epsilon > 0$, there is a $y \in A$ with $|x - y| < \epsilon$.

Intuitively, x is a limit point of A if and only if there are points of A arbitrarily close to x.

VI.1.2.4. Definition. Let A be a subset of $\mathbb{R}$. The *closure* of A is the set $\bar{A}$ of all limit points of A.

VI.1.2.5. Since every element of A is a limit point of A, we have $A \subseteq \bar{A}$. If $A \subseteq B$, then it follows immediately from the definition of limit point that every limit point of A is a limit point of B, so $\bar{A} \subseteq \bar{B}$.

The term "closure" is justified by the next result.

VI.1.2.6. Theorem. Let A be a subset of $\mathbb{R}$. Then

(i) $\bar{\bar{A}} = \bar{A}$, i.e. every limit point of $\bar{A}$ is in $\bar{A}$.

(ii) $\bar{A}$ is a closed set.

(iii) $\bar{A}$ is the smallest closed set containing A, i.e. if E is a closed set containing A, then $\bar{A} \subseteq E$.

Proof: (i): Let x be a limit point of $\bar{A}$, and U an open neighborhood of x. Then there is a $y \in \bar{A}$ with $y \in U$. Then y is a limit point of A, and U is a neighborhood of y, so there is a $z \in A$ with $z \in U$. This is true for every open neighborhood U of x, so x is a limit point of A.

(ii): Let $x \in (\bar{A})^c$. Then x is not a limit point of A, so there is an open neighborhood U of x containing no points of A. Then U also cannot contain any limit points of A, for if $y \in U$ were a limit point of A, then the neighborhood U of y would have to contain a point of A. Thus $U \subseteq (\bar{A})^c$. Since such a U exists for every $x \in (\bar{A})^c$, $(\bar{A})^c$ is open.

(iii): There is a smallest closed set F containing A, namely the intersection of all closed sets containing A (cf. VI.1.1.5.; there is at least one closed set containing A, $\mathbb{R}$ itself). Since $\bar{A}$ is a closed set containing A by (ii), we have $F \subseteq \bar{A}$. To show the opposite inclusion, let $x \notin F$. Since F is closed, F^c is an open neighborhood of x containing no point of A. Thus x cannot be a limit point of A. 👍

VI.1.3. Compactness and Continuity

VI.1.3.1. A collection $\mathcal{U} = \{U_i : i \in \Omega\}$ of open sets in $\mathbb{R}$ (or in a general topological space) is an *open cover* of a set A if $A \subseteq \cup_i U_i$. A *subcover* of $\mathcal{U}$ for A is a subset of $\mathcal{U}$ which is also a cover of A. A subset F of $\mathbb{R}$ is *compact* if every open cover of F has a finite subcover.

VI.1.3.2. LEMMA. A closed bounded interval $[a,b]$ in $\mathbb{R}$ is compact.

PROOF: Let $\mathcal{U} = \{U_i : i \in \Omega\}$ be an open cover of $[a,b]$. Let S be the set of all $c \in [a,b]$ such that there is a finite subcover of $\mathcal{U}$ for $[a,c]$. S is nonempty since $a \in S$ ($a \in U$ for some $U \in \mathcal{U}$, so $\{U\}$ is a finite subcover of $[a,a] = \{a\}$). S is bounded since $S \subseteq [a,b]$.
Let $d = \sup(S)$. Then $d \in U_0$ for some $U_0 \in \mathcal{U}$. There is an $\epsilon > 0$ such that $(d-\epsilon, d+\epsilon) \subseteq U_0$ since U_0 is open. Since d is the least upper bound of S, there is a $c \in S$ with $c > d - \epsilon$. Let $\{U_1, \ldots, U_n\}$ be a finite subcover of $\mathcal{U}$ for $[a,c]$. Then $\{U_0, U_1, \ldots, U_n\}$ is a finite subcover of $[a,d]$, so $d \in S$. Suppose $d < b$. Then if $d < x < \min(d+\epsilon, b)$, then $\{U_0, U_1, \ldots, U_n\}$ is a finite subcover of $[a,x]$, contradicting that $d = \sup(S)$. Thus $d = b$ and $b \in S$. 👍

VI.1.3.3. COROLLARY. Every closed bounded subset of $\mathbb{R}$ is compact.

PROOF: If F is closed and contained in $[a,b]$, and $\mathcal{U}$ is an open cover of F, then $\mathcal{U} \cup \{F^c\}$ is an open cover of $[a,b]$, and this open cover has a finite subcover $\mathcal{V}$ for $[a,b]$. $\mathcal{V} \setminus \{F^c\} \subseteq \mathcal{U}$ is then a finite subcover of $\mathcal{U}$ for F. 👍

Virtually the same proof shows that any closed subset of a compact set is compact. The converse is also true:

VI.1.3.4. PROPOSITION. A compact subset of $\mathbb{R}$ is closed and bounded.

PROOF: Let E be a compact subset of $\mathbb{R}$. If $U_m = (-m, m)$, then $\{U_m : m \in \mathbb{N}\}$ is an open cover of E, so there is a finite subcover $\{U_{m_1}, \ldots, U_{m_n}\}$. If $M = \max\{m_1, \ldots, m_n\}$, then $E \subseteq (-M, M)$. To see that E is closed, let $c \in E^c$, and for each $\epsilon > 0$ let $U_\epsilon = \{x \in \mathbb{R} : |x - c| > \epsilon\}$. Then $\{U_\epsilon : \epsilon > 0\}$ is an open cover of E, so there is a finite subcover $\{U_{\epsilon_1}, \ldots, U_{\epsilon_n}\}$. If $\epsilon = \min\{\epsilon_1, \ldots, \epsilon_n\}$, then $(c-\epsilon, c+\epsilon) \subseteq E^c$, so E^c is open. 👍

Combining these two results, we obtain one of the most important theorems of analysis:

VI.1.3.5. THEOREM. [HEINE-BOREL THEOREM FOR $\mathbb{R}$] A subset of $\mathbb{R}$ is compact if and only if it is closed and bounded.

The Heine-Borel Theorem gives a generalization of the Nested Interval Theorem:

VI.1.3.6. COROLLARY. Let (F_m) be a decreasing sequence of nonempty closed bounded subsets of $\mathbb{R}$. Then $\cap_m F_m$ is not empty.

PROOF: Suppose $F_1 \subseteq [a,b]$. If $\cap F_m = \emptyset$, then $\{F_m^c : m \in \mathbb{N}\}$ is an open cover of $[a,b]$, which has a finite subcover $\{F_{m_1}, \ldots, F_{m_n}\}$. If $M = \max\{m_1, \ldots, m_n\}$, then $F_M = F_{m_1} \cap \cdots \cap F_{m_n} = \emptyset$, a contradiction. 👍

From this, we get the important Bolzano-Weierstrass Theorem (see IV.1.7.1. for a different proof):

THEOREM. [BOLZANO-WEIERSTRASS THEOREM] Every bounded sequence in $\mathbb{R}$ has a convergent subsequence.

PROOF: Let (x_n) be a bounded sequence in $[a,b] \subseteq \mathbb{R}$. It suffices to show that (x_n) has a cluster point (). For each $m \in \mathbb{N}$, let F_m be the closure of $\{x_n : n \geq m\}$. Then F_m is a nonempty closed subset of $\mathbb{R}$, and $F_{m+1} \subseteq F_m$ and $F_m \subseteq [a,b]$ for all m. Thus $\cap_m F_m$ is nonempty, and any $c \in \cap_m F_m$ is a cluster point of (x_n). 👍

We then get some basic theorems about continuous functions as consequences:

VI.1.3.7. THEOREM. Let E be a compact subset of $\mathbb{R}$, and let $f : E \to \mathbb{R}$ be continuous. Then $f(E)$ is compact.

PROOF: We first show that $f(E)$ is bounded. Suppose for each n there is an $x_n \in E$ with $|f(x_n)| \geq n$. Since E is bounded, (x_n) has a subsequence (x_{k_n}) converging to some $y \in \mathbb{R}$, and $y \in E$ since E is closed. Because f is continuous, the sequence $(f(x_{k_n}))$ converges to $f(y)$ by the Sequential Criterion. But this is impossible since $(f(x_{k_n}))$ is unbounded by construction, a contradiction.

Now suppose that c is in the closure of $f(E)$, and choose $x_n \in E$ such that $f(x_n) \to c$. Again by the Bolzano-Weierstrass Theorem, (x_n) has a subsequence (x_{k_n}) converging to some $y \in E$. But then $(f(x_{k_n}))$ converges to $f(y)$ by the Sequential Criterion; since $(f(x_{k_n}))$ converges to c, we have $c = f(y) \in f(E)$ and $f(E)$ is closed. 👍

See () for a slicker proof.

VI.1.3.8. COROLLARY. [MAX-MIN THEOREM] Let E be a closed bounded subset of $\mathbb{R}$, and $f : E \to \mathbb{R}$ a continuous function. Then f is bounded on E and attains its maximum and minimum on E, i.e. there are $c, d \in E$ such that $f(c) \leq f(x) \leq f(d)$ for all $x \in E$.

For the proof, just note that $f(E)$ is compact and that a compact subset of $\mathbb{R}$ has a maximum and a minimum element.

See () for a more complete discussion of compactness.

The next theorem is a variation of the Tietze Extension Theorem of topology (). It is certainly not true that a continuous function on a subset E of $\mathbb{R}$ can be extended to a continuous function on all of $\mathbb{R}$; there are many counterexamples, such as $f(x) = \frac{1}{x}$ on $(0, \infty)$. But if E is closed, there is always an extension:

VI.1.3.9. THEOREM. [TIETZE EXTENSION THEOREM FOR $\mathbb{R}$] Let E be a closed subset of $\mathbb{R}$, and $f : E \to \mathbb{R}$ a continuous function. Then f can be extended to a continuous function on all of $\mathbb{R}$, i.e. there is a continuous function $g : \mathbb{R} \to \mathbb{R}$ which agrees with f on E.

PROOF: The definition of g is very simple. Let $U = E^c$; then U is open, so it consists of a union of countably many disjoint open intervals $I_n = (a_n, b_n)$ and possibly an unbounded interval of the form $(-\infty, a)$ (if E has a smallest element a) and/or an unbounded interval (b, ∞) (if E has a largest element b.) Define g to be

equal to f on E, linear on $[a_n, b_n]$ for each n, and if necessary constant on $(-\infty, a]$ and/or $[b, \infty)$. If $x \in I_n$, the formula for $g(x)$ is

$$g(x) = f(a_n) + \frac{f(b_n) - f(a_n)}{b_n - a_n}(x - a_n)\,.$$

It is geometrically clear that g is continuous everywhere, but takes a little work to write down a careful proof. Suppose $c \in \mathbb{R}$; we will show g is continuous at c. If $c \notin E$, this is obvious since g is linear in a neighborhood of c. Suppose $c \in E$. We will show that $\lim_{x \uparrow c} f(x) = f(c)$. Let $\epsilon > 0$ be given. If $c = b_n$ for some n, let $\delta = \min(b_n - a_n, \frac{b_n - a_n}{|f(b_n) - f(a_n)|}\epsilon)$ (if $f(a_n) = f(b_n)$, set $\delta = b_n - a_n$.) Then if $c - \delta < x < c$, g is linear on $[x, c]$, so $|f(x) - f(c)| < \epsilon$.

Now suppose that c is not one of the b_n. For $\epsilon > 0$, choose $\delta_1 > 0$ such that $c - \delta_1 < x < c$ and $x \in E$ imply $|f(x) - f(c)| < \epsilon$ (using the fact that f is continuous on E.) Since c is not one of the b_n, there is a $d \in E$ with $c - \delta_1 < d < c$. Set $\delta = c - d$. If $c - \delta < x < c$, we will show that $|f(x) - f(c)| < \epsilon$. This is obvious if $x \in E$ since $\delta < \delta_1$; and if $x \in U$, then there is an n such that $d \le a_n < x < b_n < c$, so $f(x)$ is between $f(a_n)$ and $f(b_n)$, each of which is in $(f(c) - \epsilon, f(c) + \epsilon)$, so $|f(x) - f(c)| < \epsilon$. This proves that g is continuous from the left; the proof that g is continuous from the right is almost identical. 👍

VI.1.3.10. None of the arguments in this section require any form of the Axiom of Choice.

VI.2. Metric Spaces

Much of what was done in the last section works almost verbatim in the more general setting of metric spaces. Besides Euclidean spaces, there are many other metric spaces which are important in analysis, as well as in other parts of mathematics, so it is quite worthwhile working in this generality.

VI.2.1. Definitions

A *metric space* is a set X with a specified numerical distance between any two points, which behaves reasonably like the usual distance between numbers or points in Euclidean space. The distance may be regarded as a function $\rho : X \times X \to \mathbb{R}$, with $\rho(x, y)$ denoting the distance between x and y. Formally:

VI.2.1.1. DEFINITION. A *metric* on a set X is a function $\rho : X \times X \to \mathbb{R}$ satisfying:

(i) $\rho(x, y) \geq 0$ for all $x, y \in X$.

(ii) $\rho(x, y) = 0$ if and only if $x = y$ (*definiteness*).

(iii) $\rho(x, y) = \rho(y, x)$ for all $x, y \in X$ (*symmetry*).

(iv) $\rho(x, z) \leq \rho(x, y) + \rho(y, z)$ for all $x, y, z \in X$ (*triangle inequality*).

A pair (X, ρ), where X is a set and ρ is a metric on X, is called a *metric space*.
The *diameter* of a metric space (X, ρ) is $diam(X, \rho) = \sup\{\rho(x, y) : x, y \in X\}$. The metric ρ is *bounded* if $diam(X, \rho)$ is finite.

VI.2.1.2. It is customary to call a set X with a given metric a "space", and to call elements of X "points", even though there may be no geometric picture or interpretation of X as an actual space in the usual sense. The geometric terminology helps to motivate some aspects of the theory of metric spaces.

VI.2.1.3. EXAMPLES.

(i) On $\mathbb{R}$, the function $\rho(x, y) = |x - y|$ is a metric. This is called the *standard metric* on $\mathbb{R}$, and we will often use this metric on $\mathbb{R}$ without specific mention.

(ii) On $\mathbb{R}^n$, the Euclidean distance function

$$\rho_2(x, y) = \sqrt{(x_1 - y_1)^2 + \cdots + (x_n - y_n)^2}$$

for $x = (x_1, \ldots, x_n)$, $y = (y_1, \ldots, y_n)$ in $\mathbb{R}^n$ is a metric, the *standard metric* on $\mathbb{R}^n$.

(iii) There are other important metrics on $\mathbb{R}^n$. Two of them are:

$$\rho_1(x, y) = |x_1 - y_1| + \cdots + |x_n - y_n|$$

$$\rho_\infty(x, y) = \max(|x_1 - y_1|, \ldots, |x_n - y_n|)$$

for $x = (x_1, \ldots, x_n)$, $y = (y_1, \ldots, y_n)$ in $\mathbb{R}^n$.

(iv) There are important metrics on function spaces analogous to those of (ii) and (iii). For example, let $C[a,b]$ be the set of real-valued continuous functions on the interval $[a,b]$, and for $f,g \in C[a,b]$ define

$$\rho_2(f,g) = \left[\int_a^b (f(t)-g(t))^2\,dt\right]^{1/2}$$

$$\rho_1(f,g) = \int_a^b |f(t)-g(t)|\,dt$$

$$\rho_\infty(f,g) = \max_{a\le t\le b} |f(t)-g(t)|$$

(It is not obvious that ρ_2 satisfies the triangle inequality. See Exercise () or () for a proof.)

(v) Let X be a sphere (recall that a *sphere* in mathematics is a two-dimensional surface, not including the points "inside"). If $x,y \in X$, let $\rho(x,y)$ be the arc length of the shortest great circle path between x and y. (The triangle inequality is not entirely obvious here, but can be proved.) This example has obvious practical applications: it is the appropriate "distance" to consider on the surface of the earth.

(vi) Let X be any set, $\rho(x,y) = \begin{cases} 1 & \text{if} \quad x \neq y \\ 0 & \text{if} \quad x = y \end{cases}$. Then ρ is a metric on X, called the *discrete metric*.

(vii) Let X be the set of all n-tuples of 0's and 1's, and define $\rho(x,y)$ to be the number of coordinates in which x and y differ. This is a metric, called the *Hamming metric*, which is important in coding theory.

In these examples, only the metrics in (v)–(vii) are bounded.

VI.2.1.4. A "distance function" ρ on a set X satisfying (i), (iii), and (iv) is called a *pseudometric*. Pseudometrics play an important role in more advanced parts of analysis.

VI.2.2. Balls, Limit Points, and Closures

VI.2.2.1. DEFINITION. Let (X,ρ) be a metric space, and $x_0 \in X$. If $r > 0$, the *(open) ball of radius r around x_0* (or *centered at x_0*) is

$$B_r^\rho(x_0) = \{x \in X : \rho(x_0,x) < r\}$$

(the ρ is often omitted if the metric is understood and there is no possibility of confusion.) The *closed ball of radius r around x_0* is

$$\bar{B}_r^\rho(x_0) = \{x \in X : \rho(x_0,x) \le r\}.$$

VI.2.2.2. The term "ball" is a standard term even though $B_r(x_0)$ need not look anything like a geometric ball. (In fact, there is usually no geometric interpretation of distance in a general metric space; see Exercise VI.2.8.6., for example, for interpretations of ρ_1 and ρ_∞ on $\mathbb{R}^2$.)

The term "ball" without the qualification "closed" will always mean "open ball".

VI.2.2.3. EXAMPLES.

(i) In $\mathbb{R}$ with the usual metric, the open ball of radius r around x_0 is the open interval of length $2r$ centered at x_0; $\bar{B}_r(x_0)$ is the closed interval of length $2r$ centered at x_0.

(ii) In $(\mathbb{R}^2, \rho_2)$, $B_r(x_0)$ is an open disk centered at x_0. In $(\mathbb{R}^3, \rho_2)$, $B_r(x_0)$ is the usual geometric open ball of radius r centered at x_0. The closed balls have a similar interpretation.

(iii) In $(\mathbb{R}^2, \rho_1)$, balls (open or closed) are square diamonds; in $(\mathbb{R}^2, \rho_\infty)$ they are squares with horizontal and vertical sides (see Exercise ().)

(iv) There is a geometric interpretation of balls in $C[a,b]$ for the ρ_∞ metric. Fix $f_0 \in C[a,b]$, and $r > 0$. Draw the graphs of the functions $f(t) - r$ and $f(t) + r$ (Figure ().) Then $B_r^{\rho_\infty}(f_0)$ consists of all functions in $C[a,b]$ whose graph lies within the strip strictly between the top and bottom curves. $\bar{B}_r^{\rho_\infty}(f_0)$ consists of the functions whose graphs lie in the closed strip including the two boundary functions.

(v) If ρ is the discrete metric on a set X, and $x_0 \in X$, then $B_r^\rho(x_0) = \{x_0\}$ if $r \leq 1$, and $B_r^\rho(x_0) = X$ if $r > 1$. $\bar{B}_r^\rho(x_0) = \{x_0\}$ if $r < 1$ and $\bar{B}_r^\rho(x_0) = X$ if $r \geq 1$. Thus $B_1^\rho(x_0) = \{x_0\}$ but $\bar{B}_1^\rho(x_0) = X$, so $\bar{B}_r(x_0)$ can be much larger than the "closure" of $B_r(x_0)$ in general (this will be made precise in ().)

VI.2.2.4. DEFINITION. Let (X, ρ) be a metric space, and $A \subseteq X$. A point $x \in X$ is a *limit point* (or *point of closure*) of A (with respect to ρ) if every ball centered at x contains at least one point of A, i.e. if, for every $\epsilon > 0$, there is a point $y \in A$ with $\rho(x,y) < \epsilon$. The *closure* of A (with respect to ρ), denoted $\bar{A}$, is the set of all limit points of A. The set A is *closed* if $A = \bar{A}$.

When there is any possibility of confusion about which metric is being used, we will use the terms *ρ-limit point* and *ρ-closed set*.

VI.2.2.5. Note that a limit point of A is not an element of A in general: for example, 0 and 1 are limit points of $(0,1)$ in $\mathbb{R}$. But a point of A is always a limit point of A, so $A \subseteq \bar{A}$ for any A. If $A \subseteq B$, then $\bar{A} \subseteq \bar{B}$. We also have that $\bar{\emptyset} = \emptyset$ and $\bar{X} = X$, i.e. $\emptyset$ and X are closed sets in X.

VI.2.2.6. PROPOSITION. Let (X, ρ) be a metric space, and $A \subseteq X$. Then every limit point of $\bar{A}$ is a limit point of A, i.e. $\bar{\bar{A}} = \bar{A}$, so $\bar{A}$ is closed.

PROOF: Suppose x is a limit point of $\bar{A}$, and $\epsilon > 0$. We must show that there is a $z \in A$ with $\rho(x,z) < \epsilon$. But x is a limit point of $\bar{A}$, so there is a $y \in \bar{A}$ with $\rho(x,y) < \epsilon/2$; and there is a $z \in A$ with $\rho(y,z) < \epsilon/2$. By the triangle inequality, $\rho(x,z) < \epsilon$. 👍

The complement of a ρ-closed set is called an *open set* (with respect to ρ, or *ρ-open set*). The next proposition gives two other useful characterizations of open sets:

VI.2.2.7. PROPOSITION. Let (X, ρ) be a metric space, and $U \subseteq X$. Then the following are equivalent:

(i) U is an open set.

(ii) U is a union of open balls.

(iii) For every $x \in U$, there is an $\epsilon > 0$ such that $B_\epsilon(x) \subseteq U$.

PROOF: (i) $\Rightarrow$ (iii): If $x \in U$, then x is not a limit point of U^c since U^c is closed. Thus there is an $\epsilon > 0$ such that $B_\epsilon(x)$ contains no point of U^c, i.e. $B_\epsilon(x) \subseteq U$.
(iii) $\Rightarrow$ (i): If $x \in U$, then there is an $\epsilon > 0$ such that $B_\epsilon(x) \subseteq U$, hence $B_\epsilon(x)$ contains no point of U^c and x is not a limit point of U^c. Thus U^c is closed.
(ii) $\Rightarrow$ (iii): Suppose $x \in U$. Then $x \in B_r(y) \subseteq U$ for some r and y, since U is a union of open balls. Set $\epsilon = r - \rho(x, y)$. Then by the triangle inequality, $B_\epsilon(x) \subseteq B_r(y) \subseteq U$.
(iii) $\Rightarrow$ (ii) is obvious. 👍

In particular, every open ball is an open set.

VI.2.2.8. COROLLARY. An arbitrary union of open sets is open. A finite intersection of open sets is open.
An arbitrary intersection of closed sets is closed. A finite union of closed sets is closed.

PROOF: It is obvious from either (ii) or (iii) that an arbitrary union of open sets is open. To prove that a finite intersection of open sets is open, use (iii): if $U_1, \ldots, U_n$ are open and $x \in U_1 \cap \cdots \cap U_n$, choose $\epsilon_1, \ldots, \epsilon_n > 0$ with $B_{\epsilon_k}(x) \subseteq U_k$ for each k. Set $\epsilon = \min(\epsilon_1, \ldots, \epsilon_n)$; then $\epsilon > 0$ and $B_\epsilon(x) \subseteq U_1 \cap \cdots \cap U_n$.
The statements about unions and intersections of closed sets are obtained by taking complements. 👍

VI.2.2.9. Note that an intersection of infinitely many open sets is not open in general: for example, $\cap_{n=1}^{\infty} B_{1/n}(x) = \{x\}$, which is rarely an open set ($\{x\}$ is actually a closed set for any x.) Similarly, an arbitrary union of closed sets is not closed in general: in fact, every subset of X is a union of singleton subsets, which are closed.

VI.2.2.10. It is important to note that not every subset of a metric space is either open or closed; in fact, this is far from true in most metric spaces. ✋

> "Most sets, like doors, are neither open nor closed, but ajar."
>
> *C. Pugh*[1]

In fact, the "most" can be precisely quantified: in $\mathbb{R}$ (and in most other metric spaces encountered in analysis), there are $2^{2^{\aleph_0}}$ subsets in all, but only $2^{\aleph_0}$ open sets and $2^{\aleph_0}$ closed sets (), so there are $2^{2^{\aleph_0}}$ subsets which are "ajar." Although "most" of these subsets are rather bizarre and cannot be even explicitly described, many frequently encountered and easily described sets are ajar, such as half-open intervals of the form $(a, b]$ or $[a, b)$, or the rational numbers $\mathbb{Q}$.

Interior and boundary points

[1] [Pug15, p. 60].

VI.2.3. Limits and Continuity

Convergence of sequences and limits and continuity of functions work in any metric space almost exactly as in $\mathbb{R}$. The statements and proofs are essentially identical to the case of $\mathbb{R}$; all that is needed is to "redecorate" using the metric distance in place of the absolute value. We will do a few examples of redecoration in proofs, and leave others as exercises.

Limits of Sequences

VI.2.3.1. DEFINITION. Let (X, ρ) be a metric space, $x \in X$, and (x_n) a sequence in X. Then (x_n) *converges to* x (with respect to ρ), or x is the *limit* of the sequence (x_n), written $x_n \to x$ or $x = \lim_{n\to\infty} x_n$, if for every $\epsilon > 0$ there is an $n_0 \in \mathbb{N}$ such that $\rho(x_n, x) < \epsilon$ for all $n \geq n_0$.

Where it is necessary to explicitly specify the metric ρ, or where there is any chance of confusion, we will say that (x_n) *ρ-converges* to x, or x is the *ρ-limit* of (x_n), written $x_n \to_\rho x$ or $x = \rho\text{-}\lim_{n\to\infty} x_n$.

As in $\mathbb{R}$, limits of sequences are unique:

VI.2.3.2. PROPOSITION. Let (X, ρ) be a metric space, $x, y \in X$, and (x_n) a sequence in X. If $x_n \to x$ and $x_n \to y$, then $x = y$.

PROOF: If $x \neq y$, set $\epsilon = \rho(x, y)/3 > 0$, and choose $n_1, n_2 \in \mathbb{N}$ with $\rho(x_n, x) < \epsilon$ for all $n \geq n_1$ and $\rho(x_n, y) < \epsilon$ for all $n \geq n_2$. Then, if $n \geq \max(n_1, n_2)$,

$$\rho(x, y) \leq \rho(x, x_n) + \rho(x_n, y) < 2\epsilon = 2\rho(x, y)/3 < \rho(x, y)$$

which is a contradiction. 👍

VI.2.3.3. PROPOSITION. Let (X, ρ) be a metric space, $x \in X$, and (x_n) a sequence in X. If $x_n \to x$, then every subsequence of (x_n) also converges to x.

There is also a notion of a cluster point of a sequence in a metric space:

VI.2.3.4. DEFINITION. Let (X, ρ) be a metric space, $x \in X$, and (x_n) a sequence in X. Then x is a *cluster point* of the sequence (x_n) if for every $\epsilon > 0$ and $n_0 \in \mathbb{N}$, $\rho(x_n, x) < \epsilon$ for some $n \geq n_0$. (Equivalently, $\rho(x_n, x) < \epsilon$ for infinitely many n.) When ρ needs to be specified, we say x is a *ρ-cluster point* of (x_n).

If $x_n \to x$, then x is a cluster point of (x_n), but the converse is generally not true. A sequence can have many cluster points.

VI.2.3.5. The term "limit point" is sometimes used in place of "cluster point", but this can lead to confusion, so we will use the term "limit point" only in reference to a *set*, and "cluster point" in reference to a *sequence*. If x is a cluster point of a sequence (x_n), then x is a limit point of the set $\{x_n : n \in \mathbb{N}\}$, but the converse is not necessarily true: each term x_k is a limit point of $\{x_n : n \in \mathbb{N}\}$, but x_k is usually not a cluster point of (x_n). In fact, we have:

VI.2.3.6. PROPOSITION. Let (x_n) be a sequence in a metric space (X, ρ), and let $x \in X$. Then x is a cluster point of (x_n) if and only if x is a limit point of

$$A_k = \{x_n : n \geq k\}$$

for every $k \in \mathbb{N}$.

This proposition is an immediate consequence of the definitions, and the proof is left as an exercise.

Cluster points can also be characterized using subsequences:

VI.2.3.7. PROPOSITION. Let (x_n) be a sequence in a metric space (X, ρ), and let $x \in X$. Then x is a cluster point of (x_n) if and only if there is a subsequence (x_{k_n}) which converges to x.

PROOF: Suppose there is a subsequence of (x_n) converging to x. Then, for any $\epsilon > 0$, infinitely many terms of the subsequence lie within ϵ of x, so x is a cluster point of (x_n). Conversely, if x is a cluster point of (x_n), then set $k_1 = 1$ and inductively let k_{n+1} be an integer $\geq k_n + 1$ for which $\rho(x_{k_{n+1}}, x) < 1/(n+1)$. Then $x_{k_n} \to x$. 👍

A related result about subsequences has a somewhat complicated statement, but is frequently useful:

VI.2.3.8. PROPOSITION. Let (X, ρ) be a metric space, $x \in X$, and (x_n) a sequence in X. Then $x_n \to x$ if and only if x is a cluster point of every subsequence of (x_n).

PROOF: If $x_n \to x$, then every subsequence (x_{k_n}) of (x_n) also converges to x (), hence x is a cluster point of (x_{k_n}). Conversely, suppose (x_n) does *not* converge to x. Then there is an $\epsilon > 0$ such that, for every $n_0 \in \mathbb{N}$, there is an $n \geq n_0$ with $\rho(x_n, x) \geq \epsilon$. Let $k_1 = 1$, and inductively choose $k_{n+1} \geq k_n + 1$ with $\rho(x_{k_{n+1}}, x) \geq \epsilon$. Then x is not a cluster point of the subsequence (x_{k_n}). 👍

Limits of sequences and functions, continuity, sequential criterion, dependence on metric; cluster points; subsequences; closure in terms of sequences; uniform continuity; mean and mean-square convergence

Dominant and Equivalent Metrics

It is sometimes important to compare two or more metrics on the same set. The next definition is reminiscent of the definition of continuity, and is in fact very closely related ().

VI.2.3.9. DEFINITION. Let ρ and σ be metrics on the same set X. Then ρ *dominates* σ if, for every $x_0 \in X$ and $\epsilon > 0$, there is a $\delta > 0$ such that $\sigma(x, x_0) < \epsilon$ whenever $x \in X$ and $\rho(x, x_0) < \delta$. The metric ρ *uniformly dominates* σ if, for every $\epsilon > 0$, there is a $\delta > 0$ such that $\sigma(x, y) < \epsilon$ whenever $x, y \in X$ and $\rho(x, y) < \delta$.

The metrics ρ and σ are *equivalent* if each dominates the other, and *uniformly equivalent* if each uniformly dominates the other.

The metrics ρ and σ are *incomparable* if neither one dominates the other.

VI.2.3.10. Roughly speaking, "ρ dominates σ" means that $\sigma(x,y)$ is small whenever $\rho(x,y)$ is small. The most common way a metric ρ uniformly dominates another metric σ is if there is a $C > 0$ with $\sigma(x,y) \leq C\rho(x,y)$ for all $x, y \in X$.

VI.2.3.11. PROPOSITION. Let ρ and σ be metrics on a set X. Then the following are equivalent:

(i) ρ dominates σ.

(ii) The identity function from (X,ρ) to (X,σ) is continuous.

(iii) Whenever (x_n) is a sequence in X converging to a limit x with respect to ρ (i.e. $\lim_{n\to\infty} \rho(x_n, x) = 0$), (x_n) also converges to x with respect to σ (i.e. $\lim_{n\to\infty} \sigma(x_n, x) = 0$).

(iv) Every set which is σ-closed is also ρ-closed.

(v) Every set which is σ-open is also ρ-open.

Paraphrasing (iii)–(v), if ρ dominates σ, it is *easier* for a set to be ρ-open (or ρ-closed) than σ-open (or σ-closed), but *harder* for a sequence to converge with respect to ρ than with respect to σ.
PROOF: (i) $\iff$ (ii) is a straightforward comparison of definitions, and is left to the reader. (ii) $\iff$ (iii) is the Sequential Criterion for continuity.
(iii) $\Rightarrow$ (iv): Suppose $A \subseteq X$ is σ-closed, and x is a ρ-limit point of A. We must show that $x \in A$. But by the Sequential Criterion for limit points, there is a sequence (x_n) in A with $x_n \to x$ with respect to ρ. By (iii), $x_n \to x$ with respect to σ, so $x \in A$ because A is σ-closed.
(iv) $\iff$ (v) by taking complements. (v) $\Rightarrow$ (ii) by **??**. 👍

Similarly, we obtain:

VI.2.3.12. PROPOSITION. Let ρ and σ be metrics on a set X. Then ρ uniformly dominates σ if and only if the identity function from (X,ρ) to (X,σ) is uniformly continuous.

VI.2.3.13. EXAMPLES.

(i) On $\mathbb{R}^n$, the metrics ρ_2, ρ_1, and ρ_∞ are uniformly equivalent since, for any $x, y \in \mathbb{R}^n$,

$$\rho_\infty(x,y) \leq \rho_2(x,y) \leq \rho_1(x,y) \leq n\rho_\infty(x,y) \leq n\rho_2(x,y)$$

(the inequality $\rho_2(x,y) \leq \rho_1(x,y)$ is the only one which is not obvious; see Exercise ().)

(ii) On $C[a,b]$, ρ_∞ uniformly dominates ρ_1 and ρ_2 since $\rho_1(f,g) \leq (b-a)\rho_\infty(f,g)$ and $\rho_2(f,g) \leq (b-a)^{1/2}\rho_\infty(f,g)$ for any f, g. Actually, $\rho_1(f,g) \leq (b-a)^{1/2}\rho_2(f,g)$ for any $f, g \in C[a,b]$ (Exercise ()), so ρ_2 also uniformly dominates ρ_1.

However, none of the three are equivalent. For example, let f_n be the function whose graph is in Figure ().

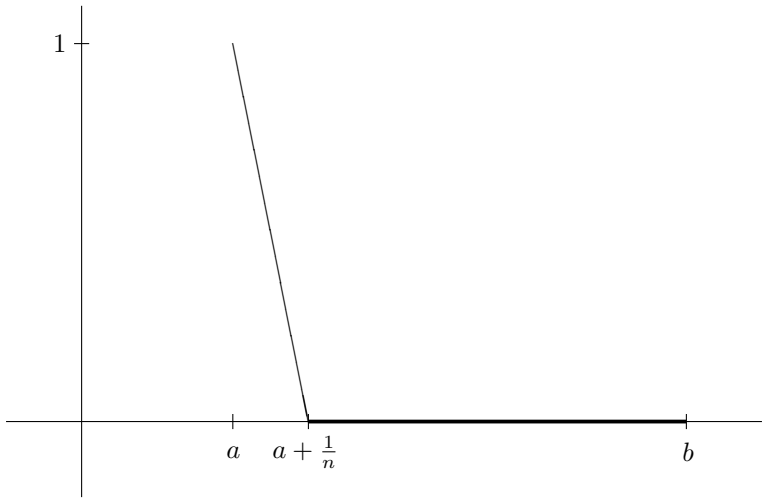

Figure VI.1: The graph of f_n

Then

$$\lim_{n\to\infty} \rho_1(f_n, 0) = \lim_{n\to\infty} \rho_2(f_n, 0) = 0,$$

but $\rho_\infty(f_n, 0) = 1$ for all n. Apply the criterion of VI.2.3.11.(iii) to conclude that ρ_1 and ρ_2 do not dominate ρ_∞. See Exercise () for a proof that ρ_1 does not dominate ρ_2.

(iii) Let ρ be a metric on X, and for $x, y \in X$, set $\sigma(x, y) = \min(\rho(x, y), 1)$. Then σ is a bounded metric on X which is uniformly equivalent to ρ [it is obvious that ρ uniformly dominates σ; to prove that σ uniformly dominates ρ, for any ϵ choose $\delta = \min(\epsilon, 1)$.]

(iv) Let ρ be the usual metric on $\mathbb{R}$, $\rho(x, y) = |x - y|$, and let $\sigma(x, y) = |\arctan x - \arctan y|$. Then σ is a metric on $\mathbb{R}$, and ρ uniformly dominates σ (in fact, $\sigma(x, y) \leq \rho(x, y)$ for all $x, y \in \mathbb{R}$.) Conversely, σ dominates ρ by continuity of the tangent function, but not uniformly since $\sigma(n, n + 1) \to 0$ as $n \to \infty$; so ρ and σ are equivalent but not uniformly equivalent.

(v) The discrete metric on a set X uniformly dominates any other metric on X [for any $\epsilon > 0$ we can choose $\delta = 1$.]

(vi) If ρ is a metric on X, then $c\rho$ is a metric which is uniformly equivalent to ρ, for any $c > 0$.

(vii) If ρ and σ are metrics on a set X, then $\rho + \sigma$ (defined by $[\rho + \sigma](x, y) = \rho(x, y) + \sigma(x, y)$) and $\max(\rho, \sigma)$ are uniformly equivalent metrics which uniformly dominate both ρ and σ. If (ρ_n) is a sequence of metrics on X, set $\sigma_n = \min(\rho_n, 1)$ for all n (cf. (iii)), and define ρ by

$$\rho(x, y) = \sum_{n=1}^{\infty} 2^{-n} \sigma_n(x, y).$$

Then ρ is a metric which uniformly dominates all the ρ_n's.

VI.2.4. Continuity Without the Countable AC

The proof () that the Sequential Criterion for continuity is equivalent to the $(\epsilon-\delta)$-definition uses the Countable AC. We can show without Choice that for functions between metric spaces, the Sequential Criterion for continuity is equivalent to the $(\epsilon-\delta)$-definition if the source space is separable.

VI.2.4.1. DEFINITION. (i) Let X and Y be topological spaces, $f: X \to Y$ a function, and $x_0 \in X$. Then f is *sequentially continuous at* x_0 if, whenever $x_n \to x_0$ in X, $f(x_n) \to f(x_0)$ in Y.

(ii) Let (X,ρ) and (Y,σ) be metric spaces, $f: X \to Y$ a function, and $x_0 \in X$. Then f is *$(\epsilon-\delta)$-continuous at* x_0 if for every $\epsilon > 0$ there is a $\delta > 0$ such that $\sigma(f(x), f(x_0)) < \epsilon$ whenever $x \in X$ and $\rho(x, x_0) < \delta$.

(iii) f is *sequentially continuous* [resp. *$(\epsilon-\delta)$-continuous*] if it is sequentially continuous [resp. $(\epsilon-\delta)$-continuous] at x_0 for each $x_0 \in X$.

A function between metric spaces is $(\epsilon-\delta)$-continuous if and only if it is continuous in the topological sense (); a function which is $(\epsilon-\delta)$-continuous at x_0 is sequentially continuous at x_0 (no Choice is needed for this).

VI.2.4.2. THEOREM. Let (X,ρ) and (Y,σ) be metric spaces, with (X,ρ) separable. Let $f: X \to Y$ be a function. Then f is $(\epsilon-\delta)$-continuous if and only if it is sequentially continuous.

PROOF: One direction has already been observed. Conversely, suppose f is sequentially continuous. Fix a countable dense set D in X and arrange it into a sequence $S = \{s_1, s_2, \dots\}$. If f is not $(\epsilon-\delta)$-continuous at x_0, there is an $\epsilon > 0$ such that, for any n, there is a $p \in X$ with $\rho(p, x_0) < \frac{1}{n}$ and $\sigma(f(p), f(x_0)) > \epsilon$. Fix n. There is a sequence (p_r) in D with $p_r \to p$ (such a sequence can be generated algorithmically if desired). Then by assumption $f(p_r) \to f(p)$, so sufficiently large r we have $\rho(p_r, x_0) < \frac{1}{n}$ and $\sigma(f(p_r), f(x_0)) > \epsilon$, i.e. there is a $q \in D$ with $\rho(q, x_0) < \frac{1}{n}$ and $\sigma(f(q), f(x_0)) > \epsilon$.

For each n let z_n be the first s_k for which $\rho(s_k, x_0) < \frac{1}{n}$ and $\sigma(f(s_k), f(x_0)) > \epsilon$. Then $z_n \to x_0$ but $f(z_n) \not\to f(x_0)$, contradicting that f is sequentially continuous. 👍

VI.2.4.3. This result does not extend to pointwise continuity, or to limits (). In the absence of separability, the result can fail without the Countable AC, even if X and Y are compact. Let (X,ρ) and $(X^\dagger,\bar{\rho})$ be as in XIII.15.12.8., and define $f: X^\dagger \to [0,1]$ by setting f identically 0 on X and $f(\infty) = 1$. Then f is sequentially continuous, but not $(\epsilon-\delta)$-continuous at ∞.

VI.2.4.4. The result applies to functions from $\mathbb{R}^n$ to any metric space, or to functions defined on an open or closed subset of $\mathbb{R}^n$ (cf. XIII.15.9.11.). But one cannot prove without the Countable AC that arbitrary subsets of $\mathbb{R}$ are separable, or even that an infinite subset of $\mathbb{R}$ contains a sequence of distinct points ().

VI.2.5. Extended Metrics

It turns out to be quite harmless to allow a metric to also take the value ∞ $(+\infty)$, i.e. to allow points to be an infinite distance apart.

VI.2.5.1. DEFINITION. An *extended metric* on a set X is a function $\rho : X \times X \to [0, \infty]$ satisfying:

(i) $\rho(x, y) \geq 0$ for all $x, y \in X$.

(ii) $\rho(x, y) = 0$ if and only if $x = y$ (*definiteness*).

(iii) $\rho(x, y) = \rho(y, x)$ for all $x, y \in X$ (*symmetry*).

(iv) $\rho(x, z) \leq \rho(x, y) + \rho(y, z)$ for all $x, y, z \in X$ (*triangle inequality*).

A pair (X, ρ), where X is a set and ρ is a metric on X, is called an *extended metric space*.

In the definition, we take the usual order on $[0, \infty]$, i.e. $x < \infty$ for all $x \in \mathbb{R}$, and $x + \infty = \infty$ for any $x \in [0, \infty]$. Note that any metric is an extended metric. We may also consider *extended pseudometrics* which have all the properties except (ii).

VI.2.5.2. All the results of this section hold for extended metrics with no modifications. If ρ is an extended metric on X, define $\tilde{\rho}$ by $\tilde{\rho}(x, y) = \min(\rho(x, y), 1)$; then $\tilde{\rho}$ is a metric on X which is equivalent to ρ, so if desired any extended metric can be converted to a metric without changing the topology.

VI.2.5.3. DEFINITION. Let (X, ρ) be an extended metric space, and $x \in X$. The *galaxy* of x in X is

$$\{y \in X : \rho(x, y) < \infty\} .$$

The proof of the next simple proposition is left as an exercise for the reader.

VI.2.5.4. PROPOSITION. Let (X, ρ) be an extended metric space. Then

(i) Any two distinct galaxies in X are disjoint. Thus X partitions into a disjoint union of galaxies. Any points in distinct galaxies are an infinite distance apart.

(ii) Each galaxy is a clopen set in X.

(iii) As a topological space, X is the separated union () of its galaxies.

(iv) The restriction of ρ to any galaxy is a metric.

A metric space is just an extended metric space with only one galaxy.

Maximal Metrics

The next simple but important observation is most naturally phrased using extended metrics:

VI.2.5.5. PROPOSITION. Let X be a set, $\{\rho_i : i \in I\}$ a collection of extended pseudometrics on X. For $x, y \in X$, set

$$\bar{\rho}_I(x,y) = \sup_{i\in I} \rho_i(x,y) \ .$$

Then $\bar{\rho}_I$ is an extended pseudometric on X.

PROOF: The only thing that needs to be checked is the triangle inequality. If $x, y, z \in X$, then, by (),

$$\bar{\rho}_I(x,z) = \sup_i \rho_i(x,z) \leq \sup_i[\rho_i(x,y) + \rho_i(y,z)] \leq \sup_i \rho_i(x,y) + \sup_i \rho_i(y,z) = \bar{\rho}_I(x,y) + \bar{\rho}_I(y,z) \ .$$

VI.2.5.6. If the ρ_i are separating (in particular, if at least one ρ_i is an extended metric), then $\bar{\rho}_I$ is an extended metric. The metric $\bar{\rho}_I$ dominates each ρ_i, i.e. the $\bar{\rho}_I$ topology is stronger than all the ρ_i topologies, but it might not be the weakest topology stronger than all the ρ_i topologies. For a simple example, let σ be a metric on X, and for each n let $\rho_n = n\sigma$. Then all the ρ_n are equivalent to σ, but $\bar{\rho}_{\mathbb{N}}$ is the discrete extended metric. (For an actual metric version, set $\rho_n(x,y) = \min(1, n\sigma(x,y))$ for $x, y \in X$.) If I is finite, then the $\bar{\rho}_I$ topology is indeed the weakest topology stronger than all the ρ_i topologies.

VI.2.5.7. A particularly important example (cf. XIII.8.4.2.) comes from a bound function. Let X be a set, and $\beta : X \times X \to [0, +\infty]$ a function. Let I be the set of all pseudometrics σ on X such that $\sigma(x,y) \leq \beta(x,y)$ for all $x, y \in X$ (I is nonempty since the zero pseudometric is in I; one could also allow extended pseudometrics without affecting the construction). Set $\rho_\beta = \bar{\rho}_I$. The extended pseudometric ρ_β is called the *maximal pseudometric* of β; it is the largest pseudometric ρ satisfying $\rho(x,y) \leq \beta(x,y)$ for all $x, y \in X$.

VI.2.6. Cauchy Sequences

VI.2.7. Normed Vector Spaces

Many of the important metric spaces in analysis are vector spaces in which the metric comes from a norm.

VI.2.7.1. DEFINITION. Let X be a vector space over $\mathbb{R}$ or $\mathbb{C}$. A *norm* on X is a function $x \mapsto \|x\|$ from X to $\mathbb{R}$ satisfying

(i) $\|x\| \geq 0$ for all $x \in X$.

(ii) $\|x\| = 0$ if and only if $x = 0$ (*definiteness*).

(iii) $\|\alpha x\| = |\alpha|\|x\|$ for all $x \in X$ and all scalars α (*homogeneity*).

(iv) $\|x + y\| \leq \|x\| + \|y\|$ for all $x, y \in X$ (*triangle inequality*).

VI.2.7.2. A norm on a vector space X defines a metric on X by $\rho(x,y) = \|x - y\|$. The metrics in VI.2.1.3.(i)–(iv) arise this way:

VI.2.7.3. EXAMPLES.

(i) The usual metric on $\mathbb{R}$ comes from the norm $\|x\| = |x|$.

(ii) The metric ρ_2 on $\mathbb{R}^n$ comes from $\|x\|_2 = \sqrt{x_1^2 + \cdots + x_n^2}$.

(iii) The metrics ρ_1 and ρ_∞ on $\mathbb{R}^n$ also come from norms:

$$\|x\|_1 = |x_1| + \cdots + |x_n|$$

$$\|x\|_\infty = \max(|x_1|, \ldots, |x_n|)$$

(iv) The metrics ρ_2, ρ_1, ρ_∞ on $C([a,b])$ come from norms

$$\|f\|_2 = \left[\int_a^b (f(t))^2\, dt\right]^{1/2}$$

$$\|f\|_1 = \int_a^b |f(t)|\, dt$$

$$\|f\|_\infty = \max_{a \le t \le b} |f(t)|$$

(See Exercise () or () for a proof that $\|\cdot\|_2$ satisfies the triangle inequality.)

(v) On $\mathbb{C}^n$, the same formulas as in (ii) and (iii) define norms, except that the 2-norm must be written

$$\|x\|_2 = \sqrt{|x_1|^2 + \cdots + |x_n|^2}\ .$$

VI.2.7.4. The metric ρ induced by a norm is *translation-invariant*, i.e. $\rho(x+z, y+z) = \rho(x,y)$ for all $x, y, z \in X$, and *homogeneous*, i.e. $\rho(\alpha x, \alpha y) = |\alpha|\rho(x,y)$ for all $x, y \in X$ and all scalars α. A consequence of translation-invariance is that $B_r(z) = z + B_r(0)$ for any $r > 0$, $z \in X$, and $B_{\alpha r}(0) = \alpha B_r(0)$ for any $\alpha, r > 0$. Thus all balls in a normed vector space "look the same" up to scaling and translation.

Another consequence of homogeneity is:

VI.2.7.5. PROPOSITION. Let X be a vector space, $\|\cdot\|$ and $\|\cdot\|'$ norms on X, ρ and σ the associated metrics. Then the following are equivalent:

(i) ρ dominates σ.

(ii) ρ uniformly dominates σ.

(iii) There is a $C > 0$ such that $\|x\|' \le C\|x\|$ for all $x \in X$.

This is actually a special case of a fundamental principle about operators between normed vector spaces ().

PROOF: (iii) ⇒ (ii) ⇒ (i) are trivial, so we need only prove (i) ⇒ (iii). Choose $\delta > 0$ so that $\|x\| = \rho(x, 0) < \delta$ implies $\|x\|' = \sigma(x, 0) < 1$, for any $x \in X$, and set $C = 1/\delta$. Then $\|x\| < 1$ implies that $\|x\|' < C$. If $x \in X$ and $\|x\|' > C\|x\|$, choose $\alpha \in \mathbb{R}$ with

$$\frac{C}{\|x\|'} < \alpha < \frac{1}{\|x\|}$$

and then $\|\alpha x\| < 1$ but $\|\alpha x\|' > C$, a contradiction; so there can be no such x, proving (iii). 👍

[Move to later section]

THEOREM. Let X and Y be vector spaces (over the same field, $\mathbb{R}$ or $\mathbb{C}$), with norms $\|\cdot\|_X$ and $\|\cdot\|_Y$ respectively, and let $T : X \to Y$ be a linear operator. Then the following are equivalent:

(i) T is continuous at 0.

(ii) T is continuous.

(iii) T is uniformly continuous.

(iv) There is a constant $K \geq 0$ such that $\|Tx\|_Y \leq K\|x\|_X$ for all $x \in X$.

If T satisfies (iv), T is said to be *bounded*; the smallest such K is called the *operator norm* of T, denoted $\|T\|_{op}$ or usually just $\|T\|$.

Seminorms

Banach Spaces

VI.2.8. Exercises

VI.2.8.6. Here are physical interpretations of ρ_1 and ρ_∞ on $\mathbb{R}^2$.
(a) The metric ρ_1 is often called the *city metric* or *driving metric*. Imagine a city in which all streets run north-south or east-west. Then the ρ_1-distance between two points located on streets is the shortest driving distance between the points (ignoring one-way streets, etc.)
(b) There is a similar, though perhaps less satisfactory, interpretation of ρ_∞. In this city, there are buses on each street. The fare structure is unusual: the cost of riding a bus is strictly proportional to the distance traveled, say \$1 per mile. However, a rider also receives a transfer good for a free ride on a bus in the perpendicular direction, of length not exceeding the length of the paid ride. The ρ_∞ distance between two points on streets is then the minimum cost of a bus ride between the two points.

VI.2.8.7. Show that ρ_1, ρ_2, and ρ_∞ are equivalent metrics on $\mathbb{R}^n$.

VI.2.8.8. (a) If $x_1, \ldots, x_n$ are nonnegative real numbers, show that

$$\sum_{k=1}^{n} x_k^2 \leq \left[\sum_{k=1}^{n} x_k\right]^2.$$

[Hint: Multiply out the right side.] Give a careful proof by induction on n.

(b) If x_1, x_2 are real numbers, show that $(x_1 + x_2)^2 \le 2(x_1^2 + x_2^2)$. [Hint: $(x_1 - x_2)^2 \ge 0$.]
(c) If $x_1, \ldots, x_n$ are arbitrary real numbers, and $n = 2^m$, show by induction on m that

$$\left[\sum_{k=1}^{n} x_k\right]^2 \le n \sum_{k=1}^{n} x_k^2.$$

(d) Let f be Riemann integrable on $[a, b]$ (e.g. $f \in C[a, b]$.) Show that

$$\left[\int_a^b |f(t)|\, dt\right]^2 \le (b - a) \int_a^b [f(t)]^2\, dt\ .$$

[Hint: approximate the integrals by Riemann sums, dividing the interval into 2^m subintervals of equal length, and apply (c).]
(e) Show that the inequality in (c) is also true if n is not a power of 2. [Given $x_1, \ldots, x_n$, let f be the function on $[0, n]$ with $f(t) = x_k$ if $k - 1 \le x < k$. Apply (d).]

The inequalities in (b)–(e) are special cases of Jensen's Inequality. See also VI.2.8.11. for an alternate proof of (c) for general n.

VI.2.8.9. (a) Show that on $C[a, b]$, the ∞-norm dominates the 2-norm, and the 2-norm dominates the 1-norm.
(b) Let g_n be the function whose graph is given in Figure VI.2, and $h_n = \sqrt{g_n}$.

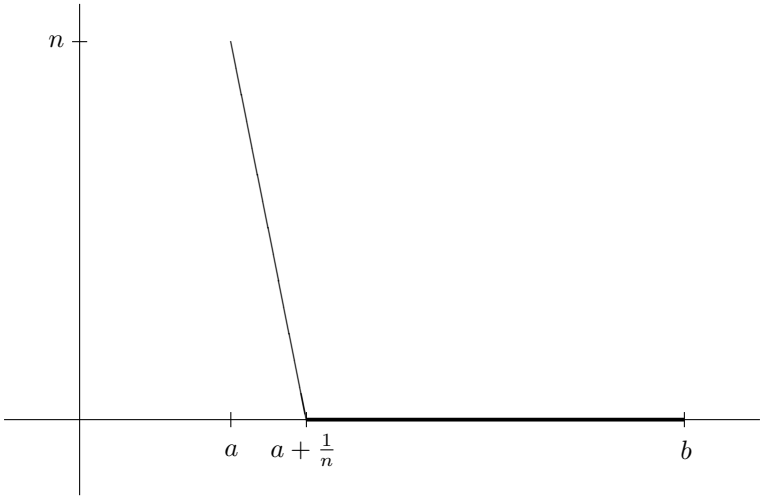

Figure VI.2: The graph of g_n

Then $\rho_1(h_n, 0) < n^{-1/2}$, so $\lim_{n\to\infty} \rho_1(h_n, 0) \to 0$. However, for any n,

$$\rho_2(h_n, 0) = \left[\int_a^b g_n(t)\, dt\right]^{1/2} = \frac{1}{\sqrt{2}}$$

so $\rho_2(h_n, 0) \not\to 0$.

VI.2.8.10. Give a direct proof (not involving taking complements) that the collection of closed sets in a metric space is closed under arbitrary intersections and under finite unions.

The graph of the Cantor function is given in Figure VI.4.

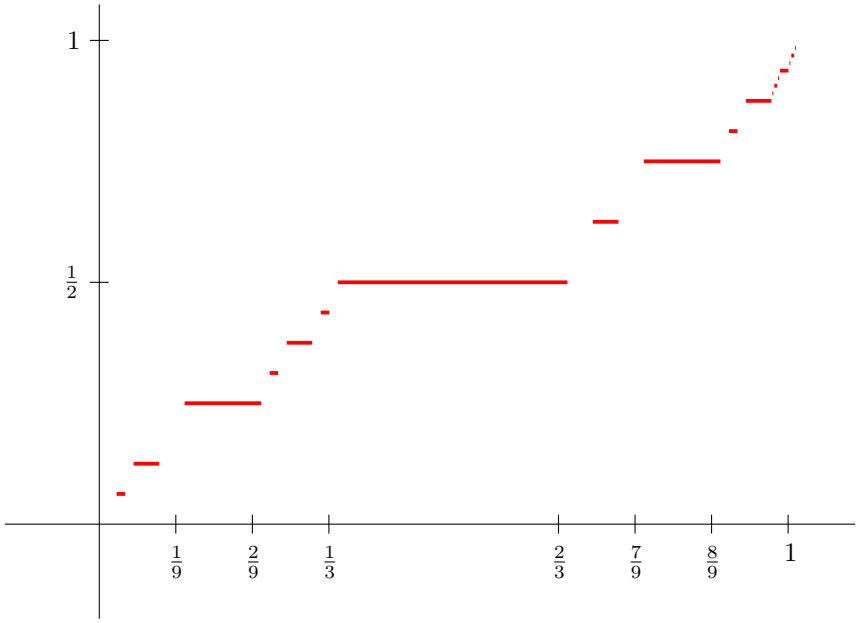

Figure VI.3: The Cantor function

[Move to later section]

VI.2.8.11. Let $x_1, \ldots, x_n, y_1, \ldots, y_n$ be real numbers. Show that

$$(x_1 + \cdots + x_n)(y_1 + \cdots + y_n) \leq n\sqrt{x_1^2 + \cdots + x_n^2}\sqrt{y_1^2 + \cdots + y_n^2} \ .$$

[Hint: let $\mathbf{x} = (x_1, \ldots, x_n)$, and for $1 \leq k \leq n$ let

$$\mathbf{y}^{(k)} = (y_k, y_{k+1}, \ldots, y_n, y_1, \ldots, y_{k-1}) \ .$$

Then $(x_1 + \cdots + x_n)(y_1 + \cdots + y_n) = \mathbf{x} \cdot \mathbf{y}^{(1)} + \cdots + \mathbf{x} \cdot \mathbf{y}^{(n)}$. Apply the CBS inequality.] In particular, $(x_1 + \cdots + x_n)^2 \leq n(x_1^2 + \cdots + x_n^2)$.
The n in this inequality is the best possible constant in general: if all the x_i and y_j are equal, we have equality.

VI.2.8.12. Adapt the proof of Theorem VI.2.4.2. to the case where X is separable metric and Y is T_3. Can the separation assumption on Y be further weakened?

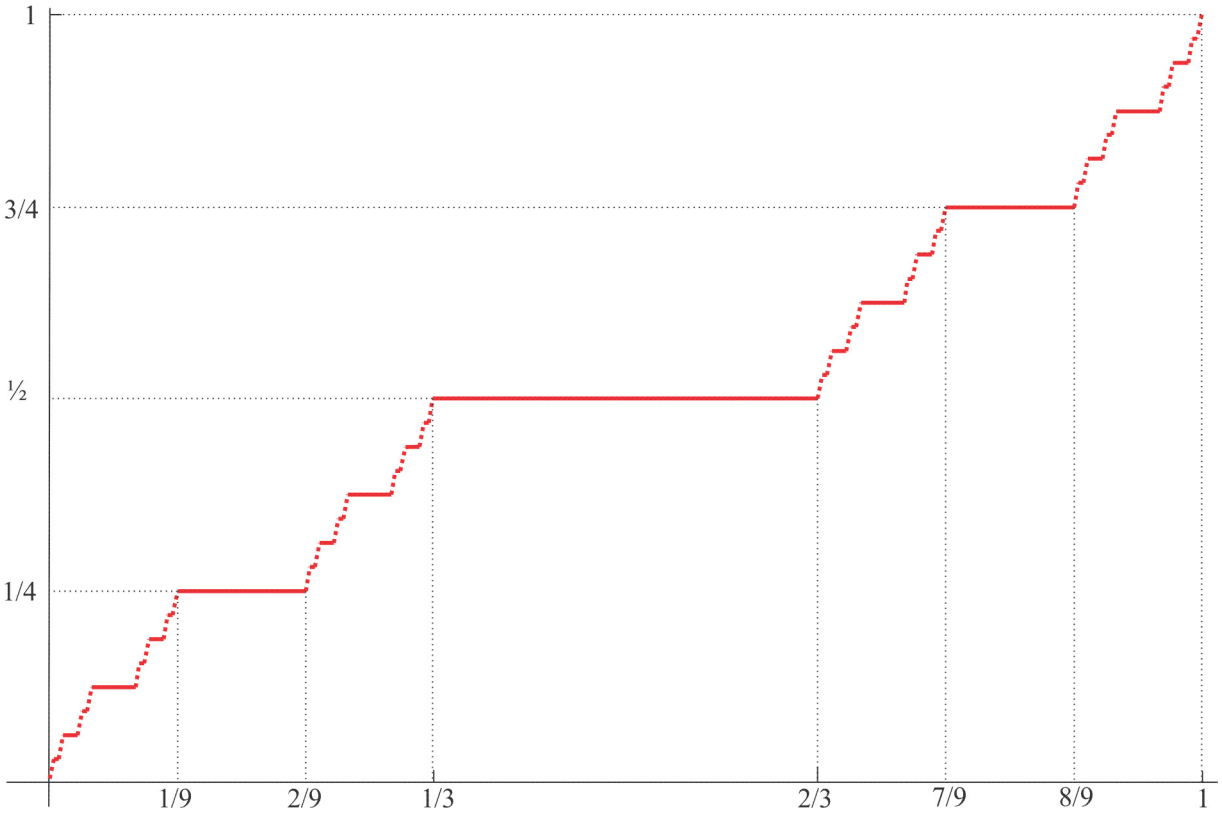

Figure VI.4: The Cantor Function

VI.2.9. How Many Separable Metric Spaces Are There?

In this subsection, we answer the following two questions:

VI.2.9.1. Question. How many separable metric spaces are there?

VI.2.9.2. Question. How many separable complete metric spaces are there?

VI.2.9.3. These questions are meaningless unless we specify a notion of equivalence. After all, there are as many one-point metric spaces as there are sets! (For a similar reason, it is meaningless to ask how many metric spaces there are, even up to isometry: any set with the discrete metric is a (complete) metric space.)

The two obvious notions of equivalence are homeomorphism and isometry. Isometry is a much finer equivalence: each homeomorphism class of metric spaces (with more than one point) includes many isometry classes. Thus we will obtain, and answer, four questions by inserting the phrase "up to homeomorphism" or "up to isometry" in each. The answers, however, will turn out not to depend on which equivalence we take: the answer to VI.2.9.1. in both cases is $2^{2^{\aleph_0}}$, and to VI.2.9.2. in both cases is $2^{\aleph_0}$.

VI.2.9.4. Proposition. There are exactly $2^{\aleph_0}$ functions from $\mathbb{N} \times \mathbb{N}$ to $\mathbb{R}$.

VI.2.9.5. Corollary. There are at most $2^{\aleph_0}$ metrics on $\mathbb{N}$. Hence up to isometry there are at most $2^{\aleph_0}$ countable metric spaces.

In fact, it is easily seen that there are at least $2^{\aleph_0}$ metrics on $\mathbb{N}$ (the distance between 1 and 2 can be any positive number), hence exactly $2^{\aleph_0}$. (One should also consider finite metric spaces: there are clearly exactly $2^{\aleph_0}$ metrics on a finite set with more than one element.)

VI.2.9.6. Corollary. Up to isometry, there are at most $2^{\aleph_0}$ separable complete metric spaces.

Proof: Every separable complete metric space is isometric to the completion of a countable metric space, and the completion of a metric space is unique up to isometry. 👍

VI.2.9.7. There are $2^{\aleph_0}$ topologically distinct compact subsets of $\mathbb{R}^2$ (XIII.19.5.1.; there are even $2^{\aleph_0}$ topologically distinct compact subsets of $\mathbb{R}$ – see XIII.19.5.4.), each of which is a separable complete metric space. Thus up to homeomorphism, there are at least $2^{\aleph_0}$ compact metric spaces, each of which is separable and complete (). Thus we obtain the answer to Question VI.2.9.2.:

VI.2.9.8. THEOREM. (i) Up to homeomorphism, there are exactly $2^{\aleph_0}$ compact metric spaces.
(ii) Up to isometry, there are exactly $2^{\aleph_0}$ compact metric spaces.
(iii) Up to homeomorphism, there are exactly $2^{\aleph_0}$ separable complete metric spaces.
(iv) Up to isometry, there are exactly $2^{\aleph_0}$ separable complete metric spaces.

Recall () that a *Polish space* is a topological space which is homeomorphic to a separable complete metric space. Thus we can rephrase (iii):

VI.2.9.9. COROLLARY. Up to homeomorphism, there are exactly $2^{\aleph_0}$ Polish spaces.

We can now answer Question VI.2.9.1.:

VI.2.9.10. THEOREM. (i) Up to homeomorphism, there are exactly $2^{2^{\aleph_0}}$ separable metric spaces.
(ii) Up to isometry, there are exactly $2^{2^{\aleph_0}}$ separable metric spaces.

PROOF: Every separable metric space is isometric to a subset of a separable complete metric space. Every separable complete metric space has cardinality $\leq 2^{\aleph_0}$ (XIII.7.10.6.(c)) (in fact, exactly $2^{\aleph_0}$ if uncountable; cf. XVI.3.1.10.). Thus a separable complete metric space has at most $2^{2^{\aleph_0}}$ subsets. Since there are $2^{\aleph_0}$ separable complete metric spaces up to isometry (VI.2.9.8.), there are up to isometry at most $2^{\aleph_0} \cdot 2^{2^{\aleph_0}} = 2^{2^{\aleph_0}}$ subsets of complete metric spaces. Hence there are at most $2^{2^{\aleph_0}}$ separable metric spaces up to isometry.

Conversely, there are $2^{2^{\aleph_0}}$ topologically distinct subsets of $\mathbb{R}$ (XIII.19.5.45.), each of which is a separable metric space. Thus there are at least $2^{2^{\aleph_0}}$ separable metric spaces up to homeomorphism. 👍

VI.2.10. The Banach Fixed-Point Theorem

There are many fixed-point theorems in topology, which assert that under certain conditions a function from a topological space to itself sends at least one, or exactly one, point to itself. Perhaps the simplest example is (); other examples are XIII.21.1.2., (), ... Here we discuss a fairly elementary but very useful example, the Banach fixed-point theorem, sometimes called the *Contraction Mapping Theorem*.

VI.2.10.1. DEFINITION. Let (X, ρ) be a metric space. A function $T : X \to X$ is a *strict contraction* if there is an α, $0 < \alpha < 1$, such that $\rho(T(x), T(y)) \leq \alpha\rho(x, y)$ for all $x, y \in X$.

A strict contraction is obviously a (uniformly) continuous function from X to X.

VI.2.10.2. **Caution:** For T to be a strict contraction, it is not sufficient that $\rho(T(x), T(y)) < \rho(x, y)$ whenever $x \neq y$; the distance must decrease by at least a constant factor less than 1. See VI.2.10.6.. ✋

VI.2.10.3. THEOREM. [BANACH FIXED-POINT THEOREM] Let (X, ρ) be a complete metric space, and $T : X \to X$ a strict contraction. Then T has a unique fixed point: there is a unique point $p \in X$ with $T(p) = p$. If x is any point of X, then the sequence $(T^n(x))$ converges to p.

PROOF: Fix $x \in X$. Inductively set $x_0 = x$ and $x_{n+1} = T(x_n)$ for all n. We claim (x_n) is a Cauchy sequence. By induction, we have $\rho(x_n, x_{n+1}) \leq \alpha^n \rho(x_0, x_1)$ for all n. Thus, if $n < m$, by the triangle inequality we have

$$\rho(x_n, x_m) \leq \rho(x_0, x_1) \sum_{k=n}^{m-1} \alpha^k \ .$$

The sum is a tail sum of the convergent geometric series $\sum_{k=1}^{\infty} \alpha^k$, hence is arbitrarily small if n is large enough. Thus (x_n) is a Cauchy sequence and therefore converges to a point $p \in X$. Then $T(x_n) \to T(p)$ since T is continuous; but $T(x_n) = x_{n+1}$, so $T(x_n) \to p$, i.e. $T(p) = p$ by uniqueness of limits in a metric space.
If q is any fixed point of T, then

$$\rho(p, q) = \rho(T(p), T(q)) \leq \alpha\rho(p, q)$$

which can only hold if $\rho(p, q) = 0$, i.e. $q = p$. Thus p is the only fixed point of T. 👍

VI.2.10.4. The proof of the theorem is constructive: the sequence of iterates of any starting point converge to the fixed point, i.e. the fixed point is a "universal attractor." Thus the fixed point can be found by an explicit iterative algorithm of successive approximation.

VI.2.10.5. If (X, ρ) is not complete, a strict contraction on X need not have a fixed point (VI.2.11.1.). However, *if* it does, the argument of the proof shows that the fixed point is unique (this part of the proof does not require completeness). And if p is a fixed point of T, then for any $x \in X$ we have $\rho(T^n(x), p) = \rho(T^n(x), T^n(p)) \leq \alpha^n \rho(x, p) \to 0$, so $T^n(x) \to p$. Alternatively, any strict contraction on (X, ρ) extends uniquely to a strict contraction $\bar{T}$ on the completion $(\bar{X}, \bar{\rho})$ of (X, ρ) by uniform continuity (); if T has a fixed point, it must be the unique fixed point of $\bar{T}$ and we have $T^n(x) \to p$ for any $x \in X$.

VI.2.10.6. EXAMPLE. To obtain a fixed point, it does not suffice to simply have $\rho(T(x),T(y)) < \rho(x,y)$ for $x \neq y$; this condition is not enough to insure that $(T^n(x))$ is a Cauchy sequence for any x. For example, let $T : [1,+\infty) \to [1,+\infty)$ be defined by $T(x) = x + \frac{1}{x}$. Then T is differentiable everywhere and $0 < T'(x) < 1$ for $1 < x < +\infty$, so by the MVT $|T(x)-T(y)| < |x-y|$ for $x, y \in [1,+\infty)$, $x \neq y$ (this also has an elementary proof not requiring calculus). But T has no fixed point.

Continuity of Fixed Points

If two strict contractions are uniformly close, their fixed points must be close:

VI.2.10.7. PROPOSITION. Let (X,ρ) be a metric space, and S, T strict contractions on X, i.e. there are $0 \leq \alpha, \beta < 1$ such that $\rho(S(x),S(y)) \leq \alpha\rho(x,y)$ and $\rho(T(x),T(y)) \leq \beta\rho(x,y)$ for all $x, y \in X$. Let p and q be (unique) fixed points of S and T respectively. If S and T are uniformly close within $\epsilon > 0$, i.e. $\rho(S(x),T(x)) < \epsilon$ for all $x \in X$, then $\rho(p,q) < \frac{\epsilon}{1-\gamma}$, where $\gamma = \min(\alpha,\beta)$.

PROOF: We have $\lim_{n\to\infty} S^n(q) = p$, and by the triangle inequality we have, for each n,

$$\rho(q,S^n(q)) = \rho(q,S(q)) + \rho(S(q),S^2(q)) + \cdots + \rho(S^{(n-1)}(q),S^n(q))$$

$$\leq (1 + \alpha + \cdots + \alpha^{n-1})\rho(q,S(q)) = \frac{1-\alpha^n}{1-\alpha}\rho(q,S(q)) < \frac{1}{1-\alpha}\rho(q,S(q))$$

and thus, letting $k \to \infty$,

$$\rho(q,p) \leq \frac{1}{1-\alpha}\rho(q,S(q)) = \frac{1}{1-\alpha}\rho(T(q),S(q)) < \frac{\epsilon}{1-\alpha}\ .$$

Similarly, we have $\rho(p,q) = \lim_{n\to\infty} \rho(p,T^n(p)) < \frac{\epsilon}{1-\beta}$. 👍

Strict Power Contractions and the Extended Banach Fixed-Point Theorem

There is a substantial extension of the Banach Fixed-Point Theorem.

VI.2.10.8. DEFINITION. Let (X,ρ) be a metric space. A function $T : X \to X$ is a *strict power contraction* if T^n is a strict contraction for some $n \in \mathbb{N}$.

VI.2.10.9. EXAMPLE. A strict power contraction is not necessarily a strict contraction. It is not necessarily even continuous! Let $X = \mathbb{R}$ with its usual metric, and define $T : \mathbb{R} \to \mathbb{R}$ by

$$T(x) = \begin{cases} x/2 & \text{if} \quad x \in \mathbb{Q} \\ -x/2 & \text{if} \quad x \notin \mathbb{Q} \end{cases}\ .$$

Then T is not continuous, but T^2 is a strict contraction, so T is a strict power contraction.
Note that T has a unique fixed point 0, and is continuous at 0 (and only at 0).

VI.2.10.10. THEOREM. [EXTENDED BANACH FIXED-POINT THEOREM] Let (X, ρ) be a complete metric space, and $T : X \to X$ a strict power contraction. Then T has a unique fixed point p. If x is any point of X, then the sequence $(T^n(x))$ converges to p.

PROOF: Suppose T^n is a strict contraction. Then T^n has a unique fixed point p by Theorem VI.2.10.3.. We have

$$T^n(T(p)) = T^{n+1}(p) = T(T^n(p)) = T(p)$$

so $T(p)$ is also a fixed point of T^n; thus $T(p) = p$ by uniqueness, and p is a fixed point of T. If q is any fixed point of T, then q is also a fixed point of T^n, hence $q = p$ by uniqueness, so T has a unique fixed point.
Fix $x \in X$. Then $\lim_{k\to\infty} T^{kn}(x) = p$. Also, for each j, $T^{kn+j}(x) = T^{kn}(T^j(x)) \to p$ as $k \to \infty$. It follows that $\lim_{m\to\infty} T^m(x) = p$. 👍

VI.2.10.11. If (X, ρ) is not complete, a strict power contraction on X need not have a fixed point (VI.2.11.1.). However, *if* it does, the fixed point is unique (VI.2.10.5.), and the proof shows that $T^n(x) \to p$ for any $x \in X$ (this part of the proof does not require completeness). The alternate argument of VI.2.10.5. does not work, however, since in general there is no reasonable way to extend a power contraction to the completion.

VI.2.11. Exercises

VI.2.11.1. Let $X = \mathbb{Q} \cap [1, 2]$ with the usual metric, and define $T : X \to X$ by

$$T(x) = \frac{1}{2}\left(x + \frac{2}{x}\right) .$$

(a) Show that T is a strict contraction on X.

(b) Show that T has no fixed point in X.

(c) Identify $\bar{X}$ with $[1, 2]$ with the usual metric, and $\bar{T}$ with the function from $\bar{X}$ to $\bar{X}$ defined by the same formula as T. Find the fixed point of $\bar{T}$.

VI.2.11.2. A strict power contraction does not have to be continuous (VI.2.10.9.). If it has a fixed point (e.g. if the metric space is complete), does it have to be continuous at the fixed point? Give a proof or counterexample.

VI.2.11.3. Discuss the difficulties in trying to extend VI.2.10.7. to power contractions. Is there any reasonable result?

VI.3. Euclidean Space

VI.3.1. Metric Axiomatization of Euclidean Space

There are several approaches one can take to defining n-dimensional Euclidean space. We can just define it to *be* $\mathbb{R}^n$ (with the standard metric ρ_2). We will eventually take this approach, but it is worth noting that Euclidean space can be defined in a more abstract manner and shown to be effectively the same as $\mathbb{R}^n$.

There are two such approaches possible, characterizing $\mathbb{R}^n$ directly as a metric space, and giving a set of purely geometric axioms. Since this is a book about analysis, we will take the metric space approach, which may be rather unsatisfying to geometers. The metric approach is, however, quite elegant (although some of the proofs are rather involved), and not as well known as it should be. Our exposition is adapted from [Blu70] (cf. also [Blu75]), where the history of various metric approaches is discussed. For the purely geometric approach, see [Gre93], [Har00], and/or [Moi90].

VI.3.1.1. One easy metric approach is to define n-dimensional Euclidean space to be a metric space isometric to $\mathbb{R}^n$. Since the isometries of $\mathbb{R}^n$ can be nicely described (XX.2.2.4.), and preserve the affine structure, an isometry from an abstract metric space E to $\mathbb{R}^n$ is almost unique (up to a choice of origin and an ordered orthonormal basis) and can be used to transfer the structure of $\mathbb{R}^n$ to E. We will regard a choice of an isometry of E with $\mathbb{R}^n$ to be a *choice of a coordinate system* in E. By choosing a coordinate system, we can identify E with $\mathbb{R}^n$ and all analysis we do on E can be described using the chosen coordinates; it will all turn out to be independent of the coordinate system chosen in an appropriate sense ().

VI.3.1.2. We can, however, characterize n-dimensional Euclidean space abstractly as a metric space by three axioms (VI.3.1.43.), or four simpler axioms plus completeness (VI.3.1.44.). These axioms will presuppose having $\mathbb{R}$ available by some previous construction; this is undesirable from a geometric point of view, but necessary from the metric standpoint (indeed, the definition of a metric space itself depends on already having $\mathbb{R}$, or at least $\mathbb{R}_+$). $\mathbb{R}$ is always assumed to have its usual metric.

We will give the three axioms for a metric space (E, ρ), and discuss some variations and equivalent versions of them.

The Line Axiom

VI.3.1.3. Definition. A subset L of a metric space (E, ρ) is a *line* if L is isometric to $\mathbb{R}$. A subset of E isometric to a closed bounded interval $[\alpha, \beta]$ in $\mathbb{R}$ is called a *line segment* in E, with the points corresponding to α and β the *endpoints*. A subset of E isometric to $[0, \infty)$ is called a *ray* in E, beginning at (or with endpoint) the point corresponding to 0.

VI.3.1.4. **Line Axiom:** For any two points $a, b \in E$ there is a line in E containing a and b.

Such a subset is called a *line through a and b*. Note that no uniqueness is required as part of the axiom (uniqueness will follow from the second axiom; cf. VI.3.1.27.). A metric space in which each pair of distinct points lies on a unique line will be said to satisfy the *Unique Line Axiom*. Similarly:

VI.3.1.5. **Line Segment Axiom:** For any two (distinct) points $a, b \in E$ there is a line segment in E with endpoints a and b.

A metric on a set which satisfies the Line Segment Axiom is called a *strictly intrinsic metric*. See () for an explanation of this terminology from metric geometry. The Line Axiom is more important than the Line Segment Axiom in this section, but the Line Segment Axiom is central in metric geometry ().

VI.3.1.6. EXAMPLES. (i) $(\mathbb{R}^2, \rho_\infty)$ () satisfies the Line Axiom (as does any normed real vector space viewed as a metric space). But lines through two given points are not unique in general: for example, the graph of any Lipschitz function from $\mathbb{R}$ to $\mathbb{R}$ () with Lipschitz constant ≤ 1 (contractive function), regarded as a subset of $\mathbb{R}^2$ in the usual way, is a line in this metric space.

(ii) Any convex set in $\mathbb{R}^n$ (or any normed vector space) satisfies the Line Segment Axiom. Again the line segment need not be unique.

(iii) A circle with the arc length metric satisfies the Line Segment Axiom, as does a 2-sphere with the great circle arc length metric. The line segment is not unique for diametrically opposed points. They do not satisfy the Line Axiom.

If the metric space (E, ρ) is assumed to be complete, an apparently much weaker assumption implies the Line Axiom. We first make a definition:

VI.3.1.7. DEFINITION. Let $a, c \in E$. A point $b \in E$ is *between* a and c if $b \neq a$, $b \neq c$, and $\rho(a, c) = \rho(a, b) + \rho(b, c)$.

In $\mathbb{R}$, b is between a and c in this sense if and only if b is between a and c with respect to the usual ordering on $\mathbb{R}$. More generally, if L is a line in a metric space, then the various isometries of L with $\mathbb{R}$ give two orderings on L, and if $a, b, c \in L$, then b is between a and c in the sense of VI.3.1.7. if and only if b is between a and c with respect to either (both) of these orderings. In particular, if a, b, and c are distinct points on a line in a metric space, exactly one of the points is between the other two.

Note, however, that the set of points between two given points in a metric space need not look anything like a line segment (cf. Exercise VI.3.3.1.); indeed, this set can easily be empty or finite.

There is a limited sense in which betweenness is transferable:

VI.3.1.8. PROPOSITION. Let a, b, c, d be points in a metric space (E, ρ). If b is between a and d and c is between b and d, then c is between a and d and b is between a and c.

PROOF: We have

$$\rho(a, d) = \rho(a, b) + \rho(b, d) = \rho(a, b) + \rho(b, c) + \rho(c, d)$$

and since $\rho(a, d) \leq \rho(a, c) + \rho(c, d)$ by the triangle inequality, we have

$$\rho(a, c) \geq \rho(a, b) + \rho(b, c)$$

by subtraction; the opposite inequality holds by the triangle inequality, so

$$\rho(a, c) = \rho(a, b) + \rho(b, c)$$

and c is between a and b. Then we have

$$\rho(a, d) = \rho(a, b) + \rho(b, c) + \rho(c, d) = \rho(a, c) + \rho(c, d)$$

so c is between a and d. 👍

VI.3.1.9. Care must be exercised in combining betweenness relations, however; overlapping relations cannot be combined in general (betweenness is not "transitive"). For example, if $(E,\rho) = (\mathbb{R}^2, \rho_\infty)$ and $a = (0,0)$, $b = (1,1)$, $c = (2,0)$, and $d = (1,-1)$, then b is between a and c and c is between b and d, but neither b nor c is between a and d.

There is a useful consequence of VI.3.1.8.:

VI.3.1.10. Corollary. Let (E,ρ) be a metric space, $a,b,c \in E$, S_1 a line segment with endpoints a and b, and S_2 a line segment with endpoints b and c. Then $S = S_1 \cup S_2$ is a line segment with endpoints a and c if and only if b is between a and c.

Proof: If S is a line segment, then b is clearly between a and c. Conversely, if b is between a and c, to show S is a line segment it suffices to show that if $x \in S_1$, $y \in S_2$, $x \neq b$, $y \neq b$, then $\rho(x,y) = \rho(x,b) + \rho(b,y)$, i.e. that b is between x and y. Apply VI.3.1.8. to a,b,y,c to conclude that b is between a and y, and then apply VI.3.1.8. again to y,b,x,a to conclude that b is between y and x. 👍

VI.3.1.11. **Between Axiom:** If $a,c \in E$, $a \neq c$, then there is a $b \in E$ which is between a and c.

VI.3.1.12. **Extension Axiom:** If $a,b \in E$, $a \neq b$, then there is a $c \in E$ such that b is between a and c.

In metric geometry (e.g. in [Blu70]), a metric space satisfying the Between Axiom is often called *metrically convex*, and a metric space satisfying the Extension Axiom is called *externally convex*. We have not used these terms since they do not seem appropriate in general: for example, the subset $[0,1) \cup \{2\}$ of $\mathbb{R}$ satisfies the Between Axiom, and $\mathbb{Z}$ satisfies the Extension Axiom, but neither resembles a convex set in the usual sense (). However, the two axioms together, along with completeness, are quite powerful:

VI.3.1.13. Theorem. Let (E,ρ) be a complete metric space satisfying the Between Axiom and the Extension Axiom. Then (E,ρ) satisfies the Line Axiom.

Completeness is essential for this result: the subsets $\mathbb{Q}$ and $(0,1)$ of $\mathbb{R}$ each satisfy both the Between Axiom and the Extension Axiom, but not the Line Axiom. Note also that even for complete metric spaces, neither axiom implies the other: consider $[0,1]$ and $\mathbb{Z}$.

The proof of VI.3.1.13. consists of three lemmas.

VI.3.1.14. Lemma. Let (E,ρ) be a complete metric space satisfying the Between Axiom. Then (E,ρ) satisfies the Line Segment Axiom.

Proof: We give a simple proof using Zorn's Lemma. A somewhat more complicated proof can be given which requires only the Axiom of Dependent Choice; cf. [Blu70, Theorem 14.1] and Exercise VI.3.3.8..

Let $\mathcal{X}$ be the set of all subsets of E containing a and b and isometric to a subset of $[0,\lambda]$, where $\lambda = \rho(a,b)$, ordered by inclusion. (Note that $\{a,b\} \in \mathcal{X}$, so $\mathcal{X}$ is nonempty.) For every set $X \in \mathcal{X}$, there is a unique

isometry ϕ_X from X to $[0,\lambda]$ with $\phi_X(a)=0$ and $\phi_X(b)=\lambda$. If $\{X_i\}$ is a chain in $\mathcal{X}$, and $X=\cup_i X_i$, define $\phi_X : X \to [0,1]$ by $\phi_X(x)=\phi_{X_i}(x)$ for $x\in X_i$; this is well defined by uniqueness of the ϕ_{X_i}: if $X_i\subseteq X_j$, then $\phi_{X_j}|_{X_i}=\phi_{X_i}$. Then ϕ_X is an isometry since if $x,y\in X$, then $x,y\in X_i$ for some i.

If $X\in\mathcal{X}$, then since ϕ_X is an isometry it extends to an isometry from the closure $\bar{X}$ in E to $[0,\lambda]$, and hence $\bar{X}\in\mathcal{X}$.

Let X be a maximal element of $\mathcal{X}$. Then X is closed in E, and hence complete; thus $K=\phi_X(X)$ is complete, hence closed in $[0,\lambda]$. If $K\neq[0,\lambda]$, there is an interval $[\alpha,\beta]\subseteq[0,\lambda]$ with $\alpha,\beta\in K$ and $(\alpha,\beta)\cap K=\emptyset$. Let $c,d\in X$ with $\phi_X(c)=\alpha$, $\phi_X(d)=\beta$. There is a $p\in E$ between c and d. Since c and d are between a and b, by VI.3.1.8. we have p between a and b. Then $p\notin X$ since $\rho(a,p)\in(\alpha,\beta)$. If x is any element of X, then x is either between a and c or between d and b; it follows from VI.3.1.8. that if $x,y\in X$, then one of x,y,p is between the other two. Thus ϕ_X extends to an isometry of $X\cup\{p\}$ to $[0,\lambda]$, contradicting maximality of X. Thus $K=[0,\lambda]$ and X is a line segment with endpoints a and b. 👍

Now we turn to the procedure of extending line segments.

VI.3.1.15. Lemma. Let (E,ρ) be a complete metric space satisfying the Extension Axiom, and let $a,b\in E$. Then

$$\sup\{\rho(a,c) : c\in E, b \text{ is between } a \text{ and } c\} = +\infty\ .$$

Proof: Suppose $\lambda_1=\sup\{\rho(a,c) : c\in E, b \text{ is between } a \text{ and } c\}$ is finite. Let $c_1\in E$ with b between a and c_1 and $\rho(a,c_1)>\lambda_1-1$. If $c\in E$ and c_1 is between a and c, then b is between a and c by VI.3.1.8.. Thus

$$\lambda_2=\sup\{\rho(a,c) : c\in E, c_1 \text{ is between } a \text{ and } c\}$$

is finite and $\lambda_2\leq\lambda_1$. Inductively let

$$\lambda_{n+1}=\sup\{\rho(a,c) : c\in E, c_n \text{ is between } a \text{ and } c\}\leq\lambda_n$$

and let c_{n+1} be a point of E with c_n between a and c_{n+1} (hence by VI.3.1.8. b is between a and c_{n+1}) and $\rho(a,c_{n+1})>\lambda_{n+1}-\frac{1}{n+1}$.

Set $\lambda=\inf\lambda_n=\lim\lambda_n$. If $n<m$, we have c_n between a and c_m, hence

$$\lambda_n-\frac{1}{n}<\rho(a,c_n)<\rho(a,c_m)\leq\lambda_n$$

so $\rho(c_n,c_m)<\frac{1}{n}$ for $n<m$ and thus (c_n) is a Cauchy sequence in E. By completeness, (c_n) converges to some $c\in E$, and we have

$$\lambda_n-\frac{1}{n}<\rho(a,c)\leq\lambda_n$$

for all n; thus $\rho(a,c)=\lambda$ by the Squeeze Theorem (). By continuity, b and c_n are between a and c for all n.

Choose $d\in E$ with c between a and d. Then $\rho(a,d)>\lambda$, so $\rho(a,d)>\lambda_n$ for some n. But c_n is between a and d, so this contradicts the definition of λ_n. Thus the assumption that $\lambda_1<+\infty$ is false. 👍

VI.3.1.16. LEMMA. Let (E, ρ) be a complete metric space satisfying the Between and Extension Axioms. Then

(i) (E, ρ) satisfies the Line Axiom.

(ii) Every line segment in E can be extended to a line in E.

(iii) If $a, b \in E$, and $x_1, \ldots, x_n$ are points of E between a and b, with x_k between a and x_{k+1} for $1 \leq k \leq n-1$, then there is a line in E containing a, b, and all the x_k.

PROOF: For (i), let $a, b \in E$. By Lemma VI.3.1.14., there is a line segment S_0 with endpoints a and b. For (ii), let S_0 be a line segment in E, and let a and b be its endpoints. For (iii), there is a line segment with endpoints a and x_1, for each $k < n$ a line segment with endpoints x_k and x_{k+1}, and a line segment with endpoints x_n and b. By repeated use of VI.3.1.10., the union of these segments is a line segment S_0 with endpoints a and b containing all the x_k.

In each case, begin with the segment S_0. By Lemma VI.3.1.15. there is a $c_1 \in E$ with b between a and c_1 and $\rho(a, c_1) \geq 2\rho(a, b)$. By Lemma VI.3.1.14. there is a line segment S_1 in E with endpoints b and c_1. Since b is between a and c_1, $S_0 \cup S_1$ is a line segment with endpoints a and c_1 by VI.3.1.10..

Now let $c_2 \in E$ with a between c_1 and c_2 and $\rho(c_1, c_2) \geq 2\rho(a, c_1)$, and let S_2 be a line segment with endpoints a and c_2. Then $S_0 \cup S_1 \cup S_2$ is a line segment in E with endpoints c_1 and c_2. Now let $c_3 \in E$ with c_1 between c_2 and c_3 and $\rho(c_2, c_3) \geq 2\rho(c_1, c_2)$, and let S_3 be a line segment between c_1 and c_3. Continue inductively placing c_{n+1} at the c_{n-1} end of the already constructed segment with endpoints c_{n-1} and c_n. Then $\cup_{k=0}^{n+1} S_k$ is a line segment between c_n and c_{n+1} extending the previous segment, and the length of this segment is at least $2^{n+1}\rho(a, b)$. The union of the S_n is a line in E through a and b. 👍

This completes the proof of Theorem VI.3.1.13..

Here are variations of the Between and Extension Axioms which are sometimes useful:

VI.3.1.17. DEFINITION. If $a, b \in E$, then (a, b) has the *Interpolation Property* if for each $t \in [0, 1]$ there is a point $c \in E$ such that

$$\rho(a, c) = t\rho(a, b) \quad \text{and} \quad \rho(b, c) = (1 - t)\rho(a, b) \ .$$

If $a, b \in E$, and $t \in \mathbb{R}$, then (a, b) has the *Extrapolation Property* if for each $t \geq 1$ there is a point $c \in E$ such that

$$\rho(a, c) = t\rho(a, b) \quad \text{and} \quad \rho(b, c) = (t - 1)\rho(a, b) \ .$$

The pair (a, b) has the *Unique Interpolation Property* (resp. the *Unique Extrapolation Property*) if the c is unique.

The Interpolation Property is symmetric in a and b, but the Extrapolation Property is not.

VI.3.1.18. If there is a line segment in E with endpoints a and b, then (a, b) has the Interpolation Property. But even the Unique Interpolation Property for (a, b) does not imply that there is a line segment in E with endpoints a and b (Exercise VI.3.3.3.). Similarly, if there is a ray from a through b, then (a, b) has the Extrapolation Property; but even the Unique Extrapolation Property does not imply existence of a ray.

A metric space with the Interpolation Property satisfies the Between Axiom; the converse is false in general if the space is incomplete (e.g. $\mathbb{Q}$). Similarly, the Extrapolation Property implies the Extension Axiom, but not conversely (e.g. $\mathbb{Z}$).

Here is a result which, among other things, can substitute for completeness in yielding the Line Axiom:

VI.3.1.19. THEOREM. (i) If every pair (a, b) of points in E has the Unique Interpolation Property, then for every $a, b \in E$, $a \neq b$, there is a unique line segment in E with endpoints a and b.

(ii) If every pair (a, b) of points in E has the Unique Interpolation Property and the Unique Extrapolation Property, then through any two distinct points of E there is a unique line.

See Exercise VI.3.3.7. for the proof.

The Pythagorean Axiom

The second axiom for Euclidean space has several equivalent forms, at least in the presence of the Line Axiom.

VI.3.1.20. **Weak Euclidean Four-Point Axiom:** If $a, b, c, d \in E$, and b, c, d lie on a line in E, then $\{a, b, c, d\}$ is isometric to a set of four points in $\mathbb{R}^2$ (with the usual Euclidean metric).

The stronger *Euclidean Four-Point Axiom* is the same without the requirement that three of the points lie on a line, and $\mathbb{R}^2$ replaced by $\mathbb{R}^3$. These axioms trivially hold in $\mathbb{R}^n$ (four points in $\mathbb{R}^n$ generate an affine subspace of dimension ≤ 3).

One can similarly define the *Euclidean n-Point Axiom* for any n. Note that every metric space satisfies the Euclidean Three-Point Axiom, since if α, β, γ are any positive real numbers with each less than or equal to the sum of the other two, there is a (possibly degenerate) triangle in $\mathbb{R}^2$ with sides α, β, γ. It turns out that the Weak Euclidean Four-Point Axiom along with the Line Axiom implies the Euclidean n-Point Axiom for all n (VI.3.1.27., VI.3.1.35.).

VI.3.1.21. DEFINITION. Let (E, ρ) be a metric space and a, b distinct points of E. A point m in E is a *midpoint* for a and b if $\rho(a, m) = \rho(m, b) = \frac{1}{2}\rho(a, b)$. A midpoint m is a *linear midpoint* if there is a line in E containing a, b, and m.

A midpoint for a and b is obviously between a and b. Each line through a and b contains a unique midpoint of a and b; however, if lines are not unique, (linear) midpoints may not be unique either (Exercise VI.3.3.2.).

If (E, ρ) is complete and satisfies the Between and Extension Axioms, then any midpoint m for a and b automatically lies on a line through a and b (VI.3.1.16.(iii)) and is thus a linear midpoint. The Line Axiom is not enough to guarantee this, however (?)

VI.3.1.22. **Parallelogram Axiom:** If $a, b, c \in E$, and m is a linear midpoint of b and c, then

$$2\left[\rho(a,b)^2 + \rho(a,c)^2\right] = \rho(b,c)^2 + 4\rho(a,m)^2 \ .$$

This law expresses the familiar geometric fact that the sum of the squares of the lengths of the diagonals of a parallelogram equals the sum of the squares of the lengths of the sides. (The fourth vertex of the "parallelogram" would be a point d for which m is also a midpoint for a and d. In the presence of the Line Axiom, it will follow that there is a unique such d, and opposite sides of the resulting figure are automatically equal length.) This axiom holds in $\mathbb{R}^n$ (XX.11.2.6.).

VI.3.1.23. Definition. Let S be a subset of a metric space (E, ρ), and a a point of E. A *foot* of a on S is a point f of S such that $\rho(a,f) = \rho(a,S) = \min\{\rho(a,c) : c \in S\}$.

If $a \in S$, then a itself is a foot of a on S (and is the only foot of a on S). The concept of foot is only interesting if $\rho(a,S) > 0$.

VI.3.1.24. Proposition. Let (E, ρ) be a metric space, S a subset of E with the Bolzano-Weierstrass property () (e.g. a subset of E isometric to $\mathbb{R}^n$ for some n), and a a point of E. Then there exists a foot of a on S.

Proof: Let c be an element of S. Let

$$K = \{x \in S : \rho(x,c) \leq 2\rho(a,c)\} \ .$$

Then the triangle inequality implies that if e is a point of L which is not in K, then $\rho(a,e) > \rho(a,c)$. So we have $\rho(a,S) = \rho(a,K)$, and K is closed and bounded in E, hence compact, so the distance is minimized at some point of K (). 👍

VI.3.1.25. In particular, if L is a line in E, and a a point of E, then a has a foot on L. A foot of a point a on a line L need not be unique in general. For example, in $(\mathbb{R}^2, \rho_\infty)$, if L is the x-axis and $a = (0,1)$, then any point $(t,0)$ with $|t| \leq 1$ is a foot of a on L.

VI.3.1.26. **Pythagorean Axiom:** If L is a line in E, and a a point of E, and f is a foot of a on L, then for any $c \in L$ we have

$$\rho(a,c)^2 = \rho(a,f)^2 + \rho(f,c)^2 \ .$$

The Pythagorean Axiom holds in $\mathbb{R}^n$ (). It obviously implies that the foot of a point on a line is unique.

VI.3.1.27. Theorem. Let (E, ρ) be a metric space satisfying the Line Axiom. The following are equivalent:

(i) (E, ρ) satisfies the Weak Euclidean Four Point Axiom.

(ii) (E, ρ) satisfies the Parallelogram Axiom.

(iii) (E, ρ) satisfies the Pythagorean Axiom.

(iv) If L is a line in E and a a point of E not on L, then $L \cup \{a\}$ can be isometrically embedded in $\mathbb{R}^2$ (with the usual metric).

These conditions imply that there is a unique line through any two distinct points of E.

PROOF: (iv) $\Rightarrow$ (i) $\Rightarrow$ (ii) and (iv) $\Rightarrow$ (iii) are trivial. We will prove (iii) $\Rightarrow$ (ii) $\Rightarrow$ (iv). (In fact, the Line Axiom is only needed for (iv) $\Rightarrow$ (i) and for the last assertion.) 👍

VI.3.1.28. LEMMA. Let (E, ρ) be a metric space satisfying the Pythagorean Axiom. Then E satisfies the Parallelogram Axiom.

PROOF: Let $a, b, c \in E$ and L a line through b and c. Let m be the midpoint of b and c on L, and let f be the foot of a on L. Set $\alpha = \rho(a, c)$, $\beta = \rho(a, b)$, $\gamma = \rho(b, c)$. There are two cases to consider: (1) $f = b$, $f = c$, or f is between b and c, and (2) c is between b and f (the case where b is between f and c is symmetric and handled by interchanging b and c). See Figure (), although the reader is cautioned that since the points are in E and not in $\mathbb{R}^2$, the accuracy of the picture cannot (yet) be justified and it should be used only as a visual aid in following the proof (this is usually a good attitude to take with any picture or diagram).

Consider case (1). By interchanging b and c if necessary, we may assume that $f = c$, $f = m$, or f is between m and c. Then there is a t, $0 \leq t \leq \frac{1}{2}$, such that $\rho(f, c) = t\gamma$, $\rho(m, f) = \left(\frac{1}{2} - t\right)\gamma$, $\rho(b, f) = (1-t)\gamma$. Set $\eta = \rho(a, f)$ and $\zeta = \rho(a, m)$. By the Pythagorean Axiom we have

$$\alpha^2 = \eta^2 + t^2\gamma^2$$
$$\beta^2 = \eta^2 + (1-t)^2\gamma^2 = \eta^2 + \gamma^2 - 2t\gamma^2 + t^2\gamma^2$$
$$\zeta^2 = \eta^2 + \left(\frac{1}{2} - t\right)^2\gamma^2 = \eta^2 + \frac{1}{4}\gamma^2 - t\gamma^2 + t^2\gamma^2$$

so we have

$$2\alpha^2 + 2\beta^2 = 2\eta^2 + 2t^2\gamma^2 + 2\eta^2 + 2\gamma^2 - 4t\gamma^2 + 2t^2\gamma^2 = 4\eta^2 + 2\gamma^2 - 4t\gamma^2 + 4t^2\gamma^2$$
$$4\zeta^2 + \gamma^2 = 4\eta^2 + \gamma^2 - 4t\gamma^2 + 4t^2\gamma^2 + \gamma^2 = 2\alpha^2 + 2\beta^2$$

which is the Parallelogram formula.

Now consider case (2). There is a $t \geq 0$ such that $\rho(f, c) = t\gamma$, $\rho(f, m) = \left(\frac{1}{2} + t\right)\gamma$, $\rho(f, b) = (1+t)\gamma$. Again by the Pythagorean Axiom

$$\alpha^2 = \eta^2 + t^2\gamma^2$$
$$\beta^2 = \eta^2 + (1+t)^2\gamma^2 = \eta^2 + \gamma^2 + 2t\gamma^2 + t^2\gamma^2$$
$$\zeta^2 = \eta^2 + \left(\frac{1}{2} + t\right)^2\gamma^2 = \eta^2 + \frac{1}{4}\gamma^2 + t\gamma^2 + t^2\gamma^2$$

so we have

$$2\alpha^2 + 2\beta^2 = 2\eta^2 + 2t^2\gamma^2 + 2\eta^2 + 2\gamma^2 + 4t\gamma^2 + 2t^2\gamma^2 = 4\eta^2 + 2\gamma^2 + 4t\gamma^2 + 4t^2\gamma^2$$
$$4\zeta^2 + \gamma^2 = 4\eta^2 + \gamma^2 + 4t\gamma^2 + 4t^2\gamma^2 + \gamma^2 = 2\alpha^2 + 2\beta^2$$

which is the Parallelogram formula. 👍

VI.3.1.29. LEMMA. Let (E,ρ) be a metric space satisfying the Parallelogram Axiom. Let L be a line in E, b, c points on L, and a a point not on L. Set $\alpha = \rho(a,c)$, $\beta = \rho(a,b)$, $\gamma = \rho(b,c)$. Then for any $t \in \mathbb{R}$, if d_t is the unique point on L with $\rho(b,d_t) = |t|\gamma$ and $\rho(d,c) = |1-t|\gamma$, we have

$$\rho(a,d_t)^2 = t\alpha^2 + (1-t)\beta^2 - t(1-t)\gamma^2 \ .$$

PROOF: By continuity, it suffices to prove the formula if t is a dyadic rational number. The formula is trivially true if $t = 0$ or $t = 1$ (and the case $t = \frac{1}{2}$ is the Pythagorean Axiom, although we do not explicitly need this case).

We first show that if the formula holds for t, it also holds for $-t$. Set $\rho(a,d_t) = \eta$. By assumption,

$$\eta^2 = t\alpha^2 + (1-t)\beta^2 - t(1-t)\gamma^2 \ .$$

Since $\rho(d_t, d_{-t}) = 2|t|\gamma$ and b is the midpoint of d_t and d_{-t} on L, by the Parallelogram Axiom we have

$$2\rho(a,d_{-t})^2 + 2\eta^2 = 4\beta^2 + 4t^2\gamma^2$$

$$\rho(a,d_{-t})^2 = 2\beta^2 - \eta^2 + 2t^2\gamma^2 = [2-(1-t)]\beta^2 - t\alpha^2 + [2t^2 + t(1-t)]\gamma^2$$

$$= -t\alpha^2 + (1+t)\beta^2 + t(1+t)\gamma^2 = (-t)\alpha^2 + (1-(-t))\beta^2 - (-t)(1-(-t))\gamma^2$$

so the formula holds for $-t$.

Similarly, we show that if the formula holds for t, it holds for $2t$. Again let $\eta = \rho(a,d_t)$. Since $\rho(b,d_{2t}) = 2|t|\gamma$ and d_t is the midpoint of b and d_{2t} on L, by the Parallelogram Axiom we have

$$2\rho(a,d_{2t})^2 + 2\beta^2 = 4\eta^2 + 4t^2\gamma^2$$

$$\rho(a,d_{2t})^2 = 2\eta^2 - \beta^2 + 2t^2\gamma^2 = 2[t\alpha^2 + (1-t)\beta^2 - t(1-t)\gamma^2] - \beta^2 + 2t^2\gamma^2$$

$$= 2t\alpha^2 + [2(1-t)-1]\beta^2 + [2t^2 - 2t(1-t)]\gamma^2 = 2t\alpha^2 + (1-2t)\beta^2 - 2t(1-2t)\gamma^2$$

so the formula holds for $2t$.

Finally, suppose $s, t \in \mathbb{R}$ and the statement is true for s and t. We will show that the statement is also true for $r = \frac{s+t}{2}$. Let d_s, d_t, d_r be the points of L corresponding to s, t, r respectively, and set $\eta = \rho(a,d_t)$, $\zeta = \rho(a,d_s)$. Then by assumption

$$\eta^2 = t\alpha^2 + (1-s)\beta^2 - t(1-t)\gamma^2$$

$$\zeta^2 = s\alpha^2 + (1-s)\beta^2 - s(1-s)\gamma^2$$

and, since $\rho(d_t,d_s) = |s-t|\gamma$ and d_r is the midpoint of d_t and d_s on L, by the Parallelogram Axiom we have

$$\rho(a,d_r)^2 = \frac{1}{2}[\zeta^2 + \eta^2] - \frac{1}{4}(s-t)^2\gamma^2$$

$$= \frac{1}{2}[s\alpha^2 + (1-s)\beta^2 - s(1-s)\gamma^2 + t\alpha^2 + (1-t)\beta^2 - t(1-t)\gamma^2] - \frac{1}{4}(s^2 - 2st + t^2)\gamma^2$$

$$= \frac{s+t}{2}\alpha^2 + \frac{(1-s)+(1-t)}{2}\beta^2 - \left[\frac{1}{2}s - \frac{1}{2}s^2 + \frac{1}{2}t - \frac{1}{2}t^2 + \frac{1}{4}s^2 + \frac{1}{4}t^2 - \frac{1}{2}st\right]\gamma^2$$

$$= \frac{s+t}{2}\alpha^2 + \left[1 - \frac{s+t}{2}\right]\beta^2 - \left[\frac{1}{2}(s+t) - \frac{1}{4}s^2 - \frac{1}{4}t^2 - \frac{1}{2}st\right]\gamma^2$$

$$= r\alpha^2 + (1-r)\beta^2 - (r-r^2)\gamma^2$$

so the formula holds for r too. Therefore the formula holds for all dyadic rational t. 👍

VI.3.1.30. Corollary. Let (E, ρ) be a metric space satisfying the Parallelogram Axiom. Let L be a line in E, and a a point of E. Then there is an isometry from $L \cup \{a\}$ to $\mathbb{R}^2$. If $b, c \in L$ and $\{a', b', c'\}$ is a subset of $\mathbb{R}^2$ isometric to $\{a, b, c\}$, then there is an isometry ϕ from $L \cup \{a\}$ to $\mathbb{R}^2$ with $\phi(a) = a'$, $\phi(b) = b'$, $\phi(c) = c'$.

Proof: Let b and c be two distinct points on L. Let $\{a', b', c'\}$ be three points in $\mathbb{R}^2$ isometric to $\{a, b, c\}$, and L' the line in $\mathbb{R}^2$ through b' and c'. If d is any point on L and d' the point on L' with $\rho_2(b', d') = \rho(b, d)$ and $\rho_2(c', d') = \rho(c, d)$, then applying Lemma VI.3.1.29. in both E and $\mathbb{R}^2$ we obtain $\rho_2(a', d') = \rho(a, d)$. Thus $L \cup \{a\}$ is isometric to $L' \cup \{a'\}$ under an isometry ϕ with $\phi(a) = a'$, $\phi(b) = b'$, $\phi(c) = c'$. 👍

VI.3.1.31. Lemma. Let (E, ρ) be a metric space satisfying the Parallelogram Axiom. Let a, b, c be points of E with $a \neq b$ and $a \neq c$, and let L_1 be a line in E through a and b, and L_2 a line in E through a and c. If ϕ is an isometry of $\{a, b, c\}$ with $\{a', b', c'\} \subseteq \mathbb{R}^2$, then ϕ extends uniquely to an isometry from $L_1 \cup L_2$ to $\mathbb{R}^2$.

Proof: Let L_1' be the (unique) line in $\mathbb{R}^2$ through a' and b', and L_2' the line in $\mathbb{R}^2$ through a' and c'. There is a unique isometry ϕ_1 from L_1 to L_1' with $\phi_1(a) = a'$ and $\phi_1(b) = b'$, since if $x \in L_1$, x is uniquely determined by $\rho(x, a)$ and $\rho(x, b)$, and similarly for L_1'. In the same way, there is a unique isometry ϕ_2 from L_2 to L_2' with $\phi_2(a) = a'$, $\phi_2(c) = c'$. It suffices to show that if $x \in L_1$ and $y \in L_2$, and $x' = \phi_1(x)$, $y' = \phi_2(y)$, then $\rho_2(x', y') = \rho(x, y)$. We may assume $x \neq a$ and $y \neq a$.

By VI.3.1.30., there is an isometry ψ from $L_1 \cup \{c\}$ to $\mathbb{R}^2$ with $\psi(a) = a'$, $\psi(b) = b'$, $\psi(c) = c'$, and we must have $\psi|_{L_1} = \phi_1$, so $\psi(x) = x'$. Thus $\rho_2(x', c') = \rho(x, c)$, so by VI.3.1.30. there is an isometry θ from $L_2 \cup \{x\}$ to $\mathbb{R}^2$ with $\theta(a) = a'$, $\theta(c) = c'$, $\theta(x) = x'$. We must have $\theta|_{L_2} = \phi_2$, so $\theta(y) = y'$ and we have $\rho_2(x', y') = \rho(x, y)$. 👍

VI.3.1.32. Corollary. Let (E, ρ) be a metric space satisfying the Parallelogram Axiom, and let a and b be distinct points of E. Then there is at most one line in E through a and b.

Proof: If L_1 and L_2 are lines in E through a and b, set $c = b$ and apply VI.3.1.31.. 👍

This completes the proof of Theorem VI.3.1.27..

Affine Subspaces

It would seem to make sense to define an n-dimensional affine subspace of a metric space to be a subset isometric to $\mathbb{R}^n$. But it will turn out to be more convenient to make the following unorthodox inductive definition, which is equivalent (VI.3.1.35.) in the presence of the Line and Parallelogram Axioms:

VI.3.1.33. Definition. Let (E, ρ) be a metric space satisfying the Line Axiom and the Parallelogram (or Pythagorean) Axiom.

(i) A *zero-dimensional affine subspace* of E is a single point.

(ii) If $n \geq 1$, an *n-dimensional affine generator* in E is a subset $G(L, a)$ consisting of all points x lying on a line through a and a point of L, where L is an $(n-1)$-dimensional affine subspace of E and a is a point of E not in L.

(iii) If $n \geq 1$, an *n-dimensional affine subspace* of E is the closure of an n-dimensional affine generator in E.

(iv) A set $\{x_0, \ldots, x_n\}$ of $n+1$ points of E is *independent* if it is not contained in any $(n-1)$-dimensional affine subspace of E.

It is easy to verify that the one-dimensional affine subspaces of E are precisely the lines in E.

VI.3.1.34. PROPOSITION. Let (E, ρ) be a metric space satisfying the Line Axiom and the Parallelogram (or Pythagorean) Axiom, and L a subset of E isometric to $\mathbb{R}^n$. Then L is an n-dimensional affine subspace of E.

PROOF: This is easily seen by induction, since if L is an $(n-1)$-dimensional affine subspace of $\mathbb{R}^n$ (in the usual sense, hence by the inductive hypothesis in the sense of VI.3.1.33.), and a is a point of $\mathbb{R}^n$ not on L, then $G(L, a)$ consists of all points of $\mathbb{R}^n$ not in the affine subspace through a parallel to L, along with a, and this set is dense in $\mathbb{R}^n$. 👍

The next theorem, essentially the converse of VI.3.1.34., is perhaps the most important result of this section.

VI.3.1.35. THEOREM. Let (E, ρ) be a metric space satisfying the Line Axiom and the Parallelogram (or Pythagorean) Axiom, and $n \in \mathbb{N}$. Then

(i) Every n-dimensional affine subspace of E is isometric to $\mathbb{R}^n$.

(ii) If $\{x_0, \ldots, x_n\}$ is an independent set of $n+1$ points of E, then there is a unique n-dimensional subspace of E containing $\{x_0, \ldots, x_n\}$.

PROOF: The proof is by induction on n. The case $n = 1$ is obvious from VI.3.1.27.. For the inductive step, we suppose that the statement is true for n for any metric space satisfying the hypotheses. Then let (E, ρ) be a metric space satisfying the hypotheses. Proofs of (i) and (ii) for $n+1$ will be done in parallel. To set up the proof, we make notational definitions for the two cases.

To prove (i), let L_{n+1} be an $(n+1)$-dimensional affine subspace of E, and let L_n be an n-dimensional affine subspace of E and a a point of E such that L_{n+1} is the closure of $G(L_n, a)$. To prove (ii), let $\{x_0, \ldots, x_{n+1}\}$ be an independent set of $n+2$ points of E. If $\{x_0, \ldots, x_n\}$ is contained in an affine $(n-1)$-dimensional subspace L_{n-1}, then $\{x_0, \ldots, x_{n+1}\}$ is contained in the n-dimensional affine subspace which is the closure of $G(L_{n-1}, x_{n+1})$, a contradiction. Thus $\{x_0, \ldots, x_n\}$ is independent and contained in a unique n-dimensional affine subspace L_n of E. Let $a = x_{n+1}$ and let L_{n+1} be the closure of $G(L_n, a)$.

In both cases we have an $(n+1)$-dimensional affine subspace L_{n+1} which is the closure of an $(n+1)$-dimensional generator $G(L_n, a)$, where L_n is an n-dimensional affine subspace of E and a a point of E not in

L_n. By the inductive hypothesis, L_n is isometric to $\mathbb{R}^n$, hence is complete and has the Bolzano-Weierstrass property, and satisfies the Line Axiom, i.e. if $b, c \in L_n$, then the unique line in E through b and c is contained in L_n.

By VI.3.1.24., there is a foot f of a on L_n. If g is another foot of a on L_n, let L be the line in L_n through f and g; then both f and g are feet of a on L, impossible by the Pythagorean Axiom if $f \neq g$. Thus f is the unique foot of a on L_n, and f is the foot of a on any line in L_n through f. So if b is any point of L_n, we have

$$\rho(a,b)^2 = \rho(a,f)^2 + \rho(f,b)^2 \ .$$

In $\mathbb{R}^{n+1}$, let L'_n be the n-dimensional subspace of points with last coordinate 0, and let $a' = (0, \ldots, 0, \lambda)$, where $\lambda = \rho(a,f)$. Let ϕ be an isometry of L_n onto L'_n sending f to the origin. Then if $b \in L_{n+1}$, we have

$$\rho_2(a', \phi(b))^2 = \lambda^2 + \rho(0, \phi(b))^2$$

so by the previous calculation $\rho_2(a', \phi(b)) = \rho(a,b)$, and ϕ extends to an isometry from $L_n \cup \{a\}$ to $L'_n \cup \{a'\}$, also denoted ϕ.

We next show that ϕ can be extended to an isometry from $G(L_n, a)$ to $G(L'_n, a')$, which consists of all the points of $\mathbb{R}^{n+1}$ whose last coordinate is not λ, along with a' (i.e. $\mathbb{R}^{n+1}$ with the horizontal hyperplane through a', except a' itself, removed).

Let $x \in G(L_n, a)$, $x \neq a$. Then there is a unique $b \in L_n$ such that x is on the line through a and b. Let $\phi(x)$ be the corresponding point on the line through a' and $\phi(b)$ in $\mathbb{R}^{n+1}$. If y is another point in $G(L_n, a)$, $y \neq a$, let y be on the line through a and $c \in L_n$. If the plane through $a', \phi(b), \phi(c)$ in $\mathbb{R}^{n+1}$ is identified with $\mathbb{R}^2$, then by VI.3.1.31. the isometry ϕ from $\{a, b, c\}$ to $\{a', \phi(b), \phi(c)\}$ extends uniquely to the lines through a and b and through a and c; hence in particular $\rho_2(\phi(x), \phi(y)) = \rho(x,y)$ and the ϕ we have defined is an isometry from $G(L_n, a)$ into $G(L'_n, a')$. To see that it is surjective, let $x' \in G(L'_n, a')$ $x' \neq a'$, and let b' be the point of L'_n on the line through a' and x' (a' and x' have different last coordinates, so there is a unique point on this line with last coordinate 0). Then $b' = \phi(b)$ for some $b \in L_n$, and there is a (unique) point x on the line in E through a and b with $x' = \phi(x)$, and ϕ maps $G(L_n, a)$ onto $G(L'_n, a')$.

Thus ϕ extends to an isometry from L_{n+1} into $\mathbb{R}^{n+1}$, also denoted ϕ. We show that this ϕ is surjective. (This would be immediate if (E, ρ) is complete, but (E, ρ) need not be complete.) We must show that if

$$m' = (\alpha_1, \ldots, \alpha_n, \lambda) \in \mathbb{R}^n \setminus G(L'_n, a')$$

then there is an $m \in E$ with $\phi(m) = m'$. Let $b' = (\alpha_1, \ldots, \alpha_n, 0)$ and $c' = (\alpha_1, \ldots, \alpha_n, 2\lambda)$ in $\mathbb{R}^{n+1}$, and let $b = \phi^{-1}(b')$, $c = \phi^{-1}(c')$, and let m be the midpoint of the line segment in E with endpoints a and b. It suffices to show that $m \in L_{n+1}$, for then necessarily $\phi(m) = m'$. But if $t \in (0,1)$, $t \neq \frac{1}{2}$, then the point $d'_t = (\alpha_1, \ldots, \alpha_n, 2t\lambda) \in G(L'_n, a')$ is between b' and c', hence $d_t = \phi^{-1}(d'_t) \in G(L_n, a)$ is between b and c; hence all the points of the line segment between b and c other than m are in $G(L_n, a)$, so m is in the closure of $G(L_n, a)$.

We have now proved (i) for $n+1$, and proved all of (ii) except uniqueness. For uniqueness, let $\tilde{L}_{n+1}$ be any $(n+1)$-dimensional affine subspace of E containing $\{x_0, \ldots, x_{n+1}\}$. Then by (i) $\tilde{L}_{n+1}$ is isometric to $\mathbb{R}^{n+1}$ and hence satisfies the Line Axiom. Any k-dimensional affine subspace of $\tilde{L}_{n+1}$ ($k \leq n+1$) is a k-dimensional affine subspace of E by VI.3.1.34.. Thus $\{x_0, \ldots, x_n\}$ is independent as a subset of $\tilde{L}_{n+1}$, so by the inductive hypothesis applied to $\tilde{L}_{n+1}$, $\{x_0, \ldots, x_n\}$ is contained in a unique n-dimensional affine subspace of $\tilde{L}_{n+1}$. But L_n is the unique n-dimensional affine subspace of E containing $\{x_0, \ldots, x_n\}$, so $L_n \subseteq \tilde{L}_{n+1}$. Then $G(L_n, x_{n+1}) \subseteq \tilde{L}_{n+1}$ since $\tilde{L}_{n+1}$ contains the line in E through any two of its points.

Thus the closure L_{n+1} of $G(L_n, x_{n+1})$ is contained in $\tilde{L}_{n+1}$ since $\tilde{L}_{n+1}$ is closed in E. But this implies that $L_{n+1} = \tilde{L}_{n+1}$ since $\mathbb{R}^{n+1}$ has no proper $(n+1)$-dimensional affine subspaces.

This completes the proof of Theorem VI.3.1.35.. 👍

VI.3.1.36. Corollary. Let (E, ρ) be a metric space satisfying the Line and Parallelogram (or Pythagorean) Axioms, and $S = \{x_0, \ldots, x_m\}$ a subset of E with $n+1$ points. Then, for some $m \leq n$, there is a (unique) m-dimensional affine subspace of E containing S which is the smallest affine subspace of E containing S, called the affine subspace of E *spanned* by S, denoted $span(S)$; $m = n$ if and only if S is independent. Any subset of an independent set is independent.

Any real inner product space with the induced metric satisfies all the axioms considered so far. Conversely:

VI.3.1.37. Theorem. Let (E, ρ) be a metric space satisfying the Line Axiom and the Parallelogram (or Pythagorean) Axiom, and let $a \in E$. Then

(i) There is a unique real vector space structure on E with a the zero vector, and a unique inner product on this vector space, such that ρ is the metric induced by the inner product.

(ii) Every subset of E satisfying the Line Axiom (in particular, every n-dimensional affine subspace in the sense of VI.3.1.33.) is an affine subspace in the linear algebra sense ().

(iii) If $S = \{x_0, \ldots, x_n\}$ is a finite subset of E, then the span of S in the sense of VI.3.1.36. is the linear span of S in the vector space structure on E with zero vector x_0. The set S is independent in the sense of VI.3.1.33. if and only if $\{x_1, \ldots, x_n\}$ is linearly independent in this vector space structure on E.

Combining this with VI.3.1.13., we obtain:

VI.3.1.38. Corollary. Let (E, ρ) be a complete metric space satisfying the Between, Extension, and Parallelogram (or Pythagorean) Axioms. Then (E, ρ) is isometric to a real Hilbert space ().

Proof: The proof of VI.3.1.37. follows easily from VI.3.1.35.. Fix $a \in E$. If $b, c \in E$, there is an isometry from the span of $\{a, b, c\}$ to $\mathbb{R}^n$ for some $n \leq 2$ sending a to 0, and we define vector addition, scalar multiplication, norm, and inner product for b, c via this isometry. Since an isometry of $\mathbb{R}^n$ fixing the origin is linear and orthogonal, these operations are well defined. All except the inner product have simple intrinsic characterizations. (The inner product can be recovered from the norm by polarization ().) We have $\|b\| = \rho(a, b)$. If $\alpha \in \mathbb{R}$ and $b \neq a$, then αb is the unique element c on the line in E through a and b with $\rho(a, c) = |\alpha|\rho(a, b)$ and a between c and b if and only if $\alpha < 0$. If m is the midpoint of b and c in E, then $b + c = 2m$. Thus this structure is the only possible vector space structure and norm compatible with ρ.

To verify that E is a normed vector space with these operations, the only axiom which is not obviously satisfied is associativity of vector addition. But if $b, c, d \in E$, then the span of $\{a, b, c, d\}$ is isometric to $\mathbb{R}^n$ for some $n \leq 3$, and the vector addition in E restricted to this subspace agrees with vector addition in this $\mathbb{R}^n$ if an isometry is chosen sending a to the origin, and associativity of vector addition follows.

Parts (ii) and (iii) are immediate from (i). 👍

The Dimension Axiom

Thus, to characterize $\mathbb{R}^n$ as a metric space, we need only one additional axiom insuring that the space is n-dimensional. The simplest way to do this is

VI.3.1.39. Dimension n Axiom: There is an independent set of $n+1$ elements of E which spans E.

The Dimension n Axiom can be rephrased in a purely metric way not requiring reference to the Unique Line Axiom.

VI.3.1.40. Definition. Let (E,ρ) be a metric space, and $(a_0,\dots,a_m)$ an $(m+1)$-tuple of points in E. The *Cayley-Menger determinant* $D(a_0,\dots,a_m)$ of $(a_0,\dots,a_m)$ is the determinant of the $(m+2)\times(m+2)$ matrix

$$\begin{bmatrix} 0 & 1 & 1 & \cdots & 1 \\ 1 & 0 & \rho(a_0,a_1)^2 & \cdots & \rho(a_0,a_n)^2 \\ 1 & \rho(a_1,a_0)^2 & 0 & \cdots & \rho(a_1,a_m)^2 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \rho(a_m,a_0)^2 & \rho(a_m,a_1)^2 & \cdots & 0 \end{bmatrix}$$

VI.3.1.41. If $E=\mathbb{R}^n$, there is a constant $c_m=\frac{(-1)^{m+1}}{2^m(m!)^2}$ depending only on m such that $c_m D(a_0,\dots,a_m)$ is the square of the m-dimensional volume of the parallelepiped with edges $a_1-a_0,\dots,a_m-a_0$ (). In particular, it is nonzero if and only if $\{a_1-a_0,\dots,a_m-a_0\}$ is linearly independent. (The constant is not relevant for our uses of the Cayley-Menger determinant in this section, since we will be concerned only whether it is 0.)

VI.3.1.42. n-Determinant Axiom: The space E has an $(n+1)$-tuple $(a_0,\dots,a_n)$ with $D(a_0,\dots,a_n)\neq 0$, but $D(b_0,\dots,b_{n+1})=0$ for any $(n+2)$-tuple $(b_0,\dots,b_{n+1})$ in E.

The Characterization Theorems

The main result of this section is:

VI.3.1.43. Theorem. Let (E,ρ) be a metric space satisfying the Line Axiom and the Parallelogram (or Pythagorean) Axiom. Then the following are equivalent:

(i) (E,ρ) satisfies the Dimension n axiom.

(ii) (E,ρ) satisfies the n-Determinant Axiom.

(iii) (E,ρ) is isometric to $(\mathbb{R}^n,\rho_2)$.

Proof: (i) ⇒ (iii) is VI.3.1.35., (iii) ⇒ (ii) and the equivalence of (i) and (ii) for $\mathbb{R}^n$ is VI.3.1.41.. 👍

Combining this result with VI.3.1.13., we obtain perhaps the nicest metric characterization of n-dimensional Euclidean space:

VI.3.1.44. Corollary. Let (E, ρ) be a complete metric space satisfying the Between, Extension, Parallelogram (or Pythagorean), and n-Determinant Axioms. Then (E, ρ) is isometric to $(\mathbb{R}^n, \rho_2)$.

In fact, the Parallelogram Axiom can be replaced with a more complicated condition involving Cayley-Menger determinants of smaller order. This was the original metric characterization of $\mathbb{R}^n$ obtained by K. Menger in 1928. See [Blu70, Theorem 48.2].

VI.3.2. $\mathbb{R}^n$ is n-Dimensional

Everyone "knows" that $\mathbb{R}^n$ is n-dimensional. But what does this mean? Specifically, what does "dimension" mean? And how can $\mathbb{R}^n$ be distinguished from $\mathbb{R}^m$ for $m \neq n$ by its properties?

$\mathbb{R}^n$ is a set with several types of structure: algebraic, geometric, topological, and analytic. Efforts have been made to define and/or describe the "dimension" of $\mathbb{R}^n$ in terms of each of these types of structure, and various theories of dimension have been studied in different contexts; the only thing these various theories have in common is that they all assign the *same* number n to $\mathbb{R}^n$, justifying the use of the name "dimension" for all of them.

VI.3.2.1. Specifically, we have:

(i) The vector space dimension () of $\mathbb{R}^n$ as a real vector space is n.

(ii) The topological dimension () of $\mathbb{R}^n$ as a topological space is n. (In fact, there are several notions of topological dimension, all of which give dimension n to $\mathbb{R}^n$.)

(iii) The Hausdorff dimension () of $\mathbb{R}^n$ is n.

VI.3.2.2. There is one respect in which all Euclidean spaces are the same, however: cardinality. Contrary to Cantor's expectations (he first thought the cardinality of $\mathbb{R}^n$ should be $\aleph_n$), the cardinality of $\mathbb{R}^n$ is $2^{\aleph_0}$ for all n (). Thus some additional structure beyond set theory is needed to distinguish $\mathbb{R}^n$ from $\mathbb{R}^m$ for $n \neq m$.

VI.3.3. Exercises

VI.3.3.1. Let X be a set, and $a, b \in X$. Define a metric ρ on X by $\rho(a, b) = 2$ and $\rho(x, y) = 1$ for all other distinct pairs x, y. Then every element of $X \setminus \{a, b\}$ is between a and b.

VI.3.3.2. In $(\mathbb{R}^2, \rho_\infty)$, the set of points between $a = (0, 0)$ and $b = (2, 0)$ is

$$\{(t, s) : 0 < t < 2, |s| \leq \min(t, 2 - t)\}$$

which is the "diamond" with corners a, b, $(1, 1)$, and $(1, -1)$.

VI.3.3.3. Let (E, ρ) be the subset

$$\{(t, t) : 0 \leq t \leq 1\} \cup \{(t, t - 2) : 1 < t \leq 2\}$$

of $(\mathbb{R}^2, \rho_\infty)$. If $a = (0, 0)$ and $b = (2, 0)$, then for every t, $0 \leq t \leq 2$, there is a unique c_t between a and b with $\rho(a, c_t) = t$ and $\rho(c_t, b) = 2 - t$ (i.e. E has the Unique Interpolation Property), but there is no line segment in E with endpoints a and b.

VI.3.3.4. Let E be the unit sphere in $\mathbb{R}^3$.

(a) If E is given the induced metric from $\mathbb{R}^3$ (sometimes called the *chord metric*), and $a, b \in E$, then there are no points of E between a and b.

(b) If the distance between points a and b is defined to be the length of the shortest great circle arc through a and b, a metric is obtained called the *arc metric*. If a and b are not diametrically opposed, then there is a unique line segment with endpoints a and b. If a and b are diametrically opposed, every other point of E is between a and b. E is complete and satisfies the Between Axiom, but E contains no lines. It almost satisfies the Extension Axiom, except for pairs of points diametrically opposed.

The same results hold in $\mathbb{R}^n$ for any $n > 1$ (in particular, for the unit circle in $\mathbb{R}^2$).

VI.3.3.5. Let (E, ρ) be a metric space satisfying the Line Axiom. A subset S of E is *collinear* if there is a line in E containing S.

(a) Prove the following theorem (cf. [Blu70, Theorem 21.3]):

THEOREM. (E, ρ) satisfies the Unique Line Axiom if and only if (E, ρ) has the *Two-Triple Property*: whenever $a, b, c, d \in E$, $\{a, b, c\}$ is collinear, and $\{b, c, d\}$ is collinear, then $\{a, b, d\}$ is collinear and $\{a, c, d\}$ is collinear.

It is then a consequence of the theorem that the four lines necessarily coincide, and therefore $\{a, b, c, d\}$ is collinear.

(b) Show directly that if E satisfies the Weak Euclidean Four-Point Axiom, then E has the Two-Triple Property.

VI.3.3.6. Show that $(\mathbb{R}^2, \rho_p)$ () has the Unique Line Property for $1 < p < \infty$, but not the Parallelogram Property (or other properties of VI.3.1.27.) if $p \neq 2$. More generally, any strictly convex normed real vector space () has the Unique Line Property.

VI.3.3.7. Let (E, ρ) be a metric space satisfying the Unique Interpolation and Unique Extrapolation Axioms. Prove that E has the Unique Line Property, as follows. Let $a, b \in E$ with $a \neq b$, and set $\lambda = \rho(a, b)$.

(a) Show the following:

(i) For each $s \geq \lambda$, there is a unique $c \in E$ with $\rho(a, c) = s$ and $\rho(b, c) = s - \lambda$.

(ii) For each s, $0 \leq s \leq \lambda$, there is a unique $c \in E$ with $\rho(a, c) = s$ and $\rho(c, b) = \lambda - s$.

(iii) For each $s < 0$, there is a unique $c \in E$ with $\rho(a, c) = -s$ and $\rho(b, c) = \lambda - s$.

If $s \in \mathbb{R}$, write $\phi(s)$ for the corresponding point c.

(b) Show that $\rho(\phi(r), \phi(s)) = |s - r|$ for all $r, s \in \mathbb{R}$; we may assume $r \leq s$. Consider six separate cases:

(i) $d \leq r \leq s$.

(ii) $0 \leq r \leq d \leq s$.

(iii) $0 \leq r \leq s \leq d$.

(iv) $r \leq 0 < d \leq s$.

(v) $r \leq 0 \leq s \leq d$.

(vi) $r \leq s \leq 0$.

For case (i), consider the unique $b \in E$ with $\rho(a_1, b) = r - \lambda$ and $\rho(b, \phi(s)) = s - r$ by (a). Use the triangle inequality twice to show that $\rho(a_0, b) = r$, so $b = \phi(r)$. Give similar (or simpler) arguments in the other five cases.

VI.3.3.8. In metric geometry (), a stronger version of the Between Axiom is often used.

Midpoint Axiom: Every pair of points in (E, ρ) has a midpoint (VI.3.1.21.).

No uniqueness is assumed. A metric space satisfying the Midpoint Axiom obviously satisfies the Between Axiom.

(a) Prove directly that a complete metric space satisfying the Midpoint Axiom satisfies the Line Segment Axiom, i.e. is strictly intrinsic. (Your proof should not need the AC, but will need the Axiom of Dependent Choice since midpoints are not necessarily unique.)

(b) [Blu70, Theorem 14.1] Adapt this proof to give a proof of Lemma VI.3.1.14. using only DC.

It is known that every Peano space () has a metric satisfying the Midpoint Axiom, or, equivalently, the Between Axiom or the Line Segment Axiom ([Bin49], [Moi49]; note that this result is incorrectly stated in [HY88, p. 130]).

Figure VI.5: A favorite subject in Croatia

VI.4. Length Structures and Metric Geometry

Metric spaces can be regarded as a first approximation to geometry (this is of course not the only interpretation or use for them!) True geometry has at least two other features in addition to a metric structure, i.e. a notion of distance between points:

(i) A notion of "shortest path," curves in the space which at least locally determine distance, i.e. the distance between nearby points is measured along such a path. Such paths, generalizing lines in Euclidean space or great circles on a sphere, are called *geodesics*. For a given point p, any other point q sufficiently close to p should be connected to p by a unique geodesic giving the metric distance between p and q, and geodesics should be extendible.

(ii) A notion of "angle" between geodesics intersecting at a point. Implicit in this is the idea that each geodesic through a point p determines a well-defined "direction" ("tangent") at p. Angles should locally give well-defined notions of area and higher-dimensional volumes, which can be extended globally.

There are at least three approaches possible to defining the additional structure, of increasing generality. First, for Euclidean space there is an "elementary" interpretation of lines and angles (although a fully rigorous treatment is more complicated than it may at first appear; cf. ()), so for "nice" subsets of Euclidean space, e.g. for smooth surfaces in $\mathbb{R}^3$, geodesics and angles can be defined analytically. This approach is described in (). Secondly, the case of smooth surfaces can be abstracted into the notion of smooth manifolds with a Riemannian or similar structure; cf. (). Finally, the notions can be directly developed straight from the general notion of metric space. This is the approach taken in this section.

As one might expect, abstract metric spaces are too general to support geometry with reasonable properties, and additional conditions on the space must be assumed. These additional conditions will be seen as the theory is developed. Ultimately, the additional conditions force the space to essentially be the type of structure from the second approach above; it is significant that the same mathematical structures can be arrived at in these two ways, reinforcing the naturality and importance of the resulting structures.

We will only cover the basic aspects of this approach. A far more extensive and detailed treatment can be found in [BBI01] and in [Gro99] (read and study the first before tackling the second!)

VI.4.1. Arc Length in Metric Spaces

The notion of curves and arc length in Euclidean space () has a straightforward generalization to metric spaces. Throughout this section, we will fix a metric space (X, ρ).

Parametrized Curves

VI.4.1.1. Definition. A *parametrized curve* in X is a continuous function $\gamma : [a, b] \to X$ for some closed bounded interval $[a, b]$ in $\mathbb{R}$. The points $p = \gamma(a)$ and $q = \gamma(b)$ are the *initial* and *final endpoints* of γ respectively, and γ is a *parametrized curve from p to q*.

Note that the interval $[a, b]$ is allowed to be degenerate, i.e. we allow $a = b$. (To be sure, parametrized curves defined on degenerate intervals are not very interesting!)

VI.4.1.2. A parametrized curve has a direction. If $\gamma : [a, b] \to X$ is a parametrized curve from p to q, its *negative* or *reversal* is $-\gamma : [a, b] \to X$ defined by $(-\gamma)(t) = \gamma(a + b - t)$ is a parametrized curve from q to p.

VI.4.1.3. We may think of the range of a parametrized curve as a "curve" in X (although it need not look anything like a geometric curve), and the parametrization as giving "motion" along this curve. This motion may "retrace" parts of the curve in a complicated way.

Restriction and Concatenation

VI.4.1.4. DEFINITION. Let $\gamma : [a,b] \to X$ be a parametrized curve, and $[c,d]$ a closed subinterval of $[a,b]$, i.e. $a \le c \le d \le b$. The parametrized curve $\gamma|_{[c,d]}$ is the *restriction* of γ to $[c,d]$; it is a parametrized curve from $\gamma(c)$ to $\gamma(d)$.

VI.4.1.5. DEFINITION. If $\gamma_1 : [a,b] \to X$ is a parametrized curve from p to q, and $\gamma_2 : [b,c] \to X$ is a parametrized curve from q to r, the *concatenation* is the parametrized curve $\gamma = \gamma_1 + \gamma_2 : [a,c] \to X$ defined by

$$\gamma(t) = \begin{cases} \gamma_1(t) & \text{if} \quad a \le t \le b \\ \gamma_2(t) & \text{if} \quad b \le t \le c \end{cases}$$

The concatenation γ is a parametrized curve from p to r.

We may extend the definition to $\gamma_1 + \cdots + \gamma_n$ if the curves line up properly.

VI.4.1.6. Note the conditions under which the concatenation is defined are rather severe: γ_1 and γ_2 must be parametrized on intervals in $\mathbb{R}$ which concatenate, and the final endpoint of γ_1 must be the initial endpoint of γ_2. Concatenation can be slightly generalized using reparametrizations (VI.4.1.16.). Also note that although additive notation is used, concatenation is not commutative: if $\gamma_1 + \gamma_2$ is defined, then $\gamma_2 + \gamma_1$ is not even defined unless one of the intervals is degenerate.

VI.4.1.7. If $\gamma = \gamma_1 + \gamma_2$ is defined, then the restriction of γ to $[a,b]$ (resp. to $[b,c]$) is γ_1 (resp. γ_2). Conversely, if $\gamma : [a,b]$ is a parametrized curve and $c \in [a,b]$, then $\gamma = \gamma|_{[a,c]} + \gamma|_{[c,b]}$. More generally, if $\mathcal{P} = \{a = t_0, t_1, \ldots, t_n = b\}$ is a partition of $[a,b]$, we have

$$\gamma = \gamma|_{[a,t_1]} + \gamma|_{[t_1,t_2]} + \cdots + \gamma|_{[t_{n-1},b]} \ .$$

Reparametrization

VI.4.1.8. DEFINITION. Let $\gamma : [a,b] \to X$ and $\tilde{\gamma} : [c,d] \to X$ be parametrized curves. Then $\tilde{\gamma}$ is a *reparametrization* of γ if $\tilde{\gamma} = \gamma \circ \phi$, where ϕ is a nondecreasing continuous function from $[c,d]$ onto $[a,b]$ (hence $\phi(c) = a$ and $\phi(d) = b$). If ϕ is strictly increasing, $\tilde{\gamma}$ is a *strict reparametrization* of γ.

VI.4.1.9. A reparametrization of a parametrized curve has the same initial and final endpoints, and the same range. But two parametrized curves with the same range, even also with the same initial and final endpoints, need not be reparametrizations. A reparametrization of a parametrized curve describes "motion" along the range "curve" in the same sense, with the same retracing, but possibly over a different interval of time at a different and varying speed.

VI.4.1.10. Various special kinds of reparametrizations can be considered. The simplest is linear reparametrizations, where ϕ is a linear (affine) function from $[c,d]$ onto $[a,b]$, i.e.

$$\phi(t) = a + \frac{b-a}{d-c}(t-c) \ .$$

One can also consider $\mathcal{C}^r$ reparametrizations, where ϕ is $\mathcal{C}^r$, and strict $\mathcal{C}^r$ reparametrizations, where both ϕ and ϕ^{-1} are $\mathcal{C}^r$ (these are also called smooth reparametrizations). There are also piecewise linear and piecewise smooth reparametrizations.

VI.4.1.11. Reparametrization is not an equivalence relation: it is reflexive and transitive, but not symmetric since the function ϕ need not be one-to-one. Strict reparametrization is symmetric, thus an equivalence relation on parametrized curves. Parametrization does generate an important equivalence relation, which can be described thus: two parametrized curves are equivalent if they are both reparametrizations of the same parametrized curve (VII.1.2.7.).

Nonstationary Curves

VI.4.1.12. Definition. Let $\gamma : [a,b] \to X$ be a parametrized curve, and $[c,d]$ a closed subinterval of $[a,b]$. Then γ is *stationary* on $[c,d]$ if $\gamma(t) = \gamma(c)$ for all $t \in [c,d]$. The curve γ is *nonstationary* if it is not stationary on any (nondegenerate) subinterval of $[a,b]$.

VI.4.1.13. A nonstationary parametrized curve need not be one-to-one; in fact, it can be very noninjective. For example, the space-filling curve of XIII.18.6.14. is nonstationary (the one in XIII.18.6.13. is not nonstationary). For a simpler example, a nonstationary parametrized curve can wrap around a circle in $\mathbb{R}^2$ several times.

VI.4.1.14. The maximal intervals on which a parametrized curve γ is stationary form a collection of disjoint closed subintervals of $[a,b]$. Every parametrized curve is a reparametrization of a nonstationary parametrized curve, which is unique up to strict reparametrization (Exercise ()), obtained by collapsing each maximal stationary subinterval to a point (there may be infinitely many such intervals!) Two parametrized curves are equivalent in the equivalence relation generated by reparametrization (VI.4.1.11.) if and only if their nonstationary versions are strict reparametrizations of each other.

Paths

VI.4.1.15. Definition. Let $p, q \in X$. A *path* from p to q is an equivalence class of parametrized curves from p to q (using the equivalence relation of VI.4.1.11. or VII.1.2.7.).

We will write $\gamma_1 \approx \gamma_2$ if γ_1 and γ_2 are equivalent, and write $\langle\gamma\rangle$ for the equivalence class of γ (the usual notation $[\gamma]$ for an equivalence class is normally reserved for the homotopy class of γ, which is a quite different thing ()).

VI.4.1.16. Paths can be concatenated: if $\langle\gamma_1\rangle$ is a path from p to q and $\langle\gamma_2\rangle$ is a path from q to r, then γ_1 can be concatenated with a suitable reparametrization $\tilde{\gamma}_2$ of γ_2 (e.g. a linear reparametrization), and the equivalence class of $\gamma_1 + \tilde{\gamma}_2$ is well defined and depends only on the classes of γ_1 and γ_2 (Exercise ()). Thus the concatenation of the paths $\langle\gamma_1\rangle + \langle\gamma_2\rangle$ is well defined as $\langle\gamma_1 + \tilde{\gamma}_2\rangle$.

Restriction of paths is a much dicier matter ().

Arc Length

So far we have not used the metric ρ (except to give the topology on X, i.e. to determine continuity of parametrized curves). We now bring ρ into the picture.

VI.4.1.17. DEFINITION. Let $\gamma : [a,b] \to X$ be a parametrized curve, and $\mathcal{P} = \{a = t_0, t_1, \ldots, t_n = b\}$ a partition of $[a,b]$. The *polygonal approximate length of* γ *from* $\mathcal{P}$ is

$$\ell_\rho(\gamma, \mathcal{P}) = \sum_{k=1}^{n} \rho(\gamma(t_{k-1}), \gamma(t_k)) \ .$$

The *arc length* of γ is

$$\ell_\rho(\gamma) = \sup_{\mathcal{P}} \ell_\rho(\gamma, \mathcal{P}) \ .$$

We often suppress the subscript if ρ is understood and there is no possibility of confusion.

VI.4.1.18. If $\mathcal{Q}$ is a partition of $[a,b]$ which refines $\mathcal{P}$, we have $\ell(\gamma, \mathcal{P}) \le \ell(\gamma, \mathcal{Q})$ by the triangle inequality. Since any two partitions have a common refinement, the polygonal approximations approach the arc length as the partitions become arbitrarily fine. The term "polygonal approximation" should not be taken too literally: there is usually not an actual "polygon" in X approximating the curve. The term is suggestive that $\rho(p,q)$ should be the "straight-line" distance between p and q.

VI.4.1.19. The arc length of a curve can easily be infinite (e.g. VI.4.1.20.). The curve γ is *rectifiable* if $\ell(\gamma)$ is finite. Arc length and rectifiability depend crucially on ρ (VI.4.1.20.(ii)).

VI.4.1.20. EXAMPLES. (i) Let $X = [0,1]$ with the ordinary metric $\rho(x,y) = |x-y|$. A parametrized curve in X is a continuous function $\gamma : [a,b] \to [0,1]$. If $\mathcal{P}$ is a partition of $[a,b]$, then $\ell(\gamma, \mathcal{P})$ is the total variation $V(\gamma, \mathcal{P})$ of γ over $\mathcal{P}$ (XIX.4.1.3.), and $\ell(\gamma)$ is the total variation $V_{[a,b]}(\gamma)$ of γ over $[a,b]$ (XIX.4.1.6.). The curve γ is rectifiable if and only if γ has bounded variation. If γ is a smooth function, then γ is rectifiable and

$$\ell(\gamma) = \int_a^b |\gamma'(t)| \, dt \ .$$

(ii) Let $X = [0,1]$, and let $\gamma : [0,1] \to X$ be the identity function $\gamma(t) = t$. If we give X the usual metric ρ, we have $\ell_\rho(\gamma) = 1$. But if $0 < s < 1$ and we give X the snowflake metric ρ^s, where $\rho^s(x,y) = |x-y|^s$ (), then for the partition $\mathcal{P} = \left\{ \frac{k}{n} : 0 \le k \le n \right\}$ of $[0,1]$, we have

$$\ell_{\rho^s}(\gamma, \mathcal{P}) = \sum_{k=1}^{n} \frac{1}{n^s} = \frac{n}{n^s} = n^{1-s}$$

so $\ell_{\rho^s}(\gamma) = +\infty$, i.e. γ is not rectifiable. In fact, in the metric space (X, ρ^s), no nonconstant parametrized curve is rectifiable.

We now develop basic properties of arc length. First note that arc length is independent of parametrization:

VI.4.1.21. PROPOSITION. Let $\tilde{\gamma} : [c,d] \to X$ be a reparametrization of $\gamma : [a,b] \to X$, i.e. $\tilde{\gamma} = \gamma \circ \phi$, $\phi : [c,d] \to [a,b]$. Then $\ell(\tilde{\gamma}) = \ell(\gamma)$.

PROOF: Let $\mathcal{P} = \{c = t_0, \ldots, t_n = d\}$ be a partition of $[c,d]$. Then $\{a = \phi(t_0), \ldots, \phi(t_n) = b\}$ is not quite a partition of $[a,b]$ since there may be repetitions if ϕ is not injective. But repeated points contribute nothing to the sum $\ell(\tilde{\gamma}, \mathcal{P})$, and if $\mathcal{Q}$ is the partition of $[a,b]$ obtained by deleting repetitions, we have $\ell(\gamma, \mathcal{Q}) = \ell(\tilde{\gamma}, \mathcal{P})$. Every partition of $[a,b]$ arises in this manner. 👍

VI.4.1.22. Thus arc length of paths is well defined.

Although the reversal $-\gamma$ of a parametrized curve is not a reparametrization of γ, we nonetheless have:

VI.4.1.23. PROPOSITION. If $\gamma : [a,b] \to X$ is a parametrized curve in X, then $\ell(-\gamma) = \ell(\gamma)$.

PROOF: If $\mathcal{P}$ is a partition of $[a,b]$, let $\tilde{\mathcal{P}}$ be the partition consisting of $\{a + b - t : t \in \mathcal{P}\}$. Then $\tilde{\mathcal{P}}$ is also a partition of $[a,b]$, and every partition of $[a,b]$ arises in this manner. We have $\ell(-\gamma, \tilde{\mathcal{P}}) = \ell(\gamma, \mathcal{P})$. 👍

VI.4.1.24. If $\gamma : [a,b] \to X$ is a parametrized curve from p to q and $\mathcal{P} = \{a,b\}$ is the trivial partition, we have

$$\rho(p,q) = \ell(\gamma, \mathcal{P}) \leq \ell(\gamma) \ .$$

More generally, we have:

VI.4.1.25. PROPOSITION. Let $\gamma : [a,b] \to X$ be a parametrized curve in X, and $a \leq c \leq d \leq b$, then

$$\rho(\gamma(c), \gamma(d)) \leq \ell(\gamma|_{[c,d]}) \leq \ell(\gamma) \ .$$

PROOF: The first inequality has already been noted. For the second, any partition $\mathcal{P}$ of $[c,d]$ can be expanded to a partition $\mathcal{Q}$ of $[a,b]$ by adding a and b if necessary. We have

$$\ell(\gamma|_{[c,d]}, \mathcal{P}) \leq \ell(\gamma, \mathcal{Q}) \leq \ell(\gamma)$$

and taking the supremum over all $\mathcal{P}$ gives the inequality. 👍

If γ is a constant path, obviously $\ell(\gamma) = 0$. Conversely:

VI.4.1.26. COROLLARY. Let γ be a parametrized curve in X. If $\ell(\gamma) = 0$, then γ is constant.

PROOF: If γ is not constant, there are $c, d \in [a,b]$, $c < d$, with $\gamma(c) \neq \gamma(d)$. Then $0 < \rho(\gamma(c), \gamma(d)) \leq \ell(\gamma)$. 👍

Here is a more precise version of VI.4.1.25.:

VI.4.1.27. PROPOSITION. Let $\gamma : [a,b] \to X$ be a parametrized curve, and $c \in [a,b]$. Then

$$\ell(\gamma) = \ell(\gamma|_{[a,c]}) + \ell(\gamma|_{[c,b]}) \ .$$

PROOF: If $\mathcal{P}$ is a partition of $[a,c]$ and $\mathcal{Q}$ a partition of $[c,b]$, then $\mathcal{P} \cup \mathcal{Q}$ is a partition of $[a,b]$, and

$$\ell(\gamma, \mathcal{P} \cup \mathcal{Q}) = \ell(\gamma|_{[a,c]}, \mathcal{P}) + \ell(\gamma|_{[c,b]}, \mathcal{Q}) \ .$$

Every partition of $[a,b]$ containing c (i.e. every sufficiently fine partition) arises in this manner. 👍

Iterating, we get:

VI.4.1.28. COROLLARY. Let $\gamma : [a,b] \to X$ be a parametrized curve, and $\mathcal{P} = \{a = x_0, \ldots, x_n = b\}$ a partition of $[a,b]$. Then

$$\ell(\gamma) = \sum_{k=1}^{n} \ell(\gamma|_{[t_{k-1}t_k]}) \ .$$

Rephrasing VI.4.1.27., we get:

VI.4.1.29. PROPOSITION. Let $\gamma_1 : [a,b] \to X$ and $\gamma_2 : [b,c] \to X$ with $\gamma_1(b) = \gamma_2(b)$, so that the concatenation $\gamma_1 + \gamma_2$ is defined. Then

$$\ell(\gamma_1 + \gamma_2) = \ell(\gamma_1) + \ell(\gamma_2) \ .$$

This can also be iterated to apply to arbitrary finite concatenations.

A crucial property of arc length is lower semicontinuity:

VI.4.1.30. PROPOSITION. For each n, let $\gamma_n : [a,b] \to X$ be a parametrized curve from p_n to q_n. Suppose (γ_n) converges pointwise to a parametrized curve $\gamma : [a,b] \to X$ from p to q, i.e. $\gamma_n(t) \to \gamma(t)$ for each $t \in [a,b]$ (so $p_n \to p$, $q_n \to q$). Then

$$\ell(\gamma) \leq \liminf_{n\to\infty} \ell(\gamma_n) \ .$$

We can have strict inequality, even if $\gamma_n \to \gamma$ uniformly on $[a,b]$ (I.6.1.16.).

PROOF: First note that if $\mathcal{P} = \{a = t_0, \ldots, t_m = b\}$ is any partition of $[a, b]$, we have

$$\ell(\gamma_n, \mathcal{P}) = \sum_{k=1}^{m} \rho(\gamma_n(t_{k-1}), \gamma_n(t_k)) \to \sum_{k=1}^{m} \rho(\gamma(t_{k-1}), \gamma(t_k)) = \ell(\gamma, \mathcal{P})$$

by continuity of ρ.

Suppose $\ell(\gamma) = +\infty$. Fix $M > 0$. Then there is a partition $\mathcal{P}$ of $[a, b]$ with $\ell(\gamma, \mathcal{P}) > M$. Then

$$M < \ell(\gamma, \mathcal{P}) = \lim_{n\to\infty} \ell(\gamma_n, \mathcal{P}) \leq \liminf_{n\to\infty} \ell(\gamma_n) \ .$$

This holds for all $M > 0$, so $\liminf_{n\to\infty} \ell(\gamma_n) = +\infty$ and the inequality holds.

Now suppose γ is rectifiable. Let $\epsilon > 0$. Then there is a partition $\mathcal{P}$ of $[a, b]$ with $\ell(\gamma, \mathcal{P}) > \ell(\gamma) - \epsilon$. Then

$$\ell(\gamma) - \epsilon < \ell(\gamma, \mathcal{P}) = \lim_{n\to\infty} \ell(\gamma_n, \mathcal{P}) \leq \liminf_{n\to\infty} \ell(\gamma_n) \ .$$

This holds for all $\epsilon > 0$, so $\liminf_{n\to\infty} \ell(\gamma_n) \geq \ell(\gamma)$. 👍

VI.4.1.31. Note for future reference that the definitions of $\ell(\gamma, \mathcal{P})$ and $\ell(\gamma)$ make perfect sense for a general function $\gamma : [a, b] \to X$, not necessarily continuous, so "arc length" is defined even for discontinuous functions (although it is typically infinite for very discontinuous functions). None of the proofs of VI.4.1.21.–VI.4.1.30. use that γ is continuous, so these properties hold also for discontinuous γ. (But VI.4.1.33. requires continuity of γ.)

Continuity of Arc Length

VI.4.1.32. Let $\gamma : [a, b] \to X$ be a rectifiable parametrized curve. Define a function $\phi : [a, b] \to [0, \ell(\gamma)]$ by setting

$$\phi(t) = \ell(\gamma|_{[a,t]}) \ .$$

Then ϕ is nondecreasing, $\phi(a) = 0$, $\phi(b) = \ell(\gamma)$. If γ is nonstationary, ϕ is strictly increasing.

VI.4.1.33. PROPOSITION. The function ϕ is continuous.

PROOF: The following lemma will provide left continuity on $[a, b]$. The simplest way to get right continuity is to apply the lemma also to $-\gamma$ and use that $\ell(\gamma|_{[a,t_0]}) = \ell(\gamma) - \ell(\gamma|_{[t_0,b]})$. 👍

VI.4.1.34. LEMMA. Let $\gamma : [a, b] \to X$ be a parametrized curve, not necessarily rectifiable. If (t_n) is an increasing sequence in $[a, b]$ converging to t_0, then

$$\ell(\gamma|_{[a,t_0]}) = \lim_{n\to\infty} \ell(\gamma|_{[a,t_n]}) = \sup_n \ell(\gamma|_{[a,t_n]}) \ .$$

PROOF: Define a sequence (γ_n) of parametrized curves on $[a,t_0]$ by setting $\gamma_n(t)=\gamma(t)$ if $a\le t\le t_n$ and $\gamma_n(t)=\gamma(t_n)$ if $t_n\le t\le t_0$ (i.e. γ_n agrees with γ on $[a,t_n]$ and is stationary on $[t_n,t_0]$). We have

$$\ell(\gamma_n)=\ell(\gamma|_{[a,t_n]})\le\ell(\gamma|_{[a,t_0]})$$

for any n by monotonicity (VI.4.1.25.). On the other hand, since γ is continuous at t_0, $\gamma_n\to\gamma$ pointwise on $[a,t_0]$. So applying VI.4.1.30. we get

$$\sup_n \ell(\gamma|_{[a,t_n]})\le\ell(\gamma|_{[a,t_0]})\le\liminf_{n\to\infty}\ell(\gamma_n)=\liminf_{n\to\infty}\ell(\gamma|_{[a,t_n]})$$

and the result follows. 👍

Parametrization by Arc Length

VI.4.1.35. Let $\gamma:[a,b]\to X$ be a nonstationary rectifiable parametrized curve, and let ϕ be the above function. Then ϕ is strictly increasing and continuous, so has a continuous strictly increasing inverse function $\phi^{-1}:[0,\ell(\gamma)]\to[a,b]$. Set $\tilde\gamma=\gamma\circ\phi^{-1}:[0,\ell(\gamma)]\to X$. Then $\tilde\gamma$ is a strict reparametrization of γ with the property that $\ell(\tilde\gamma|_{[0,t]})=t$ for $0\le t\le\ell(\gamma)$, i.e. $\tilde\gamma$ "traverses the path $\langle\gamma\rangle$ at uniform unit speed." The parametrized curve $\tilde\gamma$ is called the *reparametrization of γ by arc length.* If γ is replaced by any strict reparametrization, the $\tilde\gamma$ is unchanged; thus it depends only on $\langle\gamma\rangle$, i.e. any rectifiable path has a unique canonical parametrization by arc length.

Length of Arcs

If C is a "curve" in X, we would like to be able to say what the intrinsic "arc length" of C is. This is a tricky problem. The first question is what kind of subsets should be called "curves." It is too broad to say that the range of any parametrized curve is a "curve" (). One reasonable possibility is:

VI.4.1.36. DEFINITION. An *arc* in X is a subset of X homeomorphic to $[0,1]$.

VI.4.1.37. A subset C of X is an arc if and only if it is the range of an injective parametrized curve: a homeomorphism γ from $[0,1]$ to C is such a parametrized curve, and conversely an injective parametrized curve $\gamma:[a,b]\to X$ with $C=\gamma([a,b])$ is a homeomorphism by (). An arc thus has a unique equivalence class of oriented injective parametrizations, thus two in all; the arc length of all these parametrized curves is the same and can be taken to be the arc length of C.

VI.4.1.38. Slightly more generally, if C can be written as a finite union of arcs with only endpoints in common, the arc length of C can be taken to be the sum of the arc lengths of these arcs. For more complicated subsets, there are grave difficulties in defining arc length this way.

VI.4.1.39. There is a way to unambiguously define "arc length" for general (Borel) subsets of X: one-dimensional Hausdorff measure (). This "arc length" has the nice properties of a measure, generalizing VI.4.1.28.. Subsets whose one-dimensional Hausdorff measure is positive and finite can be regarded as "one-dimensional" (cf. (); not every "one-dimensional" subset will have these properties).

VI.4.2. Length Metrics

VI.4.2.1. The metric distance between two points in a metric space may not have much relationship to the "traveling distance." Here are some concrete examples, in part adapted from [BBI01].

(1) What is the distance between New York and Sydney? The straight-line distance is about 11,000 km. This number is relevant if one is, say, triangulating observational data to compute the distance from Earth to Mars, but is useless for travel since it would involve tunneling through the earth. The great circle distance, which is about 16,000 km, is much more relevant.

(2) What is the distance between the top of the Eiger and the top of the Jungfrau? It is about 5 km "as the crow flies." But a hiker/climber would have to go down into the valley and around or over the Mönch to get from one to the other, a much longer path. And the proper measure of the length of a route might be the time it takes to traverse it rather than the distance traveled.

(3) What is the distance between Boston and San Francisco? Even the great circle distance is not too relevant if one is driving; the road distance is the important consideration. So only certain paths are allowable for driving. And driving time might again be more important than distance – a longer route on interstate highways might be faster.

(4) On a more abstract level, if one lived in the Cantor set, it would not be possible to "move" or "travel" from one point even to very nearby ones, if time is interpreted as a real number and motion must be continuous. Something like this could happen in the real world if people lived on a chain of small islands and did not have boats or know how to swim.

We will address (1), (2), and (4) in this section, and (3) in the next section.

Intrinsic Metrics

VI.4.2.2. We would like to describe when a metric actually represents "traveling distance" and show that every metric defines a new associated "traveling distance" metric. It will be convenient to work with extended metrics, i.e. ones allowed to take values in $[0, +\infty]$ (); in some of the literature on metric geometry, "metric" means "extended metric" (we will not make this convention). The next definition is reasonable:

VI.4.2.3. Definition. An extended metric ρ on a set X is *strictly intrinsic*, or a *strict length metric*, if, for every $p, q \in X$, there is a path γ from p to q in X with $\ell(\gamma) = \rho(p, q)$.

For technical reasons, it is convenient to slightly broaden the definition:

VI.4.2.4. Definition. An extended metric ρ on a set X is *intrinsic*, or a *length metric*, if, for every $p, q \in X$, we have

$$\rho(p, q) = \inf_{\gamma} \ell(\gamma)$$

where the infimum is over all paths γ from p to q in X (with the convention that $\inf(\emptyset) = +\infty$).

VI.4.2.5. A strict length metric is a length metric (VI.4.1.24.), but not conversely. If ρ is a strict length metric, then (X, ρ) is path-connected. If ρ is a length metric, then (X, ρ) is not necessarily path-connected; but if $p, q \in X$ and $\rho(p, q) = +\infty$, then p and q are in different connected components of (X, ρ) () and hence there is no path in X from p to q. So if ρ is an extended metric which is a length metric, the following are equivalent:

(i) ρ is a metric.

(ii) (X, ρ) is path-connected.

(iii) (X, ρ) is *rectifiably path-connected*, i.e. for any $p, q \in X$, there is a rectifiable path from p to q in X.

In particular, a strictly intrinsic metric must be an actual metric, not an extended metric. The notions of length and strict length metrics are designed for and almost exclusively used in the (rectifiably) path-connected case. In fact, see VI.4.2.8..

VI.4.2.6. The term "intrinsic" is intended to mean that the metric represents "traveling distance within the space." For example, the arc-length metric on a circle is (strictly) intrinsic, but the Euclidean distance on a circle embedded in $\mathbb{R}^2$ is not intrinsic since one must travel "outside the space" to realize the Euclidean distance. Similarly, if the space is the surface of the earth (assumed to be a perfect sphere), the great-circle metric is intrinsic but not the straight-line (Euclidean) metric, which involves traveling through the earth and not within the space.

VI.4.2.7. Examples. (i) The Euclidean metric on $\mathbb{R}^n$ is strictly intrinsic.

(ii) More generally, the norm metric on any normed vector space is strictly intrinsic, as is the restriction to any convex subset.

(iii) As noted above, the arc length metric on a circle, or the great circle metric on a sphere, is strictly intrinsic. But the restriction of the Euclidean metric to an embedded circle or sphere is not intrinsic.

(iv) Let $X = \mathbb{R}^2 \setminus \{(0, 0)\}$. Then the restriction of the usual Euclidean metric to X is intrinsic but not strictly intrinsic: $(1, 0)$ and $(-1, 0)$ cannot be connected by a path of minimum length in X. See VI.4.5.1. for an example of a complete metric which is intrinsic but not strictly intrinsic.

(v) The discrete extended metric ρ on any set, where $\rho(p, q) = +\infty$ if $p \neq q$, is intrinsic.

VI.4.2.8. Proposition. Let ρ be an intrinsic metric on a set X. Then (X, ρ) is locally path-connected. In fact, every open ball in (X, ρ) is path-connected.

Proof: Let $p \in X$ and $\epsilon > 0$. Let $q \in B_\epsilon(p)$. Since $\rho(p, q) < \epsilon$, there is a parametrized curve $\gamma : [a, b] \to X$ from p to q with $\ell(\gamma) < \epsilon$. If $c \in [a, b]$, then by VI.4.1.25.

$$\rho(p, \gamma(c)) \leq \ell(\gamma|_{[a,c]}) \leq \ell(\gamma) < \epsilon$$

so the range of γ is contained in $B_\epsilon(p)$. Thus $B_\epsilon(p)$ is path-connected. 👍

The Length Metric of a Metric

Now suppose ρ is a general metric (or extended metric) on a space X. We want to define a new (extended) metric on X which describes "traveling distance" in (X, ρ).

VI.4.2.9. DEFINITION. Let (X, ρ) be a metric space. If $p, q \in X$, define

$$\rho_l(p, q) = \inf_\gamma \ell(\gamma)$$

where the infimum is over all paths γ from p to q in X (with the convention that $\inf(\emptyset) = +\infty$).

The function ρ_l is called the *length metric* of ρ; the terminology will be justified below.

VI.4.2.10. PROPOSITION. The function ρ_l is an extended metric on X.

PROOF: We need only verify the triangle inequality. Let $p, q, r \in X$; we show $\rho_l(p, r) \leq \rho_l(p, q) + \rho_l(q, r)$. If $\rho_l(p, q)$ or $\rho_l(q, r)$ is $+\infty$, there is nothing to prove, so assume both are finite. Let $\epsilon > 0$. There are paths γ_1 from p to q and γ_2 from q to r with $\ell(\gamma_1) < \rho_l(p, q) + \epsilon$ and $\ell(\gamma_2) < \rho_l(q, r) + \epsilon$. Reparametrizing if necessary, we can concatenate γ_1 and γ_2 (VI.4.1.16.) to get a path $\gamma_1 + \gamma_2$ from p to r. Thus

$$\rho_l(p, r) \leq \ell(\gamma_1 + \gamma_2) = \ell(\gamma_1) + \ell(\gamma_2) < \rho(p, q) + \rho(q, r) + 2\epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, the desired inequality follows. 👍

VI.4.2.11. Even if ρ is a metric, ρ_l is an extended metric in general. For example, if (X, ρ) is not path-connected, then ρ_l is necessarily extended: $\rho_l(p, q) = +\infty$ if p and q are in different path components. Even if (X, ρ) is path-connected, ρ_l can be an extended metric. In fact, ρ_l is a metric if and only if (X, ρ) is rectifiably path-connected.

VI.4.2.12. We have $\rho(p, q) \leq \rho_l(p, q)$ for any p, q by VI.4.1.24., i.e. ρ_l dominates ρ, so the topology of ρ_l is stronger than the topology of ρ. The metrics ρ and ρ_l are equivalent in good cases, but not in general, i.e. the ρ_l topology can be strictly stronger than the ρ-topology. If ρ is intrinsic, then $\rho_l = \rho$; the converse is also true (VI.4.2.14.).

VI.4.2.13. PROPOSITION. Let (X, ρ) be a metric space, and ρ_l the length metric of ρ. Then for any parametrized curve $\gamma : [a, b] \to X$ in (X, ρ), we have $\ell_{\rho_l}(\gamma) = \ell_\rho(\gamma)$.

Note that there is a subtlety: a continuous function from $[a, b]$ to (X, ρ) is not obviously continuous as a function from $[a, b]$ to (X, ρ_l) (and is not continuous in general). But by VII.3.1.15. arc length is also defined for discontinuous γ. In fact, we will not use continuity of γ in the proof.

PROOF: Fix γ. Since $\rho \leq \rho_l$, for any partition $\mathcal{P}$ of $[a, b]$ we have $\ell_\rho(\gamma, \mathcal{P}) \leq \ell_{\rho_l}(\gamma, \mathcal{P})$, and hence $\ell_\rho(\gamma) \leq \ell_{\rho_l}(\gamma)$. Conversely, let $\epsilon > 0$. If $\mathcal{P} = \{a = t_0, \ldots, t_n = b\}$ is a partition of $[a, b]$, set $p_k = \gamma(t_k)$ for $0 \leq k \leq n$. Then

$$\ell_{\rho_l}(\gamma, \mathcal{P}) = \sum_{k=1}^{n} \rho_l(p_{k-1}, p_k) \leq \sum_{k=1}^{n} \ell_\rho(\gamma|_{[t_{k-1}, t_k]}) = \ell_\rho(\gamma)$$

(VI.4.1.28.), and taking the supremum over all $\mathcal{P}$ we obtain $\ell_{\rho_l}(\gamma) \leq \ell_\rho(\gamma)$. 👍

VI.4.2.14. Corollary. Let (X, ρ) be a metric space, and ρ_l the length metric of ρ. Then ρ_l is intrinsic. Thus $(\rho_l)_l = \rho_l$, and $\rho = \rho_l$ if and only if ρ is intrinsic.

VI.4.2.15. It can be shown using VI.4.2.13. and VI.4.1.33. that if γ is a rectifiable parametrized curve in (X, ρ), i.e. γ is a continuous function from $[a, b]$ to (X, ρ) with $\ell_\rho(\gamma) < +\infty$, then γ is also continuous as a function from $[a, b]$ to (X, ρ_l). This can be false if γ is not rectifiable (VI.4.2.16.(iv)).

VI.4.2.16. Examples. (i) If X is a circle embedded in $\mathbb{R}^2$ and ρ is the restriction of the Euclidean metric, then ρ_l is the arc length metric. Similarly, if X is a sphere embedded in $\mathbb{R}^3$ and ρ is the Euclidean metric, then ρ_l is the great circle metric. In these cases $\rho_l \neq \rho$, but the metrics are equivalent.

(ii) Let X be the Warsaw circle (XIII.19.5.6.), and ρ the restriction of the Euclidean metric in $\mathbb{R}^2$. Since (X, ρ) is not locally path-connected and (X, ρ_l) is (VI.4.2.8.), the metrics cannot be equivalent. In fact, (X, ρ_l) is homeomorphic to a half-open interval.

(iii) Let (X, ρ) be a totally disconnected metric space, e.g. the Cantor set with the usual metric. The metric ρ_l is the discrete extended metric (VI.4.2.7.(v)), so the topology from ρ_l is the discrete topology.

(iv) Let X be $[0, 1]$ with the snowflake metric ρ^s for some s, $0 < s < 1$ (VI.4.1.20.(ii)). Then X is path-connected and locally path-connected, but has no nonconstant rectifiable paths. The metric $(\rho^s)_l$ is the discrete extended metric, so the topology from ρ_l is the discrete topology. Thus the topology from ρ_l can depend on the metric ρ and not just on the topology from ρ.

Local Characterization of Intrinsic Metrics

Intrinsic metrics are characterized locally, and are in an appropriate sense the only locally determined metrics.

VI.4.2.17. Definition. Let ρ and σ be extended metrics on a set X. The metric ρ *locally dominates* σ if, for each $x \in X$, there is a ρ-open ball B_x centered at x such that $\sigma(y, z) \leq \rho(y, z)$ for all $y, z \in B_x$. The metric ρ *uniformly locally dominates* σ if there is an $\epsilon > 0$ such that, whenever B is a ball of ρ-radius ϵ in X, $\sigma \leq \rho$ on B.

The extended metric ρ is *locally determined* if, whenever σ is an extended metric which is locally dominated by ρ, then $\sigma \leq \rho$.

VI.4.2.18. Examples. (i) The usual metric on $\mathbb{R}$, or any subset of $\mathbb{R}$ (e.g. $\mathbb{Q}$), is locally determined.

(ii) The arc length metric σ on a circle in $\mathbb{R}^2$ is locally determined. But the Euclidean metric ρ is not, since ρ locally dominates $(1 - \epsilon)\sigma$ for every $\epsilon > 0$ but does not dominate if ϵ is small enough.

(iii) If a small open arc (less than half the circumference) is removed from a circle, the restriction of arc length to the remaining space is not locally determined.

(iv) The discrete metric () on any set X is locally determined.

VI.4.2.19. PROPOSITION. Let (X, ρ) be a metric space. If ρ is intrinsic, it is locally determined.

PROOF: Suppose ρ is intrinsic, and σ is a pseudometric which is locally dominated by ρ. Let $x, y \in X$; we show $\sigma(x, y) \leq \rho(x, y)$. We may assume $\rho(x, y) < +\infty$. Fix $\epsilon > 0$. Let $\gamma : [0, 1] \to X$ be a path from x to y with $\ell(\gamma) < \rho(x, y) + \epsilon$. For $z \in \gamma([0, 1])$, there is an open neighborhood U_z of z with $\sigma(u, v) \leq \rho(u, v)$ for all $u, v \in U_z$. Since $\gamma([0, 1])$ is compact, there are finitely many such U_z which cover it, so there is a partition $\{0 = t_0, \ldots, t_n = 1\}$ of $[0, 1]$ such that, if $x_k = \gamma(t_k)$, consecutive x_k are in the same U_z. Thus we have

$$\sigma(x, y) \leq \sum_{k=1}^{n} \sigma(x_{k-1}, x_k) \leq \sum_{k=1}^{n} \rho(x_{k-1}, x_k) \leq \ell(\gamma) < \rho(x, y) + \epsilon$$

and since $\epsilon > 0$ is arbitrary, $\sigma(x, y) \leq \rho(x, y)$. 👍

VI.4.2.20. The converse is not true, even if ρ is complete (VI.4.2.18.(iv)). To obtain an appropriate converse, we make the following construction. Let ρ be an extended metric on a set X and $\epsilon > 0$. Set

$$\rho_\epsilon(x, y) = \inf \sum_{k=1}^{n} \rho(x_{k-1}, x_k)$$

where the infimum is over all finite chains $\{x = x_0, x_1, \ldots, x_n = y\}$ where $\rho(x_{k-1}, x_k) \leq \epsilon$ for all k (set $\rho_\epsilon(x, y) = +\infty$ if there is no such chain). It is easily proved by an argument almost identical to () that ρ_ϵ is an extended metric, that $\rho \leq \rho_\epsilon \leq \rho_\delta$ if $\delta < \epsilon$. We have that $\rho_\epsilon(x, y) = \rho(x, y)$ if $\rho(x, y) \leq \epsilon$, and in particular ρ uniformly locally dominates ρ_ϵ for any $\epsilon > 0$.

VI.4.2.21. By (), $\rho_{loc} = \sup_{\epsilon > 0} \rho_\epsilon$ is an extended metric, called the *local metric* of ρ. Comparing definitions, we have $\rho_{loc} \leq \rho_l$. Since $(\rho_\epsilon)_\delta = \rho_\delta$ if $\delta \leq \epsilon$, it follows that

$$(\rho_\epsilon)_{loc} = (\rho_{loc})_\epsilon = (\rho_{loc})_{loc} = \rho_{loc}$$

for any $\epsilon > 0$.

The next proposition is an immediate corollary of VI.4.2.19., or it can be easily proved directly.

VI.4.2.22. PROPOSITION. Let (X, ρ) be a metric space. If ρ is intrinsic, then $\rho = \rho_\epsilon$ for all $\epsilon > 0$.

VI.4.2.23. DEFINITION. Let ρ be a metric on a set X. Then ρ is *uniformly locally determined* if $\rho = \rho_\epsilon$ for all $\epsilon > 0$, i.e. if $\rho = \rho_{loc}$.

VI.4.2.24. EXAMPLES. (i) The usual metric on $\mathbb{Q}$ (or any other subset of $\mathbb{R}$) is uniformly locally determined.

(ii) The discrete metric on a set with more than one element is locally determined but not uniformly locally determined.

(iii) For any metric ρ, ρ_{loc} is uniformly locally determined (VI.4.2.21.).

VI.4.2.25. THEOREM. Let (X, ρ) be a complete metric space. Then $\rho_l = \rho_{loc}$.

VI.4.2.26. COROLLARY. Let (X, ρ) be a complete metric space. If ρ is uniformly locally determined, it is intrinsic.

For the proof of the theorem, we will use a variant of the Between Axiom (VI.3.1.11.) which is of independent interest:

VI.4.2.27. DEFINITION. A metric space (X, ρ) has the *approximate midpoint property* if, for every $x, y \in X$ and $\epsilon > 0$ there is a $z \in X$ with

$$\left|\rho(x,z) - \frac{\rho(x,y)}{2}\right| < \epsilon \text{ and } \left|\rho(z,y) - \frac{\rho(x,y)}{2}\right| < \epsilon \ .$$

Such a z is called an *ϵ-midpoint* of x and y.

VI.4.2.28. PROPOSITION. A uniformly locally determined metric has the approximate midpoint property.

PROOF: If (X, ρ) is locally determined, let $x, y \in X$ and $\epsilon > 0$. If $\{x = x_0, \ldots, x_n = y\}$ is a finite chain with $\rho(x_{k-1}, x_k) < \frac{\epsilon}{2}$ for all k and $\sum_k \rho(x_{k-1}, x_k) < \rho(x) + \frac{\epsilon}{2}$, then one of the x_k (for $k \approx \frac{n}{2}$) will be an ϵ-midpoint of x and y. 👍

VI.4.2.29. THEOREM. Let (X, ρ) be a complete metric space with the approximate midpoint property. Then ρ is intrinsic.

PROOF: This is somewhat similar to (), but no form of choice is needed. Let $x, y \in X$ and $\epsilon > 0$. Let $x_{1/2}$ be an $\frac{\epsilon}{4}$-midpoint of x and y. Let $x_{1/4}$ be an $\frac{\epsilon}{16}$-midpoint of $x = x_0$ and $x_{1/2}$, and $x_{3/4}$ an $\frac{\epsilon}{16}$-midpoint of $x_{1/2}$ and $y = x_1$. Continue inductively in this manner to define x_r for dyadic rational $r \in [0, 1]$, using a denominator of 4^n if the denominator of r is 2^n. It is easy to check that $r \mapsto x_r$ is uniformly continuous and thus extends to a map $\gamma : [0, 1] \to X$ since ρ is complete. Then γ is a path from x to y, and $\ell(\gamma) \leq \rho(x, y) + \epsilon$. 👍

Theorem VI.4.2.25., and hence Corollary VI.4.2.26., follow immediately.

VI.4.2.30. The example of $\mathbb{Q}$ (VI.4.2.24.(i)) shows that completeness is necessary in the theorem.

VI.4.3. Length Structures

We now change point of view. Instead of working with arc length defined by a metric, we assume directly that we have a notion of length for certain ("admissible") paths in the space X and from it derive a length metric and thus a topology. We must start with a metric, or at least a topology, on X, in order to have a notion of continuous path in X, but the initial topology will be inconsequential at the end. In order to do this, there must be enough admissible paths, and the length function must have reasonable properties.

Our exposition is largely adapted from [BBI01].

VI.4.3.1. DEFINITION. Let (X, σ) be a metric space. A *length structure* on (X, σ) is a pair $L = (A, \ell)$, where A is a set of parametrized curves in X (called *admissible paths* for L) such that

(1) If $\gamma : [a, b] \to X$ is in A, then $\gamma|_{[c,d]} \in L$ for every subinterval $[c, d]$ of $[a, b]$.

(2) If $\gamma_1, \gamma_2 \in A$ and $\gamma_1 + \gamma_2$ is defined, then $\gamma_1 + \gamma_2 \in A$.

(3) Any linear reparametrization of a parametrized curve in A is also in A. (Combined with (3), any piecewise-linear reparametrization of a parametrized curve in A is then also in A.) Also, if $\gamma \in A$, then its reversal $-\gamma$ is in A too.

and $\ell : A \to [0, +\infty]$ (called the *length function* of L) satisfying

(i) If $\gamma : [a, b] \to X$ is in A and $c \in [a, b]$, then $\ell(\gamma) = \ell(\gamma|_{[a,c]}) + \ell(\gamma_{[c,b]})$ (i.e. ℓ is additive on concatenations).

(ii) If $\gamma : [a, b] \to X$ is in A, then the function $\phi(t) = \ell(\gamma_{[a,t]}$ is continuous on $[a, b]$.

(iii) If $\gamma \in A$ and $\tilde{\gamma}$ is a linear reparametrization of γ, then $\ell(\tilde{\gamma}) = \ell(\gamma)$. (From (i) it then follows that ℓ is invariant under piecewise-linear reparametrizations, i.e. ℓ is really defined on equivalence classes of parametrized curves.) Also, $\ell(-\gamma) = \ell(\gamma)$ for any $\gamma \in A$.

(iv) If $p \in X$ and U is an open neighborhood of p (in the σ-topology), then there is a $\delta > 0$ such that any $\gamma \in A$ from p to a point $q \in U^c$ satisfies $\ell(\gamma) \geq \delta$.

The set A of admissible paths is technically encoded in the length function ℓ as its domain, and some of the literature does not distinguish between L and ℓ; but it seems a little clearer to make a notational distinction.

VI.4.3.2. Condition (iv) is an additional compatibility condition of L with the σ-topology on X besides the requirement that the curves in A are continuous. These two compatibility conditions are the only place the metric σ appears, and only depend on the σ-topology; the metric σ could be dispensed with entirely and just replaced by an initial topology on X (which should be assumed Hausdorff for a reasonable theory, although it could be dispensed with entirely by taking it to be the indiscrete topology).

VI.4.3.3. EXAMPLES. (i) Let (X, ρ) be a metric space, A the collection of all parametrized curves in X, and $\ell(\gamma) = \ell_\rho(\gamma)$. This is the *length structure induced by* ρ, denoted L_ρ.

(ii) More generally, let (X, ρ) be a metric space and $Y \subseteq X$. Let A be the set of parametrized curves in X whose range is contained in Y, and for $\gamma \in A$ set $\ell(\gamma) = \ell_\rho(\gamma)$. Then (A, ℓ) is a length structure on (X, ρ), as well as on (Y, ρ). This was the main motivating example for the theory of length structures, with $X = \mathbb{R}^n$, ρ the Euclidean metric, and Y a smooth submanifold.

(iii) Let (X, ρ) be $\mathbb{R}^n$ with the Euclidean metric, and take A to be either the set of piecewise-linear curves or piecewise-smooth curves in $\mathbb{R}^n$, with $\ell = \ell_\rho|_A$. These length structures are not essentially different from the length structure using all parametrized curves. One can also consider the restrictions to suitable subsets as in (ii).

(iv) Let (X, ρ) be $\mathbb{R}^n$ with the Euclidean metric, and take A to be the set of all parametrized curves in $\mathbb{R}^n$. Set $\ell(\gamma) = \ell_\rho(\gamma)$ if γ is piecewise-linear and $\ell(\gamma) = +\infty$ otherwise.

(v) Let $X = \mathbb{R}^2$, σ the Euclidean metric. Let A be the collection of all parametrized curves whose image consists of a union of finitely many horizontal and vertical line segments. For $\gamma \in A$, set $\ell(\gamma) = \ell_\sigma(\gamma)$.

(vi) Here is a concrete example, stated somewhat imprecisely. Let X be the United States, and A the set of driving routes (so all points, including endpoints, are points on roads). The length $\ell(\gamma)$ of a driving route is the driving time for the route. (Driving routes are taken as paths, i.e. equivalence classes of parametrized curves, and driving time is not connected with parametrization.) This must be idealized to become precise and give a length structure: driving time must be well defined and be independent of direction, and it must be assumed that a vehicle can reverse direction instantaneously to make driving time additive on curves which retrace routes.

In this example, not all points of the space are connected by admissible paths. To rectify this, we could add to A the set of all routes traversable by surface transportation, including walking (assuming that every point of the country is within walking distance of a road).

(vii) As a precise theoretical version of (vi), let X be $\mathbb{R}^n$ (or a smooth submanifold) and $f : X \to (0, +\infty)$ a continuous function (continuity can be somewhat relaxed). Let A be the set of piecewise-smooth parametrized curves in X, and for $\gamma : [a, b] \to X$ in A, set

$$\ell(\gamma) = \int_\gamma f = \int_a^b f(\gamma(t))|\gamma'(t)|\, dt$$

(this is just the integral of f along the path defined by γ ()). In the case of (v), X could be the set of all points on roads, and $f(\boldsymbol{x})$ the reciprocal of the maximum speed one can (or is allowed to) drive at the point $\boldsymbol{x}$.

(viii) As a generalization, let X be $\mathbb{R}^n$ (or a smooth submanifold) and $f : X \times \mathbb{R}^n \to (0, +\infty)$ a continuous function (continuity can be somewhat relaxed). Let A be the set of piecewise-smooth parametrized curves in X, and for $\gamma : [a, b] \to X$ in A, set

$$\ell(\gamma) = \int_a^b f(\gamma(t), \gamma'(t))\, dt\ .$$

To make ℓ invariant under linear reparametrizations, we need $f(\boldsymbol{x}, \alpha\boldsymbol{y}) = |\alpha| f(\boldsymbol{x}, \boldsymbol{y})$ for all $\boldsymbol{x}, \boldsymbol{y}, \alpha$. Such a length structure is called a *Finslerian length structure*. The idea is that the speed of travel may depend not only on the point, but also on the direction of travel (although the speed in diametrically opposite directions must be the same, not necessarily a realistic assumption in applications).

The Length Metric of a Length Structure

VI.4.3.4. Definition. Let $L = (A, \ell)$ be a length structure on a metric space (X, σ). Define an extended metric ρ_L by

$$\rho_L(p, q) = \inf_\gamma \ell(\gamma)$$

for $p \neq q$, where the infimum is over all paths $\gamma \in A$ from p to q (with the convention that $\inf(\emptyset) = +\infty$).

The proof that ρ_L is an extended metric is essentially identical to the proof of VI.4.2.10., using that a concatenation of admissible paths is admissible. The extended metric ρ_L is a metric if and only if any two points of X can be connected by an admissible path of finite length. The ρ_L-topology on X is stronger than the initial σ-topology by condition (iv); it is often strictly stronger.

VI.4.3.5. PROPOSITION. Let $L = (A, \ell)$ be a length structure on (X, σ), and ρ_L the corresponding extended metric. Then ρ_L is a length metric, and $\ell_{\rho_L}(\gamma) \leq \ell(\gamma)$ for all $\gamma \in A$.

We can have strict inequality (VI.4.3.6.(iv)).

PROOF: For the second statement, let $\gamma : [a, b] \to X$ be in A. If $\mathcal{P} = \{a = t_0, \ldots, t_n = b\}$ is any partition of $[a, b]$, we have

$$\ell_{\rho_L}(\gamma, \mathcal{P}) = \sum_{k=1}^{n} \rho_L(\gamma(t_{k-1}), \gamma(t_k)) \leq \sum_{k=1}^{n} \ell(\gamma|_{[t_{k-1}, t_k]}) = \ell(\gamma)$$

since $\gamma|_{[t_{k-1}, t_k]} \in A$ by (1), and taking the supremum over all $\mathcal{P}$ we obtain the inequality.
To show ρ_L is a length metric, let $p, q \in X$. We show that

$$\rho_L(p, q) = \lambda := \inf_{\gamma} \ell_{\rho_L}(\gamma)$$

with the infimum over all parametrized curves from p to q. We need only show $\rho_L(p, q) \geq \lambda$, since $\leq$ is automatic (VI.4.1.24.). If $\rho_L(p, q) = +\infty$, there is nothing to prove, so we may suppose $\rho_L(p, q)$ is finite. Let $\epsilon > 0$. There is a $\gamma \in A$ from p to q with $\ell(\gamma) < \rho_L(p, q) + \epsilon$. Then

$$\lambda \leq \ell_{\rho_L}(\gamma) \leq \ell(\gamma) < \rho_L(p, q) + \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, the inequality follows. 👍

VI.4.3.6. EXAMPLES. (i) If (X, ρ) is a metric space and L_ρ is the induced length structure (VI.4.3.3.(i)), then $\rho_{L_\rho} = \rho_l$.

(ii) In the situation of VI.4.3.3.(ii), if L is regarded as a length structure on (Y, ρ), then $\rho_L = \rho_l$ as in (i). If L is regarded as a length structure on (X, ρ), then ρ_L is an extended metric on X, with $\rho_L(p, q) = +\infty$ unless both p and q are in Y. In the ρ_L topology on X, Y is a clopen set and each point of $X \setminus Y$ is an isolated point.

(iii) In VI.4.3.3.(iii), the induced metric ρ_L on $\mathbb{R}^n$ is just the Euclidean metric, since the set of admissible curves includes a curve of minimal length between any two points. Thus restricting the set of admissible curves does not necessarily change the length metric, so long as the admissible curves include arbitrarily short paths (i.e. close to the minimum for all paths) between any pair of points.

(iv) In VI.4.3.3.(iv), the induced metric ρ_L on $\mathbb{R}^n$ is again just the Euclidean metric. Thus, even if the set of admissible curves is the same, changing the length function ℓ does not necessarily change the length metric, if there are short paths of (approximately) the same length under the two length functions.

(v) In VI.4.3.3.(v), the length metric is not the Euclidean metric $\rho = \rho_2$, but rather the 1-metric ρ_1 (). Thus if the set of admissible curves is changed, the length metric can change if the set of admissible curves does not contain arbitrarily short paths between points.

Recovering a Length Structure from its Metric

VI.4.3.7. If ρ is a length metric, then the induced metric from the length structure L_ρ is ρ itself (cf. VI.4.3.6.(i)). How about the converse: if $L = (A, \ell)$ is a length structure and ρ_L the induced length metric, is $L = L_{\rho_L}$? In one sense, the answer is usually no: the set of admissible paths for L_{ρ_L} is often larger than A (cf. Examples VI.4.3.6.(iii) and (v)). But ℓ_{ρ_L} may not agree with ℓ even on A (VI.4.3.6.(iv); the problem is lower semicontinuity (VI.4.3.9.)). It would be useful to know when ℓ_{ρ_L} agrees with ℓ on A, since ℓ is often given by a formula making it easier to calculate than ℓ_{ρ_L} (e.g. in VI.4.3.3.(vii)–(viii)).

VI.4.3.8. The length function ℓ_{ρ_L} is always lower semicontinuous (VI.4.1.30.), so a necessary condition that $\ell = \ell_{\rho_L}|_A$ for a length structure $L = (A, \ell)$ is that ℓ is lower semicontinuous on A. But ℓ is not necessarily lower semicontinuous, e.g. the ℓ of Example VI.4.3.3.(iv) (the ℓ of Example VI.4.3.3.(viii) is also not necessarily lower semicontinuous, cf. ()). Lower semicontinuity is the only constraint:

VI.4.3.9. PROPOSITION. Let $L = (A, \rho)$ be a length structure on (X, σ), and ρ_L the corresponding length metric. Then $\ell = \ell_{\rho_L}|_A$ if and only if ℓ is lower semicontinuous on A.

VI.4.4. Metric Geometry

VI.4.5. Exercises

VI.4.5.1. For each n let I_n be a closed interval in $\mathbb{R}$ of length $1 + \frac{1}{n}$ with endpoints a_n and b_n. Glue the I_n together by identifying all the a_n to a point a, and all the b_n to a point b. Let X be the quotient space, and ρ the length metric on X.

(a) Show that (X, ρ) is a complete metric space.

(b) Show that $\rho(a, b) = 1$, but there is no path from a to b of length 1. Thus (X, ρ) is not complete as a length space, i.e. ρ is not strictly intrinsic.

(c) Realize X concretely as a subset of $\mathbb{R}^2$ consisting of a union of circular arcs in the upper half plane through $(0, 0)$ and $(1, 0)$. Show that ρ is the length metric defined by the restriction σ of the Euclidean metric on $\mathbb{R}^2$, and that ρ is equivalent (but not uniformly equivalent) to the incomplete metric σ.

VI.4.5.2. Let (X, ρ) be a metric space, and ρ_l the associated length metric on X.

(a) Show that if ρ is complete, then ρ_l is also complete.

(b) If ρ_l is complete, then ρ is not necessarily complete, even if (X, ρ) is rectifiably path-connected and locally path-connected. [Let X be the topologist's sine curve (XIII.19.5.5.) with the points on the y-axis removed, with ρ the ordinary metric from $\mathbb{R}^2$. $\mathbb{Q}$ with the ordinary metric is an example if the space is not required to be path-connected.]

Chapter VII

Curves

> "Everyone knows what a curve is, until he has studied enough mathematics to become confused through the countless number of possible exceptions."
>
> *Felix Klein*

What is a curve? Almost everyone has a good intuitive idea of what a curve should be, but it is a surprisingly delicate matter to make a precise definition which includes all the things which should be curves and excludes everything that should not.

At a minimum, a curve should be a one-dimensional subset of a Euclidean space. Most people would agree that the following are curves:

Graphs of continuous functions, or at least graphs of differentiable functions, from $\mathbb{R}$ to $\mathbb{R}$.

Lines, circles, and polygons.

A figure 8, figure 6, figure α, and the like.

Finite separated unions of the above.

On the other hand, the following are clearly not curves:

Anything zero-dimensional, e.g. the Cantor set ().

Anything more than one-dimensional, e.g. a (solid) disk or square, or a ball or sphere in $\mathbb{R}^n$, $n > 2$.

Anything not at least locally compact.

In addition, there are many things which are in a gray area, e.g. a figure X, figure Y, figure $\otimes$, and many of the the one-dimensional subsets of $\mathbb{R}^2$ and $\mathbb{R}^3$ discussed in (), such as the Topologist's Sine Curve, the Hawaiian Earring, the Sierpiński gasket and carpet, solenoids, the pseudo-arc, even wildly embedded arcs.

We will begin by defining curves via parametrizations, although we will distinguish between curves and parametrized curves. Parametrizations are natural since they describe "motion along the curve." But defining a curve as just a continuous image of an interval is too broad: for example, there are "space-filling curves," continuous functions from $[0, 1]$ onto a square $[0, 1]^2$. In fact, the Banach-Mazurkiewicz Theorem () says

that every compact metrizable topological space which is connected and locally connected, and in particular any connected, locally connected closed bounded subset of a Euclidean space, is a continuous image of $[0,1]$. Allowing continuous images of non-closed intervals, e.g. $\mathbb{R}$, admits even more pathology: a continuous image of $\mathbb{R}$, even a one-to-one continuous image, need not even be locally compact (). On the other hand, requiring the parametrization to be a homeomorphism eliminates such a natural curve as a circle, and to relax the requirement to being a local homeomorphism rules out curves like a figure 8. So we will have to be more careful.

VII.1. Curves and Parametrized Curves in $\mathbb{R}^n$

VII.1.1. Parametrized Curves

VII.1.1.1. DEFINITION. A *parametrized curve* in $\mathbb{R}^n$ is a continuous function $\gamma : [a,b] \to \mathbb{R}^n$ for some closed bounded interval $[a,b]$ in $\mathbb{R}$. The points $p = \gamma(a)$ and $q = \gamma(b)$ are the *initial* and *final endpoints* of γ respectively, and γ is a *parametrized curve from p to q*.

Note that the interval $[a,b]$ is allowed to be degenerate, i.e. we allow $a = b$. (To be sure, parametrized curves defined on degenerate intervals are not very interesting!)

VII.1.1.2. A parametrized curve has a direction. If $\gamma : [a,b] \to \mathbb{R}^n$ is a parametrized curve from p to q, its *negative* or *reversal* is $-\gamma : [a,b] \to \mathbb{R}^n$ defined by $(-\gamma)(t) = \gamma(a+b-t)$ is a parametrized curve from q to p.

VII.1.1.3. We may think of the range of a parametrized curve as a "curve" in $\mathbb{R}^n$ (although it need not look anything like a geometric curve), and the parametrization as giving "motion" along this curve. This motion may "retrace" parts of the curve in a complicated way.

Restriction and Concatenation

VII.1.1.4. DEFINITION. Let $\gamma : [a,b] \to \mathbb{R}^n$ be a parametrized curve, and $[c,d]$ a closed subinterval of $[a,b]$, i.e. $a \le c \le d \le b$. The parametrized curve $\gamma|_{[c,d]}$ is the *restriction* of γ to $[c,d]$; it is a parametrized curve from $\gamma(c)$ to $\gamma(d)$.

VII.1.1.5. DEFINITION. If $\gamma_1 : [a,b] \to \mathbb{R}^n$ is a parametrized curve from p to q, and $\gamma_2 : [b,c] \to \mathbb{R}^n$ is a parametrized curve from q to r, the *concatenation* is the parametrized curve $\gamma = \gamma_1 + \gamma_2 : [a,c] \to \mathbb{R}^n$ defined by

$$\gamma(t) = \begin{cases} \gamma_1(t) & \text{if} \quad a \le t \le b \\ \gamma_2(t) & \text{if} \quad b \le t \le c \end{cases}$$

The concatenation γ is a parametrized curve from p to r.

We may extend the definition to $\gamma_1 + \cdots + \gamma_n$ if the curves line up properly.

VII.1.1.6. Note the conditions under which the concatenation is defined are rather severe: γ_1 and γ_2 must be parametrized on intervals in $\mathbb{R}$ which concatenate, and the final endpoint of γ_1 must be the initial endpoint of γ_2. Concatenation can be slightly generalized using reparametrizations (VI.4.1.16.). Also note that although additive notation is used, concatenation is not commutative: if $\gamma_1 + \gamma_2$ is defined, then $\gamma_2 + \gamma_1$ is not even defined unless one of the intervals is degenerate.

VII.1.1.7. If $\gamma = \gamma_1 + \gamma_2$ is defined, then the restriction of γ to $[a, b]$ (resp. to $[b, c]$) is γ_1 (resp. γ_2). Conversely, if $\gamma : [a, b]$ is a parametrized curve and $c \in [a, b]$, then $\gamma = \gamma|_{[a,c]} + \gamma|_{[c,b]}$. More generally, if $\mathcal{P} = \{a = t_0, t_1, \ldots, t_n = b\}$ is a partition of $[a, b]$, we have

$$\gamma = \gamma|_{[a,t_1]} + \gamma|_{[t_1,t_2]} + \cdots + \gamma|_{[t_{n-1},b]} \ .$$

VII.1.2. Reparametrization

VII.1.2.1. Definition. Let $\gamma : [a, b] \to \mathbb{R}^n$ and $\tilde{\gamma} : [c, d] \to \mathbb{R}^n$ be parametrized curves. Then $\tilde{\gamma}$ is a *reparametrization* of γ if $\tilde{\gamma} = \gamma \circ \phi$, where ϕ is a nondecreasing continuous function from $[c, d]$ onto $[a, b]$ (hence $\phi(c) = a$ and $\phi(d) = b$). If ϕ is strictly increasing, $\tilde{\gamma}$ is a *strict reparametrization* of γ.

VII.1.2.2. A reparametrization of a parametrized curve has the same initial and final endpoints, and the same range. But two parametrized curves with the same range, even also with the same initial and final endpoints, need not be reparametrizations. A reparametrization of a parametrized curve describes "motion" along the range "curve" in the same sense, with the same retracing, but possibly over a different interval of time at a different and varying speed.

VII.1.2.3. Various special kinds of reparametrizations can be considered. The simplest is linear reparametrizations, where ϕ is a linear (affine) function from $[c, d]$ onto $[a, b]$, i.e.

$$\phi(t) = a + \frac{b - a}{d - c}(t - c) \ .$$

One can also consider $\mathcal{C}^r$ reparametrizations, where ϕ is $\mathcal{C}^r$, and strict $\mathcal{C}^r$ reparametrizations, where both ϕ and ϕ^{-1} are $\mathcal{C}^r$ (these are also called smooth reparametrizations). There are also piecewise linear and piecewise smooth reparametrizations.

VII.1.2.4. Reparametrization is not an equivalence relation: it is reflexive and transitive, but not symmetric since the function ϕ need not be one-to-one. Strict reparametrization is symmetric, thus an equivalence relation on parametrized curves. Parametrization does generate an important equivalence relation, which can be described thus: two parametrized curves are equivalent if they are both reparametrizations of the same parametrized curve (VII.1.2.7.).

Nonstationary Curves

VII.1.2.5. Definition. Let $\gamma : [a, b] \to \mathbb{R}^n$ be a parametrized curve, and $[c, d]$ a closed subinterval of $[a, b]$. Then γ is *stationary* on $[c, d]$ if $\gamma(t) = \gamma(c)$ for all $t \in [c, d]$. The curve γ is *nonstationary* if it is not stationary on any (nondegenerate) subinterval of $[a, b]$.

VII.1.2.6. A nonstationary parametrized curve need not be one-to-one; in fact, it can be very noninjective. For example, the space-filling curve of XIII.18.6.14. is nonstationary (the one in XIII.18.6.13. is not nonstationary). For a simpler example, a nonstationary parametrized curve can wrap around a circle in $\mathbb{R}^2$ several times.

VII.1.2.7. The maximal intervals on which a parametrized curve γ is stationary form a collection of disjoint closed subintervals of $[a, b]$. Every parametrized curve is a reparametrization of a nonstationary parametrized curve, which is unique up to strict reparametrization (Exercise ()), obtained by collapsing each maximal stationary subinterval to a point (there may be infinitely many such intervals!) Two parametrized curves are equivalent in the equivalence relation generated by reparametrization (VII.1.2.4.) if and only if their nonstationary versions are strict reparametrizations of each other.

VII.1.3. Paths

VII.1.3.1. Definition. Let $p, q \in \mathbb{R}^n$. A *path* from p to q is an equivalence class of parametrized curves from p to q (using the equivalence relation of VI.4.1.11. or VII.1.2.7.).

We will write $\gamma_1 \approx \gamma_2$ if γ_1 and γ_2 are equivalent, and write $\langle\gamma\rangle$ for the equivalence class of γ (the usual notation $[\gamma]$ for an equivalence class is normally reserved for the homotopy class of γ, which is a quite different thing ()).

VII.1.3.2. Paths can be concatenated: if $\langle\gamma_1\rangle$ is a path from p to q and $\langle\gamma_2\rangle$ is a path from q to r, then γ_1 can be concatenated with a suitable reparametrization $\tilde{\gamma}_2$ of γ_2 (e.g. a linear reparametrization), and the equivalence class of $\gamma_1 + \tilde{\gamma}_2$ is well defined and depends only on the classes of γ_1 and γ_2 (Exercise ()). Thus the concatenation of the paths $\langle\gamma_1\rangle + \langle\gamma_2\rangle$ is well defined as $\langle\gamma_1 + \tilde{\gamma}_2\rangle$.

Restriction of paths is a much dicier matter ().

VII.2. Smooth and Piecewise Smooth Curves in $\mathbb{R}^n$

Roughly speaking, a smooth curve in $\mathbb{R}^n$ is the image of a smooth function from $\mathbb{R}$, or a subinterval, to $\mathbb{R}^n$. But this is not exactly correct: we have to make some additional restrictions.

VII.2.1. Smooth Functions from $\mathbb{R}$ to $\mathbb{R}^n$

VII.2.1.1. Definition. Let γ be a function from an interval I to $\mathbb{R}^n$, with coordinate functions $\gamma_1, \ldots, \gamma_n$, and let $1 \leq r \leq \infty$. Then γ is $\mathcal{C}^r$ on I if each γ_k is $\mathcal{C}^r$ on I, i.e. has continuous derivatives of orders $\leq r$ on I.

This definition generalizes V.3.7.2., and is a special case of VIII.3.3.4., i.e. the definitions are consistent. We will generically, and imprecisely, use the term *smooth* to mean a function which is at least $\mathcal{C}^1$, and usually $\mathcal{C}^\infty$; we will try to be more specific when necessary or important.

The Derivative of a Vector-Valued Function

DEFINITION. Let $\gamma = (\gamma_1, \ldots, \gamma_n)$ be a function from an interval I in $\mathbb{R}$ to $\mathbb{R}^n$, and let a be an interior point of I. Then γ is *differentiable* at a if each γ_k is differentiable at a. If γ is differentiable at a, set

$$\gamma'(a) = (\gamma_1'(a), \ldots, \gamma_n'(a)) \ .$$

One can also define one-sided derivatives, especially at endpoints of I.

VII.2.1.2. Thus if γ is $\mathcal{C}^1$ on I, then it is differentiable at every (interior) point of I and one-sided differentiable at endpoints, and the function γ' is continuous on I (in the sense of ()), and conversely.

VII.2.1.3. This definition is (essentially) compatible with VIII.3.1.4., with slightly differing language: in the language there, γ is differentiable at a if and only if the limit

$$\lim_{h \to 0} \frac{1}{h}[\gamma(a+h) - \gamma(a)]$$

exists and equals $\gamma'(a)$, or equivalently

$$\lim_{h \to 0} \frac{\gamma(a+h) - \gamma(a) - h\gamma'(a)}{|h|} = \mathbf{0} \ .$$

Geometric Interpretation of the Derivative

VII.2.1.4. Suppose $\gamma : I \to \mathbb{R}^n$ is a function which is differentiable at an interior point a of I, and set $\boldsymbol{p} = \gamma(a)$. If $\boldsymbol{v} = \gamma'(a) \neq \mathbf{0}$, we want to interpret $\boldsymbol{v}$ as a "tangent vector" to the curve γ at $\boldsymbol{p}$. We have not yet defined what this means, so we could, and will, just define the tangent line to γ at $\boldsymbol{p}$ to be the line through $\boldsymbol{p}$ parallel to $\boldsymbol{v}$. But let us first see that this definition is reasonable.

VII.2.1.5. EXAMPLE. Consider first the case where f is a differentiable function from an open interval I to $\mathbb{R}$, and set

$$\gamma(t) = (t, f(t)) \in \mathbb{R}^2$$

for $t \in I$. Then γ is a differentiable function from I to $\mathbb{R}^2$ whose image is the graph of f, and for $t \in I$ we have $\gamma'(t) = (1, f'(t))$. If $a \in I$, $\boldsymbol{p} = (a, f(a)) = \gamma(a)$, and $\boldsymbol{v} = (1, f'(a)) = \gamma'(a)$, then the line through $\boldsymbol{p}$ parallel to $\boldsymbol{v}$ has slope $f'(a)$, and is exactly the tangent line to the graph of f at $\boldsymbol{p}$, as defined in V.3.1.10..

VII.2.1.6. More generally, if $n = 2$ and γ is a $\mathcal{C}^1$ function from I to $\mathbb{R}^2$ with $\gamma'(a) \neq \mathbf{0}$, the situation can be reduced to the one of VII.2.1.5. by reparametrization (Exercise VII.2.3.1.).

VII.2.1.7. Here is a better argument which is valid for any n and which does not require γ' to be continuous or even defined anywhere but a, i.e. in the general situation of VII.2.1.4.. The geometric picture is very similar to the way the tangent line to the graph of a function from $\mathbb{R}$ to $\mathbb{R}$ is defined in V.3.1.10., although we cannot define the slope of a line in $\mathbb{R}^n$ and must instead define the line itself. Fix the point $\boldsymbol{p} = \gamma(a)$, and for t near a let $\boldsymbol{q}$ be the variable point $\gamma(t) = \gamma(a+\Delta t)$. Write $\Delta\gamma = \boldsymbol{q} - \boldsymbol{p}$, and set $\boldsymbol{w} = \frac{1}{\Delta t}\Delta\gamma$ (Figure ()):
We have

$$\lim_{\Delta t \to 0} \frac{\Delta\gamma}{\Delta t} = \boldsymbol{v}$$

i.e. we can write $\boldsymbol{v} = \frac{d\gamma}{dt}(a)$.

VII.2.1.8. In the physical situation where n is 2 or 3, we may consider the motion of a particle in $\mathbb{R}^n$ whose position at time t is $\gamma(t)$. Then the vector $\boldsymbol{w} = \frac{\Delta\gamma}{\Delta t}$ can be interpreted as the "average velocity" of the particle between $t = a$ and $t = a + \Delta t$, and $\boldsymbol{v} = \gamma'(a)$ is the "instantaneous velocity" of the particle at time a. We can also interpret $\left\| \frac{\Delta\gamma}{\Delta t} \right\|$ as the "average speed" of the particle between $t = a$ and $t = a + \Delta t$ and $\|\boldsymbol{v}\|$ as the "instantaneous speed" at a.

VII.2.1.9. Here is another way to express this. Define

$$\beta(t) = \boldsymbol{p} + (t - a)\boldsymbol{v}$$

for any $t \in \mathbb{R}$. Then $\beta : \mathbb{R} \to \mathbb{R}^n$, $\beta(a) = \boldsymbol{p}$, and β is differentiable everywhere ($\mathcal{C}^\infty$) with $\beta'(t) = \boldsymbol{v}$ for all t (this is easily verified by considering the coordinate functions of β, which are linear or affine). In fact, β parametrizes motion along the line through $\boldsymbol{p}$ parallel to $\boldsymbol{v}$ at constant speed $\|\boldsymbol{v}\|$. If t is close to a, $\beta(t)$ closely approximates $\gamma(t)$; in fact,

$$\lim_{t \to a} \frac{\|\gamma(t) - \beta(t)\|}{|t - a|} = \lim_{h \to 0} \frac{\|\gamma(a + h) - \gamma(a) - h\gamma'(a)\|}{|h|} = 0$$

or, in other words, for any $\epsilon > 0$ there is a $\delta > 0$ such that

$$\|\gamma(t) - \beta(t)\| < \epsilon|t - a|$$

for $|t - a| < \delta$, i.e. γ and β are virtually indistinguishable for t near a. Thus we can not only interpret the line L parametrized by β as the "tangent line" to γ at p, but we can also interpret $\boldsymbol{v}$ as pointing in the "direction of motion" of γ at a and $\|\boldsymbol{v}\|$ as the "instantaneous speed" of γ at a.

VII.2.2. Smooth Curves in $\mathbb{R}^n$

When $\gamma'(a) = \mathbf{0}$ in VII.2.1.4., all bets are off. Even if γ is $\mathcal{C}^\infty$ on I, the image need not be a smooth curve with a tangent line at a: it can be very pathological, as the following examples show.

VII.2.2.1. Examples. (i) Define $\gamma : \mathbb{R} \to \mathbb{R}^2$ by $\gamma(t) = (t^3, t^2)$. Then γ is $\mathcal{C}^\infty$, and $\gamma'(t) = (3t^2, 2t)$. So $\gamma'(0) = \mathbf{0}$. The image of γ is the graph of $f(t) = t^{2/3}$, which has a cusp at $\gamma(0) = \mathbf{0}$ and is not smooth there.

(ii) The situation can be far worse. Define $\gamma : \mathbb{R} \to \mathbb{R}^2$ by

$$\gamma(t) = \begin{cases} (t^2 \cos \frac{1}{t}, t^2 \sin \frac{1}{t}) & \text{if} \quad t \neq 0 \\ (0,0) & \text{if} \quad t = 0 \end{cases} .$$

Then γ is differentiable at 0 and $\gamma'(0) = \mathbf{0}$. However, as $t \to 0$ the curve spirals around the origin infinitely many times, so cannot have anything like a tangent line at $\mathbf{0}$.

This example can be modified to make it $\mathcal{C}^\infty$ by replacing t^2 by e^{-1/t^2} in the definition.

(iii) Of course, the curve *can* be smooth at a point where $\gamma'(a) = \mathbf{0}$: consider $\gamma(t) = (t^3, t^3)$. But there is no straightforward way to tell from the derivative when this is the case.

We thus make the following definition:

VII.2.2.2. DEFINITION. Let $1 \leq r \leq \infty$. A $\mathcal{C}^r$ *parametrized curve* in $\mathbb{R}^n$ is a $\mathcal{C}^r$ function γ from an interval I to $\mathbb{R}^n$ (one-sided derivatives at endpoints of I) such that $\gamma'(t) \neq 0$ for all $t \in I$.

We will imprecisely use the term *smooth parametrized curve* to denote a $\mathcal{C}^r$ parametrized curve for sufficiently large r depending on context (usually $r = \infty$).

Piecewise-Smooth Parametrized Curves

VII.2.2.3. We also define a piecewise $\mathcal{C}^r$ parametrized curve in the obvious way: a parametrized curve $\gamma : I \to \mathbb{R}^n$ is *piecewise* $\mathcal{C}^r$ *on* I if γ is continuous on I and there is a partition of I into a finite number $I_1, \ldots, I_m$ of nonoverlapping subintervals such that γ is a $\mathcal{C}^r$ parametrized curve on each I_k. Thus if a is a common endpoint for I_k and I_{k+1}, γ must have left and right derivatives at a of orders $\leq r$, but they need not coincide, although we need that $\lim_{t \to a-} \gamma(t) = \lim_{t \to a+} \gamma(t) = \gamma(a)$ and that the first derivatives are everywhere nonzero. The image of γ is thus a smooth curve on each I_k but may have an "angle" or "cusp" at a common endpoint.

VII.2.2.4. It turns out that any piecewise $\mathcal{C}^r$ parametrized curve has a reparametrization by a function which is $\mathcal{C}^r$ everywhere, but with zero derivative at the common endpoints (Exercise VII.2.3.2.). However, the image of a $\mathcal{C}^r$ function does not necessarily have a reparametrization making it a piecewise $\mathcal{C}^r$ parametrized curve (Example VII.2.2.1.(ii)).

VII.2.2.5. It is quite useful to have a notion of piecewise-smooth parametrized curves, for many reasons, including:

(i) It is frequently important to consider curves, e.g. polygonal curves, which are piecewise-smooth but not smooth.

(ii) A concatenation of smooth parametrized curves is not smooth in general, but is piecewise-smooth. In fact, a concatenation of piecewise-smooth parametrized curves is piecewise-smooth.

VII.2.3. Exercises

VII.2.3.1. Prove the statement in VII.2.1.6.. [Without loss of generality, suppose $\gamma_1'(a) \neq 0$. If $b = \gamma_1(a)$, then γ_1 has a smooth inverse function β in an interval around b. Let $\tilde{\gamma} = \gamma \circ \beta$.]

VII.2.3.2. Prove the statement in VII.2.2.4.. [For each k, let ϕ_k be a strictly increasing $\mathcal{C}^\infty$ function from I_k onto I_k with all derivatives 0 at the endpoints, with ϕ_k' nonzero on the interior of I_k, cf. V.17.2.5..]

VII.3. Rectifiable Curves and Arc Length

Throughout this section, ρ will denote the Euclidean distance function on $\mathbb{R}^d$. (We use d instead of n so that n is available as a counting parameter for partitions.)

VII.3.1. Arc Length

VII.3.1.1. DEFINITION. Let $\gamma : [a,b] \to \mathbb{R}^d$ be a parametrized curve, and $\mathcal{P} = \{a = t_0, t_1, \ldots, t_n = b\}$ a partition of $[a,b]$. The *polygonal approximate length of γ from $\mathcal{P}$* is

$$\ell(\gamma, \mathcal{P}) = \sum_{k=1}^{n} \rho(\gamma(t_{k-1}), \gamma(t_k)) \ .$$

The *arc length* of γ is

$$\ell(\gamma) = \sup_{\mathcal{P}} \ell(\gamma, \mathcal{P}) \ .$$

VII.3.1.2. If $\mathcal{Q}$ is a partition of $[a,b]$ which refines $\mathcal{P}$, we have $\ell(\gamma, \mathcal{P}) \le \ell(\gamma, \mathcal{Q})$ by the triangle inequality. Since any two partitions have a common refinement, the polygonal approximations approach the arc length as the partitions become arbitrarily fine. The term "polygonal approximation" should not be taken too literally: there is usually not an actual "polygon" in $\mathbb{R}^d$ approximating the curve. The term is suggestive that $\rho(p,q)$ should be the "straight-line" distance between p and q.

The arc length of a curve can easily be infinite (e.g. VI.4.1.20.).

VII.3.1.3. DEFINITION. The curve γ is *rectifiable* if $\ell(\gamma)$ is finite.

VII.3.1.4. EXAMPLES. (i) A parametrized curve in $\mathbb{R}^1$ is a continuous function $\gamma : [a,b] \to \mathbb{R}$. If $\mathcal{P}$ is a partition of $[a,b]$, then $\ell(\gamma, \mathcal{P})$ is the total variation $V(\gamma, \mathcal{P})$ of γ over $\mathcal{P}$ (XIX.4.1.3.), and $\ell(\gamma)$ is the total variation $V_{[a,b]}(\gamma)$ of γ over $[a,b]$ (XIX.4.1.6.). The curve γ is rectifiable if and only if γ has bounded variation. If γ is a smooth function, then γ is rectifiable and (VII.3.4.6.)

$$\ell(\gamma) = \int_a^b \|\gamma'(t)\| \, dt \ .$$

We now develop basic properties of arc length. First note that arc length is independent of parametrization:

VII.3.1.5. PROPOSITION. Let $\tilde{\gamma} : [c,d] \to \mathbb{R}^d$ be a reparametrization of $\gamma : [a,b] \to \mathbb{R}^d$, i.e. $\tilde{\gamma} = \gamma \circ \phi$, $\phi : [c,d] \to [a,b]$. Then $\ell(\tilde{\gamma}) = \ell(\gamma)$.

PROOF: Let $\mathcal{P} = \{c = t_0, \ldots, t_n = d\}$ be a partition of $[c,d]$. Then $\{a = \phi(t_0), \ldots, \phi(t_n) = b\}$ is not quite a partition of $[a,b]$ since there may be repetitions if ϕ is not injective. But repeated points contribute nothing to the sum $\ell(\tilde{\gamma}, \mathcal{P})$, and if $\mathcal{Q}$ is the partition of $[a,b]$ obtained by deleting repetitions, we have $\ell(\gamma, \mathcal{Q}) = \ell(\tilde{\gamma}, \mathcal{P})$. Every partition of $[a,b]$ arises in this manner. 👍

VII.3.1.6. Thus arc length of paths is well defined. Actually, the use of a parametrization can be regarded as merely a convenient way of "partitioning" the curve into small segments: if $\gamma : [a,b] \to \mathbb{R}^d$ is a parametrized curve, with $\boldsymbol{p} = \gamma(a)$ and $\boldsymbol{q} = \gamma(b)$, so the image of γ is a "curve" from $\boldsymbol{p}$ to $\boldsymbol{q}$, a partition $\mathcal{P} = \{a = t_0, \ldots, t_n = b\}$ of $[a,b]$ gives a "partition" $\{\boldsymbol{p} = \boldsymbol{x}_0, \ldots, \boldsymbol{x}_n = \boldsymbol{q}\}$ of the curve, where $\boldsymbol{x}_k = \gamma(t_k)$. The arc length of γ is

$$\ell(\gamma) = \sup \sum_{k=1}^{n} \rho(\boldsymbol{x}_{k-1}, \boldsymbol{x}_k)$$

where the supremum is over all such "partitions."

Although the reversal $-\gamma$ of a parametrized curve is not a reparametrization of γ, we nonetheless have:

VII.3.1.7. PROPOSITION. If $\gamma : [a,b] \to \mathbb{R}^d$ is a parametrized curve in X, then $\ell(-\gamma) = \ell(\gamma)$.

PROOF: If $\mathcal{P}$ is a partition of $[a,b]$, let $\tilde{\mathcal{P}}$ be the partition consisting of $\{a + b - t : t \in \mathcal{P}\}$. Then $\tilde{\mathcal{P}}$ is also a partition of $[a,b]$, and every partition of $[a,b]$ arises in this manner. We have $\ell(-\gamma, \tilde{\mathcal{P}}) = \ell(\gamma, \mathcal{P})$. 👍

VII.3.1.8. If $\gamma : [a,b] \to X$ is a parametrized curve from p to q and $\mathcal{P} = \{a,b\}$ is the trivial partition, we have

$$\rho(p,q) = \ell(\gamma, \mathcal{P}) \leq \ell(\gamma) \ .$$

More generally, we have:

VII.3.1.9. PROPOSITION. Let $\gamma : [a,b] \to \mathbb{R}^d$ be a parametrized curve in $\mathbb{R}^d$, and $a \leq c \leq d \leq b$, then

$$\rho(\gamma(c), \gamma(d)) \leq \ell(\gamma|_{[c,d]}) \leq \ell(\gamma) \ .$$

PROOF: The first inequality has already been noted. For the second, any partition $\mathcal{P}$ of $[c,d]$ can be expanded to a partition $\mathcal{Q}$ of $[a,b]$ by adding a and b if necessary. We have

$$\ell(\gamma|_{[c,d]}, \mathcal{P}) \leq \ell(\gamma, \mathcal{Q}) \leq \ell(\gamma)$$

and taking the supremum over all $\mathcal{P}$ gives the inequality. 👍

If γ is a constant path, obviously $\ell(\gamma) = 0$. Conversely:

VII.3.1.10. COROLLARY. Let γ be a parametrized curve in $\mathbb{R}^d$. If $\ell(\gamma) = 0$, then γ is constant.

PROOF: If γ is not constant, there are $c, d \in [a, b]$, $c < d$, with $\gamma(c) \neq \gamma(d)$. Then $0 < \rho(\gamma(c), \gamma(d)) \leq \ell(\gamma)$. 👍

Here is a more precise version of VII.3.1.9.:

VII.3.1.11. PROPOSITION. Let $\gamma : [a, b] \to \mathbb{R}^d$ be a parametrized curve, and $c \in [a, b]$. Then

$$\ell(\gamma) = \ell(\gamma|_{[a,c]}) + \ell(\gamma|_{[c,b]}) \ .$$

PROOF: If $\mathcal{P}$ is a partition of $[a, c]$ and $\mathcal{Q}$ a partition of $[c, b]$, then $\mathcal{P} \cup \mathcal{Q}$ is a partition of $[a, b]$, and

$$\ell(\gamma, \mathcal{P} \cup \mathcal{Q}) = \ell(\gamma|_{[a,c]}, \mathcal{P}) + \ell(\gamma|_{[c,b]}, \mathcal{Q}) \ .$$

Every partition of $[a, b]$ containing c (i.e. every sufficiently fine partition) arises in this manner. 👍

Iterating, we get:

VII.3.1.12. COROLLARY. Let $\gamma : [a, b] \to \mathbb{R}^d$ be a parametrized curve, and $\mathcal{P} = \{a = x_0, \ldots, x_n = b\}$ a partition of $[a, b]$. Then

$$\ell(\gamma) = \sum_{k=1}^{n} \ell(\gamma|_{[t_{k-1} t_k]}) \ .$$

Rephrasing VII.3.1.11., we get:

VII.3.1.13. PROPOSITION. Let $\gamma_1 : [a, b] \to \mathbb{R}^d$ and $\gamma_2 : [b, c] \to \mathbb{R}^d$ with $\gamma_1(b) = \gamma_2(b)$, so that the concatenation $\gamma_1 + \gamma_2$ is defined. Then

$$\ell(\gamma_1 + \gamma_2) = \ell(\gamma_1) + \ell(\gamma_2) \ .$$

This can also be iterated to apply to arbitrary finite concatenations.

A crucial property of arc length is lower semicontinuity:

VII.3.1.14. PROPOSITION. For each n, let $\gamma_n : [a,b] \to \mathbb{R}^d$ be a parametrized curve from p_n to q_n. Suppose (γ_n) converges pointwise to a parametrized curve $\gamma : [a,b] \to X$ from p to q, i.e. $\gamma_n(t) \to \gamma(t)$ for each $t \in [a,b]$ (so $p_n \to p$, $q_n \to q$). Then

$$\ell(\gamma) \leq \liminf_{n\to\infty} \ell(\gamma_n) \ .$$

We can have strict inequality, even if $\gamma_n \to \gamma$ uniformly on $[a,b]$ (I.6.1.16.).

PROOF: First note that if $\mathcal{P} = \{a = t_0, \ldots, t_m = b\}$ is any partition of $[a,b]$, we have

$$\ell(\gamma_n, \mathcal{P}) = \sum_{k=1}^{m} \rho(\gamma_n(t_{k-1}), \gamma_n(t_k)) \to \sum_{k=1}^{m} \rho(\gamma(t_{k-1}), \gamma(t_k)) = \ell(\gamma, \mathcal{P})$$

by continuity of ρ.
Suppose $\ell(\gamma) = +\infty$. Fix $M > 0$. Then there is a partition $\mathcal{P}$ of $[a,b]$ with $\ell(\gamma, \mathcal{P}) > M$. Then

$$M < \ell(\gamma, \mathcal{P}) = \lim_{n\to\infty} \ell(\gamma_n, \mathcal{P}) \leq \liminf_{n\to\infty} \ell(\gamma_n) \ .$$

This holds for all $M > 0$, so $\liminf_{n\to\infty} \ell(\gamma_n) = +\infty$ and the inequality holds.
Now suppose γ is rectifiable. Let $\epsilon > 0$. Then there is a partition $\mathcal{P}$ of $[a,b]$ with $\ell(\gamma, \mathcal{P}) > \ell(\gamma) - \epsilon$. Then

$$\ell(\gamma) - \epsilon < \ell(\gamma, \mathcal{P}) = \lim_{n\to\infty} \ell(\gamma_n, \mathcal{P}) \leq \liminf_{n\to\infty} \ell(\gamma_n) \ .$$

This holds for all $\epsilon > 0$, so $\ell(\gamma) \leq \liminf_{n\to\infty} \ell(\gamma_n)$. 👍

VII.3.1.15. Note for future reference that the definitions of $\ell(\gamma, \mathcal{P})$ and $\ell(\gamma)$ make perfect sense for a general function $\gamma : [a,b] \to \mathbb{R}^d$, not necessarily continuous, so "arc length" is defined even for discontinuous functions (although it is typically infinite for very discontinuous functions). None of the proofs of VII.3.1.5.–VII.3.1.14. use that γ is continuous, so these properties hold also for discontinuous γ. (But VII.3.2.2. requires continuity of γ.)

VII.3.2. Rectifiable Curves

Continuity of Arc Length

VII.3.2.1. Let $\gamma : [a,b] \to \mathbb{R}^d$ be a rectifiable parametrized curve. Define a function $\phi : [a,b] \to [0, \ell(\gamma)]$ by setting

$$\phi(t) = \ell(\gamma|_{[a,t]}) \ .$$

Then ϕ is nondecreasing, $\phi(a) = 0$, $\phi(b) = \ell(\gamma)$. If γ is nonstationary, ϕ is strictly increasing.

VII.3.2.2. PROPOSITION. The function ϕ is continuous.

PROOF: The following lemma will provide left continuity on $[a,b]$. The simplest way to get right continuity is to apply the lemma also to $-\gamma$ and use that $\ell(\gamma|_{[a,t_0]}) = \ell(\gamma) - \ell(\gamma|_{[t_0,b]})$. 👍

VII.3.2.3. Lemma. Let $\gamma : [a,b] \to \mathbb{R}^d$ be a parametrized curve, not necessarily rectifiable. If (t_n) is an increasing sequence in $[a,b]$ converging to t_0, then

$$\ell(\gamma|_{[a,t_0]}) = \lim_{n\to\infty} \ell(\gamma|_{[a,t_n]}) = \sup_n \ell(\gamma|_{[a,t_n]}) \ .$$

Proof: Define a sequence (γ_n) of parametrized curves on $[a,t_0]$ by setting $\gamma_n(t) = \gamma(t)$ if $a \le t \le t_n$ and $\gamma_n(t) = \gamma(t_n)$ if $t_n \le t \le t_0$ (i.e. γ_n agrees with γ on $[a,t_n]$ and is stationary on $[t_n,t_0]$). We have

$$\ell(\gamma_n) = \ell(\gamma|_{[a,t_n]}) \le \ell(\gamma|_{[a,t_0]})$$

for any n by monotonicity (VII.3.1.9.). On the other hand, since γ is continuous at t_0, $\gamma_n \to \gamma$ pointwise on $[a,t_0]$. So applying VII.3.1.14. we get

$$\sup_n \ell(\gamma|_{[a,t_n]}) \le \ell(\gamma|_{[a,t_0]}) \le \liminf_{n\to\infty} \ell(\gamma_n) = \liminf_{n\to\infty} \ell(\gamma|_{[a,t_n]})$$

and the result follows. 👍

VII.3.2.4. Corollary. Let $\gamma : [a,b] \to \mathbb{R}^d$ be a rectifiable curve. Then for any $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $a \le c < d \le b$ and $d - c < \delta$, then $\ell(\gamma|_{[c,d]}) < \epsilon$.

Proof: The function ϕ is uniformly continuous on $[a,b]$ (). 👍

Estimation of Arc Length

The next result is strongly reminiscent of the equivalence of Definitions 1A and 1B of the Riemann integral (IX.2.3.1.), and proved in a similar way.

VII.3.2.5. Theorem. Let $\gamma : [a,b] \to \mathbb{R}^d$ be a rectifiable curve. Then for any $\epsilon > 0$ there is a $\delta > 0$ such that $\ell(\gamma,\mathcal{P}) > \ell(\gamma) - \epsilon$ for any partition $\mathcal{P}$ of $[a,b]$ with $\|\mathcal{P}\| < \delta$.

Proof: Let $\mathcal{Q} = \{a = t_0, \dots, t_n = b\}$ be a partition of $[a,b]$ with $\ell(\gamma,\mathcal{Q}) > \ell(\gamma) - \frac{\epsilon}{2}$. Since γ is uniformly continuous (), there is a $\delta > 0$ such that if $a \le c < d \le b$ and $d - c < \delta$, $\rho(\gamma(c),\gamma(d)) < \frac{\epsilon}{4n}$. We may assume $3\delta < \|\mathcal{Q}\|$.
Let $\mathcal{P} = \{a = s_0, \dots, s_m = b\}$ be a partition of $[a,b]$ with $\|\mathcal{P}\| < \delta$. For $1 \le k \le n-1$ let j_k be the largest j such that $s_j \le t_k$. We then have

$$\ell(\gamma,\mathcal{P}) = \sum_{j=1}^{m} \rho(\gamma(s_{j-1}),\gamma(s_j))$$

$$= \sum_{j=1}^{j_1} \rho(\gamma(s_{j-1}),\gamma(s_j)) + \sum_{k=1}^{n-2} \sum_{j=j_k+2}^{j_{k+1}} \rho(\gamma(s_{j-1}),\gamma(s_j)) + \sum_{j=j_{n-1}+2}^{m} \rho(\gamma(s_{j-1}),\gamma(s_j)) + \sum_{k=1}^{m-1} \rho(\gamma(s_{j_k}),\gamma(s_{j_k+1})) \ .$$

By the triangle inequality, we have

$$\sum_{j=1}^{j_1} \rho(\gamma(s_{j-1}),\gamma(s_j)) \geq \rho(\gamma(a),\gamma(t_1)) - \rho(\gamma(s_{j_1}),\gamma(t_1)) > \rho(\gamma(a),\gamma(t_1)) - \frac{\epsilon}{4n} \ .$$

Similarly, for $1 \leq k \leq n-2$, we have

$$\sum_{j=j_k+2}^{j_{k+1}} \rho(\gamma(s_{j-1}),\gamma(s_j)) \geq \rho(\gamma(t_k),t_{k+1})) - \rho(\gamma(t_k),\gamma(s_{j_k+1}) - \rho(\gamma(s_{j_{k+1}}),\gamma(t_{k+1})) > \rho(\gamma(t_k),t_{k+1})) - \frac{\epsilon}{2n}$$

$$\sum_{j=j_{n-1}+2}^{m} \rho(\gamma(s_{j-1}),\gamma(s_j)) > \rho(\gamma(t_{n-1}),\gamma(b)) - \frac{\epsilon}{4n} \ .$$

Thus we have

$$\ell(\gamma,\mathcal{P}) = \sum_{j=1}^{m} \rho(\gamma(s_{j-1}),\gamma(s_j))$$

$$\geq \sum_{j=1}^{j_1} \rho(\gamma(s_{j-1}),\gamma(s_j)) + \sum_{k=1}^{n-2} \sum_{j=j_k+2}^{j_{k+1}} \rho(\gamma(s_{j-1}),\gamma(s_j)) + \sum_{j=j_{n-1}+2}^{m} \rho(\gamma(s_{j-1}),\gamma(s_j))$$

$$> \sum_{k=1}^{n} \rho(\gamma(t_{k-1}),\gamma(t_k)) - (n-2)\frac{\epsilon}{2n} - 2\frac{\epsilon}{4n} = \ell(\gamma,\mathcal{Q}) - \frac{\epsilon}{2} > \ell(\gamma) - \epsilon \ .$$

Parametrization by Arc Length

VII.3.2.6. Let $\gamma : [a,b] \to \mathbb{R}^d$ be a nonstationary rectifiable parametrized curve, and let ϕ be the above function. Then ϕ is strictly increasing and continuous, so has a continuous strictly increasing inverse function $\phi^{-1} : [0,\ell(\gamma)] \to [a,b]$. Set $\tilde{\gamma} = \gamma \circ \phi^{-1} : [0,\ell(\gamma)] \to X$. Then $\tilde{\gamma}$ is a strict reparametrization of γ with the property that $\ell(\tilde{\gamma}|_{[0,t]}) = t$ for $0 \leq t \leq \ell(\gamma)$, i.e. $\tilde{\gamma}$ "traverses the path $\langle\gamma\rangle$ at uniform unit speed." The parametrized curve $\tilde{\gamma}$ is called the *reparametrization of γ by arc length.* If γ is replaced by any strict reparametrization, the $\tilde{\gamma}$ is unchanged; thus it depends only on $\langle\gamma\rangle$, i.e. any rectifiable path has a unique canonical parametrization by arc length.

Differentiability of Rectifiable Curves

A rectifiable curve has "bounded variation" and hence should be differentiable almost everywhere, and in fact is:

VII.3.2.7. THEOREM. Let $\gamma : [a,b] \to \mathbb{R}^n$ be a rectifiable curve. Then γ is differentiable a.e.

PROOF: Let $\gamma_1,\ldots,\gamma_n$ be the coordinate functions of γ. Then each γ_k has bounded variation $V_{[a,b]}(\gamma_k) \leq \ell(\gamma)$ (VII.3.5.1.(a)). Thus γ_k is differentiable on $[a,b]$ except on a set A_k of measure 0 (XIX.4.2.4.). So γ is differentiable on $[a,b]$ except on $A_1 \cup \cdots \cup A_n$, a set of measure 0. 

A rectifiable curve can fail to be differentiable at a dense set of points, however ().

VII.3.2.8. If γ is rectifiable, one might expect that its arc length can be computed by integration of the length of the derivative. However, this fails in general since γ is not necessarily absolutely continuous (). For an extreme example, if γ is parametrized on $[0,1]$ and g is the Cantor function (), then $\gamma \circ g$ is a reparametrization of γ, and $(\gamma \circ g)' = \mathbf{0}$ a.e. But if γ is parametrized by an absolutely continuous function, it is true. This result is surprisingly hard to

(i) prove

(ii) find in books

perhaps because it falls through the crack between real analysis and differential geometry. Our proof is adapted from [Pel77], where a more general result is proved. If γ is smooth, there is an (arguably simpler) alternate proof, which we give in a more general setting in VII.3.4.6..

VII.3.2.9. THEOREM. Let $\gamma : [a,b] \to \mathbb{R}^n$ be a (necessarily rectifiable) curve, with absolutely continuous coordinate functions. Then γ is differentiable a.e., and

$$\ell(\gamma) = \int_a^b \|\gamma'(t)\| \, d\lambda(t)$$

(where the integral is a Lebesgue integral). The length function $\phi(x) = \ell(\gamma|_{[a,x]})$ is absolutely continuous, hence differentiable a.e., and $\phi'(t) = \|\gamma'(t)\|$ a.e.

The proof will mostly consist of three lemmas. The first is of independent interest, that a rectifiable curve can be "unwound" to a curve with nondecreasing coordinate functions without changing the arc length or length of the derivative (a.e.):

VII.3.2.10. LEMMA. Let $\gamma : [a,b] \to \mathbb{R}^n$ be a rectifiable curve with coordinate functions $\gamma_1, \ldots, \gamma_n$ of bounded variation. For $1 \le k \le n$ let $v_k = T\gamma_k$ be the total variation function (XIX.4.2.1.) of γ_k on $[a,b]$, i.e. $v_k(t) = V_{[a,t]}(\gamma_1)$ (the v_k are continuous by XIX.4.2.6.). Let $\bar{\gamma} : [a,b] \to \mathbb{R}^n$ have coordinate functions $v_1, \ldots, v_n$. Then $\ell(\bar{\gamma}) = \ell(\gamma)$.

PROOF: We have, for any k and any $s, t \in [a,b]$,

$$|\gamma_k(t) - \gamma_k(s)| \le |v_k(t) - v_k(s)|$$

and it follows that for any partition $\mathcal{P}$ of $[a,b]$, $\ell(\gamma, \mathcal{P}) \le \ell(\bar{\gamma}, \mathcal{P})$. Taking the supremum over all $\mathcal{P}$, we obtain $\ell(\gamma) \le \ell(\bar{\gamma})$.

For the opposite inequality, suppose $a \le c < d \le b$ and $\mathcal{P} = \{c = t_0, \ldots, t_m = d\}$ is a partition of $[c,d]$. Using the triangle inequality in $\mathbb{R}^n$ we obtain

$$\ell(\gamma|_{[c,d]}, \mathcal{P}) = \sum_{j=1}^{m} \sqrt{\sum_{k=1}^{n} (\gamma_k(t_j) - \gamma_k(t_{j-1}))^2}$$

$$\ge \sqrt{\sum_{k=1}^{n} \left[\sum_{j=1}^{m} |\gamma_k(t_j) - \gamma_k(t_{j-1})| \right]^2} = \sqrt{\sum_{k=1}^{n} [V(\gamma_k, \mathcal{P})]^2} \, .$$

Taking the supremum over all $\mathcal{P}$ we obtain

$$\ell(\gamma|_{[c,d]}) \geq \sqrt{\sum_{k=1}^{n} [V_{[c,d]}(\gamma_k)]^2} = \sqrt{\sum_{k=1}^{n} (v_k(d) - v_k(c))^2} \ .$$

If $\mathcal{Q} = \{a = s_0, \ldots, s_r = b\}$ is any partition of $[a, b]$, applying this inequality over each subinterval $[s_{j-1}, s_j]$, we obtain

$$\ell(\gamma) = \sum_{j=1}^{r} \ell(\gamma|_{[s_{j-1},s_j]}) \geq \sum_{j=1}^{r} \sqrt{\sum_{k=1}^{n} (v_k(s_j) - v_k(s_{j-1}))^2} = \ell(\bar{\gamma}, \mathcal{Q})$$

and it follows by taking the supremum over all $\mathcal{Q}$ that $\ell(\gamma) \geq \ell(\bar{\gamma})$. 👍

VII.3.2.11. If $\gamma_1, \ldots, \gamma_n$ are absolutely continuous, so are $v_1, \ldots, v_n$, and $v_k' = |\gamma_k'|$ a.e. for each k, so $\|\bar{\gamma}'\| = \|\gamma'\|$ a.e. Thus to prove VII.3.2.9. we may work with $\bar{\gamma}$, i.e. we may assume that $\gamma_k' \geq 0$ a.e. for each k.

The other two lemmas are very general:

VII.3.2.12. Lemma. Let $(X, \mathcal{A}, \mu)$ be a measure space and $f_1, \ldots, f_n$ nonnegative measurable functions. Then, for any $A \in \mathcal{A}$,

$$\sqrt{\sum_{k=1}^{n} \left[\int_A f_k \, d\mu\right]^2} \leq \int_A \sqrt{\sum_{k=1}^{n} f_k^2} \ d\mu \ .$$

Proof: This is a good example of bootstrapping. First suppose the f_k are simple functions, and are all constant on sets $E_1, \ldots, E_m$, with f_k taking value $\alpha_{k,j}$ on E_j. Then by the triangle inequality on $\mathbb{R}^n$,

$$\sqrt{\sum_{k=1}^{n} \left[\int_A f_k \, d\mu\right]^2} = \sqrt{\sum_{k=1}^{n} \left[\sum_{j=1}^{m} \int_{A\cap E_j} f_k \, d\mu\right]^2} = \sqrt{\sum_{k=1}^{n} \left[\sum_{j=1}^{m} \alpha_{k,j} \mu(A \cap E_j)\right]^2}$$

$$\leq \sum_{j=1}^{m} \sqrt{\sum_{k=1}^{n} [\alpha_{k,j} \mu(A \cap E_j)]^2} = \sum_{j=1}^{m} \left[\sqrt{\sum_{k=1}^{n} \alpha_{k,j}^2} \ \mu(A \cap E_j)\right] = \sum_{j=1}^{m} \left[\int_{A\cap E_j} \sqrt{\sum_{k=1}^{n} f_k^2} \ d\mu\right] = \int_A \sqrt{\sum_{k=1}^{n} f_k^2} \ d\mu \ .$$

For general f_k, take increasing sequences of nonnegative simple functions and apply the Monotone Convergence Theorem. 👍

VII.3.2.13. LEMMA. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f, f_1, \ldots, f_n$ nonnegative measurable functions on X. If

$$\left[\int_A f\,d\mu\right]^2 \geq \sum_{k=1}^n \left[\int_A f_k\,d\mu\right]^2$$

for all $A \in A$, then $f \geq \sqrt{\sum_{k=1}^n f_k^2}$ a.e.

PROOF: Suppose $f_1, \ldots, f_n$ are simple and all constant on $E_1, \ldots, E_m$, and f_k takes the constant value $\alpha_{k,j}$ on E_j. If $A \subseteq E_j$, then

$$\int_A f\,d\mu \geq \sqrt{\sum_{k=1}^n \left[\int_A f_k\,d\mu\right]^2} = \sqrt{\sum_{k=1}^n [\alpha_{k,j}\mu(A)]^2} = \mu(A)\sqrt{\sum_{k=1}^n \alpha_{k,j}^2}\ .$$

This is true for all $A \subseteq E_j$, which implies that

$$f \geq \sqrt{\sum_{k=1}^n \alpha_{k,j}^2} = \sqrt{\sum_{k=1}^n f_k^2}$$

a.e. on E_j. Since $\cup_{j=1}^m E_j = X$, we have $f \geq \sqrt{\sum_{k=1}^n f_k^2}$ a.e. on X.

For general f_k, take increasing sequences of nonnegative simple functions converging to the f_k. 👍

VII.3.2.14. We now give the proof of Theorem VII.3.2.9..

PROOF: We may assume γ_k' is nonnegative for all k (VII.3.2.11.). If $\mathcal{P} = \{a = t_0, \ldots, t_m = b\}$ is a partition of $[a, b]$, we have

$$\ell(\gamma, \mathcal{P}) = \sum_{j=1}^m \|\gamma(t_j) - \gamma(t_{j-1})\| = \sum_{j=1}^m \sqrt{\sum_{k=1}^n \left[\int_{t_{j-1}}^{t_j} \gamma_k'\,d\lambda\right]^2}$$

$$\leq \sum_{j=1}^m \left[\int_{t_{j-1}}^{t_j} \sqrt{\sum_{k=1}^n (\gamma_k')^2}\ d\lambda\right] = \sum_{j=1}^m \left[\int_{t_{j-1}}^{t_j} \|\gamma'\|\,d\lambda\right] = \int_a^b \|\gamma'\|\,d\lambda$$

by Lemma VII.3.2.12.. Taking the supremum over all $\mathcal{P}$, we obtain

$$\ell(\gamma) \leq \int_a^b \|\gamma'\|\,d\lambda\ .$$

For the reverse inequality, note that, if $\phi(t) = \ell(\gamma|_{[a,t]})$ for $a \leq t \leq b$, then ϕ is absolutely continuous (VII.3.5.1.(b)). If $a \leq c < d \leq b$, we have

$$\left[\int_c^d \phi'\,d\lambda\right]^2 = [\phi(d) - \phi(c)]^2 = [\ell(\gamma|_{[c,d]})]^2$$

$$\geq \|\gamma(d) - \gamma(c)\|^2 = \sum_{k=1}^{n} \left[\int_c^d \gamma_k' \, d\lambda \right]^2$$

and thus (), for every measurable A, we have

$$\left[\int_A \phi' \, d\lambda \right]^2 \geq \sum_{k=1}^{n} \left[\int_A \gamma_k' \, d\lambda \right]^2 .$$

So by Lemma VII.3.2.13. we have

$$\phi' \geq \sqrt{\sum_{k=1}^{n} [\gamma_k']^2} = \|\gamma'\| \text{ a.e.}$$

and hence

$$\ell(\gamma) = \int_a^b \phi' \, d\lambda \geq \int_a^b \|\gamma'\| \, d\lambda .$$

We have, for each $x \in [a, b]$,

$$\phi(x) = \int_a^x \phi' \, d\lambda = \int_a^x \|\gamma'\| \, d\lambda$$

so if $f = \phi' - \|\gamma'\|$, then f is an integrable function on $[a, b]$ and $\int_a^x f \, d\lambda = 0$ for all $x \in [a, b]$, so $f = 0$ a.e. (XVIII.1.8.14.). 👍

The following special case of VII.3.2.9. is especially noteworthy. The result is probably not surprising, but it is definitely nontrivial (cf. VII.3.2.16.). See () for a direct proof valid in general metric spaces.

VII.3.2.15. Corollary. Let $\gamma : [0, b] \to \mathbb{R}^n$ be a rectifiable curve, parametrized by arc length. Then γ is absolutely continuous and hence is differentiable a.e., and $\|\gamma'(t)\| = 1$ for almost all t.

Proof: Since γ is parametrized by arc length, it is a Lipschitz function with constant 1, so the coordinate functions are absolutely continuous and VII.3.2.9. applies; and ϕ' is the constant function 1. 👍

VII.3.2.16. Example. One might naïvely think that if γ is a rectifiable curve, parametrized by arc length, then $\|\gamma'(t)\| = 1$ whenever it is defined. But this is false. Here is an example, adapted from ().

Let c be the curve in $\mathbb{R}^2$ consisting of semicircular arcs between $\frac{1}{n}$ and $\frac{1}{n+1}$ for each $n \in \mathbb{N}$, alternating above and below the x-axis to make the curve differentiable on $(0, 1]$, reflected on the interval $[-1, 0)$, along with the origin. See Figure (). Then c is the graph of a function on $[-1, 1]$. Parametrize c by arc length γ, starting at $(-1, 0)$. Then $\ell(\gamma) = \pi$. We have that $\gamma\left(\frac{\pi}{2}\right) = (0, 0)$. Note that γ is differentiable everywhere except possibly at $\frac{\pi}{2}$. But it is differentiable there also, as the following calculation shows. Write γ_1 and γ_2 for the coordinate functions of γ.

The height of the semicircle between $\frac{1}{n}$ and $\frac{1}{n+1}$ is $O\left(\frac{1}{n^2}\right)$, and it follows easily that $\gamma_2'\left(\frac{\pi}{2}\right) = 0$. If $\frac{\pi}{2} + \frac{\pi}{2(n+1)} \leq t \leq \frac{\pi}{2} + \frac{\pi}{2n}$, we have $\frac{1}{n+1} \leq \gamma_1(t) \leq \frac{1}{n}$, and thus

$$\frac{2}{\pi} \cdot \frac{n}{n+1} = \frac{\frac{1}{n+1}}{\frac{\pi}{2n}} \leq \frac{\gamma_1(t) - \gamma_1\left(\frac{\pi}{2}\right)}{t - \frac{\pi}{2}} \leq \frac{\frac{1}{n}}{\frac{\pi}{2(n+1)}} = \frac{2}{\pi} \cdot \frac{n+1}{n}$$

and so by the squeeze theorem

$$\lim_{t\to\frac{\pi}{2}+}\frac{\gamma_1(t)-\gamma_1\left(\frac{\pi}{2}\right)}{t-\frac{\pi}{2}}$$

exists and equals $\frac{2}{\pi}$. The limit from the left similarly equals $\frac{2}{\pi}$. So $\gamma_1'\left(\frac{\pi}{2}\right)$ exists and equals $\frac{2}{\pi}$.

Thus γ is differentiable at $\frac{\pi}{2}$ and $\gamma'\left(\frac{\pi}{2}\right)=\left(\frac{2}{\pi},0\right)$, so

$$\left\|\gamma'\left(\frac{\pi}{2}\right)\right\|=\frac{2}{\pi}<1\ .$$

Replacing the semicircles by curves c_n of arc length $\frac{2}{\sqrt{n}}-\frac{2}{\sqrt{n+1}}=O(n^{-3/2})$ lying in the square

$$\left[\frac{1}{n+1},\frac{1}{n}\right]\times\left[-\frac{1}{n^2},\frac{1}{n^2}\right]$$

(and similarly on the left) we can get a similar example where $\gamma'=\mathbf{0}$ at the origin. Much more pathological examples, where $\|\gamma'(t)\|<1$ for many t, can be constructed similarly.

VII.3.3. Length of Arcs

If C is a "curve" in $\mathbb{R}^d$, we would like to be able to say what the intrinsic "arc length" of C is. This is a tricky problem. The first question is what kind of subsets should be called "curves." It is too broad to say that the range of any parametrized curve is a "curve" (). One reasonable possibility is:

VII.3.3.17. Definition. An *arc* in $\mathbb{R}^d$ is a subset of $\mathbb{R}^n$ homeomorphic to $[0,1]$.

VII.3.3.18. A subset C of $\mathbb{R}^d$ is an arc if and only if it is the range of an injective parametrized curve: a homeomorphism γ from $[0,1]$ to C is such a parametrized curve, and conversely an injective parametrized curve $\gamma:[a,b]\to\mathbb{R}^n$ with $C=\gamma([a,b])$ is a homeomorphism by (). An arc thus has a unique equivalence class of oriented injective parametrizations, thus two in all; the arc length of all these parametrized curves is the same and can be taken to be the arc length of C.

VII.3.3.19. Slightly more generally, if C can be written as a finite union of arcs with only endpoints in common, the arc length of C can be taken to be the sum of the arc lengths of these arcs. For more complicated subsets, there are grave difficulties in defining arc length this way.

VII.3.3.20. There is a way to unambiguously define "arc length" for general (Borel) subsets of $\mathbb{R}^d$: one-dimensional Hausdorff measure (). This "arc length" has the nice properties of a measure, generalizing VII.3.1.12.. Subsets whose one-dimensional Hausdorff measure is positive and finite can be regarded as "one-dimensional" (cf. (); such a set need not be topologically one-dimensional, and not every "one-dimensional" subset will have these properties).

VII.3.4. Integrating a Function Along a Curve

VII.3.4.1. Let $\gamma : [a,b] \to \mathbb{R}^d$ be a parametrized curve. Suppose f is a real-valued function on the image C of γ. We want to define the integral

$$\int_\gamma f$$

of f along γ. To get a reasonable definition, we need to assume $f \circ \gamma$ is continuous on $[a,b]$ (it suffices that f is continuous on C) and that γ is rectifiable. The prototype physical interpretation is to think of C as a thin wire of variable density $f(\boldsymbol{x})$ at the point $\boldsymbol{x}$; the integral should be the total mass of the wire. There are many other similar interpretations and applications of this type of integral.

VII.3.4.2. Definition. Let $\gamma : [a,b] \to \mathbb{R}^d$ be a (rectifiable) curve in $\mathbb{R}^d$ with image C, and f a real-valued function on C. If $\dot{\mathcal{P}} = \{a = t_0, \dots, t_n = b; s_1, \dots, s_n\}$ is a tagged partition of $[a,b]$ with $\Delta\boldsymbol{x}_j = \gamma(t_j) - \gamma(t_{j-1})$, set

$$\mathcal{R}(f,\gamma,\dot{\mathcal{P}}) = \sum_{j=1}^{n} f(\gamma(s_j))\|\Delta\boldsymbol{x}_j\| \ .$$

Set

$$\int_\gamma f = \lim_{\|\mathcal{P}\|\to 0} \mathcal{R}(f,\gamma,\dot{\mathcal{P}})$$

if the limit exists (and is finite).

VII.3.4.3. Rectifiability of γ is not a necessary part of the definition, but the integral will rarely exist (and will not have a reasonable interpretation) if γ is not rectifiable. Note that if γ is rectifiable and f is the constant function 1, then $\int_\gamma 1$ exists and equals $\ell(\gamma)$ by definition (and the integral will not exist if γ is not rectifiable). One would also not expect the limit to exist unless f is (at least almost) continuous. The case of continuous f is almost exclusively the one used in applications anyway.

An integral of this type is sometimes called a *line integral*, but this term is more frequently reserved for an integral of the type described in (). The term *curvilinear integral* is also used. Note that this integral is an *unoriented integral*, in contrast to the one in (): we have

$$\int_{-\gamma} f = \int_\gamma f$$

for any γ and f (for which the integral is defined).

VII.3.4.4. The integral of f over γ is clearly independent of the parametrization of γ. In fact, as in VII.3.1.6., using a parametrization at all is just a convenient way of describing partitions of the curve. If $\{\boldsymbol{p} = \boldsymbol{x}_0, \dots, \boldsymbol{x}_n = \boldsymbol{q}\}$ is a "partition" of the curve corresponding to a partition $\mathcal{P} = \{a = t_0, \dots, t_n = b\}$ as in VII.3.1.6., and for each j we choose a "tag" $\boldsymbol{y}_j$ in the j'th "segment" of the curve by taking $\boldsymbol{y}_j = \gamma(s_j)$ for some $s_j \in [t_{j-1}, t_j]$, then we have a "Riemann sum" estimate

$$\sum_{j=1}^{n} f(\boldsymbol{y}_j)\|\Delta\boldsymbol{x}_j\|$$

where $\Delta \boldsymbol{x}_j = \boldsymbol{x}_j - \boldsymbol{x}_{j-1}$, so everything is expressible without reference to a parametrization (although defining what constitutes a suitable "partition" is tricky without using a parametrization unless the curve is an arc). However, it is tricky to express the limit as $\|\mathcal{P}\| \to 0$ without reference to parametrizations unless the curve is an arc, although it is independent of the parametrization chosen (it was easier for arc length since the limit there was just a supremum, but this is not necessarily true for integrating a function along the curve).

Our main result gives a way of computing the integral by an ordinary one-dimensional integral:

VII.3.4.5. THEOREM. Let $\gamma : [a, b] \to \mathbb{R}^n$ be a piecewise-smooth ($\mathcal{C}^1$) curve in $\mathbb{R}^n$ with image C, and f a real-valued function on C such that $f \circ \gamma$ is continuous. Then $\int_\gamma f$ exists and

$$\int_\gamma f = \int_a^b f(\gamma(t)) \, \|\gamma'(t)\| \, dt \ .$$

VII.3.4.6. COROLLARY. Let $\gamma : [a, b] \to \mathbb{R}^n$ be a piecewise-smooth ($\mathcal{C}^1$) curve in $\mathbb{R}^n$. Then

$$\ell(\gamma) = \int_a^b \|\gamma'(t)\| \, dt \ .$$

We now prove Theorem VII.3.4.5..

PROOF: By reducing to subintervals we may assume γ is $\mathcal{C}^1$ on $[a, b]$. Let $\gamma_1, \ldots, \gamma_n$ be the coordinate functions of γ. Let $\mathcal{P} = \{a = t_0, \ldots, t_m = b\}$ be a partition of $[a, b]$. For each j and k, by the MVT there is an $s_j^{(k)} \in (t_{j-1}, t_j)$ such that

$$\gamma_k(t_j) - \gamma_k(t_{j-1}) = \gamma_k' \left(s_j^{(k)} \right) \Delta t_j$$

where $\Delta t_j = t_j - t_{j-1}$. If we could choose all the $s_j^{(k)}$ to be the same s_j for each j, the proof would be simple: if we take $\dot{\mathcal{P}} = \{a = t_0, \ldots, t_m = b; s_1, \ldots, s_m\}$ we would have

$$\mathcal{R}(f, \gamma, \dot{\mathcal{P}}) = \sum_{j=1}^m f(\gamma(s_j)) \sqrt{\gamma_1'(s_j)^2 + \cdots + \gamma_n'(s_j)^2} \, \Delta t_j$$

and as $\|\mathcal{P}\| \to 0$ these Riemann sums converge to

$$\int_a^b f(\gamma(t)) \, \|\gamma'(t)\| \, dt$$

since the integrand is continuous on $[a, b]$ ().

However, the $s_j^{(k)}$ cannot be all chosen the same for all k in general, complicating the proof. First, since $f \circ \gamma$ is continuous on $[a,b]$, it is bounded; fix M with $|f(\gamma(t))| \leq M$ for $t \in [a,b]$. Then, if $\epsilon > 0$, since each γ_k' is uniformly continuous on $[a,b]$, there is a $\delta > 0$ such that if $\|\mathcal{P}\| < \delta$, then

$$|\gamma_k'(t) - \gamma_k'(s)| < \frac{\epsilon}{M}$$

for $s, t \in [t_{j-1}, t_j]$ for all j.

Now fix an $s_j \in [t_{j-1}, t_j]$ for each j, and set $\dot{\mathcal{P}} = \{a = t_0, \ldots, t_m = b; s_1, \ldots, s_m\}$. If the $s_j^{(k)}$ are as above, then

$$\mathcal{R}(f, \gamma, \dot{\mathcal{P}}) = \sum_{j=1}^{m} f(\gamma(s_j)) \, \|\Delta \boldsymbol{x}_j\| = \sum_{j=1}^{m} f(\gamma(s_j)) \sqrt{\gamma_1'(s_j^{(1)})^2 + \cdots + \gamma_n'(s_j^{(n)})^2} \, \Delta t_j \ .$$

Set

$$\mathcal{S}(f, \gamma, \dot{\mathcal{P}}) = \sum_{j=1}^{m} f(\gamma(s_j)) \sqrt{\gamma_1'(s_j)^2 + \cdots + \gamma_n'(s_j)^2} \, \Delta t_j \ .$$

Then

$$\lim_{\|\mathcal{P}\| \to 0} \mathcal{S}(f, \gamma, \dot{\mathcal{P}}) = \int_a^b f(\gamma(t)) \, \|\gamma'(t)\| \, dt$$

as above. But if $\|\mathcal{P}\| < \delta$, we have

$$|\mathcal{R}(f, \gamma, \dot{\mathcal{P}}) - \mathcal{S}(f, \gamma, \dot{\mathcal{P}})| = \left| \sum_{j=1}^{m} f(\gamma(s_j)) \left[\sqrt{\gamma_1'(s_j^{(1)})^2 + \cdots + \gamma_n'(s_j^{(n)})^2} - \sqrt{\gamma_1'(s_j)^2 + \cdots + \gamma_n'(s_j)^2} \right] \Delta t_j \right|$$

$$\leq \sum_{j=1}^{m} |f(\gamma(s_j))| \left| \sqrt{\gamma_1'(s_j^{(1)})^2 + \cdots + \gamma_n'(s_j^{(n)})^2} - \sqrt{\gamma_1'(s_j)^2 + \cdots + \gamma_n'(s_j)^2} \right| \Delta t_j$$

$$\leq \sum_{j=1}^{m} M \left[\sum_{k=1}^{n} |\gamma_k'(s_j^{(k)}) - \gamma_k'(s_j)| \right] \Delta t_j \leq \sum_{j=1}^{m} Mn \frac{\epsilon}{M} \Delta t_j = n\epsilon(b-a) \ .$$

Since $\epsilon > 0$ is arbitrary, we also have

$$\lim_{\|\mathcal{P}\| \to 0} \mathcal{R}(f, \gamma, \dot{\mathcal{P}}) = \int_a^b f(\gamma(t)) \, \|\gamma'(t)\| \, dt \ .$$

VII.3.4.7. There is a generalization along the lines of VII.3.2.9., but it is somewhat delicate. Details are left to the interested reader.

VII.3.5. Exercises

VII.3.5.1. (a) Let $\gamma : [a, b] \to \mathbb{R}^n$ be a parametrized curve, with coordinate functions $\gamma_1, \ldots, \gamma_n$. Show that the total variation (XIX.4.1.6.) satisfies $V_{[a,b]}(\gamma_k) \leq \ell(\gamma) \leq \sum_{j=1}^{n} V_{[a,b]}(\gamma_j)$ for any k, and thus γ is rectifiable if and only if all coordinate functions of γ have bounded variation. [For each k and each partition $\mathcal{P}$ of $[a, b]$, we have $V(\gamma_k, \mathcal{P}) \leq \ell(\gamma, \mathcal{P}) \leq \ell(\gamma)$.]

(b) Let $\gamma : [a, b] \to \mathbb{R}^n$ be a rectifiable parametrized curve, and ϕ the function defined in VII.3.2.2.. Show that ϕ is absolutely continuous if and only if each coordinate function of γ is absolutely continuous. [If each γ_k is absolutely continuous, and $\epsilon > 0$, for each k choose δ_k which works in the definition of absolute continuity for γ_k for $\frac{\epsilon}{n}$. Show that $\delta = \min_k(\delta_k)$ works in the definition for ϕ and ϵ.]

VII.3.5.2. Prove the following result complementary to VII.3.2.5.:

THEOREM. Let $\gamma : [a, b] \to \mathbb{R}^d$ be a parametrized curve. If $\ell(\gamma) = \infty$, then for any $M > 0$ there is a $\delta > 0$ such that $\ell(\gamma, \mathcal{P}) > M$ for any partition $\mathcal{P}$ of $[a, b]$ with $\|\mathcal{P}\| < \delta$.

Chapter VIII

Multivariable and Vector Calculus

In this chapter, we discuss calculus for functions from one Euclidean space $\mathbb{R}^n$ (or a subset) to another Euclidean space $\mathbb{R}^m$. The terms *multivariable calculus* and *vector calculus* used are roughly synonymous, but "vector calculus" is slightly more general: "multivariable calculus" refers to the case where $n > 1$ (and $m \geq 1$), while "vector calculus" also includes the case where $n = 1$ and $m > 1$, which is exactly the case of curves in $\mathbb{R}^m$ discussed in Chapter (). (In developing the theories, we work with general n and m, not even excluding the case $n = m = 1$.) There is also a slight difference in point of view: multivariable calculus is generally thought of as consideration of real-valued functions, or systems of real-valued functions, of several real variables, while vector calculus is thought of as being the study of functions whose input and output are vectors in Euclidean spaces, not necessarily of the same dimension. (The two points of view are complementary and both are needed to get the full picture of the subject.)

Consideration of functions from $\mathbb{R}^n$ to $\mathbb{R}^m$ has distinct and complicating features over the case $n = m = 1$ arising from having either $n > 1$ or $m > 1$ (or both). The complications caused by considering the case $m > 1$ are quite modest, however. If $\boldsymbol{f} : \mathbb{R}^n \to \mathbb{R}^m$ is a function, write

$$\boldsymbol{f}(\boldsymbol{x}) = (f_1(\boldsymbol{x}), \ldots, f_m(\boldsymbol{x}))$$

where $f_1, \ldots, f_m : \mathbb{R}^n \to \mathbb{R}$ are the coordinate functions of $\boldsymbol{f}$ (technically, $f_k = \pi_k^{(m)} \circ \boldsymbol{f}$, where $\pi_k^{(m)} : \mathbb{R}^m \to \mathbb{R}$ is projection onto the k'th coordinate, i.e. $\pi_k^{(m)}(x_1, \ldots, x_m) = x_k$), then analysis of $\boldsymbol{f}$ can be largely reduced to analysis of the f_k. There are situations where it is undesirable to reduce to the coordinate functions, though, such as in the study of curves, and in results like the Chain Rule and the Implicit and Inverse Function Theorems, where the interplay of coordinates is crucial. Roughly speaking, the multivariable calculus approach is to reduce to coordinate functions and the vector calculus approach is to avoid doing this.

The complications arising from having $n > 1$ are essential, however, and mostly cannot be handled by considering coordinates separately (although, with considerable care, in good cases much can be reduced to one-variable calculus). Thus multivariable calculus (and vector calculus) has a quite different nature than one-variable calculus.

We also make a (somewhat arbitrary and nonstandard) distinction between *vector calculus*, the material covered in this chapter, and *vector analysis*, which includes results related to divergence and curl, as well as properties of curves, surfaces, and their generalizations, and differential forms (really the beginning of differential geometry).

VIII.1. Limits and Continuity for Vector Functions

Defining limits and continuity for functions of more than one variable can be very easy or very tricky, depending whether one takes the proper point of view.

VIII.1.1. Graphs of Functions of Several Variables

VIII.1.2. Limits of Sequences in $\mathbb{R}^n$

VIII.1.2.1. The first observation is that there is much more "room" in $\mathbb{R}^n$, $n \geq 2$, for sequences to behave in a complicated way than in $\mathbb{R} = \mathbb{R}^1$. A sequence in $\mathbb{R}$ can approach a limit only from the left or right, or more generally jump back and forth from left or right, i.e. can be decomposed into at most two subsequences which approach from the left and right respectively. But even in $\mathbb{R}^2$, a sequence can approach a limit in a very complicated way: it can approach from any direction or along any curve, can spiral around the limit wildly, etc., and cannot generally be decomposed into subsequences which approach in a controlled way (things can be even wilder in $\mathbb{R}^3$). Trying to make a definition which covers all the possibilities may seem like a daunting task.

VIII.1.2.2. However, there is a very simple solution. The definition of limit of a sequence in $\mathbb{R}$ can be used almost verbatim in $\mathbb{R}^n$ and gives exactly the right thing. The definition only needs slight redecoration to work perfectly:

VIII.1.2.3. Definition. Let $(\boldsymbol{x}_k)$ be a sequence in $\mathbb{R}^n$, and $\boldsymbol{x} \in \mathbb{R}^n$. Then $\boldsymbol{x}_k \to \boldsymbol{x}$, or $\lim_{k\to\infty} \boldsymbol{x}_k = \boldsymbol{x}$, if for every $\epsilon > 0$ there is a K such that

$$\|\boldsymbol{x}_k - \boldsymbol{x}\| < \epsilon$$

for all $k \geq K$.

This is a special case of redecorating the definition in $\mathbb{R}$ to one valid in a general metric space ().

The Coordinatewise Criterion

There is one basic fact about limits in $\mathbb{R}^n$ which will appear in various forms, which allows a reduction to the case of limits in $\mathbb{R}$ in some cases, including sequences:

VIII.1.2.4. Proposition. [Coordinatewise Criterion for Sequences in $\mathbb{R}^n$] Let $(\boldsymbol{x}_k)$ be a sequence in $\mathbb{R}^n$, and $\boldsymbol{x} \in \mathbb{R}^n$. Write

$$\boldsymbol{x}_k = (x_k^{(1)}, \ldots, x_k^{(n)}), \quad \boldsymbol{x} = (x^{(1)}, \ldots, x^{(n)})$$

in coordinates. Then $\boldsymbol{x}_k \to \boldsymbol{x}$ in $\mathbb{R}^n$ if and only if $x_k^{(j)} \to x^{(j)}$ in $\mathbb{R}$ for each j, $1 \leq j \leq n$.

Proof: Note that for each m we have

$$|x_k^{(m)} - x^{(m)}| \leq \|\boldsymbol{x}_k - \boldsymbol{x}\| \leq \sum_{j=1}^{n} |x_k^{(j)} - x^{(j)}| \ .$$

Suppose $\boldsymbol{x}_k \to \boldsymbol{x}$, and fix j. Let $\epsilon > 0$. There is a K such that

$$|x_k^{(j)} - x^{(j)}| \leq \|\boldsymbol{x}_k - \boldsymbol{x}\| < \epsilon$$

for all $k \geq K$; thus $x_k^{(j)} \to x^{(j)}$. Conversely, suppose $x_k^{(j)} \to x^{(j)}$ for all j. Let $\epsilon > 0$. For each j choose K_j such that

$$|x_k^{(j)} - x^{(j)}| < \frac{\epsilon}{n}$$

for all $k \geq K_j$. Set $K = \max(K_1, \ldots, K_n)$. Then, if $k \geq K$,

$$\|\boldsymbol{x}_k - \boldsymbol{x}\| \leq \sum_{j=1}^{n} |x_k^{(j)} - x^{(j)}| < n \cdot \frac{\epsilon}{n} = \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, $\boldsymbol{x}_k \to \boldsymbol{x}$. 👍

The Bolzano-Weierstrass Theorem in $\mathbb{R}^n$

The Bolzano-Weierstrass Theorem holds also for sequences of vectors in $\mathbb{R}^n$:

VIII.1.2.5. THEOREM. [BOLZANO-WEIERSTRASS THEOREM IN $\mathbb{R}^n$] Every bounded sequence in $\mathbb{R}^n$ has a convergent subsequence.

PROOF: Let $(\boldsymbol{x}_k) = ((x_k^{(1)}, \ldots, x_k^{(n)}))$ be a bounded sequence in $\mathbb{R}^n$. Then $(x_k^{(1)})$ is a bounded sequence in $\mathbb{R}$, hence has a convergent subsequence $(x_{k_{m,1}}^{(1)})$. The sequence $(x_{k_{m,1}}^{(2)})$ is bounded, so has a convergent subsequence $(x_{k_{m,2}}^{(2)})$; we also have that $(x_{k_{m,2}}^{(1)})$ converges since it is a subsequence of $(x_{k_{m,1}}^{(1)})$. Continuing n times, we get a subsub$\cdots$subsequence $(k_{m,n})$ of $\mathbb{N}$ such that $(x_{k_{m,n}}^{(j)})$ converges for $1 \leq j \leq n$, Thus the subsequence $(\boldsymbol{x}_{k_{m,n}})$ of $(\boldsymbol{x}_k)$ converges by the coordinatewise criterion. 👍

VIII.1.3. Multivariable Limits

We now look at limits for functions from $\mathbb{R}^n$ to $\mathbb{R}^m$. We first consider the case $m = 1$.

Limits for Real-valued Functions of Several Variables

VIII.1.3.1. Suppose f is a real-valued function defined on a deleted neighborhood U of $\boldsymbol{a} \in \mathbb{R}^n$. We want to say what $\lim_{\boldsymbol{x} \to \boldsymbol{a}} f(\boldsymbol{x})$ means. We first consider some examples with $n = 2$, where we change notation slightly by writing (x, y) for $\boldsymbol{x}$.

VIII.1.3.2. EXAMPLES. (i) Let

$$f(x,y) = \frac{xy}{x^2+y^2}$$

for $(x,y) \neq (0,0)$. Then f is defined in a deleted neighborhood of $(0,0)$ in $\mathbb{R}^2$. What should $\lim_{(x,y)\to(0,0)} f(x,y)$ be?

If $(0,0)$ is approached along either the x- or y-axis, the function is identically 0, so the limit could only reasonably be 0. On the other hand, $f(t,t) = \frac{1}{2}$ for all $t \neq 0$, so if we approach the origin along the line $x = y$ the function value approaches $\frac{1}{2}$. Since the limit should be unique and we approach different values from different directions, we should say the limit does not exist.

Geometrically, the graph is so wrinkled near the origin that no point can be added there to make the graph a reasonable unbroken surface (Figure VIII.1).

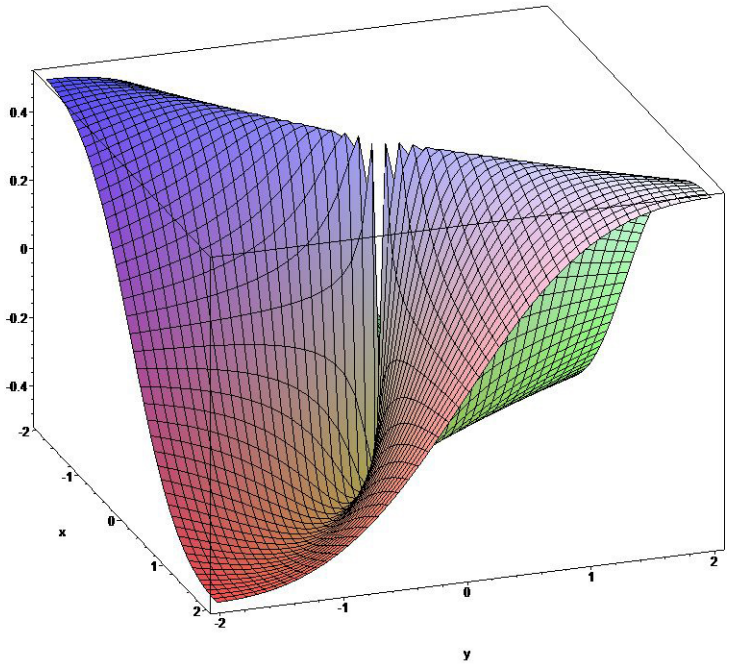

Figure VIII.1: Maple plot of $f(x,y) = \frac{xy}{x^2+y^2}$

(ii) Here is a more striking version of the same phenomenon: Let

$$f(x,y) = \frac{x^2 y}{x^4 + y^2}$$

for $(x,y) \neq (0,0)$. Then f is defined in a deleted neighborhood of $(0,0)$ in $\mathbb{R}^2$. What should $\lim_{(x,y)\to(0,0)} f(x,y)$ be?

Again, if $(0,0)$ is approached along either the x- or y-axis, the function is identically 0, so the limit could only reasonably be 0. And if we approach along the line $y = mx$, we have

$$\lim_{t\to 0} f(t,mt) = \lim_{t\to 0} \frac{mt^3}{t^4 + m^2 t^2} = 0$$

thus the function approaches 0 as $(0,0)$ is approached radially from any direction. Does this mean that we should say the limit is 0?

Suppose we approach along the parabola $y = x^2$. We then have

$$\lim_{t\to 0} f(t,t^2) = \lim_{t\to 0} \frac{t^4}{2t^4} = \frac{1}{2}$$

so the limit cannot exist. This time the crinkle in the graph is curved (Figure VIII.2).

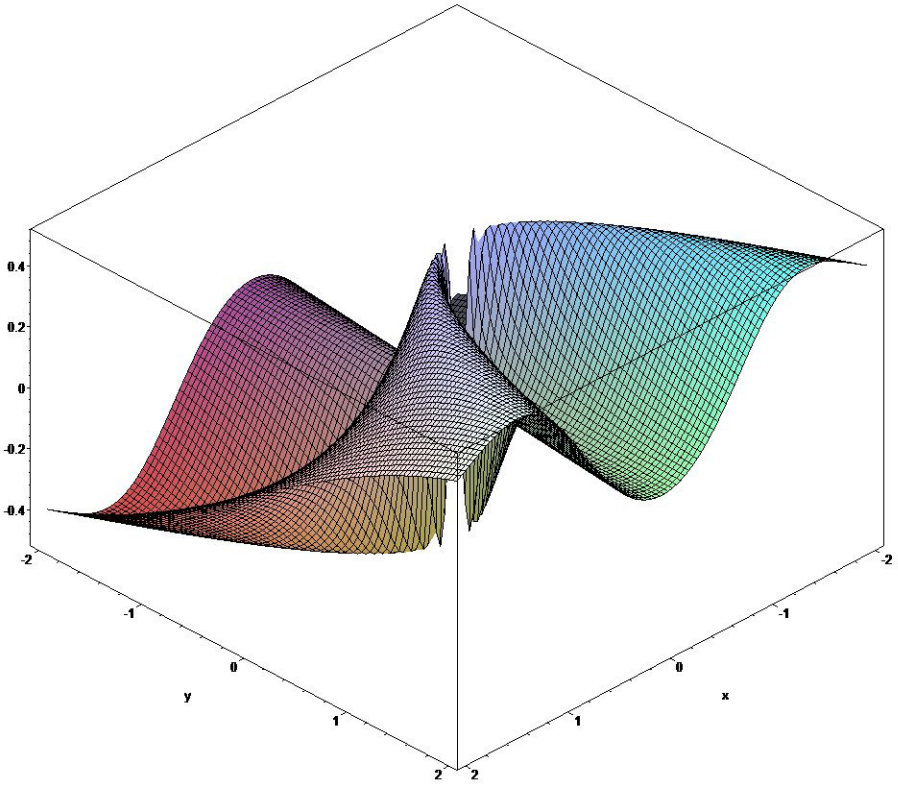

Figure VIII.2: Maple plot of $f(x,y) = \frac{x^2 y}{x^4+y^2}$

To make a good definition, we can again simply redecorate the one-dimensional definition:

VIII.1.3.3. Definition. Let $\boldsymbol{f}$ be a function from a deleted neighborhood U of $\boldsymbol{a} \in \mathbb{R}^n$ to $\mathbb{R}^m$, $\boldsymbol{L} \in \mathbb{R}^m$. Then

$$\lim_{\boldsymbol{x} \to \boldsymbol{a}} \boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{L}$$

if, for every $\epsilon > 0$, there is a $\delta > 0$ such that

$$\|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{L}\| < \epsilon$$

whenever $\boldsymbol{x} \in U$ and $0 < \|\boldsymbol{x} - \boldsymbol{a}\| < \delta$.

As in the case of sequences, limits can be taken coordinatewise. The proof of the next proposition is almost identical to the proof of VIII.1.2.4., and is left to the reader:

VIII.1.3.4. Proposition. [Coordinatewise Criterion for Functions from $\mathbb{R}^n$ to $\mathbb{R}^m$] Let $\boldsymbol{f} = (f_1, \ldots, f_m)$ be a function from a deleted neighborhood U of $\boldsymbol{a} \in \mathbb{R}^n$ to $\mathbb{R}^m$, $\boldsymbol{L} = (L_1, \ldots, L_m) \in \mathbb{R}^m$. Then

$$\lim_{\boldsymbol{x} \to \boldsymbol{a}} \boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{L}$$

if and only if

$$\lim_{\boldsymbol{x} \to \boldsymbol{a}} f_k(\boldsymbol{x}) = L_k$$

for $1 \leq k \leq m$.

VIII.1.3.5. Note that the coordinatewise criterion is in the *range* space $\mathbb{R}^m$, not the domain space. The previous examples show that it is not adequate to work coordinatewise in the domain. In fact, the limits in those examples do not exist under our definition.

Many properties of limits in the one-dimensional case hold for multidimensional limits, with essentially the same (redecorated) proofs, such as:

VIII.1.3.6. Proposition. Limits are unique: if $\boldsymbol{f}$ is a function from a deleted neighborhood U of $\boldsymbol{a} \in \mathbb{R}^n$ to $\mathbb{R}^m$, $\boldsymbol{L}, \boldsymbol{M} \in \mathbb{R}^m$, and

$$\lim_{\boldsymbol{x} \to \boldsymbol{a}} \boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{L} \text{ and } \lim_{\boldsymbol{x} \to \boldsymbol{a}} \boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{M}$$

then $\boldsymbol{L} = \boldsymbol{M}$.

Continuity

We may make the same definition of (pointwise) continuity in the multivariable case as in one dimension:

VIII.1.3.7. DEFINITION. Let $\boldsymbol{f}$ be a function from a neighborhood U of $\boldsymbol{a} \in \mathbb{R}^n$ to $\mathbb{R}^m$, $\boldsymbol{L} \in \mathbb{R}^m$. Then $\boldsymbol{f}$ is *continuous at* $\boldsymbol{a}$ if, for every $\epsilon > 0$, there is a $\delta > 0$ such that

$$\|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{f}(\boldsymbol{a})\| < \epsilon$$

whenever $\boldsymbol{x} \in U$ and $\|\boldsymbol{x} - \boldsymbol{a}\| < \delta$.

VIII.1.3.8. As in the one-dimensional case, $\boldsymbol{f}$ is continuous at $\boldsymbol{a}$ if and only if

$\boldsymbol{f}(\boldsymbol{a})$ exists.

$\lim_{\boldsymbol{x} \to \boldsymbol{a}} \boldsymbol{f}(\boldsymbol{x})$ exists.

$\lim_{\boldsymbol{x} \to \boldsymbol{a}} \boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{f}(\boldsymbol{a})$.

Continuity on a Set

Sequential Criteria for Limits and Continuity

VIII.2. Partial and Directional Derivatives

If f is a function of several variables, one simple way to partially analyze the behavior of f is to hold all but one of the variables fixed, so that f becomes simply a function of the one remaining variable. This leads to the notion of partial derivative. Partial derivatives turn out to give considerably more information about the function than might be at first expected, at least in good cases. The notion can then be generalized to directional derivatives in any direction.

VIII.2.1. Partial Derivatives

VIII.2.1.1. DEFINITION. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f} : U \to \mathbb{R}^m$ a function. Let $\boldsymbol{a} = (a_1, \ldots, a_n) \in U$. For $1 \leq k \leq n$, we define the *partial derivative*

$$\frac{\partial \boldsymbol{f}}{\partial x_k}(\boldsymbol{a}) = \lim_{h \to 0} \frac{\boldsymbol{f}(a_1, \ldots, a_{k-1}, a_k + h, a_{k+1}, \ldots, a_n) - \boldsymbol{f}(a_1, \ldots, a_n)}{h}$$

$$= \lim_{h \to 0} \frac{1}{h}[\boldsymbol{f}(a_1, \ldots, a_{k-1}, a_k + h, a_{k+1}, \ldots, a_n) - \boldsymbol{f}(a_1, \ldots, a_n)]$$

if the limit exists.

In other words, $\frac{\partial \boldsymbol{f}}{\partial x_k}$ is the derivative of $\boldsymbol{f}$ when it is thought of as only a function of x_k by holding the other variables fixed: if

$$\boldsymbol{g}(x) = \boldsymbol{f}(a_1, \ldots, a_{k-1}, x, a_{k+1}, \ldots, a_n)$$

then

$$\frac{\partial \boldsymbol{f}}{\partial x_k}(\boldsymbol{a}) = \boldsymbol{g}'(a_k) \ .$$

VIII.2.1.2. If $\frac{\partial \boldsymbol{f}}{\partial x_k}(\boldsymbol{a})$ exists, it is a vector in $\mathbb{R}^m$. Partial derivatives are most commonly discussed in the case $m = 1$, in which case $\frac{\partial \boldsymbol{f}}{\partial x_k}(\boldsymbol{a}) \in \mathbb{R}$. The relation with the general case is that if $(f_1, \ldots, f_m)$ are the coordinate functions of $\boldsymbol{f}$, then $\frac{\partial \boldsymbol{f}}{\partial x_k}(\boldsymbol{a})$ exists if and only if $\frac{\partial f_j}{\partial x_k}(\boldsymbol{a})$ exists for all $1 \leq j \leq m$, in which case

$$\frac{\partial \boldsymbol{f}}{\partial x_k}(\boldsymbol{a}) = \left(\frac{\partial f_1}{\partial x_k}(\boldsymbol{a}), \ldots, \frac{\partial f_m}{\partial x_k}(\boldsymbol{a}) \right) \ .$$

VIII.2.1.3. The partial derivative symbol ∂ appears to be an italic Cyrillic d. However, the origin of the notation is somewhat obscure (). Alternate notations are sometimes used, especially if the variables are denoted $x, y, z, \ldots$: if f is a function of, say, x, y, and z, $\frac{\partial f}{\partial x}$ is sometimes denoted f_x or f_1, $\frac{\partial f}{\partial y}$ is denoted f_y or f_2, etc. We will mostly stick to the $\frac{\partial}{\partial x}$, etc., notation, except in ().

VIII.2.1.4. It is easy to get caught in confusing or ambiguous notation concerning partial derivatives if one is not careful, and many references use sloppy notation in places. For example, suppose $u = f(x, y, z)$ and $z = g(x, y)$; then what does $\frac{\partial u}{\partial x}$ mean? As a variation, if $u = f(x, y)$ and $y = g(x)$, then one can make sense of both $\frac{\partial u}{\partial x}$ and $\frac{du}{dx}$. To avoid such nasty ambiguities, we will sometimes seem to be overly pedantic in our notation. See also Exercise VIII.2.4.2..

"All notations for the partial derivative omit crucial information: which variables are being kept constant. In modeling real phenomena, it can be difficult even to know what all the variables are. But if you don't, your partial derivatives may be meaningless."

A. Douady[1]

VIII.2.1.5. Like ordinary derivatives, partial derivatives are defined pointwise for each fixed $\boldsymbol{a} \in U$. However, after the fact each partial derivative $\frac{\partial \boldsymbol{f}}{\partial x_k}$ may be thought of as a function from U, or the subset on which it is defined, to $\mathbb{R}^m$.

VIII.2.1.6. When a function f of two or more variables is defined by a formula, partial derivatives can be calculated by the usual rules of differentiation, treating the remaining variables as constants. For example, if

$$f(x,y,z) = x^2y^3 + \frac{\cos yz}{z^2+1} - e^{xyz}$$

we have

$$\frac{\partial f}{\partial x}(x,y,z) = 2xy^3 - yze^{xyz}$$

$$\frac{\partial f}{\partial y}(x,y,z) = 3x^2y^2 - \frac{z\sin yz}{z^2+1} - xze^{xyz}$$

$$\frac{\partial f}{\partial z}(x,y,z) = \frac{(z^2+1)(-y\sin yz) - (\cos yz)(2z)}{(z^2+1)^2} - xye^{xyz} \ .$$

Showing that such calculations are valid takes a little (easy) work, though, a point overlooked in many references; see Exercise VIII.2.4.1..

Partial Derivatives and Continuity

VIII.2.1.7. A differentiable function from $\mathbb{R}$ to $\mathbb{R}$ is continuous. But existence of all partial derivatives does not imply continuity in the higher-dimensional case. For example, let

$$f(x,y) = \begin{cases} \frac{xy}{x^2+y^2} & \text{If} \quad (x,y) \neq (0,0) \\ 0 & \text{If} \quad (x,y) = (0,0) \end{cases} \ .$$

Then f has partial derivatives with respect to both x and y at all points of $\mathbb{R}^2$. But f is not continuous at $(0,0)$ (VIII.1.3.2.). See VIII.3.7.8. for a more dramatic example.

However, continuity of all partial derivatives does imply continuity of the function (VIII.3.1.14., VIII.3.3.1.) (note that the partials of this f are discontinuous at $(0,0)$).

There is one special case which is elementary and worth noting:

[1] [HH99, p. 103].

VIII.2.1.8. PROPOSITION. Let U be a nonempty connected open set in $\mathbb{R}^n$, and $f : U \to \mathbb{R}$ a function. If all partial derivatives of f exist at all points of U and are identically zero, then f is constant on U.

PROOF: First suppose U is an open ball (or, more generally, convex). It follows from () that f must be constant on the intersection with U of any line parallel to a coordinate axis. Since any two points of U can be connected by a finite sequence of such line segments within U, f is constant on U.

Now suppose U is just connected. It follows that f is locally constant, i.e. for each $\lambda \in \mathbb{R}$ the set

$$V_\lambda = \{\boldsymbol{x} \in U : f(\boldsymbol{x}) = \lambda\}$$

is an open subset of U. If we knew that f were continuous, it would follow that V_λ is relatively closed in U, hence V_λ would have to be $\emptyset$ or all of U. But we cannot assume that f is continuous, so we argue as follows. Let $\boldsymbol{a} \in U$, and $f(\boldsymbol{a}) = \lambda_0$. Then V_{λ_0} is an open subset of U containing $\boldsymbol{a}$. We have

$$W := U \setminus V_{\lambda_0} = \bigcup_{\lambda \neq \lambda_0} V_\lambda$$

so W is a union of open sets, hence open, and U is the disjoint union of V_{λ_0} and W; thus $W = \emptyset$ since U is connected. 👍

VIII.2.1.9. COROLLARY. Let U be a nonempty connected open set in $\mathbb{R}^n$, and $f, g : U \to \mathbb{R}$ two functions. If all partial derivatives of f and g exist at all points of U and $\frac{\partial f}{\partial x_k}(\boldsymbol{x}) = \frac{\partial g}{\partial x_k}(\boldsymbol{x})$ for all k and all $\boldsymbol{x} \in U$, then $f - g$ is constant on U.

Higher-Order Partials

VIII.2.1.10. If $\boldsymbol{f} : U \to \mathbb{R}^m$ is a function, and the partial derivatives $\frac{\partial \boldsymbol{f}}{\partial x_k}$ are defined on U, then partial derivatives of these partial derivatives are also (potentially) defined. For example, if $\frac{\partial \boldsymbol{f}}{\partial x_k}$ is defined in a neighborhood of $\boldsymbol{a} \in U$, then for $1 \leq j \leq n$ we can define

$$\frac{\partial^2 \boldsymbol{f}}{\partial x_j \partial x_k}(\boldsymbol{a}) = \frac{\partial \left(\frac{\partial \boldsymbol{f}}{\partial x_k}\right)}{\partial x_j} = \lim_{h \to 0} \frac{\frac{\partial \boldsymbol{f}}{\partial x_k}(a_1, \ldots, a_{j-1}, a_j + h, a_{j+1}, \ldots, a_n) - \frac{\partial \boldsymbol{f}}{\partial x_k}(a_1, \ldots, a_n)}{h}$$

if the limit exists.

Note the order of differentiation: $\frac{\partial^2 \boldsymbol{f}}{\partial x_j \partial x_k}(\boldsymbol{a})$ and $\frac{\partial^2 \boldsymbol{f}}{\partial x_k \partial x_j}(\boldsymbol{a})$ have different definitions if $j \neq k$. It turns out (VIII.2.2.2.) that under mild continuity hypotheses these two partial derivatives are numerically equal. ✋

VIII.2.1.11. We may keep going, defining third-order partial derivatives $\frac{\partial^3 \boldsymbol{f}}{\partial x_i \partial x_j \partial x_k}$, etc. The i, j, k need not be distinct.

VIII.2.1.12. In the definition, we may have $j = k$ or $j \neq k$. Thus, if f is a function $f(x, y)$ of two variables, there are four second-order partials: $\frac{\partial^2 \boldsymbol{f}}{\partial x \partial x}$ (usually denoted $\frac{\partial^2 \boldsymbol{f}}{\partial x^2}$), $\frac{\partial^2 \boldsymbol{f}}{\partial x \partial y}$, $\frac{\partial^2 \boldsymbol{f}}{\partial y \partial x}$, and $\frac{\partial^2 \boldsymbol{f}}{\partial y^2}$. The middle two, called *mixed partials*, are often but not always equal. The variety increases rapidly with higher derivatives and/or more variables.

VIII.2.1.13. We may also use the alternate notation f_{xx} or f_{11} for $\frac{\partial^2 \boldsymbol{f}}{\partial x^2}$, etc. When the alternate notation is used, it is conventional to take derivatives from left to right, unlike in the Leibniz notation where derivatives go from right to left: thus f_{xy} or f_{12} denotes $\frac{\partial^2 f}{\partial y \partial x}$, i.e. the function is first differentiated with respect to x and then with respect to y, not $\frac{\partial^2 f}{\partial x \partial y}$ which is denoted f_{yx} or f_{21}. (The distinction is academic in good cases.)

VIII.2.2. Equality of Mixed Partials

In general, the order in which the derivatives are taken in a higher-order partial derivative makes a difference. But under a mild continuity hypothesis, the order does not matter.

VIII.2.2.1. EXAMPLE. Let

$$f(x,y) = \begin{cases} \frac{xy(x^2-y^2)}{x^2+y^2} & \text{if} \quad (x,y) \neq (0,0) \\ 0 & \text{if} \quad (x,y) = (0,0) \end{cases} .$$

Then f is $\mathcal{C}^1$ on $\mathbb{R}^2$: we have

$$\frac{\partial f}{\partial x}(x,y) = \begin{cases} \frac{y(x^4+4x^2y^2-y^4)}{(x^2+y^2)^2} & \text{if} \quad (x,y) \neq (0,0) \\ 0 & \text{if} \quad (x,y) = (0,0) \end{cases}$$

$$\frac{\partial f}{\partial y}(x,y) = \begin{cases} \frac{-x(y^4+4x^2y^2-x^4)}{(x^2+y^2)^2} & \text{if} \quad (x,y) \neq (0,0) \\ 0 & \text{if} \quad (x,y) = (0,0) \end{cases} .$$

The absolute value of the numerators are bounded by $6\|(x,y)\|^5$, so the partials are continuous at $(0,0)$. Also, $\frac{\partial^2 f}{\partial x\,\partial y}$ and $\frac{\partial^2 f}{\partial y\,\partial x}$ are defined everywhere on $\mathbb{R}^2$, and

$$\frac{\partial^2 f}{\partial x\,\partial y}(0,0) = \lim_{h\to 0} \frac{\frac{\partial f}{\partial y}(h,0) - \frac{\partial f}{\partial y}(0,0)}{h} = 1$$

$$\frac{\partial^2 f}{\partial y\,\partial x}(0,0) = \lim_{k\to 0} \frac{\frac{\partial f}{\partial x}(0,k) - \frac{\partial f}{\partial x}(0,0)}{k} = -1$$

so the second-order mixed partials exist at $(0,0)$ are defined but unequal.

However, $\frac{\partial^2 f}{\partial x\,\partial y}$ and $\frac{\partial^2 f}{\partial y\,\partial x}$ are not continuous at $(0,0)$.

Actually, f has continuous partials of all orders everywhere except at the origin, i.e. f is $\mathcal{C}^\infty$ on $\mathbb{R}^2\backslash\{(0,0)\}$.

The graph has a subtle crinkle near the origin (Figure VIII.3).

VIII.2.2.2. THEOREM. Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{f} : U \to \mathbb{R}^m$, $\boldsymbol{a} \in U$. Suppose, for some i and j, $\frac{\partial \boldsymbol{f}}{\partial x_i}$ and $\frac{\partial \boldsymbol{f}}{\partial x_j}$ exist everywhere on U, and $\frac{\partial^2 \boldsymbol{f}}{\partial x_i\,\partial x_j}$ exists everywhere on U and is continuous at $\boldsymbol{a}$. Then $\frac{\partial^2 \boldsymbol{f}}{\partial x_j\,\partial x_i}(\boldsymbol{a})$ is defined and

$$\frac{\partial^2 \boldsymbol{f}}{\partial x_j\,\partial x_i}(\boldsymbol{a}) = \frac{\partial^2 \boldsymbol{f}}{\partial x_i\,\partial x_j}(\boldsymbol{a}) .$$

PROOF: There is no content to the statement if $i = j$, so we assume $i \neq j$.

We first make two reductions. By considering the coordinate functions, it suffices to assume $m = 1$. And, since only the coordinates i and j are varied in computing the partials, we may assume $n = 2$. So we suppose

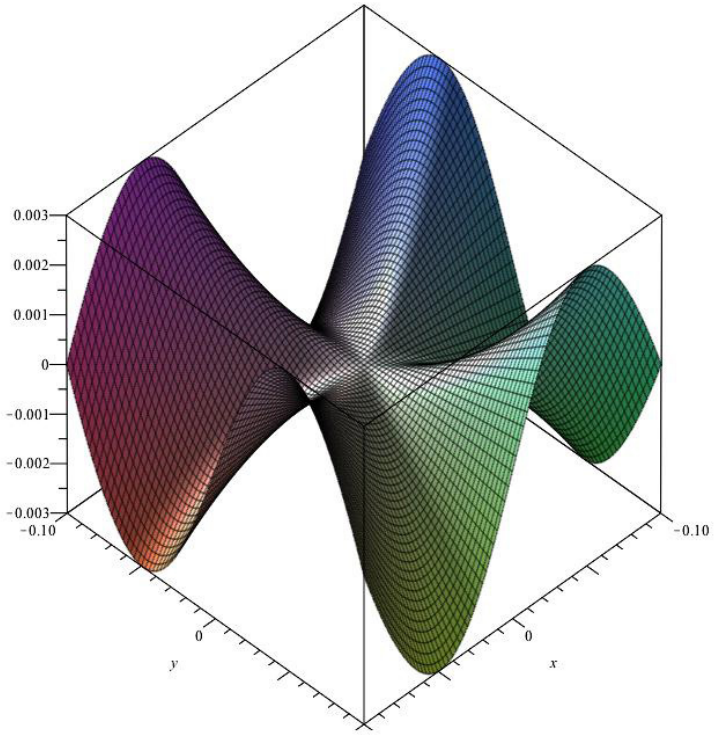

Figure VIII.3: Maple plot of graph of $f(x,y) = \frac{xy(x^2-y^2)}{x^2+y^2}$

$U \subseteq \mathbb{R}^2$, $f : U \to \mathbb{R}$, $(a,b) \in U$, that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ exist on U, and $\frac{\partial^2 f}{\partial x\,\partial y}$ is defined on U and continuous at (a,b). We want to show that $\frac{\partial^2 f}{\partial y\,\partial x}(a,b)$ is defined and equal to $c := \frac{\partial^2 f}{\partial x\,\partial y}(a,b)$.

Let $\epsilon > 0$, and fix $\delta > 0$ such that if $|h| < \delta$ and $|k| < \delta$, then $(a+h, b+k) \in U$ and

$$\left| \frac{\partial^2 f}{\partial x\,\partial y}(a+h, b+k) - c \right| < \epsilon \ .$$

Set $V = \{(h,k) : |h| < \delta, |k| < \delta\}$. Then for $(h,k) \in V$, set

$$\Delta(h,k) = f(a+h, b+k) - f(a, b+k) - f(a+h, b) + f(a,b) \ .$$

If $(h,k) \in V$ is fixed, for $0 \le t \le 1$ set

$$\phi(t) = f(a+h, b+tk) - f(a, b+tk) \ .$$

Then ϕ is differentiable on $[0,1]$ and by the Chain Rule

$$\phi'(t) = \frac{\partial f}{\partial y}(a+h, b+tk) \cdot k - \frac{\partial f}{\partial y}(a, b+tk) \cdot k \ .$$

Apply the MVT to get a $t \in (0,1)$ such that

$$k\frac{\partial f}{\partial y}(a+h, b+tk) - k\frac{\partial f}{\partial y}(a, b+tk) = \phi'(t)(1-0) = \phi(1) - \phi(0) = \Delta(h,k) \ .$$

Fix such a t, and for $0 \le s \le 1$ set

$$\psi(s) = k\frac{\partial f}{\partial y}(a+sh, b+tk) \ .$$

Then ψ is differentiable on $[0,1]$ and

$$\psi'(s) = k\frac{\partial^2 f}{\partial x\,\partial y}(a+sh, b+tk)\cdot h \ .$$

Again use the MVT to obtain an $s \in (0,1)$ such that

$$hk\frac{\partial^2 f}{\partial x\,\partial y}(a+sh, b+tk) = \psi'(s)(1-0) = \psi(1) - \psi(0) = \Delta(h,k) \ .$$

For every $(h,k) \in V$ there is such a pair $(s,t) \in (0,1)^2$ (which depends on (h,k)), and $(sh, tk) \in V$, so if $(h,k) \in V$, $h \neq 0$, $k \neq 0$, we have

$$\left| \frac{\Delta(h,k)}{hk} - c \right| < \epsilon \ .$$

Now fix k, $0 < |k| < \delta$. We have

$$\lim_{h\to 0} \frac{\Delta(h,k)}{hk} = \frac{1}{k}\lim_{h\to 0}\left[\frac{f(a+h,b+k) - f(a,b+k)}{h} - \frac{f(a+h,b) - f(a,b)}{h}\right] = \frac{1}{k}\left[\frac{\partial f}{\partial x}(a,b+k) - \frac{\partial f}{\partial x}(a,b)\right]$$

so the limit exists and we have that

$$\left| \frac{1}{k}\left[\frac{\partial f}{\partial x}(a,b+k) - \frac{\partial f}{\partial x}(a,b)\right] - c \right| \le \epsilon$$

if $0 < |k| < \delta$. Since $\epsilon > 0$ is arbitrary, we conclude that

$$\frac{\partial^2 f}{\partial y\,\partial x}(a,b) = \lim_{k\to 0} \frac{\frac{\partial f}{\partial x}(a,b+k) - \frac{\partial f}{\partial x}(a,b)}{k}$$

exists and equals c. 👍

VIII.2.2.3. REMARK. (i) In VIII.2.2.2., the hypothesis that $\frac{\partial f}{\partial x_j}$ exists on U is implicit and automatic in the hypothesis that $\frac{\partial^2 f}{\partial x_i\,\partial x_j}$ exists on U.

(ii) Let g be a continuous but nowhere differentiable function from $\mathbb{R}$ to $\mathbb{R}$, and let $f : \mathbb{R}^2 \to \mathbb{R}$ be defined by $f(x,y) = g(x)$. Then f is continuous, and $\frac{\partial f}{\partial y}$ exists everywhere and is identically zero; thus $\frac{\partial^2 f}{\partial x\,\partial y}$ also exists everywhere and is identically zero, hence continuous. But $\frac{\partial f}{\partial x}$ does not exist anywhere, so $\frac{\partial^2 f}{\partial y\,\partial x}$ does not exist anywhere. So the hypothesis that $\frac{\partial f}{\partial x_i}$ exists, which is necessary for the existence of $\frac{\partial^2 f}{\partial x_j\,\partial x_i}$, is not automatic under the other hypotheses.

VIII.2.2.4. COROLLARY. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f}$ a $\mathcal{C}^2$ function from U to $\mathbb{R}^m$. Then, for any i and j,

$$\frac{\partial^2 \boldsymbol{f}}{\partial x_j \, \partial x_i} = \frac{\partial^2 \boldsymbol{f}}{\partial x_i \, \partial x_j}$$

on U.

VIII.2.2.5. VIII.2.2.4. is called *Clairaut's Theorem*. The version in VIII.2.2.2. can be found in [Str81, p. 377]. Statements of the result in some real analysis texts have unnecessary extra hypotheses, and the "proofs" in many books have flaws. See VIII.4.1.7. for a variation, and IX.3.12.1. for a simple alternate proof of VIII.2.2.4. based on Fubini's Theorem.

VIII.2.2.6. COROLLARY. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f}$ a $\mathcal{C}^r$ function from U to $\mathbb{R}^m$ $(r > 1)$. Then any two mixed partials of $\boldsymbol{f}$ of total order $\leq r$ in which each coordinate direction appears the same number of times are equal on U.

To show this, apply VIII.2.2.4. repeatedly to $\boldsymbol{f}$ and its partial derivatives. For example, if $n \geq 5$ and $r \geq 4$, to show that

$$\frac{\partial^4 \boldsymbol{f}}{\partial x_2 \, \partial x_5 \, \partial x_3 \, \partial x_1} = \frac{\partial^4 \boldsymbol{f}}{\partial x_2 \, \partial x_3 \, \partial x_5 \, \partial x_1}$$

apply VIII.2.2.4. to $\frac{\partial \boldsymbol{f}}{\partial x_1}$ to conclude that

$$\frac{\partial^3 \boldsymbol{f}}{\partial x_5 \, \partial x_3 \, \partial x_1} = \frac{\partial^3 \boldsymbol{f}}{\partial x_3 \, \partial x_5 \, \partial x_1}$$

and then take the partial derivative of this function with respect to x_2. Any permutation of the order of derivatives can be built up from interchanges of successive derivatives, which can be justified in this way.

VIII.2.2.7. This result leads to some convenient notation. A *multi-index* of dimension n is an n-tuple $\alpha = (r_1, \ldots, r_n)$, where the r_k are in $\mathbb{N} \cup \{0\}$. The *total degree* of α is

$$|\alpha| = r_1 + \cdots r_n \ .$$

If α is a multi-index of dimension n and total degree r, U an open subset of $\mathbb{R}^n$, and $\boldsymbol{f} : U \to \mathbb{R}^m$ is $\mathcal{C}^r$, write

$$\frac{\partial^\alpha \boldsymbol{f}}{\partial x^\alpha} = \frac{\partial^r \boldsymbol{f}}{\partial x_1^{r_1} \, \partial x_2^{r_2} \cdots \partial x_n^{r_n}} \ .$$

By VIII.2.2.6., the successive partial derivatives may be taken in any order.

There is a "converse" to Clairaut's Theorem which is important in vector field theory and in differential equations (compare with IX.3.12.1.):

VIII.2.2.8. THEOREM. Let U be an open rectangle or open disk in $\mathbb{R}^2$, and g and h continuous functions from U to $\mathbb{R}$ such that $\frac{\partial g}{\partial y}$ and $\frac{\partial h}{\partial x}$ are defined, continuous, and equal everywhere on U. Then there is a $\mathcal{C}^1$ function f on U, unique up to adding a constant, with $g = \frac{\partial f}{\partial x}$ and $h = \frac{\partial f}{\partial y}$.

PROOF: For uniqueness, if f and F satisfy the conclusion, then $\phi = F - f$ is $\mathcal{C}^1$ and $D\phi = 0$, so ϕ is constant. For existence, let (a, b) be the center point of U. For $(x, y) \in U$, define

$$f_1(x, y) = \int_b^y h(a, s)\, ds + \int_a^x g(t, y)\, dt$$

$$f_2(x, y) = \int_a^x g(t, b)\, dt + \int_b^y h(x, s)\, ds$$

(note that the paths lie in U). By the Fundamental Theorem of Calculus (FTC1), $\frac{\partial f_1}{\partial x} = g$ and $\frac{\partial f_2}{\partial y} = h$. So it suffices to show $f_1 = f_2$.

Fix $(x, y) \in U$. Then, by the Fundamental Theorem of Calculus (FTC2),

$$f_1(x, y) - f_2(x, y) = \int_a^x [g(t, y) - g(t, b)]\, dt - \int_b^y [h(x, s) - h(a, s)]\, ds$$

$$= \int_a^x \int_b^y \frac{\partial g}{\partial y}(t, s)\, ds\, dt - \int_b^y \int_a^x \frac{\partial h}{\partial x}(t, s)\, dt\, ds = 0$$

by Fubini's Theorem (IX.3.4.10. or IX.3.5.2.) and the fact that $\frac{\partial g}{\partial y} = \frac{\partial h}{\partial x}$. 👍

The equality of f_1 and f_2 is a special case of Green's Theorem ().

VIII.2.2.9. The result can be extended to hold on a general simply connected open set (). But it fails in general on open sets which are not simply connected (). Using more advanced integration, the continuity hypotheses can be relaxed, but it is clumsy to make a precise statement. Of course, if g and h are $\mathcal{C}^r$, the f is $\mathcal{C}^{r+1}$ (but the uniqueness is still among $\mathcal{C}^1$ functions).

VIII.2.2.10. Note that under the hypotheses of VIII.2.2.8., the f need not be more than $\mathcal{C}^1$ since, although the second-order mixed partials of f exist and are continuous in U, $\frac{\partial^2 f}{\partial x^2} = \frac{\partial g}{\partial x}$ and $\frac{\partial^2 f}{\partial y^2} = \frac{\partial h}{\partial y}$ need not exist (anywhere!) For example, let ϕ be a continuous function from $\mathbb{R}$ to $\mathbb{R}$ which is not differentiable anywhere, and set $g(x, y) = \phi(x)$ and $h(x, y) = \phi(y)$. Then g and h satisfy the hypotheses, and $f(x, y) = \Phi(x) + \Phi(y)$, where Φ is an antiderivative for ϕ, is only $\mathcal{C}^1$.

VIII.2.3. Directional Derivatives

VIII.2.3.1. The definition of partial derivatives can be rephrased in vector notation. We write $\{\mathbf{e}_1, \ldots, \mathbf{e}_n\}$ for the standard basis vectors of $\mathbb{R}^n$, i.e. $\mathbf{e}_k$ has 1 in the k'th place and 0's elsewhere (the notation is a little ambiguous since n does not appear; we could write $\mathbf{e}_k^{(n)}$ if it is necessary to specify). If $n = 3$, $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$ are usually written $\mathbf{i}, \mathbf{j}, \mathbf{k}$ respectively.

With this notation, if $U \subseteq \mathbb{R}^n$ and $\boldsymbol{f} : U \to \mathbb{R}^m$ is a function (we normally only consider the case $m = 1$), then we have, for $\boldsymbol{a} \in U$ and $1 \leq k \leq n$,

$$\frac{\partial \boldsymbol{f}}{\partial x_k}(\boldsymbol{a}) = \lim_{h \to 0} \frac{\boldsymbol{f}(\boldsymbol{a} + h\mathbf{e}_k) - \boldsymbol{f}(\boldsymbol{a})}{h}$$

(provided the limit exists).

We may generalize this definition (we only write the generalization in the case $m = 1$, although it can be done for general m):

VIII.2.3.2. Definition. Let $U \subseteq \mathbb{R}^n$, and $f : U \to \mathbb{R}$ a function. Let $\boldsymbol{u}$ be a nonzero vector in $\mathbb{R}^n$ (which is usually taken to be a unit vector, i.e. $\|\boldsymbol{u}\| = 1$). The *directional derivative* of f at $\boldsymbol{a} \in U$ with respect to $\boldsymbol{u}$, or in the direction $\boldsymbol{u}$ if $\boldsymbol{u}$ is a unit vector, is

$$\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{a}) = \lim_{h \to 0} \frac{f(\boldsymbol{a} + h\boldsymbol{u}) - f(\boldsymbol{a})}{h}$$

(provided the limit exists).

Partial derivatives are the special case $\boldsymbol{u} = \mathbf{e}_k$ for some k (note that $\mathbf{e}_k$ is a unit vector):

$$\frac{\partial f}{\partial x_k}(\boldsymbol{a}) = \frac{\partial f}{\partial \mathbf{e}_k}(\boldsymbol{a}) \ .$$

VIII.2.3.3. There is a nice geometric interpretation of directional derivatives (and in particular partial derivatives). If $f : \mathbb{R}^n \to \mathbb{R}$, the graph of f can be regarded as a hypersurface in $\mathbb{R}^n \times \mathbb{R} \cong \mathbb{R}^{n+1}$. If $\boldsymbol{u}$ is a unit vector in $\mathbb{R}^n$, there is a vertical plane through $(\boldsymbol{a}, f(\boldsymbol{a}))$ parallel to the plane spanned by $\boldsymbol{u}$ and $\mathbf{e}_{n+1}$. The intersection of this plane with the graph is a curve. If the plane is identified with $\mathbb{R}^2$ by taking $(\boldsymbol{a}, f(\boldsymbol{a}))$ as the origin and $\boldsymbol{u}$ and $\mathbf{e}_{n+1}$ as the coordinate directions, the curve becomes a plane curve in $\mathbb{R}^2$ through the origin, and $\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{a})$ is just the slope of the tangent line to this curve at the origin (Figure ()). It also has a more elementary interpretation as the rate of increase of f as one moves from $\boldsymbol{a}$ with unit speed along the line in the direction $\boldsymbol{u}$.

VIII.2.3.4. In the case where $\boldsymbol{u}$ is not a unit vector (e.g. in X.1.4.1.), let $\boldsymbol{v} = \frac{\boldsymbol{u}}{\|\boldsymbol{u}\|}$ be a unit vector in the direction of $\boldsymbol{u}$. Then we have, writing $t = \|\boldsymbol{u}\|h$,

$$\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{a}) = \lim_{h \to 0} \frac{\boldsymbol{f}(\boldsymbol{a} + h\boldsymbol{u}) - \boldsymbol{f}(\boldsymbol{a})}{h} = \|\boldsymbol{u}\| \lim_{t \to 0} \frac{\boldsymbol{f}(\boldsymbol{a} + t\boldsymbol{v}) - \boldsymbol{f}(\boldsymbol{a})}{t} = \|\boldsymbol{u}\| \frac{\partial f}{\partial \boldsymbol{v}}(\boldsymbol{a}) \ .$$

VIII.2.4. Exercises

VIII.2.4.1. (a) Prove the following rules of partial differentiation, carefully stating each as a theorem. For each, U is an open set in $\mathbb{R}^n$, f and g are real-valued functions on U which are differentiable at $\boldsymbol{a} \in U$, $h : \mathbb{R} \to \mathbb{R}$ is differentiable at $f(\boldsymbol{a})$, $c \in \mathbb{R}$ (also denoting the constant function c from $\mathbb{R}^n$ to $\mathbb{R}$), and $1 \leq j, k \leq n$. π_j denotes the j'th coordinate function, i.e. $\pi_j(x_1, \ldots, x_n) = x_j$.

$$\frac{\partial(c)}{\partial x_k}(\boldsymbol{a}) = 0 \ .$$

$$\frac{\partial(\pi_j)}{\partial x_k}(\boldsymbol{a}) = \begin{cases} 1 & \text{if } j = k \\ 0 & \text{if } j \neq k \end{cases} \ .$$

$$\frac{\partial(f+g)}{\partial x_k}(\boldsymbol{a}) = \frac{\partial f}{\partial x_k}(\boldsymbol{a}) + \frac{\partial g}{\partial x_k}(\boldsymbol{a}) \ .$$

$$\frac{\partial(cf)}{\partial x_k}(\boldsymbol{a}) = c\frac{\partial f}{\partial x_k}(\boldsymbol{a}) \ .$$

$$\frac{\partial(fg)}{\partial x_k}(\boldsymbol{a}) = \frac{\partial f}{\partial x_k}(\boldsymbol{a})g(\boldsymbol{a}) + f(\boldsymbol{a})\frac{\partial g}{\partial x_k}(\boldsymbol{a}) \ .$$

$$\frac{\partial(f/g)}{\partial x_k}(\boldsymbol{a}) = \frac{\frac{\partial f}{\partial x_k}(\boldsymbol{a})g(\boldsymbol{a}) - f(\boldsymbol{a})\frac{\partial g}{\partial x_k}(\boldsymbol{a})}{[g(\boldsymbol{a})]^2} \text{ if } g(\boldsymbol{a}) \neq 0 \ .$$

$$\frac{\partial(h \circ f)}{\partial x_k}(\boldsymbol{a}) = h'(f(\boldsymbol{a}))\frac{\partial f}{\partial x_k}(\boldsymbol{a}) \ .$$

(b) Use these rules to justify calculating partial derivatives as in VIII.2.1.6..

VIII.2.4.2. Discuss the validity of the following computations.
Let $x = r\cos\theta$, $y = r\sin\theta$, so that $r = \sqrt{x^2+y^2}$. Then $\frac{\partial x}{\partial r} = \cos\theta$, and $\frac{\partial r}{\partial x} = \frac{x}{r} = \cos\theta$. Thus

$$\frac{\partial x}{\partial r} = \frac{\partial r}{\partial x} \neq \frac{1}{\frac{\partial x}{\partial r}}$$

unless $\theta = 0$ or $\theta = \pi$ (or πn for some n).

VIII.3. Differentiability of Multivariable Functions

VIII.3.1. Differentiability and the Derivative

VIII.3.1.1. What should it mean for a function from one Euclidean space to another to be differentiable at a point, and what kind of object should the derivative be? In the one-dimensional case, f is differentiable at a if the limit

$$\lim_{h\to 0}\frac{f(a+h)-f(a)}{h}$$

exists; if it does, the limit is called $f'(a)$. But if $\boldsymbol{f}:\mathbb{R}^n\to\mathbb{R}^m$ and $\boldsymbol{a}\in\mathbb{R}^n$, $n>1$, the analogous expression

$$\lim_{\boldsymbol{h}\to\boldsymbol{0}}\frac{\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h})-\boldsymbol{f}(\boldsymbol{a})}{\boldsymbol{h}}$$

does not even make sense since division by a vector is not defined.

VIII.3.1.2. We can change the one-dimensional definition into an equivalent one which does make sense when redecorated in this way, however. The following statements are equivalent by trivial calculation:

$$\lim_{h\to 0}\frac{f(a+h)-f(a)}{h}=f'(a)$$

$$\lim_{h\to 0}\left[\frac{f(a+h)-f(a)}{h}-f'(a)\right]=0$$

$$\lim_{h\to 0}\frac{f(a+h)-f(a)-f'(a)h}{h}=0$$

$$\lim_{h\to 0}\frac{f(a+h)-f(a)-f'(a)h}{|h|}=0$$

(for the last equivalence, consider left and right limits).

VIII.3.1.3. This last expression is almost in the form needed to make a reasonable definition in the vector case. However, it may be unclear how to modify the term $f'(a)h$ in the numerator. A key to the proper approach comes from differential approximation: the best affine approximation to f near a is the function $\phi(a+h)=f(a)+df(a)(h)=f(a)+f'(a)h$, so the numerator is $f(a+h)-\phi(a+h)$, and the statement that the limit is 0 states that f can be closely approximated by this affine function.

A reasonable geometric criterion for differentiability at $\boldsymbol{a}$ in the vector case is that the function must be closely approximable near $\boldsymbol{a}$ by an affine function, i.e. there is an affine function $\phi:\mathbb{R}^n\to\mathbb{R}^m$ (if $\boldsymbol{f}:U\subseteq\mathbb{R}^n\to\mathbb{R}^m$) such that

$$\lim_{\boldsymbol{h}\to\boldsymbol{0}}\frac{\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h})-\phi(\boldsymbol{a}+\boldsymbol{h})}{\|\boldsymbol{h}\|}=\boldsymbol{0}$$

where the fraction is interpreted as the vector

$$\frac{1}{\|\boldsymbol{h}\|}\left[\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h})-\phi(\boldsymbol{a}+\boldsymbol{h})\right]\in\mathbb{R}^m\ .$$

The affine function ϕ is of the form $\phi(\boldsymbol{x})=\boldsymbol{c}+T(\boldsymbol{x}-\boldsymbol{a})$, where $T:\mathbb{R}^n\to\mathbb{R}^m$ is a linear function and $\boldsymbol{c}$ is a constant. Since we must have $\phi(\boldsymbol{a})=\boldsymbol{f}(\boldsymbol{a})$, $\boldsymbol{c}=\boldsymbol{f}(\boldsymbol{a})$. So we conclude that the following definition is reasonable:

VIII.3.1.4. DEFINITION. Let $U \subseteq \mathbb{R}^n$ be open, and $\boldsymbol{f} : U \to \mathbb{R}^m$, $\boldsymbol{a} \in U$. Then $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$ if there is a linear transformation $T : \mathbb{R}^n \to \mathbb{R}^m$ for which

$$\lim_{\boldsymbol{h}\to\boldsymbol{0}} \frac{\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a}) - T(\boldsymbol{h})}{\|\boldsymbol{h}\|} = \boldsymbol{0} \ .$$

VIII.3.1.5. We will see that the linear transformation T, if it exists, is unique (this can be proved directly; cf. Exercise ()). This linear transformation will be called the *total differential* of $\boldsymbol{f}$ at $\boldsymbol{a}$, denoted $d\boldsymbol{f}(\boldsymbol{a})$, and its matrix the *total derivative matrix* of $\boldsymbol{f}$ at $\boldsymbol{a}$, denoted $D\boldsymbol{f}(\boldsymbol{a})$. Note that $d\boldsymbol{f}(\boldsymbol{a})$ is a linear transformation from $\mathbb{R}^n$ to $\mathbb{R}^m$ and $D\boldsymbol{f}(\boldsymbol{a})$ is an $m \times n$ matrix. $D\boldsymbol{f}(\boldsymbol{a})$ has a simple formula in terms of partial derivatives of the coordinate functions of $\boldsymbol{f}$ (VIII.3.1.10.).

VIII.3.1.6. Since a linear transformation from $\mathbb{R}$ to $\mathbb{R}$ is of the form $T(x) = cx$ for some constant c, we recover the usual one-dimensional definition as modified in VIII.3.1.2., and $df(a)$ is the linear function $df(a)(x) = f'(a)x$ and $Df(a)$ is the 1×1 matrix $[f'(a)]$. So our definitions are (up to rephrasing) consistent.

VIII.3.1.7. Note that the definition of differentiability can be rephrased to require that

$$\lim_{\boldsymbol{h}\to\boldsymbol{0}} \frac{\|\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a}) - T(\boldsymbol{h})\|}{\|\boldsymbol{h}\|} = 0$$

since a limit $\lim_{\boldsymbol{x}\to\boldsymbol{b}} \boldsymbol{g}(\boldsymbol{x}) = \boldsymbol{0}$ of a vector function $\boldsymbol{g}$ holds if and only if $\lim_{\boldsymbol{x}\to\boldsymbol{b}} \|\boldsymbol{g}(\boldsymbol{x})\| = 0$ (). It will sometimes be more convenient to use this version.

VIII.3.1.8. **Remark:** The definition applies equally well to functions between any finite-dimensional vector spaces V and W over $\mathbb{R}$ since it makes no reference to the standard coordinate system in $\mathbb{R}^n$: any norms on V and W can be used, since all such norms are equivalent (). Thus there is a well-defined notion of differentiability for functions between any finite-dimensional vector spaces over $\mathbb{R}$ (finite-dimensionality is essential here! But it does extend to functions between Banach spaces, cf. XXI.1.1.1..)

Uniqueness and a Formula

VIII.3.1.9. Suppose $\boldsymbol{f} : U \subseteq \mathbb{R}^n \to \mathbb{R}^m$ is differentiable at $\boldsymbol{a}$, with a linear transformation T which works in the definition. Fix j, $1 \leq j \leq n$. As a special case of the limit in the definition, we have

$$\lim_{t\to 0} \frac{\boldsymbol{f}(\boldsymbol{a}+t\mathbf{e}_j) - \boldsymbol{f}(\boldsymbol{a}) - T(t\mathbf{e}_j)}{|t|} = \boldsymbol{0} \ .$$

By considering left and right limits, we may eliminate the absolute value from the denominator:

$$\lim_{t\to 0} \frac{\boldsymbol{f}(\boldsymbol{a}+t\mathbf{e}_j) - \boldsymbol{f}(\boldsymbol{a}) - T(t\mathbf{e}_j)}{t} = \boldsymbol{0}$$

$$\lim_{t\to 0} \left[\frac{\boldsymbol{f}(\boldsymbol{a}+t\mathbf{e}_j) - \boldsymbol{f}(\boldsymbol{a})}{t} - T(\mathbf{e}_j) \right] = \boldsymbol{0}$$

$$\lim_{t\to 0} \frac{\boldsymbol{f}(\boldsymbol{a}+t\mathbf{e}_j) - \boldsymbol{f}(\boldsymbol{a})}{t} = T(\mathbf{e}_j) \ .$$

In particular, the limit on the left exists and equals the vector $T(\mathbf{e}_j)$, which is the j'th column of the matrix of T. But the left side is the definition of $\frac{\partial \boldsymbol{f}}{\partial x_j}(\boldsymbol{a})$. So we conclude:

VIII.3.1.10. PROPOSITION. Let $\boldsymbol{f} = (f_1, \ldots, f_m) : U \subseteq \mathbb{R}^n \to \mathbb{R}^m$ be differentiable at $\boldsymbol{a} \in U$. Then

(i) All partial derivatives $\frac{\partial f_i}{\partial x_j}(\boldsymbol{a})$ exist.

(ii) The linear transformation T in the definition of differentiability at $\boldsymbol{a}$ is unique, and the ij'th entry of $[T]$ is $\frac{\partial f_i}{\partial x_j}(\boldsymbol{a})$ for each i and j.

Thus the total differential $d\boldsymbol{f}(\boldsymbol{a})$ and total derivative $D\boldsymbol{f}(\boldsymbol{a})$ are well defined, and

$$D\boldsymbol{f}(\boldsymbol{a}) = \begin{bmatrix} \frac{\partial f_1}{\partial x_1}(\boldsymbol{a}) & \cdots & \frac{\partial f_1}{\partial x_n}(\boldsymbol{a}) \\ \vdots & & \vdots \\ \frac{\partial f_m}{\partial x_1}(\boldsymbol{a}) & \cdots & \frac{\partial f_m}{\partial x_n}(\boldsymbol{a}) \end{bmatrix}.$$

VIII.3.1.11. The matrix

$$\begin{bmatrix} \frac{\partial f_1}{\partial x_1}(\boldsymbol{a}) & \cdots & \frac{\partial f_1}{\partial x_n}(\boldsymbol{a}) \\ \vdots & & \vdots \\ \frac{\partial f_m}{\partial x_1}(\boldsymbol{a}) & \cdots & \frac{\partial f_m}{\partial x_n}(\boldsymbol{a}) \end{bmatrix}$$

is defined whenever all partial derivatives exist at $\boldsymbol{a}$, and existence of this matrix is a necessary condition for differentiability at $\boldsymbol{a}$. But existence of this matrix is not sufficient for differentiability (cf. VIII.3.7.1.–VIII.3.7.4.). This is a major difference between the one-variable case and the multidimensional case. The underlying reason is that one takes a limit as $\boldsymbol{h} \to \boldsymbol{0}$: in the one-dimensional case h can only approach 0 from the right or left, i.e. along the coordinate axis, but in the multidimensional case the approach can be very complicated, and what happens along the coordinate axes does not tell the whole story. Thus it is qualitatively harder for a multivariable function to be differentiable (i.e. for the limit to exist) than it is in the one-dimensional case.

We will not call this matrix the total derivative matrix or use the notation $D\boldsymbol{f}(\boldsymbol{a})$ unless $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$.

VIII.3.1.12. EXAMPLE. Let $T : \mathbb{R}^n \to \mathbb{R}^m$ be linear. If $\boldsymbol{a}$ and $\boldsymbol{h}$ are any vectors in $\mathbb{R}^n$, we have

$$T(\boldsymbol{a} + \boldsymbol{h}) - T(\boldsymbol{a}) - T(\boldsymbol{h}) = \boldsymbol{0}$$

so, fixing $\boldsymbol{a}$, we certainly have

$$\lim_{\boldsymbol{h} \to \boldsymbol{0}} \frac{T(\boldsymbol{a} + \boldsymbol{h}) - T(\boldsymbol{a}) - T(\boldsymbol{h})}{\|\boldsymbol{h}\|} = \boldsymbol{0}$$

and thus T is differentiable at $\boldsymbol{a}$ with $dT(\boldsymbol{a}) = T$ and $DT(\boldsymbol{a}) = [T]$. So linear functions are differentiable everywhere; the differential of a linear function at any point is the function itself, and the total derivative matrix of T at any point is $[T]$ (i.e. "the derivative of a linear function is constant").

Coordinatewise Differentiability

We can examine differentiability coordinatewise in the *range* space:

VIII.3.1.13. PROPOSITION. Let $U \subseteq \mathbb{R}^n$ be open, $\boldsymbol{f} = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$, $\boldsymbol{a} \in U$. Then $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$ if and only if each f_i is differentiable at $\boldsymbol{a}$. In this case, the total differential $d\boldsymbol{f}(\boldsymbol{a})$ has coordinate functions $df_i(\boldsymbol{a})$.

PROOF: This is an immediate consequence of the Coordinatewise Criterion for limits (): if $T = (T_1, \ldots, T_m)$ is linear, then

$$\lim_{\boldsymbol{h} \to \boldsymbol{0}} \frac{\boldsymbol{f}(\boldsymbol{a} + \boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a}) - T(\boldsymbol{h})}{\|\boldsymbol{h}\|} = \boldsymbol{0}$$

if and only if

$$\lim_{\boldsymbol{h} \to \boldsymbol{0}} \frac{f_i(\boldsymbol{a} + \boldsymbol{h}) - f_i(\boldsymbol{a}) - T_i(\boldsymbol{h})}{\|\boldsymbol{h}\|} = 0$$

for $1 \leq i \leq m$. 👍

Differentiability and Continuity

Here is a simple but important observation:

VIII.3.1.14. PROPOSITION. Let $U \subseteq \mathbb{R}^n$ be open, $\boldsymbol{f} : U \to \mathbb{R}^m$, $\boldsymbol{a} \in U$. If $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$, then $\boldsymbol{f}$ is continuous at $\boldsymbol{a}$.

PROOF: From the assumption

$$\lim_{\boldsymbol{h} \to \boldsymbol{0}} \frac{\boldsymbol{f}(\boldsymbol{a} + \boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a}) - d\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{h})}{\|\boldsymbol{h}\|} = \boldsymbol{0}$$

it follows that

$$\lim_{\boldsymbol{h} \to \boldsymbol{0}} [\boldsymbol{f}(\boldsymbol{a} + \boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a}) - d\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{h})] = \boldsymbol{0}$$

and, since linear functions are continuous (), $\lim_{\boldsymbol{h} \to \boldsymbol{0}} d\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{h}) = \boldsymbol{0}$, so $\lim_{\boldsymbol{h} \to \boldsymbol{0}} [\boldsymbol{f}(\boldsymbol{a} + \boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a})] = \boldsymbol{0}$ also. 👍

VIII.3.1.15. Note that this result relies on the continuity of linear functions. This is automatic on finite-dimensional normed spaces, but not infinite-dimensional ones; so continuity is an issue if differentiability of functions between Banach spaces is considered (XXI.1.1.1.).

VIII.3.2. Differentiability of Algebraic Combinations

The sum rule and product rule for ordinary differentiation have exact analogs in the vector case.

VIII.3.2.1. PROPOSITION. [SUM RULE] Let $U \subseteq \mathbb{R}^n$ be open, $\boldsymbol{f}, \boldsymbol{g} : U \to \mathbb{R}^m$, $\boldsymbol{a} \in U$. If $\boldsymbol{f}$ and $\boldsymbol{g}$ are differentiable at $\boldsymbol{a}$, then $\boldsymbol{f} + \boldsymbol{g}$ is differentiable at $\boldsymbol{a}$, and

$$D(\boldsymbol{f} + \boldsymbol{g})(\boldsymbol{a}) = D\boldsymbol{f}(\boldsymbol{a}) + D\boldsymbol{g}(\boldsymbol{a}) \ .$$

PROOF: We have

$$\lim_{\boldsymbol{h}\to\boldsymbol{0}} \frac{[\boldsymbol{f}+\boldsymbol{g}](\boldsymbol{a}+\boldsymbol{h}) - [\boldsymbol{f}+\boldsymbol{g}](\boldsymbol{a}) - [D\boldsymbol{f}(\boldsymbol{a}) + D\boldsymbol{g}(\boldsymbol{a})](\boldsymbol{h})}{\|\boldsymbol{h}\|}$$

$$= \lim_{\boldsymbol{h}\to\boldsymbol{0}} \left[\frac{\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a}) - D\boldsymbol{f}(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} + \frac{\boldsymbol{g}(\boldsymbol{a}+\boldsymbol{h}) - \boldsymbol{g}(\boldsymbol{a}) - D\boldsymbol{g}(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} \right]$$

$$= \lim_{\boldsymbol{h}\to\boldsymbol{0}} \frac{\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a}) - D\boldsymbol{f}(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} + \lim_{\boldsymbol{h}\to\boldsymbol{0}} \frac{\boldsymbol{g}(\boldsymbol{a}+\boldsymbol{h}) - \boldsymbol{g}(\boldsymbol{a}) - D\boldsymbol{g}(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} = \boldsymbol{0} + \boldsymbol{0} = \boldsymbol{0} \ .$$

Since products of vectors are not defined, the product rule only makes sense for real-valued functions:

VIII.3.2.2. THEOREM. [PRODUCT RULE] Let $U \subseteq \mathbb{R}^n$ be open, $f, g : U \to \mathbb{R}$, $\boldsymbol{a} \in U$. If f and g are differentiable at $\boldsymbol{a}$, then fg is differentiable at $\boldsymbol{a}$, and

$$D(fg)(\boldsymbol{a}) = f(\boldsymbol{a})D\boldsymbol{g}(\boldsymbol{a}) + g(\boldsymbol{a})D\boldsymbol{f}(\boldsymbol{a}) \ .$$

PROOF: We have

$$\lim_{\boldsymbol{h}\to\boldsymbol{0}} \frac{f(\boldsymbol{a}+\boldsymbol{h})g(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a})g(\boldsymbol{a}) - [f(\boldsymbol{a})Dg(\boldsymbol{a}) + g(\boldsymbol{a})Df(\boldsymbol{a})]\boldsymbol{h}}{\|\boldsymbol{h}\|}$$

$$= \lim_{\boldsymbol{h}\to\boldsymbol{0}} \frac{[f(\boldsymbol{a}+\boldsymbol{h})g(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a}+\boldsymbol{h})g(\boldsymbol{a})] + [f(\boldsymbol{a}+\boldsymbol{h})g(\boldsymbol{a}) - f(\boldsymbol{a})g(\boldsymbol{a})] - [f(\boldsymbol{a})Dg(\boldsymbol{a}) + g(\boldsymbol{a})Df(\boldsymbol{a})]\boldsymbol{h}}{\|\boldsymbol{h}\|}$$

$$= \lim_{\boldsymbol{h}\to\boldsymbol{0}} \left[f(\boldsymbol{a}+\boldsymbol{h}) \frac{g(\boldsymbol{a}+\boldsymbol{h}) - g(\boldsymbol{a}) - Dg(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} + [f(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a})] \frac{Dg(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} + g(\boldsymbol{a}) \frac{f(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a}) - Df(\boldsymbol{a})]\boldsymbol{h}}{\|\boldsymbol{h}\|} \right]$$

$$= \left[\lim_{\boldsymbol{h}\to\boldsymbol{0}} f(\boldsymbol{a}+\boldsymbol{h}) \right] \left[\lim_{\boldsymbol{h}\to\boldsymbol{0}} \frac{g(\boldsymbol{a}+\boldsymbol{h}) - g(\boldsymbol{a}) - Dg(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} \right] + \lim_{\boldsymbol{h}\to\boldsymbol{0}} \left[[f(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a})] \frac{Dg(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} \right]$$

$$+ g(\boldsymbol{a}) \left[\lim_{\boldsymbol{h}\to\boldsymbol{0}} \frac{f(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a}) - Df(\boldsymbol{a})]\boldsymbol{h}}{\|\boldsymbol{h}\|} \right]$$

by () and () since the four limits exist: the second and fourth exist and are 0 by hypothesis, and since f is differentiable, hence continuous, at $\boldsymbol{a}$, the first limit is $f(\boldsymbol{a})$. For the third limit, note that, for any $\boldsymbol{h} \neq \boldsymbol{0}$,

$$\left| [f(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a})] \frac{Dg(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} \right| \leq \|Dg(\boldsymbol{a})\| |f(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a})|$$

and $\lim_{\boldsymbol{h}\to\boldsymbol{0}} [f(\boldsymbol{a}+\boldsymbol{h}) - f(\boldsymbol{a})] = 0$ since f is continuous at $\boldsymbol{a}$. Thus the third limit exists and is 0. So the overall limit is $f(\boldsymbol{a}) \cdot 0 + 0 + g(\boldsymbol{a}) \cdot 0 = 0$.

VIII.3.2.3. There is a version of the product rule for vector-valued functions using the dot product. The proof is essentially immediate from the two previous results; the only trick is to find the formula with suitable notation.

If $\boldsymbol{f}, \boldsymbol{g} : \mathbb{R}^n \to \mathbb{R}^m$, then we may form $h = \boldsymbol{f} \cdot \boldsymbol{g}$; then $h : \mathbb{R}^n \to \mathbb{R}$. For $\boldsymbol{a} \in \mathbb{R}^n$, we have that $D\boldsymbol{f}(\boldsymbol{a})$ and $D\boldsymbol{g}(\boldsymbol{a})$ are $m \times n$ and $Dh(\boldsymbol{a})$ is $1 \times n$. To get the useful formula, we can regard $\boldsymbol{f}(\boldsymbol{a})$ and $\boldsymbol{g}(\boldsymbol{a})$, which are vectors in $\mathbb{R}^m$, as row vectors, i.e. $1 \times m$ matrices. Then $\boldsymbol{f}(\boldsymbol{a})D\boldsymbol{g}(\boldsymbol{a})$ and $\boldsymbol{g}(\boldsymbol{a})D\boldsymbol{f}(\boldsymbol{a})$ are defined and are $1 \times n$, the right size for $Dh(\boldsymbol{a})$. We have:

VIII.3.2.4. Proposition. [Dot Product Rule] Let $U \subseteq \mathbb{R}^n$ be open, $\boldsymbol{f}, \boldsymbol{g} : U \to \mathbb{R}^m$, $\boldsymbol{a} \in U$, $h = \boldsymbol{f} \cdot \boldsymbol{g} : U \to \mathbb{R}$. If $\boldsymbol{f}$ and $\boldsymbol{g}$ are differentiable at $\boldsymbol{a}$, then h is differentiable at $\boldsymbol{a}$, and

$$Dh(\boldsymbol{a}) = \boldsymbol{f}(\boldsymbol{a})D\boldsymbol{g}(\boldsymbol{a}) + \boldsymbol{g}(\boldsymbol{a})D\boldsymbol{f}(\boldsymbol{a}) \ .$$

Proof: If $\boldsymbol{f} = (f_1, \ldots, f_m)$ and $\boldsymbol{g} = (g_1, \ldots, g_m)$, then $h = f_1 g_1 + \cdots + f_m g_m$, so h is differentiable at $\boldsymbol{a}$ and

$$Dh(\boldsymbol{a}) = \sum_{k=1}^{m} [f_k(\boldsymbol{a})Dg_k(\boldsymbol{a}) + g_k(\boldsymbol{a})Df_k(\boldsymbol{a})] \ .$$

A simple calculation shows that this equals $\boldsymbol{f}(\boldsymbol{a})D\boldsymbol{g}(\boldsymbol{a}) + \boldsymbol{g}(\boldsymbol{a})D\boldsymbol{f}(\boldsymbol{a})$. 👍

VIII.3.3. A Criterion for Differentiability

For a function of one variable, differentiability and existence of the derivative are the same thing by definition. But for a function of more than one variable, existence of all first-order partials is not sufficient to insure differentiability, or even continuity; cf. VIII.3.7.1.–VIII.3.7.4.. However, it is rather remarkable that continuity of first-order partials is sufficient:

VIII.3.3.1. Theorem. Let U be an open subset of $\mathbb{R}^n$, and $\boldsymbol{f} = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$. If all partial derivatives $\frac{\partial f_i}{\partial x_j}$ exist on U and are continuous at $\boldsymbol{a} \in U$, then $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$.

Proof: First note that by VIII.3.1.13. it suffices to assume $m = 1$, i.e. $f : U \to \mathbb{R}$ and $\frac{\partial f}{\partial x_j}$ exists on U and is continuous at $\boldsymbol{a}$ for each j.

We prove the result by induction on n. If $n = 1$, the statement is a tautology (and the hypotheses are even unnecessarily strong!) Now assume the statement is true for n, and let U be an open set in $\mathbb{R}^{n+1}$ and $f : U \to \mathbb{R}$ with $\frac{\partial f}{\partial x_j}$ defined on U and continuous at $\boldsymbol{c} = (\boldsymbol{a}, b) \in U$ for $1 \leq j \leq n+1$. We need to show that f is differentiable at $\boldsymbol{c}$. Set

$$V = \{\boldsymbol{x} \in \mathbb{R}^n : (\boldsymbol{x}, b) \in U\} \ .$$

Then V is an open set in $\mathbb{R}^n$ and $\boldsymbol{a} \in V$. Define $g : V \to \mathbb{R}$ by $g(\boldsymbol{x}) = f(\boldsymbol{x}, b)$. For $1 \leq j \leq n$, we have $\frac{\partial g}{\partial x_j}(\boldsymbol{x}) = \frac{\partial f}{\partial x_j}(\boldsymbol{x}, b)$, so for $1 \leq j \leq n$ $\frac{\partial g}{\partial x_k}$ is defined on V and continuous at $\boldsymbol{a}$. Thus g is differentiable at $\boldsymbol{a}$ by the inductive hypothesis, i.e.

$$\lim_{\boldsymbol{h} \to \boldsymbol{0}} \frac{g(\boldsymbol{a} + \boldsymbol{h}) - g(\boldsymbol{a}) - Dg(\boldsymbol{h})}{\|\boldsymbol{h}\|} = 0$$

$$\lim_{\boldsymbol{h}\to\boldsymbol{0}} \frac{f(\boldsymbol{a}+\boldsymbol{h},b)-f(\boldsymbol{a},b)-\sum_{j=1}^{n}\frac{\partial f}{\partial x_j}(\boldsymbol{a},b)h_j}{\|\boldsymbol{h}\|}=0\ .$$

If $\boldsymbol{h}\in\mathbb{R}^n$, $k\in\mathbb{R}$, write $(\boldsymbol{h},k)\in\mathbb{R}^{n+1}$. Since $\|\boldsymbol{h}\|\le\|(\boldsymbol{h},k)\|$ for any k, we also have

$$\lim_{(\boldsymbol{h},k)\to(\boldsymbol{0},0)} \frac{f(\boldsymbol{a}+\boldsymbol{h},b)-f(\boldsymbol{a},b)-\sum_{j=1}^{n}\frac{\partial f}{\partial x_j}(\boldsymbol{a},b)h_j}{\|(\boldsymbol{h},k)\|}=0\ . \tag{VIII.1}$$

If $\boldsymbol{h}$ and k are small, by the Mean Value Theorem there is a $d_{\boldsymbol{h},k}$ between b and $b+k$ such that

$$f(\boldsymbol{a}+\boldsymbol{h},b+k)-f(\boldsymbol{a}+\boldsymbol{h},b)=\frac{\partial f}{\partial x_{n+1}}(\boldsymbol{a}+\boldsymbol{h},d_{\boldsymbol{h},k})k\ .$$

Now

$$\begin{aligned}
&\lim_{(\boldsymbol{h},k)\to(\boldsymbol{0},0)} \frac{f(\boldsymbol{a}+\boldsymbol{h},b+k)-f(\boldsymbol{a},b)-\sum_{j=1}^{n}\frac{\partial f}{\partial x_j}(\boldsymbol{a},b)h_j-\frac{\partial f}{\partial x_{n+1}}(\boldsymbol{a},b)k}{\|(\boldsymbol{h},k)\|}\\
&=\lim_{(\boldsymbol{h},k)\to(\boldsymbol{0},0)} \frac{f(\boldsymbol{a}+\boldsymbol{h},b)-f(\boldsymbol{a},b)+f(\boldsymbol{a}+\boldsymbol{h},b+k)-f(\boldsymbol{a}+\boldsymbol{h},b)-\sum_{j=1}^{n}\frac{\partial f}{\partial x_j}(\boldsymbol{a},b)h_j-\frac{\partial f}{\partial x_{n+1}}(\boldsymbol{a},b)k}{\|(\boldsymbol{h},k)\|}\\
&=\lim_{(\boldsymbol{h},k)\to(\boldsymbol{0},0)} \left[\frac{f(\boldsymbol{a}+\boldsymbol{h},b)-f(\boldsymbol{a},b)-\sum_{j=1}^{n}\frac{\partial f}{\partial x_j}(\boldsymbol{a},b)h_j}{\|(\boldsymbol{h},k)\|}+\frac{f(\boldsymbol{a}+\boldsymbol{h},b+k)-f(\boldsymbol{a}+\boldsymbol{h},b)-\frac{\partial f}{\partial x_{n+1}}(\boldsymbol{a},b)k}{\|(\boldsymbol{h},k)\|}\right]\\
&=\lim_{(\boldsymbol{h},k)\to(\boldsymbol{0},0)} \left[\frac{f(\boldsymbol{a}+\boldsymbol{h},b)-f(\boldsymbol{a},b)-\sum_{j=1}^{n}\frac{\partial f}{\partial x_j}(\boldsymbol{a},b)h_j}{\|(\boldsymbol{h},k)\|}+\frac{\left(\frac{\partial f}{\partial x_{n+1}}(\boldsymbol{a}+\boldsymbol{h},d_{\boldsymbol{h},k})-\frac{\partial f}{\partial x_{n+1}}(\boldsymbol{a},b)\right)k}{\|(\boldsymbol{h},k)\|}\right]\ .
\end{aligned}$$

The limit of the first term is 0 by VIII.1, and the limit of the second term is also 0 by continuity of $\frac{\partial f}{\partial x_{n+1}}$ at $\boldsymbol{c}$ (using $|k|\le\|(\boldsymbol{h},k)\|$). Thus f is differentiable at $\boldsymbol{c}$.

VIII.3.3.2. Remark. Examining the proof carefully, we do not need all the partial derivatives to be continuous at $\boldsymbol{a}$: the partial with respect to one variable can be discontinuous. In fact, the proof shows that if, for some r, the restriction of $\boldsymbol{f}$ to an r-dimensional coordinate subspace is differentiable at $\boldsymbol{a}$, and the additional partial derivatives are continuous at $\boldsymbol{a}$, then $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$; cf. Exercise VIII.3.7.9..

VIII.3.3.3. The hypotheses of the theorem give *sufficient* conditions for $\boldsymbol{f}$ to be differentiable at $\boldsymbol{a}$. But these conditions are not necessary: cf. V.3.1.15., V.12.1., VIII.3.7.6.–VIII.3.7.7.. The main significance of the theorem is that the continuity conditions are often satisfied and easy to check in cases of interest, and the theorem is frequently by far the easiest way to establish differentiability.

The next special case of VIII.3.3.1. is the most important and commonly used one. We first make a definition:

VIII.3.3.4. DEFINITION. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f} : U \to \mathbb{R}^m$ a function. If $r \in \mathbb{N}$, then $\boldsymbol{f}$ is a $\mathcal{C}^r$ function if $\boldsymbol{f}$ and all its partial derivatives of order $\leq r$ exist and are continuous on U.

If $n = 1$, this definition agrees with the definition in (); and the agreement goes deeper (VIII.4.1.5.). We extend the notation to say that $\boldsymbol{f}$ is $\mathcal{C}^0$ on U if it is continuous on U, and $\mathcal{C}^\infty$ on U if it is $\mathcal{C}^r$ on U for all r, i.e. all partials of $\boldsymbol{f}$ of all orders exist and are continuous on U.

The continuity condition in the definition of $\mathcal{C}^\infty$ is necessary and not automatic (VIII.3.7.8.). ✋

VIII.3.3.5. COROLLARY. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f} : U \to \mathbb{R}^m$ a $\mathcal{C}^1$ function. Then $\boldsymbol{f}$ is differentiable at all points of U.

VIII.3.3.6. COROLLARY. Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{f} : U \to \mathbb{R}^m$. If $r \in \mathbb{N}$, suppose all partial derivatives of $\boldsymbol{f}$ of order r are continuous on U. Then $\boldsymbol{f}$ itself and all partial derivatives of $\boldsymbol{f}$ of order $< r$ are differentiable on U, hence *a fortiori* continuous on U. In particular, $\boldsymbol{f}$ is $\mathcal{C}^r$ on U.

PROOF: Working backwards, any partial derivative of $\boldsymbol{f}$ of order $r-1$ has continuous first-order partials on U, hence is differentiable (thus continuous) on U. The same is then true of the partials of $\boldsymbol{f}$ of order $r-2$, etc. 👍

VIII.3.4. The Chain Rule

VIII.3.4.1. The Chain Rule concerns differentiability and the derivative of a composition of functions. Two previous results suggest that the derivative of a composition of two functions should be the product of the derivatives:

(i) If $f, g : \mathbb{R} \to \mathbb{R}$ and $a \in \mathbb{R}$, then $(g \circ f)'(a) = g'(f(a))f'(a)$ (cf. V.3.4.3.).

(ii) If $S : \mathbb{R}^n \to \mathbb{R}^m$ and $T : \mathbb{R}^m \to \mathbb{R}^p$ are linear, then $T \circ S : \mathbb{R}^n \to \mathbb{R}^p$ is linear and $[T \circ S] = [T][S]$ ().

The Chain Rule of vector calculus generalizes these two facts. Note that, as always, the Chain Rule is a theorem, not a formula: it has hypotheses (that $\boldsymbol{f}$ and $\boldsymbol{g}$ are differentiable) and a conclusion with a theoretical part (that $\boldsymbol{g} \circ \boldsymbol{f}$ is differentiable) as well as a formula for the total derivative of $\boldsymbol{g} \circ \boldsymbol{f}$.

The Chain Rule is a prime example of the utility of vector calculus notation. The corresponding statement written in coordinates is unwieldy, although this form is often needed in applications.

VIII.3.4.2. THEOREM. [CHAIN RULE] Let U and V be open sets in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, $\boldsymbol{f} : U \to \mathbb{R}^m$ and $\boldsymbol{g} : V \to \mathbb{R}^p$ with $\boldsymbol{f}(U) \subseteq V$, $\boldsymbol{a} \in U$, $\boldsymbol{b} = \boldsymbol{f}(\boldsymbol{a}) \in V$. If $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$ and $\boldsymbol{g}$ is differentiable at $\boldsymbol{b}$, then $\boldsymbol{g} \circ \boldsymbol{f}$ is differentiable at $\boldsymbol{a}$ and

$$D(\boldsymbol{g} \circ \boldsymbol{f})(\boldsymbol{a}) = D\boldsymbol{g}(\boldsymbol{b})D\boldsymbol{f}(\boldsymbol{a}) = D\boldsymbol{g}(\boldsymbol{f}(\boldsymbol{a}))D\boldsymbol{f}(\boldsymbol{a}) \ .$$

Note that under the hypotheses, $D\boldsymbol{g}(\boldsymbol{b})$ is $p \times m$, $D\boldsymbol{f}(\boldsymbol{a})$ is $m \times n$, and $D(\boldsymbol{g} \circ \boldsymbol{f})(\boldsymbol{a})$ is $p \times n$, so the product of the matrices on the right is defined and is the same size as the matrix on the left (this is of course not a proof of the theorem, only an indication that the statement makes sense!)

It is easily seen that the two examples in VIII.3.4.1. are special cases of this result (cf. VIII.3.1.12.).

PROOF: The proof is largely a matter of choosing good notation, which can be a little complicated to keep straight.

For $\boldsymbol{h}$ in a neighborhood of $\mathbf{0}$ in $\mathbb{R}^n$, set

$$\phi(\boldsymbol{h}) = \boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a}) - D\boldsymbol{f}(\boldsymbol{a})\boldsymbol{h}$$

so we have

$$\lim_{\boldsymbol{h}\to\mathbf{0}} \frac{\phi(\boldsymbol{h})}{\|\boldsymbol{h}\|} = \lim_{\boldsymbol{h}\to\mathbf{0}} \frac{\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a}) - D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{h})}{\|\boldsymbol{h}\|} = \mathbf{0} \ .$$

Similarly, for $\boldsymbol{k}$ in a neighborhood of $\mathbf{0}$ in $\mathbb{R}^m$, set

$$\psi(\boldsymbol{k}) = \boldsymbol{g}(\boldsymbol{b}+\boldsymbol{k}) - \boldsymbol{g}(\boldsymbol{b}) - D\boldsymbol{g}(\boldsymbol{b})\boldsymbol{k}$$

so we have

$$\lim_{\boldsymbol{k}\to\mathbf{0}} \frac{\psi(\boldsymbol{k})}{\|\boldsymbol{k}\|} = \lim_{\boldsymbol{k}\to\mathbf{0}} \frac{\boldsymbol{g}(\boldsymbol{b}+\boldsymbol{k}) - \boldsymbol{g}(\boldsymbol{b}) - D\boldsymbol{g}(\boldsymbol{b})(\boldsymbol{k})}{\|\boldsymbol{h}\|} = \mathbf{0} \ .$$

Set $\omega(\boldsymbol{k}) = \frac{\psi(\boldsymbol{k})}{\|\boldsymbol{k}\|}$ for $\boldsymbol{k} \neq \mathbf{0}$ and $\omega(\mathbf{0}) = \mathbf{0}$. Then ω is continuous at $\mathbf{0}$.

If $\boldsymbol{h}$ is sufficiently close to $\mathbf{0}$, then $\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h})$ is defined; and if we set

$$\boldsymbol{k} = \boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a}) = D\boldsymbol{f}(\boldsymbol{a})\boldsymbol{h} + \phi(\boldsymbol{h})$$

we have that $\boldsymbol{k} \to \mathbf{0}$ as $\boldsymbol{h} \to \mathbf{0}$ since $\boldsymbol{f}$ is continuous at $\boldsymbol{a}$, and

$$\boldsymbol{g}(\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h})) - \boldsymbol{g}(\boldsymbol{f}(\boldsymbol{a})) = \boldsymbol{g}(\boldsymbol{b}+\boldsymbol{k}) - \boldsymbol{g}(\boldsymbol{b}) = D\boldsymbol{g}(\boldsymbol{b})\boldsymbol{k} + \psi(\boldsymbol{k})$$

$$= D\boldsymbol{g}(\boldsymbol{b})[D\boldsymbol{f}(\boldsymbol{a})\boldsymbol{h} + \phi(\boldsymbol{h})] + \psi(\boldsymbol{k}) = D\boldsymbol{g}(\boldsymbol{b})D\boldsymbol{f}(\boldsymbol{a})\boldsymbol{h} + D\boldsymbol{g}(\boldsymbol{b})\phi(\boldsymbol{h}) + \psi(\boldsymbol{k})$$

so we have

$$\frac{\boldsymbol{g}(\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h})) - \boldsymbol{g}(\boldsymbol{f}(\boldsymbol{a})) - D\boldsymbol{g}(\boldsymbol{b})D\boldsymbol{f}(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} = \frac{D\boldsymbol{g}(\boldsymbol{b})\phi(\boldsymbol{h})}{\|\boldsymbol{h}\|} + \frac{\psi(\boldsymbol{k})}{\|\boldsymbol{h}\|} \ .$$

Since $\|D\boldsymbol{g}(\boldsymbol{b})\phi(\boldsymbol{h})\| \leq \|D\boldsymbol{g}(\boldsymbol{b})\|\|\phi(\boldsymbol{h})\|$ and $\lim_{\boldsymbol{h}\to\mathbf{0}} \frac{\phi(\boldsymbol{h})}{\|\boldsymbol{h}\|} = \mathbf{0}$, the first term has limit $\mathbf{0}$. We show the second term also has limit $\mathbf{0}$. We have

$$\|\boldsymbol{k}\| = \|\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h}) - \boldsymbol{f}(\boldsymbol{a})\| = \|D\boldsymbol{f}(\boldsymbol{a})\boldsymbol{h} + \phi(\boldsymbol{h})\| \leq \|D\boldsymbol{f}(\boldsymbol{a})\|\|\boldsymbol{h}\| + \|\phi(\boldsymbol{h})\|$$

$$\frac{\|\boldsymbol{k}\|}{\|\boldsymbol{h}\|} \leq \|D\boldsymbol{f}(\boldsymbol{a})\| + \frac{\|\phi(\boldsymbol{h})\|}{\|\boldsymbol{h}\|}$$

and since the second term goes to 0 as $\boldsymbol{h} \to \mathbf{0}$, it is bounded in a neighborhood of $\mathbf{0}$. Thus

$$\lim_{\boldsymbol{h}\to\mathbf{0}} \frac{\psi(\boldsymbol{k})}{\|\boldsymbol{h}\|} = \lim_{\boldsymbol{h}\to\mathbf{0}} \frac{\|\boldsymbol{k}\|}{\|\boldsymbol{h}\|}\omega(\boldsymbol{k}) = \mathbf{0}$$

since the first factor is bounded and the second factor tends to $\mathbf{0}$. Thus

$$\lim_{\boldsymbol{h}\to\mathbf{0}} \frac{\boldsymbol{g}(\boldsymbol{f}(\boldsymbol{a}+\boldsymbol{h})) - \boldsymbol{g}(\boldsymbol{f}(\boldsymbol{a})) - D\boldsymbol{g}(\boldsymbol{b})D\boldsymbol{f}(\boldsymbol{a})\boldsymbol{h}}{\|\boldsymbol{h}\|} = \mathbf{0} \ .$$

The Chain Rule in Coordinates

Writing the Chain Rule in coordinate form is more complicated and less clean than the vector-matrix form, but is usually necessary in practice. Rather than writing the general version, we will write it out in the typical notation and careful, correct form in the case $n = 3$, $m = 4$, $p = 2$.

VIII.3.4.3. We consider the case where u and v are functions of x, y, z, w, which are themselves functions of r, s, t. Specifically,

$$u = g_1(x, y, z, w)$$
$$v = g_2(x, y, z, w)$$
$$x = f_1(r, s, t)$$
$$y = f_2(r, s, t)$$
$$z = f_3(r, s, t)$$
$$w = f_4(r, s, t)$$

So, in vector notation, we have

$$(u, v) = \boldsymbol{g}(x, y, z, w)$$
$$(x, y, z, w) = \boldsymbol{f}(r, s, t)$$

where $\boldsymbol{f} = (f_1, f_2, f_3, f_4) : \mathbb{R}^3 \to \mathbb{R}^4$ and $\boldsymbol{g} = (g_1, g_2) : \mathbb{R}^4 \to \mathbb{R}^2$. So indirectly we have

$$u = h_1(r, s, t) = g_1(f_1(r, s, t), f_2(r, s, t), f_3(r, s, t), f_4(r, s, t))$$
$$v = h_2(r, s, t) = g_2(f_1(r, s, t), f_2(r, s, t), f_3(r, s, t), f_4(r, s, t))$$

where $\boldsymbol{h} = (h_1, h_2) = \boldsymbol{g} \circ \boldsymbol{f} : \mathbb{R}^3 \to \mathbb{R}^2$.

VIII.3.4.4. We suppose $\boldsymbol{f}$ is defined in a neighborhood of $\boldsymbol{a} = (r_0, s_0, t_0)$ and differentiable at (r_0, s_0, t_0), and that $\boldsymbol{g}$ is defined in a neighborhood of $\boldsymbol{b} = \boldsymbol{f}(\boldsymbol{a}) = (x_0, y_0, z_0, w_0)$ and differentiable at (x_0, y_0, z_0, w_0), where

$$x_0 = f_1(r_0, s_0, t_0)$$
$$y_0 = f_2(r_0, s_0, t_0)$$
$$z_0 = f_3(r_0, s_0, t_0)$$
$$w_0 = f_4(r_0, s_0, t_0)$$

(note that the subscript 0 denotes a particular point, while the subscripts 1, 2, 3, 4 denote coordinate functions; we use the subscript 0 instead of distinct letters so we don't run out of letters). To avoid impossibly complicated formulas which will not fit on the page, we write as abbreviations

$$\frac{\partial u}{\partial x} := \frac{\partial g_1}{\partial x}(x_0, y_0, z_0, w_0) = \frac{\partial g_1}{\partial x}(f_1(r_0, s_0, t_0), f_2(r_0, s_0, t_0), f_3(r_0, s_0, t_0), f_4(r_0, s_0, t_0))$$
$$\frac{\partial v}{\partial z} := \frac{\partial g_2}{\partial z}(x_0, y_0, z_0, w_0) = \frac{\partial g_2}{\partial z}(f_1(r_0, s_0, t_0), f_2(r_0, s_0, t_0), f_3(r_0, s_0, t_0), f_4(r_0, s_0, t_0))$$

and similarly for $\frac{\partial u}{\partial y}$, $\frac{\partial v}{\partial x}$, etc. Thus $\frac{\partial u}{\partial x}$, etc., denote particular numbers.

Similarly, write

$$\frac{\partial x}{\partial r} := \frac{\partial f_1}{\partial r}(r_0, s_0, t_0)$$
$$\frac{\partial w}{\partial s} := \frac{\partial f_4}{\partial s}(r_0, s_0, t_0)$$

and similarly for $\frac{\partial z}{\partial r}$, etc.

Finally, write

$$\frac{\partial u}{\partial r} := \frac{\partial h_1}{\partial r}(r_0, s_0, t_0)$$
$$\frac{\partial v}{\partial t} := \frac{\partial h_2}{\partial t}(r_0, s_0, t_0)$$

and similarly for $\frac{\partial u}{\partial s}$, etc.

VIII.3.4.5. The Chain Rule then says that $\boldsymbol{h}$ is differentiable at (r_0, s_0, t_0), and

$$D\boldsymbol{h}(r_0, s_0, t_0) = D\boldsymbol{g}(x_0, y_0, z_0, w_0) D\boldsymbol{f}(r_0, s_0, t_0)$$

$$= \begin{bmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} & \frac{\partial u}{\partial z} & \frac{\partial u}{\partial w} \\ \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} & \frac{\partial v}{\partial z} & \frac{\partial v}{\partial w} \end{bmatrix} \begin{bmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial s} & \frac{\partial x}{\partial t} \\ \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial s} & \frac{\partial y}{\partial t} \\ \\ \frac{\partial z}{\partial r} & \frac{\partial z}{\partial s} & \frac{\partial z}{\partial t} \\ \\ \frac{\partial w}{\partial r} & \frac{\partial w}{\partial s} & \frac{\partial w}{\partial t} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{\partial u}{\partial x}\frac{\partial x}{\partial r} + \frac{\partial u}{\partial y}\frac{\partial y}{\partial r} + \frac{\partial u}{\partial z}\frac{\partial z}{\partial r} + \frac{\partial u}{\partial w}\frac{\partial w}{\partial r} & \cdots \\ \vdots & \ddots \end{bmatrix}$$

$$= \begin{bmatrix} \frac{\partial u}{\partial r} & \frac{\partial u}{\partial s} & \frac{\partial u}{\partial t} \\ \\ \frac{\partial v}{\partial r} & \frac{\partial v}{\partial s} & \frac{\partial v}{\partial t} \end{bmatrix}$$

so we obtain formulas like

$$\frac{\partial v}{\partial s} = \frac{\partial v}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial v}{\partial y}\frac{\partial y}{\partial s} + \frac{\partial v}{\partial z}\frac{\partial z}{\partial s} + \frac{\partial v}{\partial w}\frac{\partial w}{\partial s}$$

and similarly for the other five entries. The masochistic reader should write out the careful version of this formula replacing the symbols $\frac{\partial u}{\partial x}$, etc., by their proper definitions, and all readers should note that there is a fundamental difference between expressions like $\frac{\partial u}{\partial r}$ and expressions like $\frac{\partial u}{\partial x}$ which is obscured by the abbreviated notation (cf. VIII.2.1.4.).

VIII.3.5. The Gradient and Tangent Planes

For a real-valued differentiable function f on a region in $\mathbb{R}^n$, there is an alternate representation or interpretation of the total derivative Df which has a nice geometric interpretation.

VIII.3.5.1. If $U \subseteq \mathbb{R}^n$, $\boldsymbol{a} \in U$, and $f : U \to \mathbb{R}$ is differentiable at $\boldsymbol{a}$, then $Df(\boldsymbol{a})$ is a $1 \times n$ matrix:

$$Df(\boldsymbol{a}) = \left[\begin{array}{cccc} \frac{\partial f}{\partial x_1}(\boldsymbol{a}) & \frac{\partial f}{\partial x_2}(\boldsymbol{a}) & \cdots & \frac{\partial f}{\partial x_n}(\boldsymbol{a}) \end{array} \right] .$$

A $1 \times n$ matrix can be interpreted as a row vector in $\mathbb{R}^n$, and thus $Df(\boldsymbol{a})$ can be alternately interpreted as a vector in $\mathbb{R}^n$. When it is, it is given a different name to emphasize the change of point of view:

VIII.3.5.2. Definition. Let $U \subseteq \mathbb{R}^n$, $\boldsymbol{a} \in U$, and $f : U \to \mathbb{R}$ a real-valued function. If f is differentiable at $\boldsymbol{a}$, the *gradient* of f at $\boldsymbol{a}$ is the vector $\nabla f(\boldsymbol{a})$ in $\mathbb{R}^n$ defined by

$$\nabla f(\boldsymbol{a}) = \left(\frac{\partial f}{\partial x_1}(\boldsymbol{a}), \frac{\partial f}{\partial x_2}(\boldsymbol{a}), \cdots, \frac{\partial f}{\partial x_n}(\boldsymbol{a}) \right) .$$

Note that, as usual, ∇f is regarded as a single symbol. Some references use the alternate notation $Grad(f)$.

VIII.3.5.3. Just as the total derivative matrix of a function at $\boldsymbol{a}$ is technically defined when all first-order partials exist at $\boldsymbol{a}$, even if the function is not differentiable at $\boldsymbol{a}$, the formula for the gradient makes sense if all first-order partials are just defined at $\boldsymbol{a}$. But just as we only use the notation $D\boldsymbol{f}(\boldsymbol{a})$ if $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$, we only use the notation $\nabla f(\boldsymbol{a})$ and say the gradient exists at $\boldsymbol{a}$ if f is actually differentiable at $\boldsymbol{a}$ (e.g. if all first-order partials of f are continuous at $\boldsymbol{a}$).

Directional Derivatives Revisited

If $f : U \to \mathbb{R}$ is differentiable at $\boldsymbol{a} \in U \subseteq \mathbb{R}^n$, then the directional derivatives can be easily calculated using the gradient. Let $\boldsymbol{u}$ be a nonzero vector in $\mathbb{R}^n$, and define $\gamma : \mathbb{R} \to \mathbb{R}^n$ by

$$\gamma(t) = \boldsymbol{a} + t\boldsymbol{u} .$$

Then $\gamma'(0) = \boldsymbol{u}$, or in matrix terms $D\gamma(0)$ is the $n \times 1$ matrix $\boldsymbol{u}$, regarded as a column vector. Set $\phi(t) = f(\gamma(t))$. If U is open, then ϕ is defined in an interval around 0, and by definition we have

$$\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{a}) = \phi'(0)$$

and by the Chain Rule we have

$$\phi'(0) = D\phi(0) = Df(\gamma(0))\gamma'(0) = Df(\boldsymbol{a})\boldsymbol{u}$$

where $\boldsymbol{u}$ is regarded as an $n \times 1$ matrix (column vector). However, observe that the scalar $Df(\boldsymbol{a})\boldsymbol{u}$ is exactly the dot product $\nabla f(\boldsymbol{a}) \cdot \boldsymbol{u}$ (). Thus we conclude:

VIII.3.5.4. PROPOSITION. Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{a} \in U$, and $f : U \to \mathbb{R}$ a real-valued function. If f is differentiable at $\boldsymbol{a}$, then for any nonzero vector $\boldsymbol{u} \in \mathbb{R}^n$, the directional derivative of f at $\boldsymbol{a}$ with respect to $\boldsymbol{u}$ is defined and

$$\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{a}) = \nabla f(\boldsymbol{a}) \cdot \boldsymbol{u} \ .$$

VIII.3.5.5. This simple relationship does not necessarily hold if f is not differentiable at $\boldsymbol{a}$, even if all directional derivatives (and in particular all first-order partials) of f exist at $\boldsymbol{a}$. For example, if $f : \mathbb{R}^2 \to \mathbb{R}$ is the function of VIII.3.7.5., then $\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{0})$ exists for all $\boldsymbol{u}$. But $\frac{\partial f}{\partial x}(\boldsymbol{0}) = \frac{\partial f}{\partial y}(\boldsymbol{0}) = 0$, so "$\nabla f(\boldsymbol{0})$" is $\boldsymbol{0}$, although $\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{0}) \neq 0$ for some $\boldsymbol{u}$'s. This shows again that f cannot be differentiable at $\boldsymbol{0}$ (and, in particular, $\nabla f(\boldsymbol{0})$ is actually undefined).

Geometric Interpretation of the Gradient

Returning to the case where f is differentiable at $\boldsymbol{a}$, we can interpret VIII.3.5.4. geometrically:

VIII.3.5.6. COROLLARY. Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{a} \in U$, and $f : U \to \mathbb{R}$ a real-valued function. If f is differentiable at $\boldsymbol{a}$ and $\nabla f(\boldsymbol{a}) \neq \boldsymbol{0}$, then for any unit vector $\boldsymbol{u} \in \mathbb{R}^n$, the directional derivative of f at $\boldsymbol{a}$ in the direction $\boldsymbol{u}$ is defined and

$$\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{a}) = \|\nabla f(\boldsymbol{a})\| \cos\theta$$

where θ is the angle between $\nabla f(\boldsymbol{a})$ and $\boldsymbol{u}$.

The conclusion also holds if $\nabla f(\boldsymbol{a}) = \boldsymbol{0}$ (although θ is not defined): then $\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{a}) = 0$ for any $\boldsymbol{u}$.

VIII.3.5.7. Thus $\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{a})$ is maximum when $\theta = 0$, i.e. if and only if $\boldsymbol{u}$ is a unit vector in the direction of $\nabla f(\boldsymbol{a})$ (in the case $\nabla f(\boldsymbol{a}) \neq \boldsymbol{0}$). So if $\nabla f(\boldsymbol{a}) \neq \boldsymbol{0}$, it points in the direction of greatest increase of f at $\boldsymbol{a}$, and the length of the gradient gives the maximum rate of increase. In the case $n = 2$, the graph of f can be regarded as a surface in $\mathbb{R}^3$, and at any point of the surface where the function is differentiable with nonzero gradient the gradient points "straight uphill" (see Figure ()).

The Tangent Hyperplane

VIII.3.5.8. If $\nabla f(\boldsymbol{a}) \neq 0$, then for a unit vector $\boldsymbol{u} \in \mathbb{R}^n$ we have $\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{a}) = 0$ if and only if $\boldsymbol{u} \perp \nabla f(\boldsymbol{a})$. The set of all such vectors spans an $(n-1)$-dimensional subspace (hyperplane) of $\mathbb{R}^n$. The hyperplane Through $\boldsymbol{a}$ parallel to this is the obvious candidate for the tangent hyperplane to the hypersurface

$$S = \{\boldsymbol{x} : f(\boldsymbol{x}) = c\}$$

where $c = f(\boldsymbol{a})$. (It may not be obvious that this set is a hypersurface in the usual sense, but it follows from the Implicit Function Theorem.)

VIII.3.6. Functional Independence

VIII.3.6.1. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f} = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$ a $\mathcal{C}^1$ function. We say $\{f_1, \ldots, f_m\}$ is *functionally dependent* on U if there is a $\mathcal{C}^1$ function g on an open set V in $\mathbb{R}^{n-1}$ such that, for some k, $1 \leq k \leq m$, we have

$$(f_1(\boldsymbol{x}), \ldots, f_{k-1}(\boldsymbol{x}), f_{k+1}(\boldsymbol{x}), \ldots, f_m(\boldsymbol{x})) \in V$$

$$f_k(\boldsymbol{x}) = g(f_1(\boldsymbol{x}), \ldots, f_{k-1}(\boldsymbol{x}), f_{k+1}(\boldsymbol{x}), \ldots, f_m(\boldsymbol{x}))$$

for all $\boldsymbol{x} \in U$. Otherwise $\{f_1, \ldots, f_m\}$ is *functionally independent* on U. (The $\mathcal{C}^1$ requirement can be relaxed in various ways, but this is the most useful form of the definition.)

Geometrically, functional dependence says that $\boldsymbol{f}(\boldsymbol{x})$ lies on the graph of g in $\mathbb{R}^m \cong \mathbb{R}^{m-1} \times \mathbb{R}$ for all $\boldsymbol{x} \in U$. Note that functional independence implies, but is much stronger than, linear independence (Exercise ()).

VIII.3.6.2. An apparently more general functional dependence is to just require that there is a function F, $\mathcal{C}^1$ on an open set in $\mathbb{R}^m$ containing $\boldsymbol{f}(U)$ with nonvanishing derivative, such that $F(\boldsymbol{f}(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in U$. But this is actually not really more general, at least locally, by the Implicit Function Theorem.

VIII.3.6.3. In general, it is a difficult problem to determine whether a set of functions is functionally dependent. We will obtain from the Chain Rule a simple necessary condition in the case $n \geq m$, although this condition is by no means sufficient.

VIII.3.6.4. Proposition. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f} = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$ a $\mathcal{C}^1$ function, with $n \geq m$. If $\{f_1, \ldots, f_m\}$ is functionally dependent, then for every $\{j_1, \ldots, j_m\} \subseteq \{1, \ldots, n\}$ and every $\boldsymbol{x} \in U$ we have

$$det \begin{bmatrix} \frac{\partial f_1}{\partial x_{j_1}}(\boldsymbol{x}) & \cdots & \frac{\partial f_1}{\partial x_{j_m}}(\boldsymbol{x}) \\ \vdots & \ddots & \vdots \\ \frac{\partial f_m}{\partial x_{j_1}}(\boldsymbol{x}) & \cdots & \frac{\partial f_m}{\partial x_{j_m}}(\boldsymbol{x}) \end{bmatrix} = 0 \ .$$

Proof: By reordering $f_1, \ldots, f_m$, we may assume the k in the definition of functional dependence is m, i.e. there is a $\mathcal{C}^1$ function g such that $f_m(\boldsymbol{x}) = g(f_1(\boldsymbol{x}), \ldots, f_{m-1}(\boldsymbol{x}))$ for all $\boldsymbol{x} \in U$, to simplify notation. Fix $\boldsymbol{x} \in U$, and write $\boldsymbol{y} = (f_1(\boldsymbol{x}), \ldots, f_{m-1}(\boldsymbol{x})) \in \mathbb{R}^{m-1}$. Then by the Chain Rule, for each j we have

$$\frac{\partial f_m}{\partial x_j} = \sum_{k=1}^{m-1} \frac{\partial g}{\partial y_k}(\boldsymbol{y}) \frac{\partial f_k}{\partial x_j}(\boldsymbol{x})$$

so the last row in the matrix is a linear combination of the first $m-1$ rows (the k'th row is multiplied by $\frac{\partial g}{\partial y_k}(\boldsymbol{y})$), hence the matrix has zero determinant. 👍

VIII.3.6.5. Corollary. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f} = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$ a $\mathcal{C}^1$ function, with $n \geq m$. If there is an $\boldsymbol{a} \in U$ and $\{j_1, \ldots, j_m\} \subseteq \{1, \ldots, n\}$ such that

$$det \begin{bmatrix} \frac{\partial f_1}{\partial x_{j_1}}(\boldsymbol{a}) & \cdots & \frac{\partial f_1}{\partial x_{j_m}}(\boldsymbol{a}) \\ \vdots & \ddots & \vdots \\ \frac{\partial f_m}{\partial x_{j_1}}(\boldsymbol{a}) & \cdots & \frac{\partial f_m}{\partial x_{j_m}}(\boldsymbol{a}) \end{bmatrix} \neq 0$$

then $\{f_1, \ldots, f_m\}$ is functionally independent.

VIII.3.6.6. In fact, under the hypotheses of VIII.3.6.5., a stronger consequence holds: the Inverse Function Theorem (applied to a suitable m-dimensional affine subspace of $\mathbb{R}^n$) implies that the range of $\boldsymbol{f}$ has nonempty interior (which clearly implies functional independence).

VIII.3.6.7. The converse of VIII.3.6.4. does not hold, and there are no reasonable sufficient conditions for functional dependence along these lines. If the conclusion of VIII.3.6.4. holds, or if $n < m$, then the Straightening Theorem says that generically $\{f_1, \ldots, f_m\}$ is *locally* functionally dependent.

VIII.3.7. Exercises

VIII.3.7.1. Define $f : \mathbb{R}^2 \to \mathbb{R}$ by

$$f(x,y) = \begin{cases} \frac{xy}{x^2+y^2} & \text{if} \quad (x,y) \neq (0,0) \\ 0 & \text{if} \quad (x,y) = (0,0) \end{cases} .$$

(a) Show that f is not continuous at $\mathbf{0}$.
(b) Show that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ exist everywhere.
(c) Show that $D_{\boldsymbol{u}} f(0,0)$ does not exist unless $\boldsymbol{u} = \boldsymbol{e}_1$ or $\boldsymbol{u} = \boldsymbol{e}_2$.

VIII.3.7.2. Define $f : \mathbb{R}^2 \to \mathbb{R}$ by

$$f(x,y) = \begin{cases} \frac{xy}{\sqrt{x^2+y^2}} & \text{if} \quad (x,y) \neq (0,0) \\ 0 & \text{if} \quad (x,y) = (0,0) \end{cases} .$$

(a) Show that f is continuous at $\mathbf{0}$.
(b) Show that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ exist everywhere.
(c) Show that $D_{\boldsymbol{u}} f(0,0)$ does not exist unless $\boldsymbol{u} = \boldsymbol{e}_1$ or $\boldsymbol{u} = \boldsymbol{e}_2$.
(d) Show that f is not differentiable at $\mathbf{0}$. [Use VIII.3.5.4..]

VIII.3.7.3. Define $f : \mathbb{R}^2 \to \mathbb{R}$ by

$$f(x,y) = \begin{cases} \frac{x^2 y}{x^4+y^2} & \text{if} \quad (x,y) \neq (0,0) \\ 0 & \text{if} \quad (x,y) = (0,0) \end{cases} .$$

(a) Show that f is not continuous at $\mathbf{0}$. [Consider $\lim_{t\to 0} f(t,t^2)$.] Then f is *a fortiori* not differentiable at $\mathbf{0}$.
(b) Show that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ exist everywhere.
(c) Show that $D_{\boldsymbol{u}} f(x,y)$ exists for all $\boldsymbol{u}$ and for all (x,y) (and in particular for $(x,y) = (0,0)$).

VIII.3.7.4. Define $f : \mathbb{R}^2 \to \mathbb{R}$ by

$$f(x,y) = (x^{1/3} + y^{1/3})^3 .$$

(a) Show that f is continuous everywhere, and in particular at $\mathbf{0}$.
(b) Show that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ exist everywhere.
(c) Show that $D_{\boldsymbol{u}} f(0,0)$ exists and equals $f(\boldsymbol{u})$ for all $\boldsymbol{u}$.
(d) Show that f is not differentiable at $\mathbf{0}$. [Use VIII.3.5.4..]

VIII.3.7.5. Define $f : \mathbb{R}^2 \to \mathbb{R}$ by

$$f(x,y) = \begin{cases} \frac{x^2 y}{x^2+y^2} & \text{if} \quad (x,y) \neq (0,0) \\ 0 & \text{if} \quad (x,y) = (0,0) \end{cases} .$$

(a) Show that f is continuous everywhere, and in particular at $\mathbf{0}$.

(b) Show that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ exist everywhere.

(c) Show that $\frac{\partial f}{\partial \boldsymbol{u}}(0,0)$ exists for all $\boldsymbol{u}$.

(d) Show that f is not differentiable at $\mathbf{0}$.

VIII.3.7.6. Define $f : \mathbb{R}^2 \to \mathbb{R}$ by

$$f(x,y) = \begin{cases} x^2+y^2 & \text{if} \quad x^2+y^2 \text{ is rational} \\ 0 & \text{if} \quad x^2+y^2 \text{ is irrational} \end{cases} .$$

(a) Show that f is continuous only at $\mathbf{0}$.

(b) Show that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ only exist at $\mathbf{0}$.

(c) Show that f is differentiable at $\mathbf{0}$.

VIII.3.7.7. Define $f : \mathbb{R}^2 \to \mathbb{R}$ by

$$f(x,y) = \begin{cases} (x^2+y^2)\sin\frac{1}{x^2+y^2} & \text{if} \quad (x,y) \neq (0,0) \\ 0 & \text{if} \quad (x,y) = (0,0) \end{cases} .$$

(a) Show that f is differentiable everywhere, and in particular at $\mathbf{0}$.

(b) Show that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ are not continuous at $\mathbf{0}$.

VIII.3.7.8. Let g be a $\mathcal{C}^\infty$ bump function on $[0, 2\pi]$ (V.17.2.4.) with $g(\pi/4) = 1$ and g identically 0 outside the interval $[\pi/8, 3\pi/8]$. Define $f : \mathbb{R}^2 \setminus \{\mathbf{0}\} \to \mathbb{R}$ using polar coordinates by

$$f(r,\theta) = g(\theta) .$$

Then f is constant on open rays from the origin. Extend f to $\mathbb{R}^2$ by setting $f(\mathbf{0}) = 0$.

(a) Show that f is $\mathcal{C}^\infty$ on $\mathbb{R}^2 \setminus \{\mathbf{0}\}$.

(b) If $x \neq 0$, then f is identically 0 in a neighborhood of $(x, 0)$, and thus all partials of f of all orders are also identically 0 on this neighborhood. The same holds for points of the form $(0, y)$ for $y \neq 0$. In particular, all partials of f of all orders are identically zero on the nonzero axes.

(c) Show that all partials of f of all orders exist and are 0 at $\mathbf{0}$.

(d) Show that f is not continuous, let alone differentiable, at $\mathbf{0}$.

VIII.3.7.9. Modify the proof of Theorem VIII.3.3.1. to give the following precise version of Remark VIII.3.3.2.:

THEOREM. Let U be an open subset of $\mathbb{R}^n$, and $\boldsymbol{f} = (f_1, \ldots, f_m) : U \to \mathbb{R}^m$. Suppose that, for some r, $1 \leq r < n$, and $\boldsymbol{c} = (\boldsymbol{a}, \boldsymbol{b}) \in U$, where $\boldsymbol{a} \in \mathbb{R}^r$ and $\boldsymbol{b} \in \mathbb{R}^{n-r}$, we have that

(1) The function $\boldsymbol{g}(\boldsymbol{x}) = \boldsymbol{f}(\boldsymbol{x}, \boldsymbol{b})$ is differentiable at $\boldsymbol{a}$.

(2) All partial derivatives $\frac{\partial f_i}{\partial x_j}$, $1 \leq i \leq n$, $r+1 \leq j \leq n$, exist on U and are continuous at $\boldsymbol{c}$.

Then $\boldsymbol{f}$ is differentiable at $\boldsymbol{c}$.

VIII.3.7.10. Derive the Product Rule (V.3.3.3.) for functions of one variable from the multivariable Chain Rule as follows. Let f and g be defined on an open interval I in $\mathbb{R}$ and differentiable at $a \in I$, and set $h = fg$.

(a) Let $\gamma : I \to \mathbb{R}^2$ be defined by $\gamma(t) = (f(t), g(t))$. Then γ is differentiable at a and

$$D\gamma(a) = \begin{bmatrix} f'(a) \\ g'(a) \end{bmatrix} \text{ (or } \gamma'(a) = (f'(a), g'(a)) \text{).}$$

(b) Define $\phi : \mathbb{R}^2 \to \mathbb{R}$ by $\phi(x, y) = xy$. Then ϕ is differentiable everywhere and

$$D\phi(x, y) = \begin{bmatrix} y & x \end{bmatrix} \text{ (or } \nabla\phi(x, y) = (y, x) \text{).}$$

(c) Apply the Chain Rule to $h = \phi \circ \gamma$ to obtain that h is differentiable at a and the Product Rule formula.

This is a rather perverse and roundabout way to obtain the Product Rule, although it is logically sound since nowhere in the derivation or proof of the multivariable Chain Rule is the Product Rule used. However, it is instructive to see that from the right point of view, the Product Rule is just a consequence of matrix multiplication or the dot product. This helps demonstrate the unity and consistency of the operations of algebra and calculus.

VIII.4. Higher-Order Derivatives and Critical Point Analysis

VIII.4.1. Higher-Order Differentiability

VIII.4.1.1. If U is an open set in $\mathbb{R}^n$ and $\boldsymbol{f} : U \to \mathbb{R}^m$ is differentiable on U (i.e. at every point of U), the total derivative $d\boldsymbol{f}$ is a function from U to the set $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ of linear transformations from $\mathbb{R}^n$ to $\mathbb{R}^m$. $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ is a vector space over $\mathbb{R}$ of dimension nm and can thus be identified with $\mathbb{R}^{nm}$ in a natural way (Exercise VIII.4.6.1.). Alternatively, $D\boldsymbol{f}$ is a function from U to the $m \times n$ matrices $\mathbb{M}_{m\times n}$, which can evidently be identified with $\mathbb{R}^{nm}$. Thus $d\boldsymbol{f}$ or, equivalently, $D\boldsymbol{f}$, may be regarded as a function from U to $\mathbb{R}^{nm}$.

VIII.4.1.2. Definition. If U is an open set in $\mathbb{R}^n$ and $\boldsymbol{f} : U \to \mathbb{R}^m$ is differentiable on U, then $\boldsymbol{f}$ is *second-order differentiable* at $\boldsymbol{a} \in U$ if $d\boldsymbol{f}$ (or, equivalently, $D\boldsymbol{f}$) is differentiable at $\boldsymbol{a}$. Write $d^2\boldsymbol{f}(\boldsymbol{a})$ for $d(d\boldsymbol{f})(\boldsymbol{a})$ and $D^2\boldsymbol{f}(\boldsymbol{a})$ for $D(D\boldsymbol{f})(\boldsymbol{a})$.

VIII.4.1.3. We can go on. If $d\boldsymbol{f}$ ($D\boldsymbol{f}$) is differentiable at $\boldsymbol{a}$, then $D^2\boldsymbol{f}(\boldsymbol{a})$ is an $nm\times n$ matrix, identifiable with $\mathbb{R}^{n^2m}$. Thus if $\boldsymbol{f}$ is second-order differentiable on U and $D^2\boldsymbol{f}$ is differentiable at $\boldsymbol{a} \in U$, then $\boldsymbol{f}$ is third-order differentiable at $\boldsymbol{a}$. Continuing, we can define what it means for $\boldsymbol{f}$ to be r'th order differentiable at a point or on the set U, for any $r \in \mathbb{N}$. We also say $\boldsymbol{f}$ is *infinitely differentiable* on U if it is r'th order differentiable on U for every r. We can also write $d^r\boldsymbol{f}(\boldsymbol{a})$ and $D^r\boldsymbol{f}(\boldsymbol{a})$ if $\boldsymbol{f}$ is differentiable to order r at $\boldsymbol{a}$; $D^r\boldsymbol{f}(\boldsymbol{a})$ is an $n^{r-1}m \times n$ matrix, which can be identified with a point in $\mathbb{R}^{n^rm}$.

The coordinate functions of $D^r\boldsymbol{f}$ are just the r'th order partials of the coordinate functions of $\boldsymbol{f}$ (Exercise VIII.4.6.1.). By VIII.3.1.13., we have:

VIII.4.1.4. Proposition. If U is an open set in $\mathbb{R}^n$ and $\boldsymbol{f} : U \to \mathbb{R}^m$, then $\boldsymbol{f}$ is r'th order differentiable at $\boldsymbol{a} \in U$ if and only if each partial derivative of $\boldsymbol{f}$ of order $r-1$ is defined in a neighborhood of $\boldsymbol{a}$ and is differentiable at $\boldsymbol{a}$.

We thus have the following immediate corollary of VIII.3.1.14. and VIII.3.3.1.:

VIII.4.1.5. Corollary. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f} : U \to \mathbb{R}^m$, and $r \in \mathbb{N}$. If $\boldsymbol{f}$ is r'th order differentiable on U, then $\boldsymbol{f}$ is $\mathcal{C}^{r-1}$ on U. If $\boldsymbol{f}$ is $\mathcal{C}^r$ on U, then it is r'th order differentiable on U. The function $\boldsymbol{f}$ is $\mathcal{C}^\infty$ on U if and only if it is infinitely differentiable on U.

Note that an r'th order differentiable function does not have to be $\mathcal{C}^r$ (VIII.3.3.3.).

VIII.4.1.6. There is a little more structure to higher derivatives: $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ has more structure than $\mathbb{R}^{nm}$. If $\boldsymbol{f}$ is second-order differentiable at $\boldsymbol{a}$, then $d^2\boldsymbol{f}(\boldsymbol{a})$ is actually a linear transformation from $\mathbb{R}^n$ to $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$, which can be thought of as a *bilinear* () function from $\mathbb{R}^n \times \mathbb{R}^n$ to $\mathbb{R}^m$. Similarly, for any r, $d^r\boldsymbol{f}(\boldsymbol{a})$ can be regarded as an r-multilinear function from $\mathbb{R}^n \times \cdots \times \mathbb{R}^n$ to $\mathbb{R}^m$. This point of view is important in formulating the multivariable version of Taylor's Theorem (VIII.4.3.5.), for example. (The two points of view are actually equivalent, since bilinear functions from $\mathbb{R}^n \times \mathbb{R}^n$ to $\mathbb{R}^m$ correspond naturally to linear functions from $\mathbb{R}^n \otimes \mathbb{R}^n \cong \mathbb{R}^{n^2}$ to $\mathbb{R}^m$, etc.)

Equality of Mixed Partials Again

There is a variation of Theorem VIII.2.2.2. involving differentiability:

VIII.4.1.7. THEOREM. Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{f} : U \to \mathbb{R}^m$, $\boldsymbol{a} \in U$. If $\boldsymbol{f}$ is second-order differentiable at $\boldsymbol{a}$, then, for $1 \leq i, j \leq n$,

$$\frac{\partial^2 \boldsymbol{f}}{\partial x_j \, \partial x_i}(\boldsymbol{a}) = \frac{\partial^2 \boldsymbol{f}}{\partial x_i \, \partial x_j}(\boldsymbol{a}) \ .$$

For the proof, which is similar to the proof of VIII.2.2.2. and of comparable difficulty, see [Pug15].

VIII.4.1.8. Theorems VIII.2.2.2. and VIII.4.1.7. are complementary: neither directly implies the other. (Clairaut's Theorem, the version of the equality of mixed partials used most frequently, is a special case of both VIII.2.2.2. and VIII.4.1.7., so the distinction between these results is mostly academic.) In VIII.4.1.7. there is no assumption of continuity for any second-order partial, so it might seem to be more general than VIII.2.2.2.. However, the hypotheses of VIII.4.1.7. imply that *all* second-order partials of $\boldsymbol{f}$ exist at $\boldsymbol{a}$ (and even more), which is not necessary for VIII.2.2.2., as the next example shows.

VIII.4.1.9. EXAMPLE. Let $g : \mathbb{R} \to \mathbb{R}$ be a function which is $\mathcal{C}^1$, but does not have a second derivative anywhere, i.e. g is an antiderivative of a continuous but nondifferentiable function. Define $f : \mathbb{R}^2 \to \mathbb{R}$ by $f(x, y) = g(x)$. Then $\frac{\partial f}{\partial x}$, $\frac{\partial f}{\partial y}$, $\frac{\partial^2 f}{\partial x \partial y}$, $\frac{\partial^2 f}{\partial y \partial x}$, and $\frac{\partial^2 f}{\partial y^2}$ all exist and are continuous everywhere (the last four are identically 0), so the hypotheses (and conclusion!) of VIII.2.2.2. are satisfied everywhere. But f is not second-order differentiable anywhere: in fact, $\frac{\partial^2 f}{\partial x^2}$ does not exist anywhere.

Theorem VIII.4.1.7. has an extension which is a true generalization of VIII.2.2.6.:

VIII.4.1.10. COROLLARY. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f}$ an r'th order differentiable function from U to $\mathbb{R}^m$ ($r > 1$). Then any two mixed partials of $\boldsymbol{f}$ of total order $\leq r$ in which each coordinate direction appears the same number of times are equal on U.

VIII.4.1.11. From the point of view of VIII.4.1.6. (cf. VIII.4.6.1.), VIII.4.1.7. has a nice rephrasing: the bilinear form $d^2\boldsymbol{f}(\boldsymbol{a})$, when defined, is *symmetric*: $d\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x}, \boldsymbol{y}) = d\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{y}, \boldsymbol{x})$ for all $\boldsymbol{x}, \boldsymbol{y} \in \mathbb{R}^n$. Similarly, the r-multilinear map $d^r\boldsymbol{f}(\boldsymbol{a})$, when defined, is symmetric in the sense that is invariant under any permutation of the arguments.

VIII.4.2. Smooth Partitions of Unity and the Smooth Urysohn Lemma

We give multidimensional analogs of the results of ().

VIII.4.2.1. PROPOSITION. Let $\boldsymbol{x} \in \mathbb{R}^n$, and $0 < s < r$. Then there is a $\mathcal{C}^\infty$ function from $\mathbb{R}^n$ to $[0,1]$ which is identically 1 on $B_s(\boldsymbol{x})$, strictly positive on $B_r(\boldsymbol{x})$, and identically 0 outside $B_r(\boldsymbol{x})$. In particular, there is a $\mathcal{C}^\infty$ function which is 1 at $\boldsymbol{x}$, strictly positive on $B_r(\boldsymbol{x})$, and 0 outside $B_r(\boldsymbol{x})$.

PROOF: Let g be a $\mathcal{C}^\infty$ function from $\mathbb{R}$ to $[0,1]$ which is 1 precisely on $(-\infty, s]$ and 0 precisely on $[r, +\infty)$ (), and set $f(\boldsymbol{y}) = g(\|\boldsymbol{y} - \boldsymbol{x}\|)$. 👍

Convergence of Series of Smooth Functions

VIII.4.2.2. THEOREM. Let U be an open set in $\mathbb{R}^n$ and V a bounded open set with $\bar{V} \subseteq U$. Let $0 \leq r \leq \infty$, and (f_k) a sequence of $\mathcal{C}^r$ functions from U to $\mathbb{R}$. Then there is a sequence (ϵ_k) of positive numbers such that if (c_k) is a sequence in $\mathbb{R}$ with $|c_k| \leq \epsilon_k$ for all k, then the series

$$\sum_{k=1}^{\infty} c_k f_k$$

converges uniformly on V to a $\mathcal{C}^r$ function f on V, and for any multi-index α of total degree $\leq r$, the series

$$\sum_{k=1}^{\infty} c_k \frac{\partial^\alpha f_k}{\partial x^\alpha}$$

converges uniformly on V to $\frac{\partial^\alpha f}{\partial x^\alpha}$.

Smooth Functions With Prescribed Zeroes

VIII.4.2.3. THEOREM. Let A be a closed subset of $\mathbb{R}^n$. Then there is a $\mathcal{C}^\infty$ function f from $\mathbb{R}^n$ to $[0,1)$ such that $Z_f = A$ (i.e. f is identically zero on A and strictly positive on A^c).

PROOF: Let $E_1 = A \cup \{\boldsymbol{x} : \|\boldsymbol{x}\| \geq 2\}$, and for each $m > 1$ let $E_m = A \cup \{\boldsymbol{x} : \|\boldsymbol{x}\| \geq m+1\} \cup B_{m-1}(\mathbf{0})$. Then E_m is a closed set, and E_m^c is a bounded open set. Fix m. Then E_m^c is a countable union of open balls (B_{mk}). ByVIII.4.2.1., for each k there is a $\mathcal{C}^\infty$ function f_{mk} from $\mathbb{R}^n$ to $[0,1]$ which is positive precisely on B_{mk}. By VIII.4.2.2. there is a sequence of positive numbers (ϵ_{mk}) such that

$$\sum_{k=1}^{\infty} \epsilon_{mk} f_{mk}$$

converges uniformly on $B_{m+2}(\mathbf{0})$ to a $\mathcal{C}^\infty$ function f_m, which is zero precisely on $E_m \cap B_{m+2}(\mathbf{0})$; f_m extends to a $\mathcal{C}^\infty$ function on all of $\mathbb{R}$ by setting it equal to 0 outside $B_{m+2}(\mathbf{0})$. The function f_m is nonnegative, and nonzero exactly on the points of A^c whose norm is between $m-1$ and $m+1$ (and at $\mathbf{0}$ if $\mathbf{0} \notin A$). Then $\sum_m f_m$ converges pointwise to a $\mathcal{C}^\infty$ function f on $\mathbb{R}$ since, for each $\boldsymbol{x} \in \mathbb{R}^n$, on any open ball around $\boldsymbol{x}$ only finitely many f_m are nonzero. This f is nonnegative, and zero precisely on A. To make the values in $[0,1)$, compose with a $\mathcal{C}^\infty$ function on $\mathbb{R}$ such as $\frac{2}{\pi}\arctan$. 👍

The Smooth Urysohn Lemma

VIII.4.2.4. THEOREM. [SMOOTH URYSOHN LEMMA] Let A be a closed subset of $\mathbb{R}^n$ and U an open set in $\mathbb{R}^n$ containing A. Then there is a C^∞ function ϕ from $\mathbb{R}^n$ to $[0,1]$ such that $\phi \equiv 1$ on A and $\phi \equiv 0$ on $\mathbb{R} \setminus U$. We may choose ϕ so that $\phi^{-1}(\{1\}) = A$ and $\phi^{-1}(\{0\}) = \mathbb{R} \setminus U$.

Alternatively, if E and F are disjoint closed subsets of $\mathbb{R}^n$, there is a smooth function $\phi : \mathbb{R}^n \to [0,1]$ such that $\phi^{-1}(\{1\}) = E$ and $\phi^{-1}(\{0\}) = F$ (set $A = E$ and $U = \mathbb{R}^n \setminus F$).

PROOF: We prove the alternate form. First suppose E is compact. For $\boldsymbol{x} \in E$, let $g(\boldsymbol{x}) = d(\boldsymbol{x}, A)$. Then g is continuous and strictly positive on E, so has a minimum $\epsilon > 0$. The open balls of radius ϵ centered at points of E cover E, so have a finite subcover, centered at points $\boldsymbol{x}_1, \ldots, \boldsymbol{x}_k \in E$. Let D_j $(1 \le j \le k)$ be the open ball of radius ϵ centered at $\boldsymbol{x}_j$, and f_j a $\mathcal{C}^\infty$ function which is strictly positive on D_j and 0 outside D_j. Set $f = f_1 + \cdots + f_k$; then f is $\mathcal{C}^\infty$, identically 0 on F, and strictly positive on E. If $c > 0$ is the minimum of f on E, let h be a $\mathcal{C}^\infty$ function on $\mathbb{R}$ with $h(0) = 0$ and h identically 1 on $[c, +\infty)$, and set $\phi = h \circ f$. Then ϕ is $\mathcal{C}^\infty$ on $\mathbb{R}^n$, identically 0 on F, and identically 1 on E.

To make ϕ have the property that $\phi^{-1}(\{1\}) = E$ and $\phi^{-1}(\{0\}) = F$, let θ be a C^∞ function from $\mathbb{R}^n$ to $[0,1)$ such that $\theta = 0$ precisely on $E \cup F$ (V.17.2.9.). Then $\psi_1 = \phi(1-\theta)$ is a C^∞ function from $\mathbb{R}^n$ to $[0,1]$ which is 0 on F and which is 1 precisely on E. Similarly, $\psi_2 = 1 - (1-\phi)(1-\theta)$ is a C^∞ function from $\mathbb{R}^n$ to $[0,1]$ which is 1 on E and 0 precisely on F. Then $\psi = \frac{1}{2}(\psi_1 + \psi_2)$ is a C^∞ function from $\mathbb{R}^n$ to $[0,1]$ which is 1 precisely on E and 0 precisely on F.

Now consider the case of general E and F. Let (h_m) $(m \ge 0)$ be a sequence of $\mathcal{C}^\infty$ functions from $\mathbb{R}$ to $[0,1]$ such that h_m is identically 0 outside $(m-1, m+1)$, h_0 is identically 1 in an interval around 0, and $\sum_m h_m$ is identically 1 (the sum makes sense since only finitely many $h_m(t)$ are nonzero at any particular t). For each m let $E_m = E \cap \{\boldsymbol{x} : m-1 \le \|\boldsymbol{x}\| \le m+1\}$ $(E_1 = E \cap \bar{B}_2(\boldsymbol{0}))$ and $F_m = F \cap \{\boldsymbol{x} : m-1 \le \|\boldsymbol{x}\| \le m+1\}$ $(F_1 = F \cap \bar{B}_2(\boldsymbol{0}))$. Let ϕ_m be a $\mathcal{C}^\infty$ function from $\mathbb{R}^n$ to $[0,1]$ with $E_m = f_m^{-1}(\{1\})$ and $F_m = f_m^{-1}(\{0\})$, and for $\boldsymbol{x} \in \mathbb{R}^n$ set

$$\phi(\boldsymbol{x}) = \sum_{m=1}^{\infty} h_m(\|\boldsymbol{x}\|)\phi_m(\boldsymbol{x})$$

(the sum is well defined and $\mathcal{C}^\infty$ since on any open ball only finitely many terms are not identically 0). Then ϕ has the desired properties. 👍

Smooth Partitions of Unity

VIII.4.2.5. THEOREM. Let $X \subseteq \mathbb{R}^n$, and $\mathcal{U}$ an open cover of X. Then there is a sequence (ϕ_k) of $\mathcal{C}^\infty$ functions from $\mathbb{R}^n$ to $[0,1]$ such that

(i) For each k there is a $U_k \in \mathcal{U}$ such that ϕ_k is identically 0 outside U_k.

(ii) For every compact subset E of X only finitely many ϕ_k are not identically 0 on E.

(iii) For every $\boldsymbol{x} \in X$, $\sum_k \phi_k(\boldsymbol{x}) = 1$ (this is a finite sum for each $\boldsymbol{x}$ by (ii)).

PROOF: We first refine the open cover $\mathcal{U}$. For each $\boldsymbol{x} \in X$ there is an open neighborhood (even ball) V of $\boldsymbol{x}$ such that there is a $U \in \mathcal{U}$ with $\bar{V} \subseteq U$. Thus the set of all nonempty open sets V in $\mathbb{R}^n$ such that there is

a $U \in \mathcal{U}$ with $\bar{V} \subseteq U$ is an open cover $\mathcal{V}$ of X. Since X is second countable in the relative topology, there is a countable subcover $\{V_k : k \in \mathbb{N}\}$ of $\mathcal{V}$ (). For each k choose a $U_k \in \mathcal{U}$ with $\bar{V}_k \subseteq U_k$.

For each k let f_k be a $\mathcal{C}^\infty$ function from $\mathbb{R}^n$ to $[0,1]$ which is 1 on $\bar{V}_k$ and 0 outside U_k (VIII.4.2.4.). Set $\phi_1 = f_1$ and for $k > 1$

$$\phi_k = f_k(1 - f_1) \cdots (1 - f_{k-1}) \ .$$

By induction we have

$$\sum_{k=1}^{m} \phi_k = 1 - (1 - f_1) \cdots (1 - f_m)$$

for any m. If E is any compact subset of X, then $E \subseteq V_1 \cup \cdots \cup V_m$ for some m, so if $\boldsymbol{x} \in E$, $f_k(\boldsymbol{x}) = 1$ for some k, $1 \leq k \leq m$; hence $\phi_k(\boldsymbol{x}) = 0$ for $k > m$ and $\sum_{k=1}^{m} \phi_k(\boldsymbol{x}) = 1$. If $\boldsymbol{x} \in X$, setting $E = \{x\}$ we obtain $\sum_{k=1}^{m} \phi_k(\boldsymbol{x}) = 1$. 👍

The Countable AC is used in this proof.

VIII.4.3. Taylor's Theorem in Several Variables

We can obtain a version of Taylor's Theorem () for real-valued functions of several variables, using the one-variable version. The notation becomes complicated, but the generalization is straightforward.

VIII.4.3.1. The setup throughout this subsection is as follows. We have a convex open set $U \subseteq \mathbb{R}^d$, $\boldsymbol{a} \in U$, and $f : U \to \mathbb{R}$ $(n+1)$'st order differentiable on U. This implies that all partial derivatives of f of order $\leq n+1$ are defined on U, and that the ones of order $\leq n$ are differentiable, hence continuous, on U.

We fix an $\boldsymbol{x} \in U$, $\boldsymbol{x} \neq \boldsymbol{a}$. Parametrize the line through $\boldsymbol{a}$ and $\boldsymbol{x}$ by

$$\gamma(t) = \boldsymbol{a} + t(\boldsymbol{x} - \boldsymbol{a}) \ .$$

Then γ is an affine function from $\mathbb{R}$ to $\mathbb{R}^d$, and $\gamma(0) = \boldsymbol{a}$, $\gamma(1) = \boldsymbol{x}$. Set $\boldsymbol{h} = \boldsymbol{x} - \boldsymbol{a}$, and $I = \{t : \boldsymbol{a} + t\boldsymbol{h} \in U\}$. Then I is an open interval in $\mathbb{R}$ containing $[0, 1]$. Define $g : I \to \mathbb{R}$ by

$$g(t) = f(\gamma(t)) = f(\boldsymbol{a} + t\boldsymbol{h}) \ .$$

By the Chain Rule, g is $(n+1)$-times differentiable on I, so by the one-variable Taylor's Theorem () we have

$$g(t) = \sum_{k=0}^{n} \frac{g^{(k)}(0)}{k!} t^k + r_n(t)$$

for $t \in I$, where

$$r_n(t) = \frac{g^{(n+1)}(s)}{(n+1)!} t^{n+1}$$

for some s, $0 < s < t$ (depending on t). In particular, taking $t = 1$, we have

$$f(\boldsymbol{x}) = \sum_{k=0}^{n} \frac{g^{(k)}(0)}{k!} + \frac{g^{(n+1)}(s)}{(n+1)!}$$

for some s, $0 < s < 1$.

We just need to convert this formula into a formula involving f, its partial derivatives, and $\boldsymbol{x}$ (or, equivalently, $\boldsymbol{h}$).

VIII.4.3.2. The first couple of terms are no problem:

$$g(0) = f(\boldsymbol{a})$$

and, by the Chain Rule, if $\boldsymbol{h} = (h_1, \ldots, h_d)$, we have $\gamma'(t) = \boldsymbol{h}$ for all t, so

$$g'(0) = df(\gamma(0))\boldsymbol{h} = Df(\boldsymbol{a})\boldsymbol{h} = \nabla f(\boldsymbol{a}) \cdot \boldsymbol{h}$$

in our various points of view (the reader should interpret each of these expressions appropriately). In coordinates, we have

$$g'(0) = \sum_{k=1}^{d} \frac{\partial f}{\partial x_k}(\boldsymbol{a}) h_k \ .$$

VIII.4.3.3. More generally, for $t \in I$ we have

$$g'(t) = \sum_{k=1}^{d} \frac{\partial f}{\partial x_k}(\gamma(t))(\boldsymbol{a})h_k$$

so we can compute $g''(0)$ by applying the Chain Rule again:

$$g''(0) = \sum_{k=1}^{d} h_k D\left(\frac{\partial f}{\partial x_k}\right)(\boldsymbol{a})\boldsymbol{h} = \sum_{k=1}^{d} h_k \nabla\left(\frac{\partial f}{\partial x_k}\right)(\boldsymbol{a}) \cdot \boldsymbol{h} \ .$$

We have

$$\nabla\left(\frac{\partial f}{\partial x_k}\right)(\boldsymbol{a}) = \left(\frac{\partial^2 f}{\partial x_1\, \partial x_k}(\boldsymbol{a}), \ldots, \frac{\partial^2 f}{\partial x_d\, \partial x_k}(\boldsymbol{a})\right)$$

so, expanding the dot product in coordinates, we get

$$g''(0) = \sum_{j=1}^{d}\sum_{k=1}^{d} \frac{\partial^2 f}{\partial x_j\, \partial x_k}(\boldsymbol{a})h_j h_k \ .$$

This can be written as

$$\boldsymbol{h} \cdot \left[D^2 f(\boldsymbol{a})\boldsymbol{h}\right]$$

where

$$D^2 f(\boldsymbol{a}) = \begin{bmatrix} \frac{\partial^2 f}{\partial x_1\, \partial x_1} & \frac{\partial^2 f}{\partial x_1\, \partial x_2} & \cdots & \frac{\partial^2 f}{\partial x_1\, \partial x_d} \\ \frac{\partial^2 f}{\partial x_2\, \partial x_1} & \frac{\partial^2 f}{\partial x_2\, \partial x_2} & \cdots & \frac{\partial^2 f}{\partial x_2\, \partial x_d} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_d\, \partial x_1} & \frac{\partial^2 f}{\partial x_d\, \partial x_2} & \cdots & \frac{\partial^2 f}{\partial x_d\, \partial x_d} \end{bmatrix} .$$

This matrix is called the *Hessian matrix* of f at $\boldsymbol{a}$, especially if $\nabla f(\boldsymbol{a}) = \boldsymbol{0}$. This matrix actually gives a tensor of rank 2 (). Note that if $n \geq 2$, the Hessian matrix is symmetric (VIII.2.2.2.). We can use the symbolic notation (cf. VIII.4.1.6.)

$$d^2 f(\boldsymbol{a})\boldsymbol{h}^2 = \boldsymbol{h} \cdot \left[D^2 f(\boldsymbol{a})\boldsymbol{h}\right] = \sum_{j=1}^{d}\sum_{k=1}^{d} \frac{\partial^2 f}{\partial x_j\, \partial x_k}(\boldsymbol{a})h_j h_k \ .$$

VIII.4.3.4. In the same way, we can compute the higher derivatives of g:

$$g'''(0) = \sum_{i=1}^{d}\sum_{j=1}^{d}\sum_{k=1}^{d} \frac{\partial^3 f}{\partial x_i\, \partial x_j\, \partial x_k}(\boldsymbol{a})h_i h_j h_k$$

which we may write symbolically as $d^3 f(\boldsymbol{a})\boldsymbol{h}^3$, corresponding to the three-dimensional array $D^3 f(\boldsymbol{a})$ whose (i,j,k) entry is $\frac{\partial^3 f}{\partial x_i\,\partial x_j\,\partial x_k}(\boldsymbol{a})$. (This is a tensor of rank 3.) Continuing, we get for arbitrary $r \leq n+1$:

$$g^{(r)}(0) = d^m f(\boldsymbol{a})\boldsymbol{h}^r = \sum_{j_1=1}^{d}\sum_{j_2=1}^{d}\cdots\sum_{j_r=1}^{d}\frac{\partial^r f}{\partial x_{j_1}\,\partial x_{j_2}\cdots\partial x_{j_r}}(\boldsymbol{a})h_{j_1}h_{j_2}\cdots h_{j_r}\ .$$

We also write $d^0 f(\boldsymbol{a}) = f(\boldsymbol{a})$.

Thus we obtain the final result:

VIII.4.3.5. Theorem. [Taylor's Theorem With Remainder, Multivariable Version] Let U be a convex open set in $\mathbb{R}^d$, $\boldsymbol{a} \in U$, and $f : U \to \mathbb{R}$ a function which is $(n+1)$'st order differentiable ($n \geq 0$) on U. Then, for $\boldsymbol{x} \in U$, we have

$$f(\boldsymbol{x}) = \sum_{k=0}^{n}\frac{1}{k!}d^k f(\boldsymbol{a})(\boldsymbol{x}-\boldsymbol{a})^k + r_n(\boldsymbol{x})$$

where

$$r_n(\boldsymbol{x}) = \frac{1}{(n+1)!}d^{n+1}f(\boldsymbol{c})(\boldsymbol{x}-\boldsymbol{a})^{n+1}$$

for some $\boldsymbol{c}$ on the line segment between $\boldsymbol{a}$ and $\boldsymbol{x}$.

We can relax the hypothesis that U be convex to just requiring that U be star-shaped with respect to $\boldsymbol{a}$, i.e. for every $\boldsymbol{x} \in U$, the line segment between $\boldsymbol{a}$ and $\boldsymbol{x}$ is contained in U.

The Two-Dimensional Case

VIII.4.3.6. Let us write out the case $d = 2$. We write (x,y) for the coordinates, and (a,b) for the point we expand around. We combine together terms which are equal due to the equality of mixed partials ().

VIII.4.3.7. Corollary. [Taylor's Theorem With Remainder, Two-Dimensional Version] Let U be a convex open set in $\mathbb{R}^2$, $(a,b) \in U$, $f : U \to \mathbb{R}$ an $(n+1)$'st order differentiable function. Then, for any $(x,y) \in U$,

$$f(x,y) = f(a,b) + \left[\frac{\partial f}{\partial x}(a,b)(x-a) + \frac{\partial f}{\partial y}(a,b)(y-b)\right]$$
$$+\frac{1}{2}\left[\frac{\partial^2 f}{\partial x^2}(a,b)(x-a)^2 + 2\frac{\partial^2 f}{\partial x\,\partial y}(a,b)(x-a)(y-b) + \frac{\partial^2 f}{\partial y^2}(a,b)(y-b)^2\right]$$
$$+\frac{1}{6}\left[\frac{\partial^3 f}{\partial x^3}(a,b)(x-a)^3 + 3\frac{\partial^3 f}{\partial x^2\,\partial y}(a,b)(x-a)^2(y-b) + 3\frac{\partial^3 f}{\partial x\,\partial y^2}(a,b)(x-a)(y-b)^2 + \frac{\partial^3 f}{\partial y^3}(a,b)(y-b)^3\right]$$
$$+\cdots+\frac{1}{n!}\sum_{k=0}^{n}\binom{n}{k}\frac{\partial^n f}{\partial x^k\,\partial y^{n-k}}(a,b)(x-a)^k(y-b)^{n-k} + r_n(x,y)$$

where

$$r_n(x,y) = \frac{1}{(n+1)!} d^{n+1} f(\boldsymbol{c})((x-a, y-b)^{n+1}$$

for some $\boldsymbol{c}$ on the line segment between (a,b) and (x,y).

Taylor Polynomials in the Multivariable Case

VIII.4.3.8. The multivariable Taylor's Theorem VIII.4.3.5. can also be developed from scratch in the same way as the one-variable case, although the *proof* via the one-variable case is much simpler. We begin by defining the Taylor polynomials:

VIII.4.3.9. DEFINITION. Let U be a convex open set in $\mathbb{R}^d$, $\boldsymbol{a} \in U$, and $f : U \to \mathbb{R}$ a function which is n'th order differentiable ($n \geq 0$) on U. Then, for $\boldsymbol{x} \in U$,

$$p_n(\boldsymbol{x}) = \sum_{k=0}^{n} \frac{1}{k!} d^k f(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a})^k$$

is the *n'th order Taylor polynomial of f around $\boldsymbol{a}$*.

The next result is a straightforward but somewhat ugly computation:

VIII.4.3.10. PROPOSITION. Let U be a convex open set in $\mathbb{R}^d$, $\boldsymbol{a} \in U$, and $f : U \to \mathbb{R}$ a function which is n'th order differentiable ($n \geq 0$) on U. Then the n'th order Taylor polynomial of f around $\boldsymbol{a}$ is a polynomial of degree $\leq n$ in the coordinates, and is the unique polynomial of degree $\leq n$ whose partial derivatives of all orders $\leq n$ at $\boldsymbol{a}$ agree with those of f at $\boldsymbol{a}$.

Taylor's Theorem then becomes:

VIII.4.3.11. THEOREM. [TAYLOR'S THEOREM, MULTIVARIABLE VERSION] Let U be a convex open set in $\mathbb{R}^d$, $\boldsymbol{a} \in U$, and $f : U \to \mathbb{R}$ a function which is $(n+1)$'st order differentiable ($n \geq 0$) on U. Let p_n be the n'th order Taylor polynomial of f around $\boldsymbol{a}$. Then, for $\boldsymbol{x} \in U$, we have

$$f(\boldsymbol{x}) = p_n(\boldsymbol{x}) + r_n(\boldsymbol{x})$$

where

$$r_n(\boldsymbol{x}) = \frac{1}{(n+1)!} d^{n+1} f(\boldsymbol{c})(\boldsymbol{x} - \boldsymbol{a})^{n+1}$$

for some $\boldsymbol{c}$ on the line segment between $\boldsymbol{a}$ and $\boldsymbol{x}$. In particular,

$$\lim_{\boldsymbol{x} \to \boldsymbol{a}} \frac{f(\boldsymbol{x}) - p_n(\boldsymbol{x})}{\|\boldsymbol{x} - \boldsymbol{a}\|^n} = 0$$

and p_n is the unique polynomial of order $\leq n$ with this property.

PROOF: Only the last statement needs proof. We only give the proof in the case where f is $\mathcal{C}^{n+1}$ on U; the statement is true if f is just $(n+1)$'st order differentiable on U, and even if it is only n'th order differentiable at $\boldsymbol{a}$, but the proof is more delicate (). If f is $\mathcal{C}^{n+1}$, and V is a bounded neighborhood of $\boldsymbol{a}$ with $\bar{V} \subseteq U$, then the $(n+1)$'st order partials of f are uniformly bounded on V, and it follows that there is a constant M such that $|r_n(\boldsymbol{x})| \leq M\|\boldsymbol{x}-\boldsymbol{a}\|^{n+1}$ for $\boldsymbol{x} \in V$, so

$$\lim_{\boldsymbol{x}\to\boldsymbol{a}} \frac{r_n(\boldsymbol{x})}{\|\boldsymbol{x}-\boldsymbol{a}\|^n} = 0 \ .$$

VIII.4.4. Critical Point Analysis

We can give a second-derivative test to determine local and maxima and minima of functions of several variables in analogy with the one-dimensional case, although, as might be expected, the criterion is a little more complicated. Note that all the definitions and results we give here exactly reduce to the usual ones in the one-dimensional case.

We first note the definition of local extrema and the analog of ():

VIII.4.4.1. DEFINITION. Let U be an open set in $\mathbb{R}^d$, and f a function from U to $\mathbb{R}$. Then f has a *local maximum* at $\boldsymbol{a} \in U$ if there is an open ball B around $\boldsymbol{a}$, contained in U, such that $f(\boldsymbol{x}) \leq f(\boldsymbol{a})$ for all $\boldsymbol{x} \in B$; the local maximum is *strict* if there is a B such that $f(\boldsymbol{x}) < f(\boldsymbol{a})$ for all $\boldsymbol{x} \in B$, $\boldsymbol{x} \neq \boldsymbol{a}$. The function f has a *local minimum* at $\boldsymbol{a} \in U$ if there is an open ball B around $\boldsymbol{a}$, contained in U, such that $f(\boldsymbol{x}) \geq f(\boldsymbol{a})$ for all $\boldsymbol{x} \in B$. The function f has a *local extremum* at $\boldsymbol{a}$ if it has either a local maximum or a local minimum at $\boldsymbol{a}$. Strict local minima and strict local extrema are defined accordingly.

The next result is an immediate consequence of () by fixing all but one coordinate and noting that if f has a local extremum at $\boldsymbol{a}$, so does any such restricted function.

VIII.4.4.2. PROPOSITION. Let U be an open set in $\mathbb{R}^d$, $f : U \to \mathbb{R}$, and $\boldsymbol{a} \in U$. If f has a local extremum at $\boldsymbol{a}$, then any first-order partial derivative of f which exists at $\boldsymbol{a}$ is zero at $\boldsymbol{a}$.

VIII.4.4.3. COROLLARY. Let U be an open set in $\mathbb{R}^d$, $f : U \to \mathbb{R}$, and $\boldsymbol{a} \in U$. If f has a local extremum at $\boldsymbol{a}$, and f is differentiable at $\boldsymbol{a}$, then $Df(\boldsymbol{a}) = 0$ (i.e. $\nabla f(\boldsymbol{a}) = \boldsymbol{0}$).

VIII.4.4.4. DEFINITION. Let U be an open set in $\mathbb{R}^d$, $f : U \to \mathbb{R}$, and $\boldsymbol{a} \in U$. Then $\boldsymbol{a}$ is a *critical point* of f if $\nabla f(\boldsymbol{a}) = \boldsymbol{0}$ or if f is not differentiable at $\boldsymbol{a}$.

The Second Derivative or Hessian Matrix

VIII.4.4.5. Recall () that if f is second-order differentiable at $\boldsymbol{a}$, the matrix

$$D^2 f(\boldsymbol{a}) = \begin{bmatrix} \frac{\partial^2 f}{\partial x_1^2}(\boldsymbol{a}) & \frac{\partial^2 f}{\partial x_1 \partial x_2}(\boldsymbol{a}) & \cdots & \frac{\partial^2 f}{\partial x_1 \partial x_d}(\boldsymbol{a}) \\ \frac{\partial^2 f}{\partial x_2 \partial x_1}(\boldsymbol{a}) & \frac{\partial^2 f}{\partial x_2^2}(\boldsymbol{a}) & \cdots & \frac{\partial^2 f}{\partial x_2 \partial x_d}(\boldsymbol{a}) \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_d \partial x_1}(\boldsymbol{a}) & \frac{\partial^2 f}{\partial x_d \partial x_2}(\boldsymbol{a}) & \cdots & \frac{\partial^2 f}{\partial x_d^2}(\boldsymbol{a}) \end{bmatrix}$$

is called the *Hessian matrix* of f at $\boldsymbol{a}$. It is a symmetric matrix which is the multidimensional version of the second derivative of f at $\boldsymbol{a}$. If $\boldsymbol{a}$ is a critical point of f, this matrix can determine whether f has a local extremum at $\boldsymbol{a}$.

Directional Second Derivatives

VIII.4.4.6. Let f be second-order differentiable on an open set $U \subseteq \mathbb{R}^d$, and $\boldsymbol{a} \in U$. If $\boldsymbol{u}$ is a unit vector in $\mathbb{R}^d$, let $\gamma(t) = \boldsymbol{a} + t\boldsymbol{u}$ and $g(t) = f(\gamma(t))$. Then γ and g are defined and second-order differentiable in an interval around 0, and $g'(0)$ is exactly the directional derivative $\frac{\partial f}{\partial \boldsymbol{u}}(\boldsymbol{a})$. It makes sense to interpret $g''(0)$ as the *directional second derivative* of f in the direction $\boldsymbol{u}$, and write it $\frac{\partial^2 f}{\partial \boldsymbol{u}^2}(\boldsymbol{a})$. By a computation identical to the one in VIII.4.3.3., we have:

VIII.4.4.7. Proposition. We have

$$\frac{\partial^2 f}{\partial \boldsymbol{u}^2}(\boldsymbol{a}) = d^2 f(\boldsymbol{a})\boldsymbol{u}^2 = (D^2 f(\boldsymbol{a})\boldsymbol{u}) \cdot \boldsymbol{u} \ .$$

Positive Definite Matrices

Recall the following facts from linear algebra ():

VIII.4.4.8. Proposition. Let A be a symmetric $d \times d$ matrix with real entries. Then all eigenvalues of A are real; A has d real eigenvalues, counted with multiplicity, and the eigenvectors of A span $\mathbb{R}^d$. Eigenvectors corresponding to different eigenvalues are orthogonal.

VIII.4.4.9. Proposition. Let A be a symmetric $d \times d$ matrix with real entries. The following are equivalent:

(i) $(A\boldsymbol{x}) \cdot \boldsymbol{x} > 0$ for every nonzero $\boldsymbol{x} \in \mathbb{R}^d$.

(ii) All eigenvalues of A are strictly positive.

A (symmetric) A satisfying these conditions is called *positive definite*. In fact, if A is positive definite and $\lambda > 0$ is the smallest eigenvalue of A, then $(A\boldsymbol{x}) \cdot \boldsymbol{x} \geq \lambda \|\boldsymbol{x}\|^2$ for every $\boldsymbol{x}$.

VIII.4.4.10. Similarly, $(A\boldsymbol{x}) \cdot \boldsymbol{x} < 0$ for every nonzero $\boldsymbol{x} \in \mathbb{R}^d$ if and only if all eigenvalues of A are strictly negative. Such a matrix is called *negative definite*. We also make the following definitions, which are perhaps not quite standard:

VIII.4.4.11. Definition. Let A be a symmetric $d \times d$ matrix.

A is *indefinite* if it has both positive and negative eigenvalues (it may or may not have 0 as an eigenvalue).

A is *degenerate* if 0 is an eigenvalue, and all the other eigenvalues (if any) have the same sign.

VIII.4.4.12. Thus, if A is a symmetric $d \times d$ matrix, there are four mutually exclusive possibilities:

A is positive definite.

A is negative definite.

A is indefinite.

A is degenerate.

If $d = 1$, the indefinite case cannot occur, and the other three mean the 1×1 matrix (number) is positive, negative, or zero respectively.

The last statement of VIII.4.4.9. has an important consequence:

VIII.4.4.13. Corollary. Let A be a positive definite [negative definite, indefinite] $d \times d$ matrix. Then there is an $\epsilon > 0$ such that every symmetric $n \times n$ matrix B with $\|A - B\| < \epsilon$ is positive definite [negative definite, indefinite]. In fact, we can take ϵ to be the minimum of the absolute values of the nonzero eigenvalues of A.

The main result is:

VIII.4.4.14. THEOREM. [SECOND DERIVATIVE TEST, MULTIVARIABLE VERSION] Let U be an open set in $\mathbb{R}^d$, and $f : U \to \mathbb{R}$ a $\mathcal{C}^2$ function. If $\boldsymbol{a} \in U$ and $\nabla f(\boldsymbol{a}) = \mathbf{0}$, then

(i) If $D^2 f(\boldsymbol{a})$ is positive definite, then f has a strict local minimum at $\boldsymbol{a}$.

(ii) If $D^2 f(\boldsymbol{a})$ is negative definite, then f has a strict local maximum at $\boldsymbol{a}$.

(iii) If $D^2 f(\boldsymbol{a})$ is indefinite, then f has neither a local maximum nor local minimum at $\boldsymbol{a}$.

(iv) If $D^2 f(\boldsymbol{a})$ is degenerate, then f may or may not have a local extremum at $\boldsymbol{a}$ and a local extremum may or may not be strict, and almost no conclusion may be drawn, i.e. the test fails. The only conclusion is that if $D^2 f(\boldsymbol{a})$ has a positive eigenvalue, f cannot have a local maximum at $\boldsymbol{a}$, and if it has a negative eigenvalue, then f cannot have a local minimum at $\boldsymbol{a}$.

PROOF: We first prove (iii) and part of (iv). This argument only requires that f be second-order differentiable at $\boldsymbol{a}$, not necessarily $\mathcal{C}^2$ on a neighborhood. Suppose $D^2 f(\boldsymbol{a})$ has a positive eigenvalue λ, and let $\boldsymbol{u}$ be a unit eigenvector with eigenvalue λ. If g denotes the restriction of f to the line L through $\boldsymbol{a}$ in the direction $\boldsymbol{u}$, then

$$g''(0) = \frac{\partial^2 f}{\partial \boldsymbol{u}^2}(\boldsymbol{a}) = (D^2 f(\boldsymbol{a})\boldsymbol{u}) \cdot \boldsymbol{u} = (\lambda \boldsymbol{u}) \cdot \boldsymbol{u} = \lambda > 0$$

and thus f restricted to L has a strict minimum at $\boldsymbol{a}$ (). So f cannot have a local maximum, strict or not, at $\boldsymbol{a}$. Similarly, if $D^2 f(\boldsymbol{a})$ has a negative eigenvalue, then f cannot have a local minimum at $\boldsymbol{a}$.

This argument does not obviously suffice to prove (i) and (ii): radial behavior does not obviously tell the whole story without some uniformity. But we can easily obtain (i) and (ii) from Taylor's Theorem with $n = 1$. Suppose $D^2 f(\boldsymbol{a})$ is positive definite. Then there is a ball B centered at $\boldsymbol{a}$ such that $B \subseteq U$ and $D^2 f(\boldsymbol{b})$ is positive definite for all $\boldsymbol{b} \in B$ (). Since $\nabla f(\boldsymbol{a}) = \mathbf{0}$, Taylor's Theorem with $n = 1$ says that, for any $\boldsymbol{x} \in B$, $\boldsymbol{x} \neq \boldsymbol{a}$,

$$f(\boldsymbol{x}) = f(\boldsymbol{a}) + \frac{1}{2} d^2 f(\boldsymbol{c})(\boldsymbol{x} - \boldsymbol{a})^2 = f(\boldsymbol{a}) + [D^2 f(\boldsymbol{c})(\boldsymbol{x} - \boldsymbol{a})] \cdot (\boldsymbol{x} - \boldsymbol{a})$$

for some $\boldsymbol{c}$ on the line segment between $\boldsymbol{a}$ and $\boldsymbol{x}$. Any such $\boldsymbol{c}$ is in B and hence $D^2 f(\boldsymbol{c})$ is positive definite, $[D^2 f(\boldsymbol{c})(\boldsymbol{x} - \boldsymbol{a})] \cdot (\boldsymbol{x} - \boldsymbol{a}) > 0$, $f(\boldsymbol{x}) > f(\boldsymbol{a})$. The case where $D^2 f(\boldsymbol{a})$ is negative definite is analogous.

There are 1-dimensional examples () giving the other statements of (iv). See VIII.4.4.18. for some two-dimensional examples. 👍

The Two-Dimensional Case

VIII.4.4.15. The case $d = 2$ is slightly simpler than the general case. In this case, $D^2 f(\boldsymbol{a})$ has two eigenvalues, which may coincide (exactly when $D^2 f(\boldsymbol{a})$ is a scalar multiple of I_2). It is positive definite if both eigenvalues are positive, negative definite if both are negative, indefinite if they are of opposite sign, and degenerate if one (or both) are zero. In fact, a symmetric (real) 2×2 matrix is

positive definite if and only if the diagonal entries and the determinant are positive.

negative definite if and only if the diagonal entries are negative and the determinant is positive.

indefinite if and only if the determinant is negative.

degenerate if and only if the determinant is zero.

[The determinant of a symmetric matrix is the product of the eigenvalues (counted with multiplicity).]

Two-Dimensional Examples

The following examples are generic:

VIII.4.4.16. EXAMPLES. (i) Let $f(x, y) = x^2 + y^2$. Then $\nabla f(x, y) = (2x, 2y)$, so $\nabla f(0, 0) = \mathbf{0}$.

$$D^2 f(0, 0) = \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}$$

which is positive definite, so f has a strict local minimum (actually a strict global minimum) at $(0, 0)$. See Figure VIII.4.

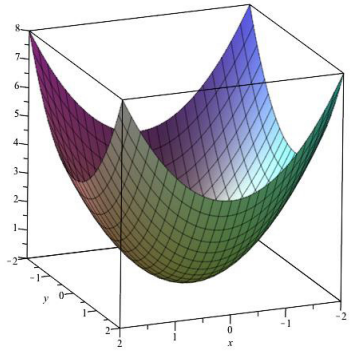

Figure VIII.4: Maple plot of graph of $f(x, y) = x^2 + y^2$

If the eigenvalues are different, the surface is elongated in one direction. For example, if $f(x, y) = x^2+2y^2$, we have

$$D^2 f(0, 0) = \begin{bmatrix} 2 & 0 \\ 0 & 4 \end{bmatrix} .$$

See Figure VIII.5.

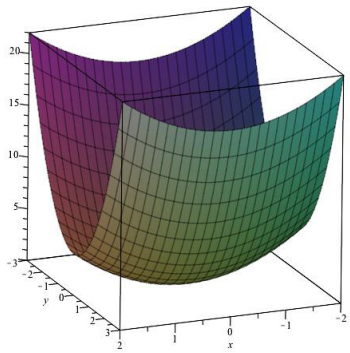

Figure VIII.5: Maple plot of graph of $f(x, y) = x^2 + 2y^2$

(ii) The negatives of these examples give strict local maxima (the Hessians are negative definite):

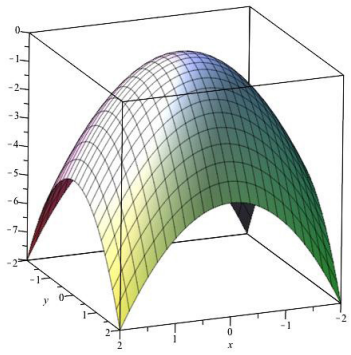

Figure VIII.6: Maple plot of graph of $f(x, y) = -x^2 - y^2$

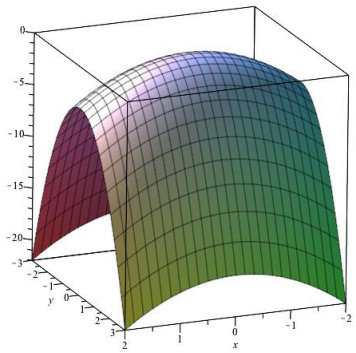

Figure VIII.7: Maple plot of graph of $f(x, y) = -x^2 - 2y^2$

(iii) Let $f(x,y) = x^2 - y^2$. Then $\nabla f(x,y) = (2x, -2y)$, so $\nabla f(0,0) = \mathbf{0}$.

$$D^2 f(0,0) = \begin{bmatrix} 2 & 0 \\ 0 & -2 \end{bmatrix}$$

which is indefinite, so f does not have a local extremum at $(0,0)$; it has what is called a *saddle point* at $(0,0)$. See Figure VIII.8.

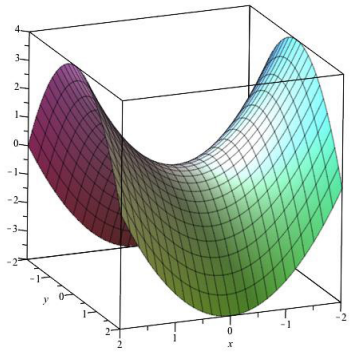

Figure VIII.8: Maple plot of graph of $f(x,y) = x^2 - y^2$

VIII.4.4.17. In the general two-dimensional case, since the corresponding eigenvectors are orthogonal, we can make an affine change of coordinates so that $\boldsymbol{a} = \mathbf{0}$, $f(\boldsymbol{a}) = 0$, and $D^2 f(\boldsymbol{a})$ is a diagonal matrix. Thus, if $D^2 f(\boldsymbol{a})$ is not degenerate, f locally approximately looks like one of the above cases (by the Morse Lemma (), there is a smooth change of coordinates so it is locally *exactly* one of these).

VIII.4.4.18. EXAMPLES. If $D^2f(\boldsymbol{a})$ is degenerate, almost any sort of behavior nearby is possible:
(i) Let $f(x,y) = x^2 + y^4$. Then

$$D^2f(0,0) = \begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix}$$

and f has a strict local minimum at $\mathbf{0}$. See Figure VIII.9.

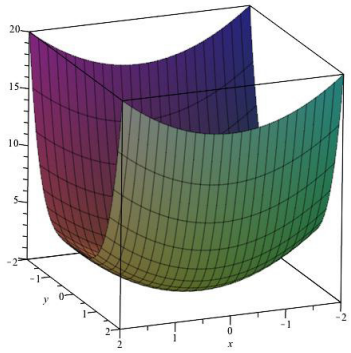

Figure VIII.9: Maple plot of graph of $f(x,y) = x^2 + y^4$

(ii) Let $f(x,y) = x^2$. Then

$$D^2f(0,0) = \begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix}$$

and f has a local minimum at $\mathbf{0}$, but it is not strict. See Figure VIII.10.

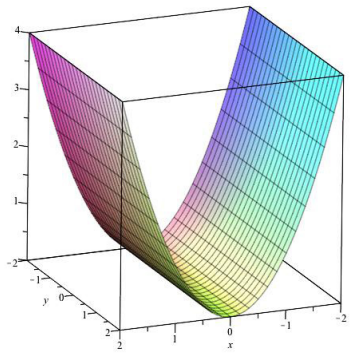

Figure VIII.10: Maple plot of graph of $f(x,y) = x^2$

(iii) Let $f(x,y) = x^2 - y^4$. Then

$$D^2 f(0,0) = \begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix}$$

and f has a saddle point at $\mathbf{0}$. See Figure VIII.11.

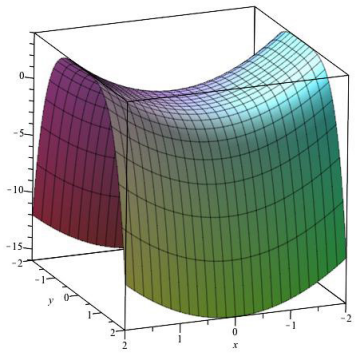

Figure VIII.11: Maple plot of graph of $f(x,y) = x^2 - y^4$

(iv) Let $f(x,y) = x^2 + y^3$. Then

$$D^2 f(0,0) = \begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix}$$

and f has what may be called a chair point at $\mathbf{0}$. See Figure VIII.12.

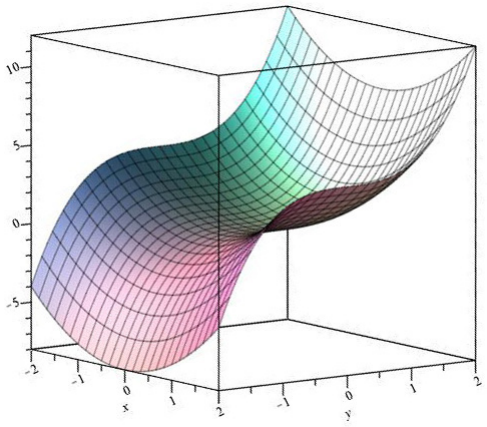

Figure VIII.12: Maple plot of graph of $f(x,y) = x^2 + y^3$

(v) In (i)–(iv), we can instead take $f(x,y)$ to be x^4+y^4, x^4, x^4-y^4, or x^4+y^3 respectively; then $D^2f(0,0)=0$ and the same conclusion holds. Also try $f(x,y)=x^3+y^3$. We can also take $f(x,y)$ to be $-x^4-y^4$ or $-x^4$ to get a local maximum, strict or not, with the same Hessian.
(vi) Let $f(x,y)=x^3-3xy^2$. Then $\nabla f(0,0)=\mathbf{0}$ and $D^2f(0,0)=0$. The graph is called a *monkey saddle* for obvious reasons. See Figure VIII.13.

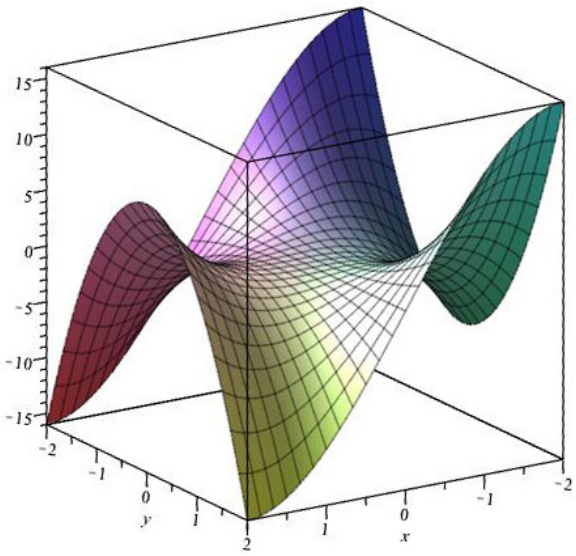

Figure VIII.13: Maple plot of graph of $f(x,y)=x^3-3xy^2$

(vii) There are much more complicated examples if $D^2f(\boldsymbol{a})$ is degenerate even if $d=1$, such as () and (). These can be made into two-dimensional examples by taking $g(x,y)=f(x)$, $g(x,y)=f(x)f(y)$, etc.

VIII.4.5. The Morse Lemma

VIII.4.6. Exercises

VIII.4.6.1. (a) Let $\boldsymbol{f}:U\subseteq\mathbb{R}^n\to\mathbb{R}^m$ be second-order differentiable at $\boldsymbol{a}\in U$. Show that

$$d^2\boldsymbol{f}(\boldsymbol{a})(\mathbf{e}_j)(\mathbf{e}_k)=\frac{\partial^2\boldsymbol{f}}{\partial x_j\partial x_k}(\boldsymbol{a})$$

for any j,k. Thus the second-order partials of $\boldsymbol{f}$ are the natural coordinates for the identification of $d^2\boldsymbol{f}$ regarded as a function from U to $\mathbb{R}^{nm}$.
(b) More generally, if $\boldsymbol{f}$ is r'th order differentiable at $\boldsymbol{a}$, and $d^r\boldsymbol{f}(\boldsymbol{a})$ is regarded as an r-multilinear map from $\mathbb{R}^n\times\cdots\times\mathbb{R}^n$ to $\mathbb{R}^m$, then for any $i_1,\dots,i_r$ we have

$$d^r\boldsymbol{f}(\boldsymbol{a})(\mathbf{e}_{i_1},\dots,\mathbf{e}_{i_r})=\frac{\partial^r\boldsymbol{f}}{\partial x_{i_1}\cdots\partial x_{i_r}}(\boldsymbol{a})\ .$$

(c) Give a similar description of $D^r \boldsymbol{f}(\boldsymbol{a})$.

VIII.5. The Implicit and Inverse Function Theorems

The Implicit and Inverse Function Theorems are the deepest results from differential calculus, and among the most important; they are the primary means of passing from the *infinitesimal* to the *local* in analysis and geometry. Although they are distinct results, each is a relatively easy corollary of the other, so one only needs to carry out the (rather difficult) proof of one of them to obtain both (and in fact the two theorems have a common generalization, cf. VIII.5.2.1.). They can both be regarded as aspects of the general problem of solving systems of functional equations; existence and uniqueness theorems for solutions to differential equations fall into the same class of results (see XI.1.10.12.). See III.5.3.7. and III.5.3.8. for purely algebraic versions.

These results are stated in less generality than they have to be in many references, with proofs more difficult than they have to be (and at that not even always entirely complete or correct). There are several standard proofs, and some of these proofs arguably give better insight into *why* the theorems are true than the simplest ones. We will give proofs of each theorem which illustrate two common approaches; each approach gives versions not obtainable from the others.

These theorems have a long and complicated history, going back at least to Descartes and used extensively by Newton, cf. VIII.5.11.7. (although for a long time it was not always appreciated that they had to be *proved*), and there are many versions. We will give only a few. The Smooth ($\mathcal{C}^1$) Implicit Function Theorem (VIII.5.1.7.) was first proved by Dini in the 1870's, although Dini's contributions were not properly recognized for a long time since he published them only in his lecture notes, which had a limited circulation. For continuous and higher-order smooth versions, see [Gou03] and [You09]. The book [KP02a] contains the most thorough treatment available of the various forms of the Implicit and Inverse Function Theorems.

VIII.5.1. Statements of the Theorems

VIII.5.1.1. The idea of the theorems is that if one has n equations in m unknowns, then there is "usually" a unique solution if $n = m$, many solutions if $n < m$, and no solutions if $n > m$; if $n < m$, it should be possible to solve for n of the variables as functions of the others (specifying values for $m - n$ of the variables yields a system of n equations in the remaining n variables). These statements are literally true if the equations are linear (cf. ()) unless there is degeneracy in the system. Since smooth functions are "approximately linear", it might also be possible (and in fact *is*) to do the same locally in the smooth case.

VIII.5.1.2. Vector notation is a convenient way to rephrase systems of equations. An equation in unknowns $x_1, \ldots, x_m$ can, by moving everything to one side of the equation, be written as $F(x_1, \ldots, x_m) = 0$, where $F : \mathbb{R}^m \to \mathbb{R}$ is a function. A set of n equations

$$F_1(x_1, \ldots, x_m) = 0$$

$$F_2(x_1, \ldots, x_m) = 0$$

$$\ldots$$

$$F_n(x_1, \ldots, x_m) = 0$$

can be written as $\boldsymbol{F}(x_1, \ldots, x_m) = \mathbf{0}$, or $\boldsymbol{F}(\boldsymbol{x}) = \mathbf{0}$, where $\boldsymbol{F}$ is the function from $\mathbb{R}^m$ (or a subset) to $\mathbb{R}^n$ with coordinate functions $(F_1, \ldots, F_n)$, and $\boldsymbol{x} = (x_1, \ldots, x_m)$.

VIII.5.1.3. In the case $m > n$, it is convenient to change notation slightly by setting $p = m - n$. We would like to be able to solve the system $\boldsymbol{F}(\boldsymbol{x}) = \boldsymbol{0}$ for n of the variables in terms of the other p variables. (Here the relative sizes of n and p do not matter; we could have $n < p$, $n = p$, or $n > p$.) We can in general choose any n of the variables to solve for in terms of the other ones; we will notationally choose the last n and rename them $y_1, \ldots, y_n$, i.e. our equation to solve is of the form

$$\boldsymbol{F}(x_1, \ldots, x_p, y_1, \ldots, y_n) = \boldsymbol{0}$$

or $\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) = \boldsymbol{0}$, where $\boldsymbol{x} = (x_1, \ldots, x_p) \in \mathbb{R}^p$ and $\boldsymbol{y} = (y_1, \ldots, y_n) \in \mathbb{R}^n$. A *solution* on a subset W of $\mathbb{R}^p$ is a function $\boldsymbol{f} : W \to \mathbb{R}^n$ such that the pair $(\boldsymbol{x}, \boldsymbol{y})$ for $\boldsymbol{y} = \boldsymbol{f}(\boldsymbol{x})$ satisfies the equation for all $\boldsymbol{x} \in W$, i.e. $\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) = \boldsymbol{0}$ for all $\boldsymbol{x} \in W$. We say the function $\boldsymbol{f}$ is *implicitly defined* by the equation $\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) = \boldsymbol{0}$. It is rarely possible to find an explicit formula for an implicitly defined function in the nonlinear case.

VIII.5.1.4. Examples with $n = p = 1$ from elementary calculus (e.g. the one in VIII.5.1.11.) show that one can only expect the equation $\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) = \boldsymbol{0}$ to define $\boldsymbol{y}$ as a continuous function of $\boldsymbol{x}$ locally, i.e. in some neighborhood of a point $\boldsymbol{a}$ where $(\boldsymbol{a}, \boldsymbol{b})$ satisfies the equation, and then only around points where there is some nondegeneracy condition on $\boldsymbol{F}$. If $n = p = 1$ and F is smooth, the graph of the equation $F(x, y) = 0$ is a curve in $\mathbb{R}^2$, and this curve is in general only locally the graph of a smooth function, and not even necessarily around every point of the curve; points where the curve crosses itself or has a vertical tangent must be excluded (see Exercise VIII.5.11.2.).

VIII.5.1.5. In the statements of the theorems, we will use the following notation. Let $\boldsymbol{F}$ be a function from an open set U in $\mathbb{R}^{p+n}$ to $\mathbb{R}^n$. Write the coordinates of $\mathbb{R}^{p+n}$ as $(x_1, \ldots, x_p, y_1, \ldots, y_n)$, or $(\boldsymbol{x}, \boldsymbol{y})$ with $\boldsymbol{x} = (x_1, \ldots, x_p) \in \mathbb{R}^p$ and $\boldsymbol{y} = (y_1, \ldots, y_n) \in \mathbb{R}^n$ as above, and let $F_1, \ldots, F_n$ be the coordinate functions of $\boldsymbol{F}$. So, in coordinates,

$$\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) = (F_1(\boldsymbol{x}, \boldsymbol{y}), \ldots, F_n(\boldsymbol{x}, \boldsymbol{y})) = (F_1(x_1, \ldots, x_p, y_1, \ldots, y_n), \ldots, F_n(x_1, \ldots, x_p, y_1, \ldots, y_n))) \ .$$

Let $(\boldsymbol{x}, \boldsymbol{y}) \in U$, and suppose all partial derivatives of the form $\frac{\partial F_i}{\partial y_j}(\boldsymbol{x}, \boldsymbol{y})$ exist. Write

$$D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) = \frac{\partial(F_1, \ldots, F_n)}{\partial(y_1, \ldots, y_n)}(\boldsymbol{x}, \boldsymbol{y}) = \begin{bmatrix} \frac{\partial F_1}{\partial y_1}(\boldsymbol{x}, \boldsymbol{y}) & \cdots & \frac{\partial F_1}{\partial y_n}(\boldsymbol{x}, \boldsymbol{y}) \\ \vdots & \ddots & \vdots \\ \frac{\partial F_n}{\partial y_1}(\boldsymbol{x}, \boldsymbol{y}) & \cdots & \frac{\partial F_n}{\partial y_n}(\boldsymbol{x}, \boldsymbol{y}) \end{bmatrix}$$

and, if all partial derivatives of the form $\frac{\partial F_i}{\partial x_j}(\boldsymbol{x}, \boldsymbol{y})$ exist, write

$$D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) = \frac{\partial(F_1, \ldots, F_n)}{\partial(x_1, \ldots, x_p)}(\boldsymbol{x}, \boldsymbol{y}) = \begin{bmatrix} \frac{\partial F_1}{\partial x_1}(\boldsymbol{x}, \boldsymbol{y}) & \cdots & \frac{\partial F_1}{\partial x_p}(\boldsymbol{x}, \boldsymbol{y}) \\ \vdots & \ddots & \vdots \\ \frac{\partial F_n}{\partial x_1}(\boldsymbol{x}, \boldsymbol{y}) & \cdots & \frac{\partial F_n}{\partial x_p}(\boldsymbol{x}, \boldsymbol{y}) \end{bmatrix}$$

(note that $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y})$ is $n \times n$ and $D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y})$ is $n \times p$ if they are defined). Then if $\boldsymbol{F}$ is differentiable at $(\boldsymbol{x}, \boldsymbol{y})$, we have that the $n \times (p + n)$ matrix $D\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y})$ partitions as

$$D\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) = \left[\begin{array}{ccc} & \vdots & \\ D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) & \vdots & D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) \\ & \vdots & \end{array}\right] .$$

VIII.5.1.6. THEOREM. [IMPLICIT FUNCTION THEOREM, CONTINUOUS VERSION] Let U be an open set in $\mathbb{R}^{p+n}$ and $(\boldsymbol{a},\boldsymbol{b}) \in U$. Let $\boldsymbol{F} : U \to \mathbb{R}^n$ with $\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b}) = \boldsymbol{0}$. Suppose $\boldsymbol{F}$ is continuous on U and that $D_{\boldsymbol{y}}\boldsymbol{F}$ exists and is continuous on U, i.e. that $\frac{\partial \boldsymbol{F}}{\partial y_j}$ exists and is continuous on U for $1 \le j \le n$. If $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$ is invertible, i.e. $det(D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})) \neq 0$, then there are:

(i) An open set V in $\mathbb{R}^{p+n}$ containing $(\boldsymbol{a},\boldsymbol{b})$, with $V \subseteq U$, such that $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})$ is invertible for all $(\boldsymbol{x},\boldsymbol{y}) \in V$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $\boldsymbol{f} : W \to \mathbb{R}^n$ such that $\boldsymbol{f}(\boldsymbol{a}) = \boldsymbol{b}$ and, for all $\boldsymbol{x} \in W$, $(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) \in V$ and

$$\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) = \boldsymbol{0} \ .$$

Additionally, $\boldsymbol{f}$ is continuous on W.

VIII.5.1.7. THEOREM. [IMPLICIT FUNCTION THEOREM, SMOOTH VERSION] Let U be an open set in $\mathbb{R}^{p+n}$ and $(\boldsymbol{a},\boldsymbol{b}) \in U$. Let $\boldsymbol{F} : U \to \mathbb{R}^n$ with $\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b}) = \boldsymbol{0}$. Suppose $\boldsymbol{F}$ is $\mathcal{C}^r$ on U for some r, $1 \le r \le \infty$. If $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$ is invertible, i.e. $det(D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})) \neq 0$, then there are:

(i) An open set V in $\mathbb{R}^{p+n}$ containing $(\boldsymbol{a},\boldsymbol{b})$, with $V \subseteq U$, such that $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})$ is invertible for all $(\boldsymbol{x},\boldsymbol{y}) \in V$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $\boldsymbol{f} : W \to \mathbb{R}^n$ such that $\boldsymbol{f}(\boldsymbol{a}) = \boldsymbol{b}$ and, for all $\boldsymbol{x} \in W$, $(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) \in V$ and

$$\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) = \boldsymbol{0} \ .$$

Additionally, $\boldsymbol{f}$ is $\mathcal{C}^r$ on W, and for any $\boldsymbol{x} \in W$, we have

$$D\boldsymbol{f}(\boldsymbol{x}) = -D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))^{-1} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))$$

(in particular, $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))$ is invertible for all $\boldsymbol{x} \in W$).

Slightly informally, for $\boldsymbol{x}$ sufficiently near $\boldsymbol{a}$, $\boldsymbol{y} = \boldsymbol{f}(\boldsymbol{x})$ is the unique $\boldsymbol{y}$ near $\boldsymbol{b}$ such that $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{0}$, i.e. we have "solved" the equation $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{0}$ for $\boldsymbol{y}$ as a function of $\boldsymbol{x}$.

VIII.5.1.8. Note that the difference between the continuous version and the $\mathcal{C}^1$ version (smooth version with $r = 1$) is merely in the differentiability of $\boldsymbol{F}$ in the $\boldsymbol{x}$-coordinates; continuity of $\boldsymbol{F}$ and continuous differentiability in the $\boldsymbol{y}$-coordinates are necessary in both cases (there is a version with this weakened: see VIII.5.3.9. and VIII.5.7.7.). To obtain continuous differentiability of higher order for the implicitly defined function, higher-order continuous differentiability of $\boldsymbol{F}$ in both $\boldsymbol{x}$- and $\boldsymbol{y}$-coordinates is needed.

VIII.5.1.9. The uniqueness of the implicitly defined function $\boldsymbol{f}$ precisely means that there is an open neighborhood V' of $(\boldsymbol{a},\boldsymbol{b})$ (specifically, $V' = \{(\boldsymbol{x},\boldsymbol{y}) \in V : \boldsymbol{x} \in W\}$) such that the part of the level set $\Gamma = \{(\boldsymbol{x},\boldsymbol{y}) \in U : \boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{0}\}$ in V' is exactly the graph of $\boldsymbol{f}$, i.e. Γ is locally the graph of a (continuous or smooth) function (cf. VIII.5.1.17.).

The use of $\boldsymbol{0}$ in the statements is arbitrary: it could be replaced by any constant $\boldsymbol{c} \in \mathbb{R}^n$ by applying the theorems to $\tilde{\boldsymbol{F}} = \boldsymbol{F} - \boldsymbol{c}$.

VIII.5.1.10. EXAMPLE. [?] To see how this works in practice, consider the following set of three equations in five variables x, y, u, v, w:

$$u^5 + xv^2 - y + w = 0$$
$$v^5 + yu^2 - x + w = 0$$
$$w^4 + y^5 - x^4 = 1$$

We want to solve these equations for u, v, w as functions of x and y near $(1,1)$ with $u(1,1) = 1$, $v(1,1) = 1$, $w(1,1) = -1$ [note that $(x, y, u, v, w) = (1, 1, 1, 1, -1)$ satisfies the equations] and compute the partial derivatives of u, v, w at $(1,1)$.

We will apply the Implicit Function Theorem VIII.5.1.7. with $p = 2$, $n = 3$ (x, y play the role of x_1, x_2 and u, v, w play the role of y_1, y_2, y_3). Define $\boldsymbol{F} : \mathbb{R}^5 \to \mathbb{R}^3$ by

$$\boldsymbol{F}(x, y, u, v, w) = (u^5 + xv^2 - y - w, v^5 + yu^2 - x + w, w^4 + y^5 - x^4 - 1)$$

and note that $\boldsymbol{F}$ is $\mathcal{C}^\infty$ on all of $\mathbb{R}^5$, so the differentiability hypothesis is satisfied on $U = \mathbb{R}^5$. We set $\boldsymbol{a} = (1,1)$, $\boldsymbol{b} = (1,1,-1)$, so $\boldsymbol{c} := (\boldsymbol{a}, \boldsymbol{b}) = (1,1,1,1,-1)$. Set

$$\Gamma = \{(x, y, u, v, w) : \boldsymbol{F}(x, y, u, v, w) = \boldsymbol{0}\}$$

and note that $\boldsymbol{c} \in \Gamma$.

We want to show there is a neighborhood V of $\boldsymbol{c}$ and a unique differentiable ($\mathcal{C}^\infty$) function $\boldsymbol{f} : \mathbb{R}^2 \to \mathbb{R}^3$, defined on a neighborhood W of $(1,1)$, $\boldsymbol{f}(x, y) = (u(x, y), v(x, y), w(x, y))$, with $\boldsymbol{f}(1,1) = (1,1,-1)$ and

$$(x, y, u(x, y), v(x, y), w(x, y)) \in \Gamma \cap V$$

for all $(x, y) \in W$, i.e. $\boldsymbol{F}(x, y, u(x, y), v(x, y), w(x, y)) = \boldsymbol{0}$ for all $(x, y) \in W$.

We have

$$D\boldsymbol{F}(x, y, u, v, w) = \begin{bmatrix} v^2 & -1 & 5u^4 & 2xv & 1 \\ -1 & u^2 & 2yu & 5v^4 & 1 \\ -4x^3 & 5y^4 & 0 & 0 & 4w^3 \end{bmatrix}.$$

Partition this matrix after the second column:

$$D\boldsymbol{F}(x, y, u, v, w) = \left[\begin{array}{cc:ccc} v^2 & -1 & 5u^4 & 2xv & 1 \\ -1 & u^2 & 2yu & 5v^4 & 1 \\ -4x^3 & 5y^4 & 0 & 0 & 4w^3 \end{array}\right]$$

to obtain

$$D_{(x,y)}\boldsymbol{F}(x, y, u, v, w) = \begin{bmatrix} v^2 & -1 \\ -1 & u^2 \\ -4x^3 & 5y^4 \end{bmatrix}$$

$$D_{(u,v,w)}\boldsymbol{F}(x, y, u, v, w) = \begin{bmatrix} 5u^4 & 2xv & 1 \\ 2yu & 5v^4 & 1 \\ 0 & 0 & 4w^3 \end{bmatrix}.$$

Thus

$$D\boldsymbol{F}(1,1,1,1,-1) = \begin{bmatrix} 1 & -1 & 5 & 2 & 1 \\ -1 & 1 & 2 & 5 & 1 \\ -4 & 5 & 0 & 0 & -4 \end{bmatrix}$$

$$D_{(x,y)}\boldsymbol{F}(1,1,1,1,-1) = \begin{bmatrix} 1 & -1 \\ -1 & 1 \\ -4 & 5 \end{bmatrix}.$$

$$D_{(u,v,w)}\boldsymbol{F}(1,1,1,1,-1) = \begin{bmatrix} 5 & 2 & 1 \\ 2 & 5 & 1 \\ 0 & 0 & -4 \end{bmatrix}.$$

We have that $det(D_{(u,v,w)}\boldsymbol{F}(1,1,1,1,-1)) = -84 \neq 0$, so this matrix is invertible and the hypotheses of the Implicit Function Theorem are satisfied. Thus the desired function $\boldsymbol{f}$ exists (and is $\mathcal{C}^\infty$).

We have

$$D\boldsymbol{f}(1,1) = \begin{bmatrix} 5 & 2 & 1 \\ 2 & 5 & 1 \\ 0 & 0 & -4 \end{bmatrix}^{-1} \begin{bmatrix} 1 & -1 \\ -1 & 1 \\ -4 & 5 \end{bmatrix}$$

$$= \begin{bmatrix} 5/21 & -2/21 & 1/28 \\ -2/21 & 5/21 & 1/28 \\ 0 & 0 & -1/4 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ -1 & 1 \\ -4 & 5 \end{bmatrix} = \begin{bmatrix} 4/21 & -13/84 \\ -10/21 & -11/12 \\ 1 & -5/4 \end{bmatrix}.$$

Thus, for example, $\frac{\partial v}{\partial y}(1,1) = -\frac{11}{12}$.

If (x_0, y_0) is near $(1,1)$, we could compute $D\boldsymbol{f}(x_0, y_0)$ the same way:

$$D\boldsymbol{f}(x_0,y_0) = \begin{bmatrix} 5u(x_0,y_0)^4 & 2x_0v(x_0,y_0) & 1 \\ 2y_0u(x_0,y_0) & 5v(x_0,y_0)^4 & 1 \\ 0 & 0 & 4w(x_0,y_0)^3 \end{bmatrix}^{-1} \begin{bmatrix} v(x_0,y_0)^2 & -1 \\ -1 & u(x_0,y_0)^2 \\ -4x_0^3 & 5y_0^4 \end{bmatrix}$$

but we have no effective way to compute $u(x_0, y_0)$, $v(x_0, y_0)$, $w(x_0, y_0)$, so this is of limited use. If we know $(x_0, y_0, u_0, v_0, w_0)$ is a point of Γ close to $\boldsymbol{c}$, we could put in these values u_0, v_0, w_0 for $u(x_0, y_0)$, $v(x_0, y_0)$, $w(x_0, y_0)$ and evaluate $D\boldsymbol{f}(x_0, y_0)$. (We have glossed over the difficult question just *how* close $(x_0, y_0, u_0, v_0, w_0)$ must be to $\boldsymbol{c}$ for this to work.)

We could have solved for other variables. For example, we could (in principle) solve for x, y, u as functions of v and w around $(1, -1)$. To verify this, we must show that

$$D_{(x,y,u)}\boldsymbol{F}(1,1,1,1,-1) = \begin{bmatrix} 1 & -1 & 5 \\ -1 & 1 & 2 \\ -4 & 5 & 0 \end{bmatrix}$$

is invertible, which it is (the determinant is -7), or for x, y, w as functions of u, v around $(1, 1)$, since

$$D_{(x,y,w)}\boldsymbol{F}(1,1,1,1,-1) = \begin{bmatrix} 1 & -1 & 1 \\ -1 & 1 & 1 \\ -4 & 5 & -4 \end{bmatrix}$$

is invertible (the determinant is -2). The reader is invited to check the other seven possibilities.

VIII.5.1.11. EXAMPLE. In the statement of the theorems, one would expect the neighborhood V to be contained in U (this of course does not preclude the possibility that the conclusion could hold on a larger V). To show the necessity in general of passing to a smaller neighborhood V of $(\boldsymbol{a}, \boldsymbol{b})$ as well as the (expected) passage to a small neighborhood W of $\boldsymbol{a}$, consider the basic example of implicit differentiation every calculus class begins with: the case $p = n = 1$ and

$$F(x, y) = x^2 + y^2 - 25 \ .$$

The set $\{(x, y) : F(x, y) = 0\}$ is, of course, the circle of radius 5 around the origin in $\mathbb{R}^2$. Let $(a, b) = (3, 4)$. In this case the set U could be taken to be all of $\mathbb{R}^2$, but no matter how small an open interval W around $a = 3$ in $\mathbb{R}$ is taken, there is not a unique function f on W giving a solution, since we could have $f(x) = \pm\sqrt{25 - x^2}$ with the sign chosen arbitrarily for each x (so long as $f(3) = 4$). There is a unique *continuous solution* for W small, but to obtain a unique *solution*, one must cut down to a smaller neighborhood V of $(3, 4)$. Actually V does not have to be all that small in this case: it only needs not to contain any points on the lower half-circle with x-coordinate close to 3.

In this case, if f is the unique solution on an interval W (which must be contained in the interval $(-5, 5)$), then by the theorem

$$f'(x) = -\frac{\frac{\partial F}{\partial x}(x, f(x))}{\frac{\partial F}{\partial y}(x, f(x))} = -\frac{2x}{2f(x)} = -\frac{x}{f(x)}$$

for any $x \in W$. Here we can find an explicit formula for f: $f(x) = \sqrt{25 - x^2}$, and verify the formula for f' directly. In most examples it is impossible to find an explicit formula for the implicitly defined function.

VIII.5.1.12. EXAMPLE. For a simpler and more dramatic example showing that V must be chosen smaller than U in general, let $F(x, y) = \sin y$, with $U = \mathbb{R}^2$. The set

$$\Gamma = \{(x, y) : F(x, y) = 0\}$$

consists of the union of the horizontal lines $y = n\pi$ for $n \in \mathbb{Z}$. $(0, 0)$ is a point of Γ, and within the horizontal strip

$$V = \{(x, y) : -\pi < y < \pi\}$$

the equation $F(x, y) = 0$ can be solved for y as a (constant) function of x, but not in all of U. (To satisfy conclusion (i) of the theorem, we must further reduce V to

$$\left\{(x, y) : -\frac{\pi}{2} < y < \frac{\pi}{2}\right\}$$

to have $\frac{\partial F}{\partial y} \neq 0$ on V.) In fact, the equation $F(x, y) = 0$ can be locally solved for y as a function of x around every point of Γ, but not globally on Γ.

VIII.5.1.13. EXAMPLE. In Example VIII.5.1.12., the zero set Γ is naturally a disjoint union of graphs of functions. But the situation can be more complicated in higher dimensions. Let

$$U = \{(x, y, z) : x^2 + y^2 > 0\}$$

be $\mathbb{R}^3$ with the z-axis removed, and define ϕ and F on U by

$$\phi(x,y,z) = \begin{cases} z - \tan^{-1}\frac{y}{x} & \text{if} \quad x > 0 \\ z - \frac{\pi}{2} & \text{if} \quad x = 0,\ y > 0 \\ z - \tan^{-1}\frac{y}{x} - \pi & \text{if} \quad x < 0 \\ z + \frac{\pi}{2} & \text{if} \quad x = 0,\ y < 0 \end{cases}$$

and $F(x,y,z) = \sin\phi(x,y,z)$. Then ϕ is discontinuous where $x = 0$ and $y < 0$, but F is $\mathcal{C}^\infty$ on U. If $\Gamma = \{(x,y,z) \in U : F(x,y,z) = 0\}$, then $\frac{\partial F}{\partial z} \neq 0$ at all points of Γ, so the equation $F(x,y,z) = 0$ can be (even explicitly) locally solved for z at every point of Γ, but not globally (this phenomenon is called *holonomy* ()). The surface Γ consists of two intertwined helicoids, the surfaces with equations $z = \theta$ and $z = \theta + \pi$ in cylindrical coordinates, intersected with U. Neither helicoid is globally the graph of a function.

VIII.5.1.14. To obtain a reasonable Implicit Function Theorem, the function $\boldsymbol{F}$ must be continuous. This in itself is not enough to guarantee an implicitly defined function, even a nonunique one, even if $p = n = 1$ (Exercise VIII.5.11.4.). But if there is a (unique) implicitly defined function, it is automatically continuous:

VIII.5.1.15. Proposition. Let F be a continuous function on a subset U of $\mathbb{R}^{p+n}$, with values in $\mathbb{R}^n$, and K a compact subset of U. Suppose there is an open set W in $\mathbb{R}^p$ on which there is a unique function $\boldsymbol{f} : W \to \mathbb{R}^n$ implicitly defined by the equation $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{0}$ with respect to K, i.e. for each $\boldsymbol{x} \in W$ there is a unique $\boldsymbol{y} \in \mathbb{R}^n$ such that $(\boldsymbol{x},\boldsymbol{y}) \in K$ and $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{0}$. Then $\boldsymbol{f}$ is continuous.

Proof: Let $(\boldsymbol{x}_k)$ be a sequence in W with $\boldsymbol{x}_k \to \boldsymbol{a} \in W$. Suppose $\boldsymbol{f}(\boldsymbol{x}_k) \not\to \boldsymbol{f}(\boldsymbol{a})$. Then by compactness of K there is a subsequence $(\boldsymbol{x}_{k_j})$ such that $(\boldsymbol{f}(\boldsymbol{x}_{k_j}))$ converges to a point $\boldsymbol{y} \in \mathbb{R}^n$, $\boldsymbol{y} \neq \boldsymbol{f}(\boldsymbol{a})$, with $(\boldsymbol{a},\boldsymbol{y}) \in K$. But then $\boldsymbol{0} = \boldsymbol{F}(\boldsymbol{x}_{k_j}, \boldsymbol{f}(\boldsymbol{x}_{k_j})) \to \boldsymbol{F}(\boldsymbol{a},\boldsymbol{y})$ by continuity of $\boldsymbol{F}$, so $\boldsymbol{F}(\boldsymbol{a},\boldsymbol{y}) = \boldsymbol{F}(\boldsymbol{a},\boldsymbol{f}(\boldsymbol{a})) = \boldsymbol{0}$, contradicting the uniqueness assumption on $\boldsymbol{F}$ and K. 👍

VIII.5.1.16. The Implicit Function Theorem is strictly a local result, i.e. the conclusion just holds on *some* neighborhood W of $\boldsymbol{a}$. If $D\boldsymbol{F}$ is locally Lipschitz, in particular if $\boldsymbol{F}$ is $\mathcal{C}^2$, it is possible to determine an explicit W on which the conclusion holds (cf. XI.1.10.12.).

Geometric Interpretation of the Implicit Function Theorem

We can interpret the result of the Implicit Function Theorem geometrically as showing that the level set of $\boldsymbol{F}$ through $(\boldsymbol{a},\boldsymbol{b})$ is locally a "smooth hypersurface":

VIII.5.1.17. Corollary. Let U be an open set in $\mathbb{R}^{p+n}$ and $(\boldsymbol{a},\boldsymbol{b}) \in U$. Let $\boldsymbol{F} : U \to \mathbb{R}^n$ with $\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b}) = \boldsymbol{0}$. Suppose $\boldsymbol{F}$ is $\mathcal{C}^r$ on U for some r, $1 \leq r \leq \infty$. Set

$$\Gamma = \{(\boldsymbol{x},\boldsymbol{y}) \in \mathbb{R}^{p+n} : \boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{0}\}\ .$$

If $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$ is invertible, i.e. $det(D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})) \neq 0$, then there is an open neighborhood V of $(\boldsymbol{a},\boldsymbol{b})$ in $\mathbb{R}^{p+n} \cong \mathbb{R}^p \times \mathbb{R}^n$ such that $\Gamma \cap V$ is the graph of a $\mathcal{C}^r$ function from an open set W in $\mathbb{R}^p$ to $\mathbb{R}^n$. Thus $\Gamma \cap V$ is a p-dimensional $\mathcal{C}^r$ submanifold of $\mathbb{R}^{p+n}$ (XIV.1.1.12.).

The result can be rephrased more symmetrically if it is not specified in advance which n coordinates are being locally solved for:

VIII.5.1.18. Corollary. Let U be an open set in $\mathbb{R}^{p+n}$ and $\boldsymbol{c} \in U$. Let $\boldsymbol{F} : U \to \mathbb{R}^n$ with $\boldsymbol{F}(\boldsymbol{c}) = \boldsymbol{0}$. Suppose $\boldsymbol{F}$ is $\mathcal{C}^r$ on U for some r, $1 \leq r \leq \infty$. Set

$$\Gamma = \{\boldsymbol{z} \in \mathbb{R}^{p+n} : \boldsymbol{F}(\boldsymbol{z}) = \boldsymbol{0}\} .$$

If $D\boldsymbol{F}(\boldsymbol{c})$ has rank n, then there is an open neighborhood V of $\boldsymbol{c}$ in $\mathbb{R}^{p+n}$ such that $\Gamma \cap V$ is a p-dimensional $\mathcal{C}^r$ submanifold of $\mathbb{R}^{p+n}$. If $D\boldsymbol{F}(\boldsymbol{z})$ has rank n at every $\boldsymbol{z} \in \Gamma$, then Γ is a p-dimensional $\mathcal{C}^r$ submanifold of $\mathbb{R}^{p+n}$.

Note that since $D\boldsymbol{F}(\boldsymbol{c})$ is $n \times (p+n)$, its rank must be $\leq n$; thus the hypothesis is that $D\boldsymbol{F}(\boldsymbol{c})$ has maximal rank possible. If $n = 1$, the condition is just that $DF(\boldsymbol{c}) \neq 0$.

Proof: The hypothesis implies (and is equivalent to) that there is a set $\{x_{j_1}, \ldots, x_{j_n}\}$ of n coordinates such that the corresponding columns of $D\boldsymbol{F}(\boldsymbol{c})$ are linearly independent. By reordering the coordinates we may make these coordinates be the last n and rename them $y_1, \ldots, y_n$. Then with the renamed coordinates, $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{c})$ is invertible, so VIII.5.1.17. applies to give the result. 👍

VIII.5.1.19. There is often more than one choice for the n coordinates to be solved for, although not every set of n coordinates can be solved for in general. For example, in the situation of VIII.5.1.11., if $\boldsymbol{c}$ is any point on the level curve $F(x,y) = 0$, i.e.

$$\Gamma = \{(x,y) : x^2 + y^2 = 25\}$$

except for one of the four points on the coordinate axes, one can implicitly (and, in this case, even explicitly) locally solve for either of x and y as a function of the other. In this case, $DF(x,y)$ has rank 1 (i.e. is nonzero) at every point of Γ, so the conclusion is that Γ is a smooth 1-manifold (an obvious fact in this case).

VIII.5.1.20. If $\boldsymbol{c}$ is a point of Γ where $D\boldsymbol{F}(\boldsymbol{c})$ has rank less than n, then Γ is not a smooth manifold around $\boldsymbol{c}$ in general, and the local structure can be (but is not necessarily) quite pathological (VIII.5.1.22., VIII.5.1.23., VIII.5.11.23., VIII.5.11.1.). Indeed, if $F(x,y) = x^2 + y^2$, the set $\{(x,y) : F(x,y) = 0\}$ is a single point!

VIII.5.1.21. In fact, under the hypotheses of VIII.5.1.17. or VIII.5.1.18., one can be more specific about the local structure of Γ (VIII.5.8.8.).

VIII.5.1.22. EXAMPLE. Define $F : \mathbb{R}^2 \to \mathbb{R}$ (i.e. $p = n = 1$) by

$$F(x, y) = x^3 - 2xy + y^3$$

and set $\Gamma = \{(x, y) : F(x, y) = 0\}$. Then Γ is a "curve" in $\mathbb{R}^2$ (a *folium of Descartes*). We have

$$DF(x, y) = \begin{bmatrix} 3x^2 - 2y & 3y^2 - 2x \end{bmatrix}$$

which is nonzero at all points of Γ except $\mathbf{0}$; thus Γ is indeed a smooth curve except at the origin. See Figure VIII.14.

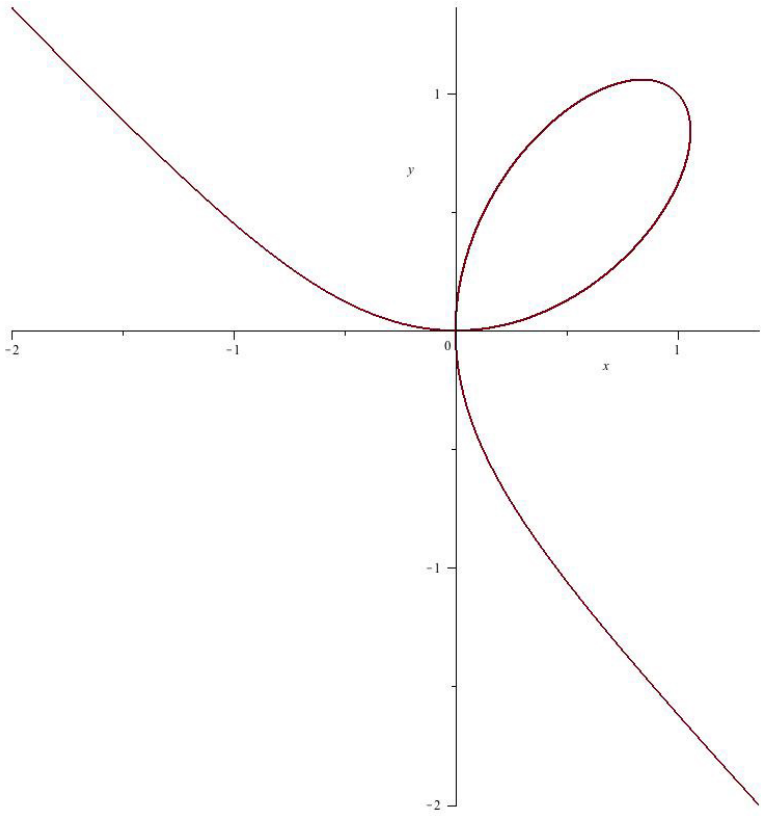

Figure VIII.14: Maple plot of $x^3 - 2xy + y^3 = 0$

The curve can be locally solved for y as a function of x around any point (a, b) on Γ where $3b^2 - 2a \neq 0$, i.e. everywhere except at the origin and the point in the first quadrant where the tangent line is vertical, $\left(\frac{2^{5/3}}{3}, \frac{2^{4/3}}{3}\right) \approx (1.058, 0.84)$. The slope of the tangent line at (a, b) is $-\frac{3a^2-2b}{3b^2-2a}$. In particular, at $(1, 1)$ the tangent line has slope -1.

VIII.5.1.23. EXAMPLE. Define $F : \mathbb{R}^3 \to \mathbb{R}$ (i.e. $p = 2$, $n = 1$) by

$$F(x, y, z) = x^2 + y^2 - z^2$$

and set $\Gamma = \{(x, y, z) : F(x, y, z) = 0\}$. Then Γ is a "surface" in $\mathbb{R}^2$; in fact, Γ is a cone with vertex at the origin (Figure VIII.15). We have

$$DF(x, y, z) = \begin{bmatrix} 2x & 2y & -2z \end{bmatrix}$$

which is rank 1 (nonzero) everywhere except at $\mathbf{0}$. Thus the Implicit Function Theorem implies that the cone is a smooth surface except possibly at the origin (which is geometrically obvious). It is in fact not a surface in any neighborhood of $\mathbf{0}$. If u stands for x, y, or z, then the equation $F(x, y, z) = 0$ can be locally solved for u as a function of the other two variables in a neighborhood of any point where $u \neq 0$.

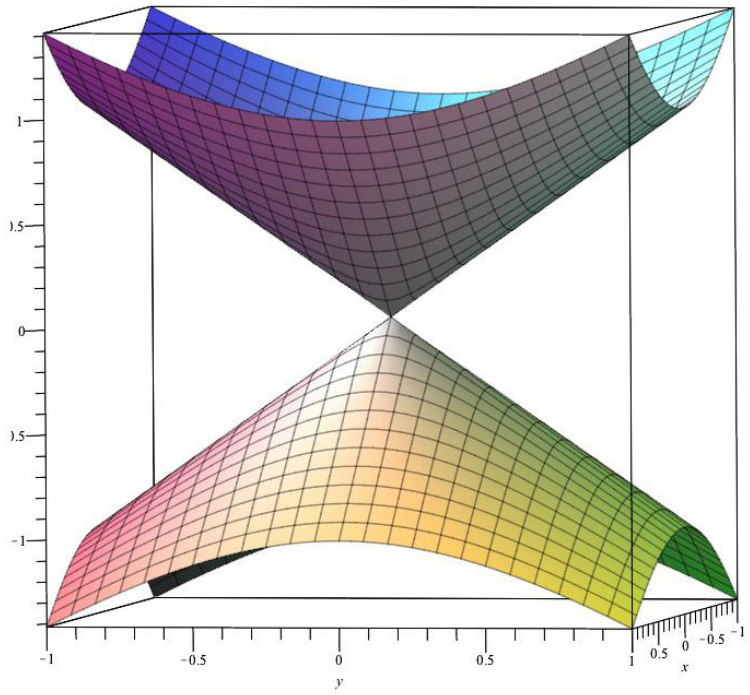

Figure VIII.15: Maple plot of $x^2 + y^2 = z^2$

VIII.5.1.24. The result VIII.5.1.18. can be used also to analyze intersections of surfaces or hypersurfaces. We illustrate with the case of two surfaces in $\mathbb{R}^3$, but the same principles apply to the case of k hypersurfaces in $\mathbb{R}^{p+n}$ for any $k, n, p \in \mathbb{N}$, $k \leq n$ (Exercise VIII.5.11.24.).

Suppose F_1, F_2 are smooth ($\mathcal{C}^r$) functions from $\mathbb{R}^3$ to $\mathbb{R}$, and set $\Gamma_1 = \{(x, y, z) : F_1(x, y, z) = 0\}$, $\Gamma_2 = \{(x, y, z) : F_2(x, y, z) = 0\}$. Then Γ_1 and Γ_2 are smooth surfaces, at least where DF_1 and DF_2 are nonzero. We would expect that $\Gamma = \Gamma_1 \cap \Gamma_2$ should be a smooth curve, at least where the surfaces intersect transversally, i.e. where DF_1 and DF_2 satisfy some nondegeneracy condition.

The proper condition is most easily described by considering DF_1 and DF_2 as ∇F_1 and ∇F_2, interpreting them as vectors in $\mathbb{R}^3$. The result is:

VIII.5.1.25. Corollary. Let F_1 and F_2 be $\mathcal{C}^r$ functions ($1 \leq r \leq \infty$) from $\mathbb{R}^3$ to $\mathbb{R}$, $\Gamma_1 = \{(x, y, z) : F_1(x, y, z) = 0\}$, $\Gamma_2 = \{(x, y, z) : F_2(x, y, z) = 0\}$, $\Gamma = \Gamma_1 \cap \Gamma_2$. Let $\boldsymbol{c} \in \Gamma$. If $\nabla F_1(\boldsymbol{c})$ and $\nabla F_2(\boldsymbol{c})$ are linearly independent, then there is an open neighborhood V of $\boldsymbol{c}$ in $\mathbb{R}^3$ such that $\Gamma \cap V = (\Gamma_1 \cap V) \cap (\Gamma_2 \cap V)$ is a one-dimensional $\mathcal{C}^r$ submanifold of $\mathbb{R}^3$ (i.e. a smooth curve through $\boldsymbol{c}$). If $\nabla F_1(\boldsymbol{x})$ and $\nabla F_2(\boldsymbol{x})$ are linearly independent for all $\boldsymbol{x} \in \Gamma$, then Γ is a one-dimensional $\mathcal{C}^r$ submanifold of $\mathbb{R}^3$.

Note that the hypotheses imply that Γ_1 and Γ_2 are smooth surfaces in a neighborhood of $\boldsymbol{c}$. The condition is then that the surfaces are not tangent at $\boldsymbol{c}$ (i.e. have distinct tangent planes).

Proof: Define $\boldsymbol{F} : \mathbb{R}^3 \to \mathbb{R}^2$ by $\boldsymbol{F} = (F_1, F_2)$. The condition that $\nabla F_1(\boldsymbol{c})$ and $\nabla F_2(\boldsymbol{c})$ are linearly independent is equivalent to the statement that $D\boldsymbol{F}(\boldsymbol{c})$ has rank two. Thus VIII.5.1.18. applies. 👍

VIII.5.1.26. Under the hypotheses, Γ_1 and Γ_2 intersect transversally at $\boldsymbol{c}$ in the sense of ().

The Derivative Formula

VIII.5.1.27. There is wide variation in the literature about the importance of the formula for the derivative in the Implicit Function Theorem (there is more uniform respect for it in the Inverse Function Theorem). Some texts like [**?**] do not mention it at all, whereas in [HH99] we read, "What would we do with an implicit function if we didn't know how to differentiate it?" The formula is more central to the "one-variable" case, the only case done in some references, in the guise of justifying implicit differentiation as done in first-semester calculus. We take a somewhat middle attitude: while the derivative formula is unquestionably important, the essence of the Implicit/Inverse Function Theorem is the *existence* of the implicit/inverse function and the fact that it is unique and $\mathcal{C}^r$. Once we know that, the derivative formula is just a straightforward application of the Chain Rule.

The Inverse Function Theorem

VIII.5.1.28. If $\boldsymbol{f}$ is a function defined on an open subset U of $\mathbb{R}^n$, with values in $\mathbb{R}^m$, we would like to know when $\boldsymbol{f}$ has an inverse function with the same continuity or differentiability properties as $\boldsymbol{f}$. An obvious necessary condition is that $\boldsymbol{f}$ be one-to-one (injective) on U, and to discuss differentiability we also need that $\boldsymbol{f}(U)$ is open in $\mathbb{R}^m$.

The Invariance of Domain Theorem () gives a complete answer to the continuous version of the question: if $\boldsymbol{f}$ is continuous and one-to one, then $\boldsymbol{f}(U)$ is open if and only if $n = m$, and in this case $\boldsymbol{f}^{-1}$ is automatically continuous on $\boldsymbol{f}(U)$.

The answer to the differentiability question is more elementary. The next result does not depend on the Invariance of Domain Theorem:

VIII.5.1.29. PROPOSITION. Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{a} \in U$, V an open set in $\mathbb{R}^m$, and $\boldsymbol{f}$ a one-to-one function from U onto V. Set $\boldsymbol{b} = \boldsymbol{f}(\boldsymbol{a})$. Suppose $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$. Then $\boldsymbol{f}^{-1} : V \to U$ is differentiable at $\boldsymbol{b}$ if and only if $m = n$ and $D\boldsymbol{f}(\boldsymbol{a})$ is invertible. If these conditions hold, then $D(\boldsymbol{f}^{-1})(\boldsymbol{b}) = [D\boldsymbol{f}(\boldsymbol{a})]^{-1}$.

PROOF: One direction is almost immediate. If $\boldsymbol{f}^{-1}$ is differentiable at $\boldsymbol{b}$, then by the Chain Rule we have

$$I_n = D(\boldsymbol{f}^{-1} \circ \boldsymbol{f})(\boldsymbol{a}) = D(\boldsymbol{f}^{-1})(\boldsymbol{b}) D\boldsymbol{f}(\boldsymbol{a})$$

$$I_m = D(\boldsymbol{f} \circ \boldsymbol{f}^{-1})(\boldsymbol{b}) = D\boldsymbol{f}(\boldsymbol{a}) D(\boldsymbol{f}^{-1})(\boldsymbol{b})$$

and so $m = n$, $D\boldsymbol{f}(\boldsymbol{a})$ is invertible, and $D(\boldsymbol{f}^{-1})(\boldsymbol{b}) = D\boldsymbol{f}(\boldsymbol{a})^{-1}$ by (). 👍

For the converse direction, we need a lemma:

VIII.5.1.30. LEMMA. Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{a} \in U$, and $\boldsymbol{f}$ a one-to-one function from U to $\mathbb{R}^n$. Suppose $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$ and $D\boldsymbol{f}(\boldsymbol{a})$ is invertible. Then there are strictly positive constants c, d and a neighborhood W of $\boldsymbol{a}$ contained in U, such that

$$c\|\boldsymbol{x} - \boldsymbol{a}\| < \|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{f}(\boldsymbol{a})\| < d\|\boldsymbol{x} - \boldsymbol{a}\|$$

for all $\boldsymbol{x} \in W \setminus \{\boldsymbol{a}\}$. In fact, we may choose c to be any positive number less than $\|D\boldsymbol{f}(\boldsymbol{a})^{-1}\|^{-1}$ and d any number greater than $\|D\boldsymbol{f}(\boldsymbol{a})\|$.

PROOF: Fix c, d with $0 < c < \|D\boldsymbol{f}(\boldsymbol{a})^{-1}\|^{-1}$ and $d > \|D\boldsymbol{f}(\boldsymbol{a})\|$, and set

$$\epsilon = \min\left(\|D\boldsymbol{f}(\boldsymbol{a})^{-1}\|^{-1} - c, d - \|D\boldsymbol{f}(\boldsymbol{a})\|\right) > 0 \ .$$

Since $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$, there is a $\delta > 0$ such that, whenever $0 < \|\boldsymbol{x} - \boldsymbol{a}\| < \delta$, $\boldsymbol{x} \in U$ and

$$\left| \frac{\|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{f}(\boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|} - \frac{\|D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|} \right| \leq \frac{\|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{f}(\boldsymbol{a}) - D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|} < \epsilon$$

$$-\epsilon < \frac{\|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{f}(\boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|} - \frac{\|D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|} < \epsilon \ .$$

But we have $\|D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a})\| \leq \|D\boldsymbol{f}(\boldsymbol{a})\|\|\boldsymbol{x} - \boldsymbol{a}\|$ by definition of the operator norm, so

$$\frac{\|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{f}(\boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|} < \frac{\|D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|} + \epsilon \leq \|D\boldsymbol{f}(\boldsymbol{a})\| + \epsilon \leq d$$

and similarly

$$\|\boldsymbol{x} - \boldsymbol{a}\| = \|D\boldsymbol{f}(\boldsymbol{a})^{-1}(D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a}))\| \leq \|D\boldsymbol{f}(\boldsymbol{a})^{-1}\|\|D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a})\|$$

$$c \leq \|D\boldsymbol{f}(\boldsymbol{a})^{-1}\|^{-1} - \epsilon \leq \frac{\|D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|} - \epsilon < \frac{\|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{f}(\boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|}$$

so we may take W to be the open ball of radius δ around $\boldsymbol{a}$. 👍

VIII.5.1.31. We now prove the other direction of VIII.5.1.29.. Suppose $m = n$ and $D\boldsymbol{f}(\boldsymbol{a})$ is invertible. Since f is a bijection between U and V, for each $\boldsymbol{x} \in U$ there is a unique $\boldsymbol{y} \in V$ with $\boldsymbol{y} = \boldsymbol{f}(\boldsymbol{x})$, and conversely for each $\boldsymbol{y} \in V$ there is a unique $\boldsymbol{x} \in U$ with $\boldsymbol{x} = \boldsymbol{f}^{-1}(\boldsymbol{y})$. We will suppress the function names and just use $\boldsymbol{x}$ and $\boldsymbol{y}$ with the understanding that they are related in this manner.

We must show that for any $\epsilon > 0$, there is a $\delta > 0$ such that, whenever $0 < \|\boldsymbol{y} - \boldsymbol{b}\| < \delta$, $\boldsymbol{y} \in V$ and

$$\frac{\|\boldsymbol{x} - \boldsymbol{a} - D\boldsymbol{f}(\boldsymbol{a})^{-1}(\boldsymbol{y} - \boldsymbol{b})\|}{\|\boldsymbol{y} - \boldsymbol{b}\|} < \epsilon \ .$$

By VIII.5.1.30., reducing U if necessary we may assume there are positive constants c and d such that

$$c\|\boldsymbol{x} - \boldsymbol{a}\| < \|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{f}(\boldsymbol{a})\| < d\|\boldsymbol{x} - \boldsymbol{a}\|$$

$$\frac{1}{d} < \frac{\|\boldsymbol{x} - \boldsymbol{a}\|}{\|\boldsymbol{y} - \boldsymbol{b}\|} < \frac{1}{c}$$

for all $\boldsymbol{x} \in U$, $\boldsymbol{x} \neq \boldsymbol{a}$. Since $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$, there is an $\eta > 0$ such that, whenever $0 < \|\boldsymbol{x} - \boldsymbol{a}\| < \eta$, $\boldsymbol{x} \in U$ and

$$\frac{\|\boldsymbol{y} - \boldsymbol{b} - D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|} < \frac{\epsilon c}{\|D\boldsymbol{f}(\boldsymbol{a})^{-1}\|} \ .$$

Since

$$\boldsymbol{x} - \boldsymbol{a} - D\boldsymbol{f}(\boldsymbol{a})^{-1}(\boldsymbol{y} - \boldsymbol{b}) = D\boldsymbol{f}(\boldsymbol{a})^{-1}[D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a}) - (\boldsymbol{y} - \boldsymbol{b})]$$

we have, for $\|\boldsymbol{y} - \boldsymbol{b}\| < c\eta$, $\|\boldsymbol{x} - \boldsymbol{a}\| < \eta$ and

$$\frac{\|\boldsymbol{x} - \boldsymbol{a} - D\boldsymbol{f}(\boldsymbol{a})^{-1}(\boldsymbol{y} - \boldsymbol{b})\|}{\|\boldsymbol{y} - \boldsymbol{b}\|} \leq \frac{\|D\boldsymbol{f}(\boldsymbol{a})^{-1}\|\|D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a}) - (\boldsymbol{y} - \boldsymbol{b})\|}{\|\boldsymbol{y} - \boldsymbol{b}\|}$$

$$= \frac{\|\boldsymbol{x} - \boldsymbol{a}\|}{\|\boldsymbol{y} - \boldsymbol{b}\|}\|D\boldsymbol{f}(\boldsymbol{a})^{-1}\|\frac{\|\boldsymbol{y} - \boldsymbol{b} - D\boldsymbol{f}(\boldsymbol{a})(\boldsymbol{x} - \boldsymbol{a})\|}{\|\boldsymbol{x} - \boldsymbol{a}\|} < \frac{1}{c}\|D\boldsymbol{f}(\boldsymbol{a})^{-1}\|\frac{\epsilon c}{\|D\boldsymbol{f}(\boldsymbol{a})^{-1}\|} = \epsilon$$

so we may take $\delta = c\eta$. 👍

VIII.5.1.32. Corollary. Let U be an open set in $\mathbb{R}^n$, V an open set in $\mathbb{R}^m$, and $\boldsymbol{f}$ a one-to-one function from U onto V. If $\boldsymbol{f}$ is differentiable at every point of U, then $\boldsymbol{f}^{-1} : V \to U$ is differentiable at every point of V if and only if $m = n$ and, for every $\boldsymbol{x} \in U$, $D\boldsymbol{f}(\boldsymbol{x})$ is invertible. If these conditions hold, then $D(\boldsymbol{f}^{-1})(\boldsymbol{y})$ is invertible for every $\boldsymbol{y} \in V$ and $D(\boldsymbol{f}^{-1})(\boldsymbol{y}) = D\boldsymbol{f}(\boldsymbol{f}^{-1}(\boldsymbol{y}))^{-1}$.

Actually, if $\boldsymbol{f} : U \to V$ is one-to-one, onto, and differentiable, then m must equal n even without the assumption that $D\boldsymbol{f}(\boldsymbol{x})$ is invertible for every $\boldsymbol{x} \in U$, by Invariance of Domain; but we do not need to use this fact for the Corollary.

VIII.5.1.33. There are two principal drawbacks to these results, however. First, the Invariance of Domain is a deep theorem requiring a considerable excursion into topology to prove. And second, even for the differentiable result which is more elementary, it must be verified that the function is locally one-to-one, with open range, which is often not easy to do directly. The most useful result would be one in which (local) injectivity can be deduced simply from nondegeneracy of the derivative. This is the principal content of the Inverse Function Theorem:

VIII.5.1.34. THEOREM. [INVERSE FUNCTION THEOREM] Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{a} \in U$, and $\boldsymbol{f} : U \to \mathbb{R}^n$ a $\mathcal{C}^r$ function for some r, $1 \leq r \leq \infty$. If $D\boldsymbol{f}(\boldsymbol{a})$ is invertible, then there is a neighborhood V of $\boldsymbol{a}$, $V \subseteq U$, such that

(i) $\boldsymbol{f}$ is one-to-one on V.

(ii) $\boldsymbol{f}(V)$ is open in $\mathbb{R}^n$.

(iii) $D\boldsymbol{f}(\boldsymbol{x})$ is invertible for all $\boldsymbol{x} \in V$.

(iv) $\boldsymbol{f}^{-1}$ is $\mathcal{C}^r$ on $\boldsymbol{f}(V)$ and, for all $\boldsymbol{y} \in \boldsymbol{f}(V)$,

$$D(\boldsymbol{f}^{-1})(\boldsymbol{y}) = [D\boldsymbol{f}(\boldsymbol{f}^{-1}(\boldsymbol{y}))]^{-1} \ .$$

VIII.5.1.35. If $D\boldsymbol{f}(\boldsymbol{x})$ is not invertible everywhere on U, it will obviously be necessary to restrict to a smaller neighborhood V of $\boldsymbol{a}$ to get (iii) and (iv). But this may be necessary even if $D\boldsymbol{f}(\boldsymbol{x})$ is invertible for all $\boldsymbol{x} \in U$ to make $\boldsymbol{f}$ injective.

If $n = 1$ and I is an interval in $\mathbb{R}$, and $f : I \to R$ is differentiable on I with $f'(x) \neq 0$ for all $x \in I$, then f is strictly monotone on I () and thus one-to-one; so if $U = I$ we may take $V = U$. But if $n > 1$ invertibility of $D\boldsymbol{f}$ on U does not guarantee that $\boldsymbol{f}$ is one-to-one on U, even if U is connected. A simple and important example is the following function, which is the transformation from rectangular coordinates to polar coordinates in $\mathbb{R}^2$ (hence we use (r, θ) for the coordinates). Set $U = \{(r, \theta) : r > 0\}$, and define $\boldsymbol{f} : U \to \mathbb{R}^2$ by

$$\boldsymbol{f}(r, \theta) = (r \cos\theta, r \sin\theta) \ .$$

Then $D\boldsymbol{f}(r, \theta)$ is invertible everywhere on U; but $\boldsymbol{f}$ is not one-to-one on all of U, only locally one-to-one.

VIII.5.2. Twin Theorems and a Generalization

The Inverse Function Theorem and Implicit Function Theorem (smooth version) are twin theorems in the sense that each is easily derivable from the other; the arguments are much easier than proving either theorem from scratch. In fact, either argument can be used to prove a common generalization:

VIII.5.2.1. THEOREM. [GENERAL IMPLICIT/INVERSE FUNCTION THEOREM] Let $n \in \mathbb{N}$, $p \in \mathbb{N} \cup \{0\}$, $\boldsymbol{a} \in \mathbb{R}^p$, $\boldsymbol{b}, \boldsymbol{c} \in \mathbb{R}^n$, U an open neighborhood of $(\boldsymbol{a}, \boldsymbol{b})$ in $\mathbb{R}^{p+n}$, $\boldsymbol{F} : U \to \mathbb{R}^n$ a $\mathcal{C}^r$ function ($1 \leq r \leq \infty$) with $\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b}) = \boldsymbol{c}$ and $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b})$ invertible. Then there are:

(i) An open neighborhood V of $(\boldsymbol{a}, \boldsymbol{b})$ in $\mathbb{R}^{p+n}$, contained in U, such that $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y})$ is invertible for all $(\boldsymbol{x}, \boldsymbol{y}) \in V$;

(ii) An open neighborhood W of $(\boldsymbol{a}, \boldsymbol{c})$ in $\mathbb{R}^{p+n}$;

(iii) A unique function $\boldsymbol{G} : W \to \mathbb{R}^n$ satisfying $\boldsymbol{G}(\boldsymbol{a}, \boldsymbol{c}) = \boldsymbol{b}$ and, for all $(\boldsymbol{x}, \boldsymbol{z}) \in W$, $(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})) \in V$ and

$$\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})) = \boldsymbol{z} \ .$$

Additionally, $\boldsymbol{G}$ is $\mathcal{C}^r$ on W, and for all $(\boldsymbol{x},\boldsymbol{z})\in W$,

$$D\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})=\begin{bmatrix} & \vdots & \\ -D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z}))^{-1}D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})) & \vdots & D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z}))^{-1} \\ & \vdots & \end{bmatrix}.$$

Slightly informally, for $(\boldsymbol{x},\boldsymbol{z})$ sufficiently near $(\boldsymbol{a},\boldsymbol{c})$, $\boldsymbol{y}=\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})$ is the unique $\boldsymbol{y}$ near $\boldsymbol{b}$ such that $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})=\boldsymbol{z}$, i.e. we have "solved" the equation $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})=\boldsymbol{z}$ for $\boldsymbol{y}$ as a function of $\boldsymbol{x}$ and $\boldsymbol{z}$.

VIII.5.2.2. Note that the Inverse Function Theorem is the case $p=0$ (so the $\boldsymbol{a}$ is absent). The Smooth Implicit Function Theorem is a corollary by taking $\boldsymbol{c}=\boldsymbol{0}$ and setting $\boldsymbol{f}(\boldsymbol{x})=\boldsymbol{G}(\boldsymbol{x},\boldsymbol{0})$. In fact, the Smooth Implicit Function Theorem says that for certain fixed $\boldsymbol{z}$ near $\boldsymbol{c}$, there is a function $\boldsymbol{f}_{\boldsymbol{z}}$ implicitly defined near $\boldsymbol{a}$ by $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})=\boldsymbol{z}$, which is $\mathcal{C}^r$ in $\boldsymbol{x}$; we have $\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})=\boldsymbol{f}_{\boldsymbol{z}}(\boldsymbol{x})$, and the additional content of the above theorem is that the $\boldsymbol{f}_{\boldsymbol{z}}$ are defined for all $\boldsymbol{z}$ near $\boldsymbol{c}$ and "vary smoothly" in $\boldsymbol{z}$. Thus Theorem VIII.5.2.1. is a "parametrized version" of both the Implicit and Inverse Function Theorems: holding $\boldsymbol{x}$ fixed gives the Inverse Function Theorem and holding $\boldsymbol{z}$ fixed gives the (Smooth) Implicit Function Theorem.

The situation is symmetric in $\boldsymbol{F}$ and $\boldsymbol{G}$. $\boldsymbol{G}$ satisfies the hypotheses of the theorem, so there is a $\mathcal{C}^r$ function $\boldsymbol{H}$ defined near $(\boldsymbol{a},\boldsymbol{b})$ for which $\boldsymbol{H}(\boldsymbol{a},\boldsymbol{b})=\boldsymbol{c}$ and $\boldsymbol{G}(\boldsymbol{x},\boldsymbol{H}(\boldsymbol{x},\boldsymbol{y}))=\boldsymbol{y}$ for $(\boldsymbol{x},\boldsymbol{y})$ near $(\boldsymbol{a},\boldsymbol{b})$. By the formula, $D\boldsymbol{H}(\boldsymbol{x},\boldsymbol{y})=D\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})$ for all $(\boldsymbol{x},\boldsymbol{y})$ near $(\boldsymbol{a},\boldsymbol{b})$, and since $\boldsymbol{H}(\boldsymbol{a},\boldsymbol{b})=\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$, we have $\boldsymbol{H}=\boldsymbol{F}$ on a neighborhood of $(\boldsymbol{a},\boldsymbol{b})$, i.e. $\boldsymbol{H}=\boldsymbol{F}$ (perhaps restricted to a smaller neighborhood of $(\boldsymbol{a},\boldsymbol{b})$). In particular, we have $\boldsymbol{G}(\boldsymbol{x},\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}))=\boldsymbol{y}$ for $(\boldsymbol{x},\boldsymbol{y})$ near $(\boldsymbol{a},\boldsymbol{b})$ (this can be verified directly).

We will give simple proofs of VIII.5.2.1. from both the Inverse Function Theorem and the Smooth Implicit Function Theorem.

Proof From Inverse Function Theorem

VIII.5.2.3. Assume the Inverse Function Theorem VIII.5.1.34.. We will deduce VIII.5.2.1..

Suppose $U\subseteq\mathbb{R}^{p+n}$ is open, $(\boldsymbol{a},\boldsymbol{b})\in U$, and $\boldsymbol{F}:U\to\mathbb{R}^n$ is a $\mathcal{C}^r$ function with $\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})=\boldsymbol{c}$ and $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$ invertible. Define

$$\tilde{\boldsymbol{F}}(\boldsymbol{x},\boldsymbol{y})=(\boldsymbol{x},\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}))$$

for $(\boldsymbol{x},\boldsymbol{y})\in U$. Then $\tilde{\boldsymbol{F}}$ is a $\mathcal{C}^r$ function from U to $\mathbb{R}^{p+n}$. We have

$$D\tilde{\boldsymbol{F}}(\boldsymbol{x},\boldsymbol{y})=\begin{bmatrix} I_p & 0 \\ D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) & D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) \end{bmatrix}$$

for $(\boldsymbol{x},\boldsymbol{y})\in U$; thus $D\tilde{\boldsymbol{F}}(\boldsymbol{a},\boldsymbol{b})$ is invertible (). So by the Inverse Function Theorem there is a neighborhood V of $(\boldsymbol{a},\boldsymbol{b})$ on which $\tilde{\boldsymbol{F}}$ is one-to-one, $W=\tilde{\boldsymbol{F}}(V)$ is open, and the inverse function $\Phi:W\to V$ is $\mathcal{C}^r$. Since $\tilde{\boldsymbol{F}}(\boldsymbol{a},\boldsymbol{b})=(\boldsymbol{a},\boldsymbol{c})$, we have $(\boldsymbol{a},\boldsymbol{c})\in W$ and $\Phi(\boldsymbol{a},\boldsymbol{c})=(\boldsymbol{a},\boldsymbol{b})$.

Write $\Phi(\boldsymbol{x},\boldsymbol{z})=(\boldsymbol{H}(\boldsymbol{x},\boldsymbol{z}),\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z}))$, where $\boldsymbol{H}:W\to\mathbb{R}^p$ and $\boldsymbol{G}:W\to\mathbb{R}^n$. Then $\boldsymbol{H}$ and $\boldsymbol{G}$ are $\mathcal{C}^r$, and $\boldsymbol{G}(\boldsymbol{a},\boldsymbol{c})=\boldsymbol{b}$. Since for $(\boldsymbol{x},\boldsymbol{z})\in W$ we have

$$(\boldsymbol{x},\boldsymbol{z})=\tilde{\boldsymbol{F}}(\Phi(\boldsymbol{x},\boldsymbol{z}))=\tilde{\boldsymbol{F}}(\boldsymbol{H}(\boldsymbol{x},\boldsymbol{z}),\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z}))=(\boldsymbol{H}(\boldsymbol{x},\boldsymbol{z}),\boldsymbol{F}(\boldsymbol{H}(\boldsymbol{x},\boldsymbol{z}),\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})))$$

we obtain that $\boldsymbol{H}(\boldsymbol{x},\boldsymbol{z}) = \boldsymbol{x}$ and

$$\boldsymbol{F}(\boldsymbol{H}(\boldsymbol{x},\boldsymbol{z}),\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})) = \boldsymbol{F}(\boldsymbol{x},\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})) = \boldsymbol{z}$$

for $(\boldsymbol{x},\boldsymbol{z}) \in W$.

Uniqueness of $\boldsymbol{G}$ follows from the fact that $\tilde{\boldsymbol{F}}$ is one-to-one: if $\tilde{\boldsymbol{G}}$ is a function from W to $\mathbb{R}^n$ with $(\boldsymbol{x},\tilde{\boldsymbol{G}}(\boldsymbol{x},\boldsymbol{z})) \in V$ and $\boldsymbol{F}(\boldsymbol{x},\tilde{\boldsymbol{G}}(\boldsymbol{x},\boldsymbol{z})) = \boldsymbol{z}$ for all $(\boldsymbol{x},\boldsymbol{z}) \in W$, then for $(\boldsymbol{x},\boldsymbol{z}) \in W$ we have

$$\tilde{\boldsymbol{F}}(\boldsymbol{x},\tilde{\boldsymbol{G}}(\boldsymbol{x},\boldsymbol{z})) = (\boldsymbol{x},\boldsymbol{z}) = \tilde{\boldsymbol{F}}(\boldsymbol{x},\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z}))$$

so $\tilde{\boldsymbol{G}}(\boldsymbol{x},\boldsymbol{z}) = \boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})$.

Thus VIII.5.2.1. is proved (see Exercise VIII.5.11.5. for the derivative formula). 👍

Proof From Implicit Function Theorem

VIII.5.2.4. Now assume the Smooth Implicit Function Theorem VIII.5.1.7. holds. We will deduce VIII.5.2.1..

Suppose $U \subseteq \mathbb{R}^{p+n}$ is open, $(\boldsymbol{a},\boldsymbol{b}) \in U$, and $\boldsymbol{F} : U \to \mathbb{R}^n$ is as in the statement of VIII.5.2.1.. Set $\boldsymbol{c} = \boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$. Write $\mathbb{R}^{p+2n} \cong \mathbb{R}^p \times \mathbb{R}^n \times \mathbb{R}^n$, and set

$$U' = \{(\boldsymbol{x},\boldsymbol{z},\boldsymbol{y}) \in \mathbb{R}^{p+2n} : (\boldsymbol{x},\boldsymbol{y}) \in U\} .$$

Then U' is open in $\mathbb{R}^{p+2n}$, and $(\boldsymbol{a},\boldsymbol{c},\boldsymbol{b}) \in U'$. Define $\tilde{\boldsymbol{F}} : U' \to \mathbb{R}^n$ by

$$\tilde{\boldsymbol{F}}(\boldsymbol{x},\boldsymbol{z},\boldsymbol{y}) = \boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) - \boldsymbol{z} .$$

Then $\tilde{\boldsymbol{F}}$ is $\mathcal{C}^r$ on U', $\tilde{\boldsymbol{F}}(\boldsymbol{a},\boldsymbol{c},\boldsymbol{b}) = \boldsymbol{0}$, and

$$D\tilde{\boldsymbol{F}}(\boldsymbol{x},\boldsymbol{z},\boldsymbol{y}) = \begin{bmatrix} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) & -I_n & D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) \end{bmatrix}$$

for $(\boldsymbol{x},\boldsymbol{z},\boldsymbol{y}) \in U'$, and in particular $D_{\boldsymbol{y}}\tilde{\boldsymbol{F}}(\boldsymbol{a},\boldsymbol{c},\boldsymbol{b}) = D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$ is invertible.

We can thus solve the equation $\tilde{\boldsymbol{F}}(\boldsymbol{x},\boldsymbol{z},\boldsymbol{y}) = \boldsymbol{0}$ implicitly for $\boldsymbol{y}$ as a function of $(\boldsymbol{x},\boldsymbol{z})$, i.e. there are open neighborhoods W of $(\boldsymbol{a},\boldsymbol{c})$ and V of $(\boldsymbol{a},\boldsymbol{b})$ and a unique function $\boldsymbol{G} : W \to \mathbb{R}^n$ such that $\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z}) \in V$ and $\tilde{\boldsymbol{F}}(\boldsymbol{x},\boldsymbol{z},\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})) = \boldsymbol{0}$ for all $(\boldsymbol{x},\boldsymbol{z}) \in W$, and $\boldsymbol{G}$ is $\mathcal{C}^r$. But $\tilde{\boldsymbol{F}}(\boldsymbol{x},\boldsymbol{z},\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})) = \boldsymbol{0}$ is equivalent to $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{G}(\boldsymbol{x},\boldsymbol{z})) = \boldsymbol{z}$.

Thus VIII.5.2.1. is proved (cf. Exercise VIII.5.11.5.). 👍

VIII.5.2.5. There are versions of the Continuous and Mixed Implicit Function Theorems similar to VIII.5.2.1. (Exercise VIII.5.11.16.).

VIII.5.3. Proof of the Implicit Function Theorem, Case $n = 1$

It is much easier to prove the Implicit Function Theorem in the case where we are only solving for one variable in terms of the others. We also obtain the desired results under somewhat weaker hypotheses. It does not make any difference in the proof how many other variables there are, i.e. we will prove the case where $n = 1$ and p is arbitrary.

VIII.5.3.1. The general setup for this case is a function $F : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(\boldsymbol{a}, b) = (a_1, \ldots, a_p, b) \in U$ with $F(\boldsymbol{a}, b) = 0$. Write $(\boldsymbol{x}, y) = (x_1, \ldots, x_p, y)$ for the coordinates of a general point of U. We will need to assume at a minimum that F is continuous on U and that $\frac{\partial F}{\partial y}(\boldsymbol{a}, b)$ exists and is nonzero. To obtain most of the conclusions we will need a little more. Of course, the conditions need only hold on *some* neighborhood of $(\boldsymbol{a}, b)$, since for the conclusion we will have to restrict to a smaller neighborhood of $(\boldsymbol{a}, b)$ anyway in general, i.e. the conclusion will be only a local one.

The Continuous Version

VIII.5.3.2. Theorem. [One-Dimensional Weak Implicit Function Theorem, Continuous Version] Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(\boldsymbol{a}, b) = (a_1, \ldots, a_p, b) \in U$ with $F(\boldsymbol{a}, b) = 0$. Suppose F is continuous on U and $\frac{\partial F}{\partial y}$ exists and is nonzero at $(\boldsymbol{a}, b)$. Then there are:

(i) An open set V in $\mathbb{R}^{p+1}$ containing $(\boldsymbol{a}, b)$, with $V \subseteq U$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) Functions $\overline{f}, \underline{f} : W \to \mathbb{R}$ such that $\overline{f}(\boldsymbol{a}) = \underline{f}(\boldsymbol{a}) = b$, $(\boldsymbol{x}, \overline{f}(\boldsymbol{x}))$ and $(\boldsymbol{x}, \underline{f}(\boldsymbol{x}))$ are in V and

$$F(\boldsymbol{x}, \overline{f}(\boldsymbol{x})) = F(\boldsymbol{x}, \underline{f}(\boldsymbol{x})) = 0$$

for all $\boldsymbol{x} \in W$, and such that if f is any function from W to $\mathbb{R}$ with $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$, then $\underline{f} \leq f \leq \overline{f}$.

Additionally, $\overline{f}$ is upper semicontinuous and $\underline{f}$ is lower semicontinuous on W, and $\overline{f}$ and $\underline{f}$ are continuous at $\boldsymbol{a}$.

Proof: By passing to a smaller neighborhood, we may assume U is convex. Suppose $\frac{\partial F}{\partial y}(\boldsymbol{a}, b) > 0$. Then there are $y_1 > b$ and $y_2 < b$ such that $(\boldsymbol{a}, y_1)$ and $(\boldsymbol{a}, y_2)$ are in U and $\frac{F(\boldsymbol{a},z)-F(\boldsymbol{a},b)}{z-b} > 0$ for $y_2 \leq z \leq y_1$, $z \neq b$ (in fact, this will be true for all such y_1, y_2 sufficiently close to b). It follows that $F(\boldsymbol{a}, y_1) > 0$ and $F(\boldsymbol{a}, y_2) < 0$ (and in fact, $F(\boldsymbol{a}, z) > 0$ for $b < z \leq y_1$ and $F(\boldsymbol{a}, z) < 0$ for $y_2 \leq z < b$). Then there is an open neighborhood W of $\boldsymbol{a}$ in $\mathbb{R}^p$ such that, for all $\boldsymbol{x} \in W$, $(\boldsymbol{x}, y_1)$ and $(\boldsymbol{x}, y_2)$ are in U, $F(\boldsymbol{x}, y_1) > 0$, and $F(\boldsymbol{x}, y_2) < 0$. So for each fixed $\boldsymbol{x} \in W$, there is at least one y between y_2 and y_1 for which $F(\boldsymbol{x}, y) = 0$ by the Intermediate Value Theorem, since F is continuous on U. Among these, there is a largest $\overline{y}$ and a smallest $\underline{y}$. Set $\overline{f}(\boldsymbol{x}) = \overline{y}$ and $\underline{f}(\boldsymbol{x}) = \underline{y}$. This defines $\overline{f}$ and $\underline{f}$ on W. We obviously have $\overline{f}(\boldsymbol{a}) = \underline{f}(\boldsymbol{a}) = b$.

Set $V = W \times (y_2, y_1) \subseteq U$. If f is any real-valued function on W such that $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$, we obviously have $\underline{f}(\boldsymbol{x}) \leq f(\boldsymbol{x}) \leq \overline{f}(\boldsymbol{x})$ for all $\boldsymbol{x} \in W$.

It remains to show that $\overline{f}$ and $\underline{f}$ are semicontinuous on W. We give the argument for $\overline{f}$; the one for $\underline{f}$ is essentially identical. Let $\boldsymbol{x}_n \in W$, $\boldsymbol{x}_n \to \boldsymbol{x}_0$. Passing to a subsequence we may assume $\overline{f}(\boldsymbol{x}_n) \to z$ for some z between y_2 and y_1. But then $0 = F(\boldsymbol{x}_n, \overline{f}(\boldsymbol{x}_n)) \to F(\boldsymbol{x}_0, z)$ by continuity of F, so $F(\boldsymbol{x}_0, z) = 0$ and

$z \leq \overline{f}(\boldsymbol{x}_0)$. Thus $\limsup_{\boldsymbol{x}\to\boldsymbol{x}_0} \overline{f}(\boldsymbol{x}) \leq \overline{f}(\boldsymbol{x}_0)$ for any $\boldsymbol{x}_0 \in W$. Similarly $\liminf_{\boldsymbol{x}\to\boldsymbol{x}_0} \underline{f}(\boldsymbol{x}) \geq \underline{f}(\boldsymbol{x}_0)$ for any $\boldsymbol{x}_0 \in W$. Since

$$b = \underline{f}(\boldsymbol{a}) \leq \liminf_{\boldsymbol{x}\to\boldsymbol{a}} \underline{f}(\boldsymbol{x}) \leq \limsup_{\boldsymbol{x}\to\boldsymbol{a}} \overline{f}(\boldsymbol{x}) \leq \overline{f}(\boldsymbol{a}) = b$$

we have that $\overline{f}$ and $\underline{f}$ are continuous at $\boldsymbol{a}$.

The argument in the case $\frac{\partial F}{\partial y}(\boldsymbol{a}, b) < 0$ is essentially identical. 👍

VIII.5.3.3. Under the hypotheses of VIII.5.3.2., even if $p = 1$, there is not necessarily a continuous function f on a neighborhood W of $\boldsymbol{a}$ with $f(\boldsymbol{a}) = b$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$(Exercise VIII.5.11.4.).

VIII.5.3.4. Theorem. [One-Dimensional Implicit Function Theorem, Continuous Version] Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(\boldsymbol{a}, b) = (a_1, \ldots, a_p, b) \in U$ with $F(\boldsymbol{a}, b) = 0$. Suppose F is continuous on U and $\frac{\partial F}{\partial y}$ exists and is nonzero at all points of U. Then there are:

(i) An open set V in $\mathbb{R}^{p+1}$ containing $(\boldsymbol{a}, b)$, with $V \subseteq U$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(\boldsymbol{a}) = b$, and $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$.

Additionally, f is continuous on W.

Proof: Everything follows immediately from VIII.5.3.2. except the uniqueness of f, i.e. that $\overline{f} = \underline{f}$. Define V and W as in the proof of VIII.5.3.2.. Fix $\boldsymbol{x} \in W$. If there were y and z, $y \neq z$, with $(\boldsymbol{x}, y)$ and $(\boldsymbol{x}, z)$ in V and $F(\boldsymbol{x}, y) = F(\boldsymbol{x}, z) = 0$, then by Rolle's Theorem there would be a c between y and z with $\frac{\partial F}{\partial y}(\boldsymbol{x}, c) = 0$, contradicting the assumption that $\frac{\partial F}{\partial y}$ is never zero on U. Thus there is a unique y such that $(\boldsymbol{x}, y) \in V$ and $F(\boldsymbol{x}, y) = 0$, and we may set $f(\boldsymbol{x}) = y$. This f is the unique real-valued function defined on W with $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$. 👍

VIII.5.3.5. Corollary. Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(\boldsymbol{a}, b) = (a_1, \ldots, a_p, b) \in U$ with $F(\boldsymbol{a}, b) = 0$. Suppose F is continuous on U and $\frac{\partial F}{\partial y}$ exists at all points of U, and is continuous at $(\boldsymbol{a}, b)$, with $\frac{\partial F}{\partial y}(\boldsymbol{a}, b) \neq 0$. Then there are:

(i) An open set V in $\mathbb{R}^{p+1}$ containing $(\boldsymbol{a}, b)$, with $V \subseteq U$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(\boldsymbol{a}) = b$, and $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$.

Additionally, f is continuous on W.

Proof: By continuity of $\frac{\partial F}{\partial y}$ at $(\boldsymbol{a}, b)$, there is a neighborhood U' of $(\boldsymbol{a}, b)$ contained in U such that $\frac{\partial F}{\partial y}(\boldsymbol{x}, y) \neq 0$ for all $(\boldsymbol{x}, y) \in U'$. Apply VIII.5.3.4. with U' in place of U. 👍

A Pictorial Version

VIII.5.3.6. We illustrate the argument in the case $p = n = 1$ (the picture represents the case of general p if the horizontal axis is regarded as multidimensional). Suppose U is an open set in $\mathbb{R}^2$, and F is a continuous function from U to $\mathbb{R}$ such that $\frac{\partial F}{\partial y}$ exists and is nonzero on U, and let $(a, b) \in U$ with $F(a, b) = 0$. Fix an open rectangle R centered at (a, b) and contained in U, and do the following construction within R. We assume that $\frac{\partial F}{\partial y}(a, b) > 0$; the proof in the case $\frac{\partial F}{\partial y}(a, b) < 0$ is identical with red and blue reversed. Because of the shapes in the diagrams (the proportions may vary), this proof can be called the "T proof."

Since $F(a, b) = 0$ and $\frac{\partial F}{\partial y}(a, b) > 0$, $g(y) = F(a, y)$ is increasing at b (V.3.6.8.), i.e. there are $y_1 < b$ and $y_2 > b$ such that (a, y_1) and $(a, y_2) \in R$ and $F(a, y) > F(a, b) = 0$ for $b < y \leq y_2$, and $F(a, y) < 0$ for $y_1 \leq y < b$, i.e. $F(x, y) > 0$ for all points (x, y) in red in Figure VIII.16 and $F(x, y) < 0$ for all (x, y) in blue:

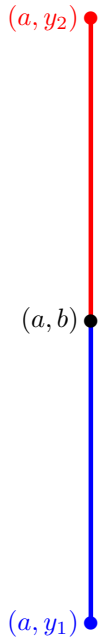

Figure VIII.16: Implicit Function Theorem I

We may assume $y_2 - b = b - y_1$ if desired by taking a minimum; although this is not necessary for the proof, it will be convenient later since this can be called ϵ.

Since $F(a, y_2) > 0$ and F is continuous, there are $x_1 < a$ and $x_2 > a$ such that (x_1, y_2) and (x_2, y_2) are in R and $F(x, y_2) > 0$ for $x_1 \leq x \leq x_2$ (). Similarly, since $F(a, y_1) < 0$, there are $x_3 < a$ and $x_4 > a$ with (x_3, y_1) and (x_4, y_1) in R and $F(x, y_1) < 0$ for $x_3 \leq x \leq x_4$. As before, we may assume $x_3 = x_1$ and $x_4 = x_2$ and that $x_2 - a = a - x_1$ by taking a minimum; this can be called δ. Thus all red points (x, y) in Figure VIII.17 have $F(x, y) > 0$, and all blue points have $F(x, y) < 0$:

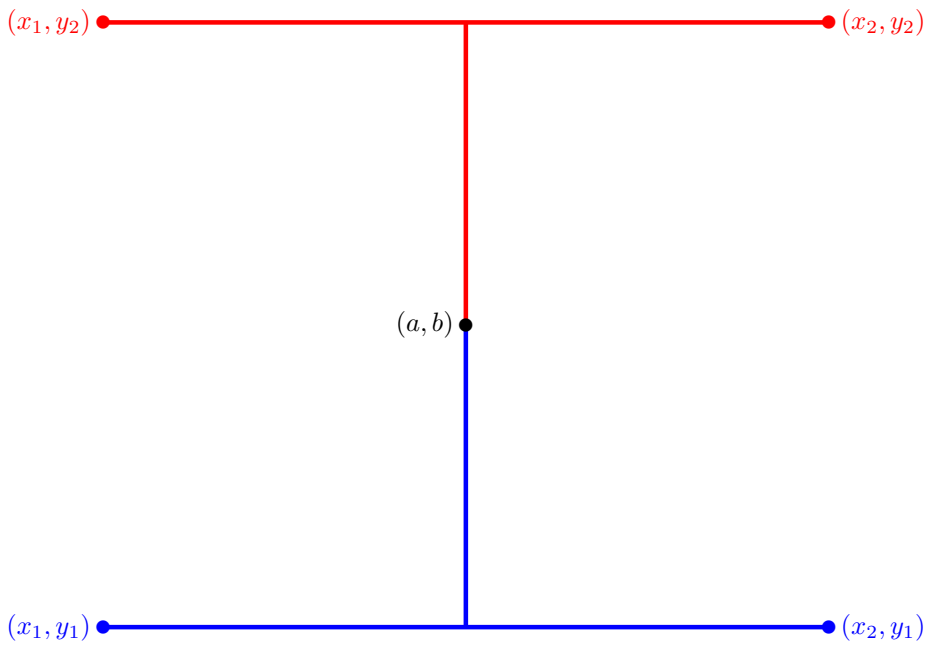

Figure VIII.17: Implicit Function Theorem II

In the case of general p, the top and bottom horizontal segments become balls in $\mathbb{R}^p$ centered at $\boldsymbol{a}$, which can be taken to have the same radius which we can call δ.

Now fix x_0, $x_1 \leq x_0 \leq x_2$. We have that $F(x_0, y_1) < 0$ and $F(x_0, y_2) > 0$. Since $F(x_0, y)$ is a continuous function of y, there must be a y, $y_1 < y < y_2$, with $F(x_0, y) = 0$. If there were more than one such y, by Rolle's Theorem there would be a y in between with $\frac{\partial F}{\partial y}(x_0, y) = 0$, contradicting that $\frac{\partial F}{\partial y}$ is nonzero on U. Thus there is a *unique* y between y_1 and y_2 with $F(x_0, y) = 0$, and we call this y $f(x_0)$. This procedure uniquely defines a function f on the interval $[x_1, x_2]$ with values in (y_1, y_2), which satisfies $F(x, f(x)) = 0$ for $x_1 \leq x \leq x_2$. We also have $F(x, y) > 0$ for $f(x) < y \leq y_2$ and $F(x, y) < 0$ if $y_1 \leq y < f(x)$, for any $x \in [x_1, x_2]$. See Figure VIII.18.

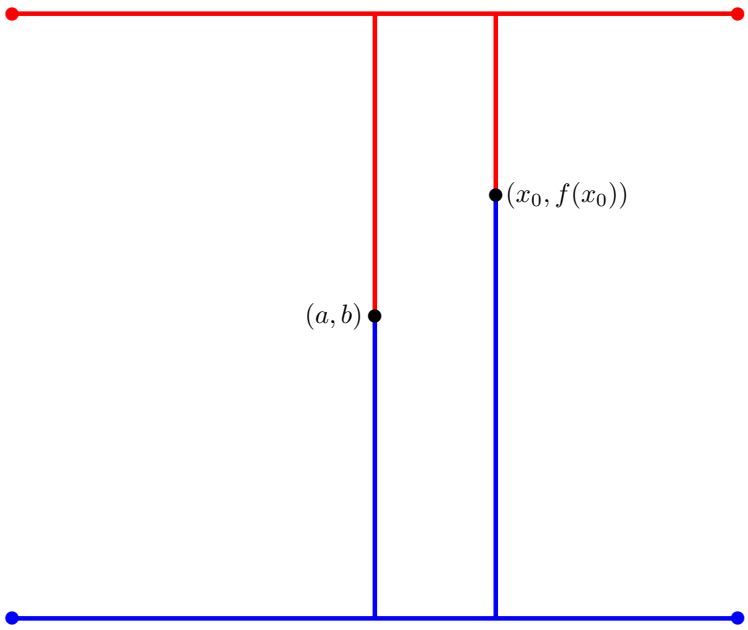

Figure VIII.18: Implicit Function Theorem III

To show f is continuous, fix x_0, $x_1 < x_0 < x_2$. Let $\epsilon > 0$. We may assume $\epsilon \leq \min(y_2 - f(x_0), f(x_0) - y_1)$ without loss of generality. We repeat the first part of the proof replacing a and b by x_0 and $f(x_0)$, and y_1 and y_2 by $f(x_0) \pm \epsilon$: $F(x_0, y) > 0$ for $f(x_0) < y \leq f(x_0) + \epsilon$ and $F(x_0, y) < 0$ for $f(x_0) - \epsilon \leq y < f(x_0)$, so there is a δ, $0 < \delta \leq \min(x_2 - x_0, x_0 - x_1)$, such that $F(x, y) > 0$ for all red points in Figure VIII.19 and $F(x, y) < 0$ for all blue points.

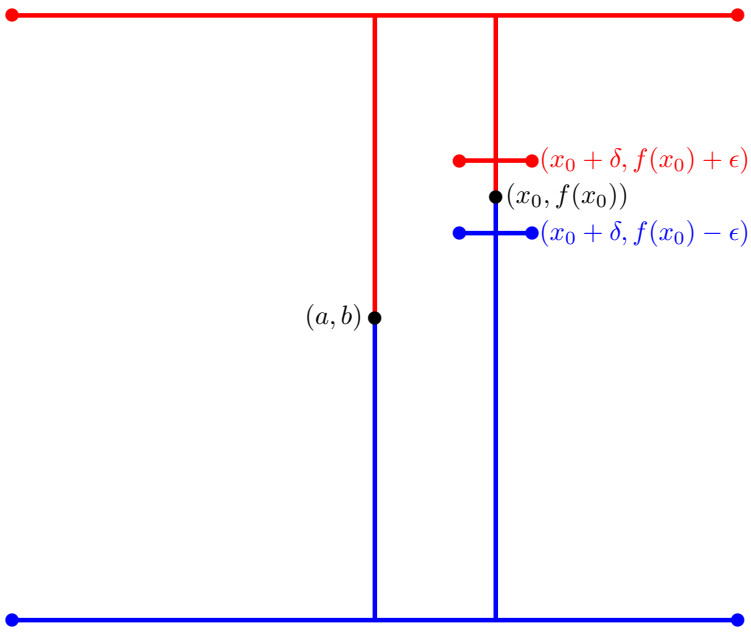

Figure VIII.19: Implicit Function Theorem IV

If $|x - x_0| < \delta$, there is thus a unique y, $f(x_0) - \epsilon < y < f(x_0) + \epsilon$, with $F(x, y) = 0$; this y must be $f(x)$, i.e. $|f(x) - f(x_0)| < \epsilon$. Thus f is continuous at x_0.

The Differentiable Version

The next lemma contains the most delicate part of the entire proof of the Implicit Function Theorem. It is needed for the differentiable and smooth versions of the theorem if $n = 1$, and even for the continuous version for general n. If the first-order partials of F are continuous at $(\boldsymbol{a}, b)$, the proof can be simplified (Exercise VIII.5.11.9.).

VIII.5.3.7. LEMMA. Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(\boldsymbol{a}, b) = (a_1, \ldots, a_p, b) \in U$ with $F(\boldsymbol{a}, b) = 0$. Suppose F is continuous on U and differentiable at $(\boldsymbol{a}, b)$, and that $\frac{\partial F}{\partial y}(\boldsymbol{a}, b) \neq 0$. Then there are:

(i) An open set V in $\mathbb{R}^{p+1}$ containing $(\boldsymbol{a}, b)$, with $V \subseteq U$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

such that whenever f is a real-valued function on W with $f(\boldsymbol{a}) = b$ and $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$ (there exist such functions by VIII.5.3.2.), then f is differentiable at $\boldsymbol{a}$ and, for $1 \leq j \leq p$,

$$\frac{\partial f}{\partial x_j}(\boldsymbol{a}) = -\frac{\frac{\partial F}{\partial x_j}(\boldsymbol{a}, b)}{\frac{\partial F}{\partial y}(\boldsymbol{a}, b)} \ .$$

PROOF: The little-o notation () is very helpful in this proof. As $\boldsymbol{h} = (\Delta\boldsymbol{x}, \Delta y) = (\Delta x_1, \ldots, \Delta x_p, \Delta y) \to 0$, we have

$$\Delta F = F(\boldsymbol{a}+\Delta\boldsymbol{x}, b+\Delta y) - F(\boldsymbol{a}, b) = \frac{\partial F}{\partial x_1}(\boldsymbol{a}, b)\Delta x_1 + \cdots + \frac{\partial F}{\partial x_p}(\boldsymbol{a}, b)\Delta x_p + o(1)\|\Delta x\| + \frac{\partial F}{\partial y}(\boldsymbol{a}, b)\Delta y + o(1)\Delta y$$

and if we set $y = f(\boldsymbol{x})$, so $\Delta y = f(\boldsymbol{a}+\Delta\boldsymbol{x}) - f(\boldsymbol{a})$, we have $\Delta F = 0$ since $F(\boldsymbol{a}+\Delta\boldsymbol{x}, b+\Delta y) = F(\boldsymbol{a}, b) = 0$, i.e.

$$\Delta y \left[\frac{\partial F}{\partial y}(\boldsymbol{a}, b) + o(1)\right] = -\frac{\partial F}{\partial x_1}(\boldsymbol{a}, b)\Delta x_1 - \cdots - \frac{\partial F}{\partial x_p}(\boldsymbol{a}, b)\Delta x_p + o(1)\|\Delta x\| \ .$$

By VIII.5.3.2., we have $\underline{f} \leq f \leq \overline{f}$, and hence by the Squeeze Theorem f is continuous at $\boldsymbol{a}$; thus $\Delta y = o(1)$ as $\Delta\boldsymbol{x} \to \boldsymbol{0}$, and hence $\overline{\boldsymbol{h}} = \boldsymbol{o}(1)$ as $\Delta\boldsymbol{x} \to \boldsymbol{0}$. Thus we have that the $o(1)$'s in the last expression are still $o(1)$ as $\Delta\boldsymbol{x} \to \boldsymbol{0}$. Also, if $\Delta\boldsymbol{x}$ is sufficiently small, we can divide by the expression in brackets on the left (using that $\frac{\partial F}{\partial y}(\boldsymbol{a}, b) \neq 0$ by assumption) to obtain

$$\Delta y = \frac{-\frac{\partial F}{\partial x_1}(\boldsymbol{a}, b)\Delta x_1 - \cdots - \frac{\partial F}{\partial x_p}(\boldsymbol{a}, b)\Delta x_p + o(1)\|\Delta x\|}{\frac{\partial F}{\partial y}(\boldsymbol{a}, b) + o(1)}$$

as $\Delta\boldsymbol{x} \to \boldsymbol{0}$. By (), the last expression is

$$\Delta y = \|\Delta\boldsymbol{x}\| \frac{-\frac{\partial F}{\partial x_1}(\boldsymbol{a}, b)\frac{\Delta x_1}{\|\Delta\boldsymbol{x}\|} - \cdots - \frac{\partial F}{\partial x_p}(\boldsymbol{a}, b)\frac{\Delta x_p}{\|\Delta\boldsymbol{x}\|} + o(1)}{\frac{\partial F}{\partial y}(\boldsymbol{a}, b) + o(1)}$$

$$= \|\Delta\boldsymbol{x}\| \left[-\frac{\frac{\partial F}{\partial x_1}(\boldsymbol{a}, b)}{\frac{\partial F}{\partial y}(\boldsymbol{a}, b)}\frac{\Delta x_1}{\|\Delta\boldsymbol{x}\|} - \cdots - \frac{\frac{\partial F}{\partial x_p}(\boldsymbol{a}, b)}{\frac{\partial F}{\partial y}(\boldsymbol{a}, b)}\frac{\Delta x_p}{\|\Delta\boldsymbol{x}\|} + o(1)\right]$$

$$= -\frac{\frac{\partial F}{\partial x_1}(\boldsymbol{a}, b)}{\frac{\partial F}{\partial y}(\boldsymbol{a}, b)}\Delta x_1 - \cdots - \frac{\frac{\partial F}{\partial x_p}(\boldsymbol{a}, b)}{\frac{\partial F}{\partial y}(\boldsymbol{a}, b)}\Delta x_p + o(1)\|\Delta \boldsymbol{x}\|$$

as $\Delta \boldsymbol{x} \to \boldsymbol{0}$; thus f is differentiable at $\boldsymbol{a}$ and

$$\frac{\partial f}{\partial x_j}(\boldsymbol{a}) = -\frac{\frac{\partial F}{\partial x_j}(\boldsymbol{a}, b)}{\frac{\partial F}{\partial y}(\boldsymbol{a}, b)} \ .$$

The following technical strengthening will be used in the inductive proof of the general Implicit Function Theorem. It can be proved in the same way, or it follows immediately from VIII.5.3.7. by simply holding the other coordinates constant:

VIII.5.3.8. Lemma. Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(\boldsymbol{a}, b) = (a_1, \ldots, a_p, b) \in U$ with $F(\boldsymbol{a}, b) = 0$. Let $S = \{x_{k_1}, \ldots, x_{k_m}\}$ be a subset of $\{x_1, \ldots, x_p\}$. Suppose F is continuous on U and differentiable with respect to $S \cup \{y\}$ at $(\boldsymbol{a}, b)$, and that $\frac{\partial F}{\partial y}(\boldsymbol{a}, b) \neq 0$. Then there are:

(i) An open set V in $\mathbb{R}^{p+1}$ containing $(\boldsymbol{a}, b)$, with $V \subseteq U$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

such that whenever f is a real-valued function on W with $f(\boldsymbol{a}) = b$ and $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$ (there exist such functions by VIII.5.3.2.), then f is differentiable with respect to S at $\boldsymbol{a}$ and, for $x_j \in S$,

$$\frac{\partial f}{\partial x_j}(\boldsymbol{a}) = -\frac{\frac{\partial F}{\partial x_j}(\boldsymbol{a}, b)}{\frac{\partial F}{\partial y}(\boldsymbol{a}, b)} \ .$$

VIII.5.3.9. Theorem. [One-Dimensional Implicit Function Theorem, Differentiable Version] Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(\boldsymbol{a}, b) = (a_1, \ldots, a_p, b) \in U$ with $F(\boldsymbol{a}, b) = 0$. Suppose F is differentiable at all points of U and $\frac{\partial F}{\partial y}$ is nonzero at all points of U. Then there are:

(i) An open set V in $\mathbb{R}^{p+1}$ containing $(\boldsymbol{a}, b)$, with $V \subseteq U$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(\boldsymbol{a}) = b$, and $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$.

Additionally, f is differentiable at every point of W and, for all $\boldsymbol{x} \in W$ and $1 \leq j \leq p$,

$$\frac{\partial f}{\partial x_j}(\boldsymbol{x}) = -\frac{\frac{\partial F}{\partial x_j}(\boldsymbol{x}, f(\boldsymbol{x}))}{\frac{\partial F}{\partial y}(\boldsymbol{x}, f(\boldsymbol{x}))} \ .$$

PROOF: The existence of V, W, and f, and the uniqueness (and continuity) of f, follow immediately from VIII.5.3.4., and if $\boldsymbol{x}_0 \in V$, differentiability of f at $\boldsymbol{x}_0$ follows from VIII.5.3.7. applied at the point $(\boldsymbol{x}_0, f(\boldsymbol{x}_0))$. 👍

In the case $p = 1$, we get the version of the Implicit Function Theorem which justifies implicit differentiation in first-semester calculus (note that there is no truly "one-dimensional" version of the Implicit Function Theorem – one-variable implicit differentiation must be justified by the "two-dimensional" version):

VIII.5.3.10. COROLLARY. [ONE-VARIABLE IMPLICIT FUNCTION THEOREM, DIFFERENTIABLE VERSION] Let $F(x, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^2$ is open, and $(a, b) \in U$ with $F(a, b) = 0$. Suppose F is differentiable at all points of U and $\frac{\partial F}{\partial y}$ is nonzero at all points of U. Then there are:

(i) An open set V in $\mathbb{R}^2$ containing (a, b), with $V \subseteq U$;

(ii) An open interval W in $\mathbb{R}$ containing a;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(a) = b$, and $(x, f(x)) \in V$ and $F(x, f(x)) = 0$ for all $x \in W$.

Additionally, f is differentiable at every point of W and, for all $x \in W$,

$$f'(x) = -\frac{\frac{\partial F}{\partial x}(x, f(x))}{\frac{\partial F}{\partial y}(x, f(x))} .$$

VIII.5.3.11. The fact that the slope of the tangent line to the level curve at (x, y) is $-\frac{\frac{\partial F}{\partial x}(x,y)}{\frac{\partial F}{\partial y}(x,y)}$ should come as no surprise, since this level curve should be perpendicular to $\nabla F(x, y) = \left(\frac{\partial F}{\partial x}(x, y), \frac{\partial F}{\partial y}(x, y)\right)$ (). But what is not obvious is that the level curve through (x, y) is a smooth curve with a tangent line, or indeed that the level set is a "curve" at all; this is the theoretical conclusion of the theorem (cf. VIII.5.1.9.).

The formula for $f'(x)$ given in the theorem is equivalent to but more efficient than the one obtained by first-semester calculus methods before partial derivatives are introduced (VIII.5.11.8.); indeed, the partial derivative version is the "right" way to do one-variable implicit differentiation.

We also get a mixed version in which differentiability with respect to only some of the variables is assumed and concluded:

VIII.5.3.12. THEOREM. [ONE-DIMENSIONAL IMPLICIT FUNCTION THEOREM, MIXED VERSION] Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(\boldsymbol{a}, b) = (a_1, \ldots, a_p, b) \in U$ with $F(\boldsymbol{a}, b) = 0$. Let $S = \{x_{k_1}, \ldots, x_{k_m}\}$ be a subset of $\{x_1, \ldots, x_p\}$. Suppose F is differentiable with respect to $S \cup \{y\}$ at all points of U and $\frac{\partial F}{\partial y}$ is nonzero at all points of U. Then there are:

(i) An open set V in $\mathbb{R}^{p+1}$ containing $(\boldsymbol{a}, b)$, with $V \subseteq U$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(\boldsymbol{a}) = b$, and $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$.

Additionally, f is continuous on W and differentiable with respect to S at every point of W and, for all $\boldsymbol{x} \in W$ and $x_j \in S$,

$$\frac{\partial f}{\partial x_j}(\boldsymbol{x}) = -\frac{\frac{\partial F}{\partial x_j}(\boldsymbol{x}, f(\boldsymbol{x}))}{\frac{\partial F}{\partial y}(\boldsymbol{x}, f(\boldsymbol{x}))} \ .$$

The continuous version (VIII.5.3.5.) and the differentiable version (VIII.5.3.9.) are the special cases $S = \emptyset$ and $S = \{x_1, \ldots, x_p\}$ respectively.

The Smooth Version

VIII.5.3.13. Theorem. [One-Dimensional Implicit Function Theorem, Smooth Version] Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(\boldsymbol{a}, b) = (a_1, \ldots, a_p, b) \in U$ with $F(\boldsymbol{a}, b) = 0$. Suppose F is $\mathcal{C}^r$ on U $(1 \leq r \leq \infty)$ and $\frac{\partial F}{\partial y}(\boldsymbol{a}, b) \neq 0$. Then there are:

(i) An open set V in $\mathbb{R}^{p+1}$ containing $(\boldsymbol{a}, b)$, with $V \subseteq U$, such that $\frac{\partial F}{\partial y}(\boldsymbol{x}, y) \neq 0$ for all $(\boldsymbol{x}, y) \in V$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(\boldsymbol{a}) = b$, and $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$.

Additionally, f is $\mathcal{C}^r$ on W and, for all $\boldsymbol{x} \in W$ and $1 \leq j \leq p$,

$$\frac{\partial f}{\partial x_j}(\boldsymbol{x}) = -\frac{\frac{\partial F}{\partial x_j}(\boldsymbol{x}, f(\boldsymbol{x}))}{\frac{\partial F}{\partial y}(\boldsymbol{x}, f(\boldsymbol{x}))} \ .$$

Proof: By continuity, there is an open neighborhood U' of $(\boldsymbol{a}, b)$ contained in U such that $\frac{\partial F}{\partial y}$ is nonzero everywhere on U'. Everything then follows immediately from VIII.5.3.9. (applied with U' in place of U) except the fact that f is $\mathcal{C}^r$. We prove this by induction on r.

First suppose F is $\mathcal{C}^1$. Then, for $1 \leq j \leq p$, $\frac{\partial F}{\partial x_j}$ is continuous on V, and f is continuous on W, so $g_j(\boldsymbol{x}) = \frac{\partial F}{\partial x_j}(\boldsymbol{x}, f(\boldsymbol{x}))$ is continuous on W. Similarly, $g(\boldsymbol{x}) = \frac{\partial F}{\partial y}(\boldsymbol{x}, f(\boldsymbol{x}))$ is continuous and nonzero on W, so

$$\frac{\partial f}{\partial x_j}(\boldsymbol{x}) = -\frac{g_j(\boldsymbol{x})}{g(\boldsymbol{x})}$$

is also continuous on W for each j. Thus f is $\mathcal{C}^1$ on W.

Now assume the result for r, and suppose F is $\mathcal{C}^{r+1}$. Then by the inductive hypothesis f is $\mathcal{C}^r$, so g and each g_j are $\mathcal{C}^r$ by the higher-order Chain Rule (). We then obtain that $\frac{\partial f}{\partial x_j}$ is $\mathcal{C}^r$ for each j since it is a quotient of $\mathcal{C}^r$ functions with nonvanishing denominator. Thus f is $\mathcal{C}^{r+1}$. 👍

VIII.5.3.14. Corollary. [One-Variable Implicit Function Theorem, Smooth Version] Let $F(x,y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^2$ is open, and $(a,b) \in U$ with $F(a,b) = 0$. Suppose F is $\mathcal{C}^r$ on U $(1 \leq r \leq \infty)$ and $\frac{\partial F}{\partial y}(a,b) \neq 0$. Then there are:

(i) An open set V in $\mathbb{R}^2$ containing (a,b), with $V \subseteq U$, such that $\frac{\partial F}{\partial y}(x,y) \neq 0$ for all $(x,y) \in V$;

(ii) An open set W in $\mathbb{R}$ containing a;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(a) = b$, and $(x, f(x)) \in V$ and $F(x, f(x)) = 0$ for all $x \in W$.

Additionally, f is $\mathcal{C}^r$ on W and, for all $x \in W$,

$$f'(x) = -\frac{\frac{\partial F}{\partial x}(x, f(x))}{\frac{\partial F}{\partial y}(x, f(x))} .$$

We also get a mixed version which will be used in the inductive proof of the general theorem:

VIII.5.3.15. Theorem. [One-Dimensional Implicit Function Theorem, Mixed Smooth Version] Let $F(x_1, \ldots, x_p, y) : U \to \mathbb{R}$, where $U \subseteq \mathbb{R}^{p+1}$ is open, and $(\boldsymbol{a}, b) = (a_1, \ldots, a_p, b) \in U$ with $F(\boldsymbol{a}, b) = 0$. Let $S = \{x_{k_1}, \ldots, x_{k_m}\}$ be a subset of $\{x_1, \ldots, x_p\}$. Suppose F, $\frac{\partial F}{\partial y}$, and $\frac{\partial F}{\partial x_j}$ are continuous on U $(1 \leq r \leq \infty)$ for all $x_j \in S$, and $\frac{\partial F}{\partial y}(\boldsymbol{a}, b) \neq 0$. Then there are:

(i) An open set V in $\mathbb{R}^{p+1}$ containing $(\boldsymbol{a}, b)$, with $V \subseteq U$, such that $\frac{\partial F}{\partial y}(\boldsymbol{x}, y) \neq 0$ for all $(\boldsymbol{x}, y) \in V$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $f : W \to \mathbb{R}$ such that $f(\boldsymbol{a}) = b$, and $(\boldsymbol{x}, f(\boldsymbol{x})) \in V$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$.

Additionally, f and $\frac{\partial f}{\partial x_j}$ are continuous on W for all $x_j \in S$ and, for all $\boldsymbol{x} \in W$, $x_j \in S$, and $1 \leq j \leq p$,

$$\frac{\partial f}{\partial x_j}(\boldsymbol{x}) = -\frac{\frac{\partial F}{\partial x_j}(\boldsymbol{x}, f(\boldsymbol{x}))}{\frac{\partial F}{\partial y}(\boldsymbol{x}, f(\boldsymbol{x}))} .$$

Proof: The conclusion follows from VIII.5.3.12. just as VIII.5.3.13. follows from VIII.5.3.9.. 👍

VIII.5.4. Proof of the General Implicit Function Theorem

VIII.5.4.1. The most straightforward proof of the general Implicit Function Theorem is by induction on the number n of variables being solved for (this was also the first proof). The inductive proof requires a stronger continuity hypothesis on the partial derivatives of $\boldsymbol{F}$ than the one-dimensional version, as explained in VIII.5.4.3..

We will prove the following mixed version of the Implicit Function Theorem, which includes both the continuous version (VIII.5.1.6.) and the smooth ($\mathcal{C}^1$) version (VIII.5.1.7.):

VIII.5.4.2. THEOREM. [IMPLICIT FUNCTION THEOREM, MIXED VERSION] Let U be an open set in $\mathbb{R}^{p+n}$ and $(\boldsymbol{a},\boldsymbol{b}) \in U$. Let $\boldsymbol{F} : U \to \mathbb{R}^n$ with $\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b}) = \boldsymbol{0}$. Suppose $\boldsymbol{F}$ is continuous on U and that $D_{\boldsymbol{y}}\boldsymbol{F}$ exists and is continuous on U, i.e. that $\frac{\partial \boldsymbol{F}}{\partial y_j}$ exists and is continuous on U for $1 \le j \le n$. If $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$ is invertible, i.e. $det(D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})) \neq 0$, then there are:

(i) An open set V in $\mathbb{R}^{p+n}$ containing $(\boldsymbol{a},\boldsymbol{b})$, with $V \subseteq U$, such that $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})$ is invertible for all $(\boldsymbol{x},\boldsymbol{y}) \in V$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $\boldsymbol{f} : W \to \mathbb{R}^n$ such that $\boldsymbol{f}(\boldsymbol{a}) = \boldsymbol{b}$ and, for all $\boldsymbol{x} \in W$, $(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) \in V$ and

$$\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) = \boldsymbol{0} \ .$$

Additionally, $\boldsymbol{f}$ is continuous on W. If additionally $S = \{x_{k_1}, \ldots, x_{k_m}\}$ is a subset of $\{x_1, \ldots, x_p\}$ and $\frac{\partial \boldsymbol{F}}{\partial x_{k_j}}$ exists and is continuous on U for each $x_{k_j} \in S$, then $\frac{\partial \boldsymbol{f}}{\partial x_{k_j}}$ exists and is continuous on W for each $x_{k_j} \in S$ and these partials satisfy

$$D_S\boldsymbol{f}(\boldsymbol{x}) = -D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))^{-1} D_S\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))$$

for all $\boldsymbol{x} \in W$, where $D_S\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})$ is the $n \times m$ matrix

$$D_S\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) = \begin{bmatrix} \frac{\partial F_1}{\partial x_{k_1}}(\boldsymbol{x},\boldsymbol{y}) & \cdots & \frac{\partial F_1}{\partial x_{k_m}}(\boldsymbol{x},\boldsymbol{y}) \\ \vdots & \ddots & \vdots \\ \frac{\partial F_n}{\partial x_{k_1}}(\boldsymbol{x},\boldsymbol{y}) & \cdots & \frac{\partial F_n}{\partial x_{k_m}}(\boldsymbol{x},\boldsymbol{y}) \end{bmatrix} \ .$$

PROOF: The case $n = 1$ is VIII.5.3.15.. We now assume the theorem is true for n, and show it is true for $n+1$. So suppose $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{F}(x_1, \ldots, x_p, y_1, \ldots, y_{n+1})$ is a continuous function from an open set $U \subseteq \mathbb{R}^{p+n+1}$ to $\mathbb{R}^{n+1}$, $(\boldsymbol{a},\boldsymbol{b}) = (a_1, \ldots, a_p, b_1, \ldots, b_{n+1}) \in U$, that $D_{\boldsymbol{y}}\boldsymbol{F}$ and $D_S\boldsymbol{F}$ are continuous on U for some subset S of $\{x_1, \ldots, x_p\}$, and $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$ is invertible. The strategy for finding the implicit function $\boldsymbol{f} : \mathbb{R}^p \to \mathbb{R}^{n+1}$ will be to show that for some i, $1 \le i \le n+1$, the y_k for $2 \le k \le n+1$ can be written as implicit functions g_k of $(x_1, \ldots, x_p, y_1)$ satisfying

$$F_j(x_1, \ldots, x_p, y_1, g_2(x_1, \ldots, x_p, y_1), \ldots, g_{n+1}(x_1, \ldots, x_p, y_1)) = 0$$

for $j \neq i$ and $(x_1, \ldots, x_p, y_1)$ close to $(a_1, \ldots, a_p, b_1)$ by the inductive hypothesis, and that y_1 can then be written as an implicit function h of $(x_1, \ldots, x_p)$ satisfying

$$F_i(x_1, \ldots, x_p, h(\boldsymbol{x}), g_2(\boldsymbol{x}, h(\boldsymbol{x})), \ldots, g_{n+1}(\boldsymbol{x}, h(\boldsymbol{x}))) = 0$$

for $\boldsymbol{x}$ near $\boldsymbol{a}$ by an application of VIII.5.3.15.. Then $\boldsymbol{f}$ can be defined by

$$\boldsymbol{f}(\boldsymbol{x}) = (h(\boldsymbol{x}), g_2(\boldsymbol{x}, h(\boldsymbol{x})), \ldots, g_{n+1}(\boldsymbol{x}, h(\boldsymbol{x}))) \ .$$

For the details, we will use the following notation. Write $J(\boldsymbol{x},\boldsymbol{y})$ for the determinant of the $(n+1)\times(n+1)$ matrix $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})$. For each i, let $J_i(\boldsymbol{x},\boldsymbol{y})$ be the determinant of the i'th minor in the first column, i.e.

$$J_i(\boldsymbol{x},\boldsymbol{y}) = (-1)^{i+1} det \begin{bmatrix} \frac{\partial F_1}{\partial y_2}(\boldsymbol{x},\boldsymbol{y}) & \cdots & \frac{\partial F_1}{\partial y_{n+1}}(\boldsymbol{x},\boldsymbol{y}) \\ \vdots & \ddots & \vdots \\ \frac{\partial F_{n+1}}{\partial y_2}(\boldsymbol{x},\boldsymbol{y}) & \cdots & \frac{\partial F_{n+1}}{\partial y_{n+1}}(\boldsymbol{x},\boldsymbol{y}) \end{bmatrix}$$

with the i'th row (partials of F_i) deleted. Then

$$J(\boldsymbol{x},\boldsymbol{y}) = J_1(\boldsymbol{x},\boldsymbol{y})\frac{\partial F_1}{\partial y_1}(\boldsymbol{x},\boldsymbol{y}) + J_2(\boldsymbol{x},\boldsymbol{y})\frac{\partial F_2}{\partial y_1}(\boldsymbol{x},\boldsymbol{y}) + \cdots + J_{n+1}(\boldsymbol{x},\boldsymbol{y})\frac{\partial F_{n+1}}{\partial y_1}(\boldsymbol{x},\boldsymbol{y})$$

and so, since $J(\boldsymbol{a},\boldsymbol{b}) \neq 0$, there is an i, $1 \leq i \leq n+1$, such that $J_i(\boldsymbol{a},\boldsymbol{b}) \neq 0$ and $\frac{\partial F_i}{\partial y_1}(\boldsymbol{a},\boldsymbol{b}) \neq 0$. Then there is an open neighborhood U' of $(\boldsymbol{a},\boldsymbol{b})$ such that $J_i(\boldsymbol{x},\boldsymbol{y}) \neq 0$ and $\frac{\partial F_i}{\partial y_1}(\boldsymbol{x},\boldsymbol{y}) \neq 0$ for all $(\boldsymbol{x},\boldsymbol{y}) \in U'$. Apply the inductive hypothesis with $S' = S \cup \{y_1\}$ to obtain an open neighborhood V_1 of $(\boldsymbol{a},\boldsymbol{b})$ in $\mathbb{R}^{p+n+1}$, an open neighborhood W_1 of $(a_1,\ldots,a_p,b_1)$ in $\mathbb{R}^{p+1}$, and unique functions $g_k : W_1 \to \mathbb{R}$ $(2 \leq k \leq n+1)$ which satisfy, for $(x_1,\ldots,x_p,y_1) \in W_1$,

$$(x_1,\ldots,x_p,y_1,g_2(x_1,\ldots,x_p,y_1),\ldots,g_{n+1}(x_1,\ldots,x_p,y_1)) \in V_1$$

$$F_j(x_1,\ldots,x_p,y_1,g_2(x_1,\ldots,x_p,y_1),\ldots,g_{n+1}(x_1,\ldots,x_p,y_1)) = 0$$

for $j \neq i$, and g_k, $\frac{\partial g_k}{\partial y_1}$, and $\frac{\partial g_k}{\partial x_j}$ for $x_j \in S$ continuous on W_1 for each k.

Now, for $(x_1,\ldots,x_p,y_1) \in W_1$, set

$$G(x_1,\ldots,x_p,y_1) = F_i(x_1,\ldots,x_p,y_1,g_2(x_1,\ldots,x_p,y_1),\ldots,g_{n+1}(x_1,\ldots,x_p,y_1)) \ .$$

Then G is continuous on W_1, and $G(a_1,\ldots,a_p,b_1) = 0$. We show that G satisfies the hypotheses of VIII.5.3.15. on W_1. By the Chain Rule, $\frac{\partial G}{\partial y_1}$ exists on W_1 and

$$\frac{\partial G}{\partial y_1}(\boldsymbol{x},y_1) = \frac{\partial F_i}{\partial y_1}(\boldsymbol{x},y_1,g_2(\boldsymbol{x},y_1),\ldots,g_{n+1}(\boldsymbol{x},y_1)) + \frac{\partial F_i}{\partial y_2}(\boldsymbol{x},y_1,g_2(\boldsymbol{x},y_1),\ldots,g_{n+1}(\boldsymbol{x},y_1))\frac{\partial g_2}{\partial y_1}(\boldsymbol{x},y_1) +$$

$$\cdots + \frac{\partial F_i}{\partial y_{n+1}}(\boldsymbol{x},y_1,g_2(\boldsymbol{x},y_1),\ldots,g_{n+1}(\boldsymbol{x},y_1))\frac{\partial g_{n+1}}{\partial y_1}(\boldsymbol{x},y_1) \ .$$

Thus $\frac{\partial G}{\partial y_1}$ is continuous on W_1. It remains to show that $\frac{\partial G}{\partial y_1}(\boldsymbol{a},b_1) \neq 0$. If we set $G_i = G$ and define, for $j \neq i$,

$$G_j(x_1,\ldots,x_p,y_1) = F_j(x_1,\ldots,x_p,y_1,g_2(x_1,\ldots,x_p,y_1),\ldots,g_{n+1}(x_1,\ldots,x_p,y_1))$$

we similarly have

$$\frac{\partial G_j}{\partial y_1}(\boldsymbol{x},y_1) = \frac{\partial F_j}{\partial y_1}(\boldsymbol{x},y_1,g_2(\boldsymbol{x},y_1),\ldots,g_{n+1}(\boldsymbol{x},y_1)) + \frac{\partial F_j}{\partial y_2}(\boldsymbol{x},y_1,g_2(\boldsymbol{x},y_1),\ldots,g_{n+1}(\boldsymbol{x},y_1))\frac{\partial g_2}{\partial y_1}(\boldsymbol{x},y_1) +$$

$$\cdots + \frac{\partial F_j}{\partial y_{n+1}}(\boldsymbol{x},y_1,g_2(\boldsymbol{x},y_1),\ldots,g_{n+1}(\boldsymbol{x},y_1))\frac{\partial g_{n+1}}{\partial y_1}(\boldsymbol{x},y_1) \ .$$

But G_j is identically 0, so abbreviating notation we have

$$\frac{\partial G_i}{\partial y_1} = \frac{\partial F_i}{\partial y_1} + \frac{\partial F_i}{\partial y_2}\frac{\partial g_2}{\partial y_1} + \cdots + \frac{\partial F_i}{\partial y_{n+1}}\frac{\partial g_{n+1}}{\partial y_1}$$

$$0 = \frac{\partial F_j}{\partial y_1} + \frac{\partial F_j}{\partial y_2}\frac{\partial g_2}{\partial y_1} + \cdots + \frac{\partial F_j}{\partial y_{n+1}}\frac{\partial g_{n+1}}{\partial y_1}$$

for $j \neq i$. Multiplying the j'th equation by J_j and adding the equations together, we get

$$J_i \frac{\partial G_i}{\partial y_1} = \sum_{j=1}^{n+1} J_j \frac{\partial F_j}{\partial y_1} + \frac{\partial g_2}{\partial y_1} \sum_{j=1}^{n+1} J_j \frac{\partial F_j}{\partial y_2} + \cdots + \frac{\partial g_{n+1}}{\partial y_1} \sum_{j=1}^{n+1} J_j \frac{\partial F_j}{\partial y_{n+1}} \ .$$

The first sum is J, and the second sum is the determinant of the matrix

$$\begin{bmatrix} \frac{\partial F_1}{\partial y_2} & \frac{\partial F_1}{\partial y_2} & \cdots & \frac{\partial F_1}{\partial y_{n+1}} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial F_{n+1}}{\partial y_2} & \frac{\partial F_{n+1}}{\partial y_2} & \cdots & \frac{\partial F_n}{\partial y_{n+1}} \end{bmatrix}$$

expanded by minors on the first column. This matrix has two identical columns, hence has determinant 0 (), so the second sum is 0. Similarly, the other sums are 0. Thus

$$J_i(\boldsymbol{x}, \boldsymbol{y}) \frac{\partial G}{\partial y_1}(\boldsymbol{x}, y_1) = J(\boldsymbol{x}, \boldsymbol{y})$$

for all $(\boldsymbol{x}, \boldsymbol{y})$; so $\frac{\partial G}{\partial y_1}(\boldsymbol{a}, b_1) \neq 0$ since $J(\boldsymbol{a}, \boldsymbol{b}) \neq 0$.

Then by VIII.5.3.15. there is an open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$ and an open set V_2 in $\mathbb{R}^{p+1}$ containing $(\boldsymbol{a}, b_1)$, $V_2 \subseteq W_1$, and a unique function $h : W \to \mathbb{R}$, such that $(\boldsymbol{x}, h(\boldsymbol{x})) \in V_2$ and $G(\boldsymbol{x}, h(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$. Set

$$V = \{(x_1, \ldots, x_p, y_1, \ldots, y_n) \in V_1 : (x_1, \ldots, x_p, y_1) \in V_2\}$$

and define

$$\boldsymbol{f}(\boldsymbol{x}) = (h(\boldsymbol{x}), g_2(\boldsymbol{x}, h(\boldsymbol{x})), \ldots, g_{n+1}(\boldsymbol{x}, h(\boldsymbol{x})))$$

for $\boldsymbol{x} \in W$. Then, for $\boldsymbol{x} \in W$, we have $(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) \in V$, and $F_i(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) = G(\boldsymbol{x}, h(\boldsymbol{x})) = 0$. And if $j \neq i$,

$$F_j(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) = F_j(\boldsymbol{x}, h(\boldsymbol{x}), g_2(\boldsymbol{x}, h(\boldsymbol{x})), \ldots, g_{n+1}(\boldsymbol{x}, h(\boldsymbol{x}))) = 0 \ .$$

Thus $\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) = \boldsymbol{0}$.

The uniqueness of $\boldsymbol{f}$ follows immediately from the uniqueness of the g_k and of h, and continuity of $\boldsymbol{f}$ follows from continuity of the g_k and h. Continuity of $\frac{\partial \boldsymbol{f}}{\partial x_j}$ on W for $x_j \in S$ then follows from continuity of the partials of the g_k and h for $x_j \in S$.

The formula for $D_S \boldsymbol{f}$ now follows easily from the Chain Rule. We write the case $S = \{x_1, \ldots, x_p\}$; the case of general S is identical with notational complications (or can be obtained immediately by restricting coordinates). Define $\boldsymbol{H} : W \to \mathbb{R}^{p+n}$ by $\boldsymbol{H}(\boldsymbol{x}) = (\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))$. Then $\boldsymbol{H}$ is $\mathcal{C}^1$ on W, and

$$D\boldsymbol{H}(\boldsymbol{x}) = \begin{bmatrix} I_p \\ D\boldsymbol{f}(\boldsymbol{x}) \end{bmatrix}$$

for $\boldsymbol{x} \in W$, where I_p is the $p \times p$ identity matrix and $D\boldsymbol{f}(\boldsymbol{x})$ is $n \times p$. Then by the Chain Rule we have

$$D(\boldsymbol{F} \circ \boldsymbol{H})(\boldsymbol{x}) = D\boldsymbol{F}(\boldsymbol{H}(\boldsymbol{x}))D\boldsymbol{H}(\boldsymbol{x}) = \begin{bmatrix} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) & D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) \end{bmatrix} \begin{bmatrix} I_p \\ Df(\boldsymbol{x}) \end{bmatrix}$$

$$= D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) + D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))D\boldsymbol{f}(\boldsymbol{x})$$

for $\boldsymbol{x} \in W$. But $\boldsymbol{F} \circ \boldsymbol{H}$ is identically zero on W, so $D(\boldsymbol{F} \circ \boldsymbol{H})(\boldsymbol{x}) = \boldsymbol{0}$ for all $\boldsymbol{x} \in W$. Since $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))$ is invertible for $\boldsymbol{x} \in W$, we have, for $\boldsymbol{x} \in W$,

$$D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))^{-1} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) + D\boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{0} \ .$$

This completes the proof of VIII.5.4.2., and hence of the continuous version VIII.5.1.6. (the case $S = \emptyset$) and the $\mathcal{C}^1$ smooth version VIII.5.1.7. (the case $S = \{x_1, \ldots, x_p\}$). 

VIII.5.4.3. The reason this proof requires continuity of the partials, and not just that the partials exist and $J(\boldsymbol{x}, \boldsymbol{y}) \neq 0$ in a neighborhood of $(\boldsymbol{a}, \boldsymbol{b})$, is that not only must J be nonzero, but at least one of the minors J_i must also be nonzero in a neighborhood of $(\boldsymbol{a}, \boldsymbol{b})$ to apply the inductive assumption. The continuity can be replaced by an assumption that not only is the J nonzero in a neighborhood of $(\boldsymbol{a}, \boldsymbol{b})$, but also a decreasing chain of minors of smaller and smaller size are nonzero in a neighborhood of $(\boldsymbol{a}, \boldsymbol{b})$. This version was explicitly stated in [You09], but is quite clumsy so we have stuck to the cleaner statement of VIII.5.4.2., which is adequate for almost all applications. For a full extension of VIII.5.3.10. to the n-dimensional case, see VIII.5.7.7.. It does not appear to be known whether the assumption of the decreasing sequence of nonzero minors is automatic (cf. Exercise VIII.5.11.14.(b)).

VIII.5.4.4. To finish the proof of the smooth version, it remains only to show that if $\boldsymbol{F}$ is $\mathcal{C}^r$, then $\boldsymbol{f}$ is also $\mathcal{C}^r$. The entries of $D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))$ and $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))$ are $\mathcal{C}^{r-1}$ by assumption. Since the determinant of $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, f(\boldsymbol{x}))$ is a polynomial in the entries, it is also $\mathcal{C}^{r-1}$ on W, and since the determinant is never 0 on W, it follows that the reciprocal of the determinant is also $\mathcal{C}^{r-1}$ on W. Thus the entries of $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))^{-1}$ are also $\mathcal{C}^{r-1}$ on W by the formula in III.11.10.45., and therefore so are the entries of

$$D\boldsymbol{f}(\boldsymbol{x}) = -D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))^{-1} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))$$

which is equivalent to $\boldsymbol{f}$ being $\mathcal{C}^r$ on W.

This completes the full proof of the smooth version VIII.5.1.7.. 

VIII.5.5. Proof of the Inverse Function Theorem

The Inverse Function Theorem can now be proved from the Implicit Function Theorem as in (). In this section we give an alternate direct proof, which "explains" better why the theorem is true and which generalizes to other settings, such as Banach spaces (). This proof uses the Contraction Mapping Principle (). This argument first appeared, in somewhat disguised form, in [Gou03]; cf. Exercise VIII.5.11.11..

To prove the Inverse Function Theorem, it suffices the prove the following theorem. Differentiability of the inverse function then follows from VIII.5.1.29., and the formula there shows that the inverse function is $\mathcal{C}^1$; and if $\boldsymbol{f}$ is $\mathcal{C}^r$, the inverse function is also $\mathcal{C}^r$ by the argument in VIII.5.4.4..

VIII.5.5.1. THEOREM. Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{a} \in \mathbb{R}^n$, and $\boldsymbol{f} : U \to \mathbb{R}^n$ a $\mathcal{C}^1$ function. If $D\boldsymbol{f}(\boldsymbol{a})$ is invertible, then there is a neighborhood V of $\boldsymbol{a}$, $V \subseteq U$, such that

(i) $\boldsymbol{f}$ is one-to-one on V.

(ii) $W = \boldsymbol{f}(V)$ is open in $\mathbb{R}^n$.

(iii) $D\boldsymbol{f}(\boldsymbol{x})$ is invertible for all $\boldsymbol{x} \in V$.

VIII.5.5.2. The first reduction is to make an affine change of variables to make $\boldsymbol{a} = \boldsymbol{0}$, $\boldsymbol{f}(\boldsymbol{0}) = \boldsymbol{0}$, and $D\boldsymbol{f}(\boldsymbol{0}) = I_n$, which greatly simplifies the notation of the rest of the proof. We define

$$\boldsymbol{T}(\boldsymbol{x}) = D\boldsymbol{f}(\boldsymbol{a})^{-1}(\boldsymbol{x}) \ .$$

Then $\boldsymbol{T}$ is an invertible linear function from $\mathbb{R}^n$ to $\mathbb{R}^n$; $\boldsymbol{T}$ is $\mathcal{C}^1$ and $D\boldsymbol{T}(\boldsymbol{x}) = D\boldsymbol{f}(\boldsymbol{a})^{-1}$ for all $\boldsymbol{x}$. Define

$$\boldsymbol{g}(\boldsymbol{x}) = \boldsymbol{T}(\boldsymbol{f}(\boldsymbol{x} + \boldsymbol{a})) - \boldsymbol{c}$$

for $\boldsymbol{x} \in U - \boldsymbol{a}$, where $\boldsymbol{c} = \boldsymbol{T}(\boldsymbol{f}(\boldsymbol{a}))$; then by the Chain Rule $\boldsymbol{g}$ is $\mathcal{C}^1$ on $U - \boldsymbol{a}$ and

$$D\boldsymbol{g}(\boldsymbol{x}) = D\boldsymbol{T}(\boldsymbol{f}(\boldsymbol{x} + \boldsymbol{a}))D\boldsymbol{f}(\boldsymbol{x} + \boldsymbol{a}) = D\boldsymbol{f}(\boldsymbol{a})^{-1}D\boldsymbol{f}(\boldsymbol{x} + \boldsymbol{a})$$

for $\boldsymbol{x} \in U - \boldsymbol{a}$. In particular, $D\boldsymbol{g}(\boldsymbol{0}) = I_n$.

It suffices to prove VIII.5.5.1. for $\boldsymbol{g}$ on $U - \boldsymbol{a}$, since we would then have

$$\boldsymbol{f}^{-1}(\boldsymbol{y}) = \boldsymbol{g}^{-1}(\boldsymbol{T}(\boldsymbol{y}) - \boldsymbol{c}) + \boldsymbol{a}$$

on $T^{-1}(W + \boldsymbol{c})$ with values in $V + \boldsymbol{a}$.

So, changing notation, in VIII.5.5.1. we will assume $\boldsymbol{a} = \boldsymbol{0}$, $\boldsymbol{f}(\boldsymbol{0}) = \boldsymbol{0}$, and $D\boldsymbol{f}(\boldsymbol{0}) = I_n$.

VIII.5.5.3. Now define $\boldsymbol{g}(\boldsymbol{x}) = \boldsymbol{x} - \boldsymbol{f}(\boldsymbol{x})$. Then $\boldsymbol{g}$ is $\mathcal{C}^r$. Since $D\boldsymbol{g}(\boldsymbol{0}) = \boldsymbol{0}$, there is an $\epsilon > 0$ such that $\|Dg_k(\boldsymbol{x})\| < \frac{1}{2n}$ for all k whenever $\|\boldsymbol{x}\| < \epsilon$. Set $W_1 = B_\epsilon(\boldsymbol{0})$. If $\boldsymbol{x}, \boldsymbol{z} \in W_1$, then by the MVT () for each k there is a $\boldsymbol{c}_k$ between $\boldsymbol{x}$ and $\boldsymbol{z}$ with $g_k(x) - g_k(z) = Dg_k(\boldsymbol{c}_k)(\boldsymbol{x} - \boldsymbol{z})$; $\boldsymbol{c}_k \in W_1$ since W_1 is convex. Thus

$$\|\boldsymbol{g}(\boldsymbol{x}) - \boldsymbol{g}(\boldsymbol{z})\| \leq \sum_{k=1}^{n} |g_k(x) - g_k(z)| = \sum_{k=1}^{n} |Dg_k(\boldsymbol{c}_k)(\boldsymbol{x} - \boldsymbol{z})| \leq \sum_{k=1}^{n} \|Dg_k(\boldsymbol{c}_k)\|\|\boldsymbol{x} - \boldsymbol{z}\| < \frac{1}{2}\|\boldsymbol{x} - \boldsymbol{z}\|$$

for $\boldsymbol{x}, \boldsymbol{z} \in W_1$. In particular, $\|\boldsymbol{g}(\boldsymbol{x})\| < \frac{1}{2}\|\boldsymbol{x}\|$ for all $\boldsymbol{x} \in W_1$.

VIII.5.5.4. Now fix η, $0 < \eta < \epsilon$, and fix $\boldsymbol{y} \in \mathbb{R}^n$ with $\|y\| \leq \frac{\eta}{2}$. Define $\boldsymbol{g}_{\boldsymbol{y}} : \mathbb{R}^n \to \mathbb{R}^n$ by

$$\boldsymbol{g}_{\boldsymbol{y}}(\boldsymbol{x}) = \boldsymbol{y} + \boldsymbol{x} - \boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{y} + \boldsymbol{g}(\boldsymbol{x}) \ .$$

If $\|\boldsymbol{x}\| \leq \eta$, then $\|\boldsymbol{g}(\boldsymbol{x})\| < \frac{\eta}{2}$, so $\|\boldsymbol{g}_{\boldsymbol{y}}(\boldsymbol{x})\| < \eta$; thus $\boldsymbol{g}_{\boldsymbol{y}}$ maps $\bar{B}_\eta(\boldsymbol{0})$ into itself. If $\boldsymbol{x}, \boldsymbol{z} \in \bar{B}_\eta(\boldsymbol{0})$, then

$$\|\boldsymbol{g}_{\boldsymbol{y}}(\boldsymbol{x}) - \boldsymbol{g}_{\boldsymbol{y}}(\boldsymbol{z})\| = \|\boldsymbol{g}(\boldsymbol{x}) - \boldsymbol{g}(\boldsymbol{z})\| < \frac{1}{2}\|\boldsymbol{x} - \boldsymbol{z}\|$$

and so $\boldsymbol{g_y}$ is a contractive mapping of the complete metric space $\bar{B}_\eta(\mathbf{0})$ to itself. By the Contractive Mapping Principle (), $\boldsymbol{g_y}$ has a unique fixed point $\boldsymbol{x} \in \bar{B}_\eta(\mathbf{0})$, i.e. there is a unique $\boldsymbol{x}$ with $\|\boldsymbol{x}\| \leq \eta$ and $\boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{y}$. Thus, if $W = B_{\epsilon/2}(\mathbf{0})$, for any $\boldsymbol{y} \in W$ there is a unique $\boldsymbol{x} \in B_\epsilon(\mathbf{0})$ with $\boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{y}$ (such a $\boldsymbol{y}$ is in $\bar{B}_{\eta/2}(\mathbf{0})$ for $2\|\boldsymbol{y}\| \leq \eta < \epsilon$). Set $V = B_\epsilon(\mathbf{0}) \cap \boldsymbol{f}^{-1}(W)$; then V is an open set in $\mathbb{R}^n$ containing $\mathbf{0}$ and $\boldsymbol{f}$ maps V bijectively to W.

This completes the proof of VIII.5.5.1.. 👍

VIII.5.5.5. Of course, this argument is not a full proof of the Inverse Function Theorem; the arguments of VIII.5.1.29. and VIII.5.4.4. are also needed to finish the proof.

VIII.5.6. How Do We Find The Implicit/Inverse Function?

VIII.5.6.1. In the approach we have taken, the Implicit/Inverse Function Theorems are pure existence theorems: the desired functions are shown to exist (uniquely and differentiably) on *some* neighborhood, but we have no control over the size of the neighborhood and seemingly no effective way of finding (computing) the function. A philosophy expressed in [HH99, p. 148] (with which I only partially agree) is:

> "In the days before computers, finding solutions [to nonlinear equations] was virtually impossible; even in the good cases, where mathematicians could prove that solutions existed, they were usually not concerned with whether their proof could be turned into a practical algorithm to find the solutions in question. The advent of computers has made such an abstract approach unreasonable. Knowing that a system of equations has solutions is no longer enough; we want a practical algorithm that will enable us to solve them."

(In fact, this philosophy largely underlies most of that book.) By "solving" the equations the authors mean solving them numerically to arbitrary accuracy in a specific region; it is impossible in principle to find exact closed-form solutions in most cases.

VIII.5.6.2. Actually, in the Implicit/Inverse Function Theorems, since we know a value for the solution at one point and an expression for the derivative, the solution can be computed nearby by an iterative numerical integration (convert to a system of differential equations, cf. XI.1.10.12.), although this is not very efficient numerically and can take one out of the region where a unique solution exists (). But it turns out that with slightly more restrictive hypotheses, both an explicit region in which the solution exists and an iterative procedure, based on Newton's Method, that converges efficiently to the solution are possible.

VIII.5.7. How Much Can the Theorems be Generalized?

VIII.5.7.1. One might hope that the hypotheses of the Inverse Function Theorem can be relaxed to only require differentiability at $\boldsymbol{a}$, or at least nondegeneracy of the derivative at $\boldsymbol{a}$. But this is not enough to force the function to be locally injective around $\boldsymbol{a}$, even in one dimension:

VIII.5.7.2. Example. Let

$$f(x) = \begin{cases} x + x^2 \sin \frac{1}{x^2} & \text{if} \quad x \neq 0 \\ 0 & \text{if} \quad x = 0 \end{cases}$$

for $x \in \mathbb{R}$. Then f is differentiable on $\mathbb{R}$ and $f'(0) = 1$, but f is not injective (strictly increasing) on any neighborhood of 0. In fact, f' takes all real number values (in particular, both positive and negative values) in any neighborhood of 0.

VIII.5.7.3. Suppose we *assume* $\boldsymbol{f}$ is injective in an open neighborhood V of $\boldsymbol{a}$, with $f(V)$ open, and that $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$ and $D\boldsymbol{f}(\boldsymbol{a})$ is invertible. Then there is an inverse function $\boldsymbol{g}$ defined on $\boldsymbol{f}(V)$. By VIII.5.1.29., $\boldsymbol{g}$ is differentiable at $\boldsymbol{f}(\boldsymbol{a})$.

VIII.5.7.4. However, one of the main points of the Inverse Function Theorem is that nondegeneracy of the derivative of $\boldsymbol{f}$ at $\boldsymbol{a}$ forces $\boldsymbol{f}$ to be injective in a neighborhood V of $\boldsymbol{a}$, with $\boldsymbol{f}(V)$ open. Continuity of the partial derivatives is seemingly used mainly to insure that the derivative is nondegenerate in an entire neighborhood of $\boldsymbol{a}$ (this can fail if the derivative is discontinuous; cf. VIII.5.7.2.). So what if this is just assumed? In the one-dimensional case, if the derivative of a function is nonzero in an open interval around a, then $\boldsymbol{f}$ must be strictly monotone in that interval by () and hence locally injective. Remarkably, this remains true in higher dimensions:

VIII.5.7.5. THEOREM. Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{a} \in U$, and $\boldsymbol{f} : U \to \mathbb{R}^n$. Suppose $\boldsymbol{f}$ is differentiable at every point of U and that $D\boldsymbol{f}(\boldsymbol{x})$ is invertible for all $\boldsymbol{x} \in U$. Then there is a neighborhood V of $\boldsymbol{a}$ such that $\boldsymbol{f}$ is one-to-one on V, $\boldsymbol{f}(V)$ is open in $\mathbb{R}^n$, and the inverse function $\boldsymbol{g} : \boldsymbol{f}(V) \to V$ is differentiable at every point of $\boldsymbol{f}(V)$ with

$$D\boldsymbol{g}(\boldsymbol{f}(\boldsymbol{x})) = D\boldsymbol{f}(\boldsymbol{x})^{-1}$$

for all $x \in V$.

VIII.5.7.6. Curiously, this theorem appears to have been first stated and proved by J. SAINT RAYMOND in 2002 [Ray02], although it is implicit in an earlier result of CHERNAVSKII in 1964 [Čer64]; see also [Hal74], [Cri92]), and http://terrytao.wordpress.com/2011/09/12/the-inverse-function-theorem-for-everywhere-differe It should be pointed out, however, that as a practical matter this result is of limited use beyond the case covered in the usual Inverse Function Theorem if $n > 1$, since in most cases the only reasonable way to verify that a function is differentiable is to show that the partial derivatives are continuous (cf. ()), although there are cases where the partial derivatives are continuous except at one point $\boldsymbol{a}$ and it can be shown by brute force that the function is differentiable at $\boldsymbol{a}$ (cf. ()), and this version but not the usual version can be applied in such a situation (provided, of course, that the nondegeneracy condition is satisfied).

There is a corresponding version of the Implicit Function Theorem, proved from VIII.5.7.5. the same way VIII.5.1.7. is deduced from VIII.5.1.34. (). The one-dimensional version of this result is VIII.5.3.10.. I am not aware of any analogous version of the Continuous or Mixed Implicit Function Theorems; cf. Exercises VIII.5.11.13. and VIII.5.11.14.(b). There is also a corresponding version of VIII.5.2.1..

VIII.5.7.7. THEOREM. Let U be an open set in $\mathbb{R}^{p+n}$ and $(\boldsymbol{a}, \boldsymbol{b}) \in U$. Let $\boldsymbol{F} : U \to \mathbb{R}^n$ with $\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b}) = \boldsymbol{0}$. Suppose $\boldsymbol{F}$ is differentiable at every point of U. If $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y})$ is invertible, i.e. $det(D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y})) \neq 0$, for all $(\boldsymbol{x}, \boldsymbol{y}) \in U$, then there is an open set V in $\mathbb{R}^{p+n}$ containing $(\boldsymbol{a}, \boldsymbol{b})$, an open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$, and

a unique function $\boldsymbol{f} : W \to \mathbb{R}^n$ such that $\boldsymbol{f}(\boldsymbol{a}) = \boldsymbol{b}$ and, for all $\boldsymbol{x} \in W$, $(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) \in V$ and $\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) = \boldsymbol{0}$. Additionally, $\boldsymbol{f}$ is differentiable at every point of W, and for any $\boldsymbol{x} \in W$, we have

$$D\boldsymbol{f}(\boldsymbol{x}) = -D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))^{-1} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) \ .$$

VIII.5.7.8. It should be noted that the results of this section are technically not "generalizations" of the usual Implicit and Inverse Function Theorems – they are distinct results (but obviously closely related) since both the hypotheses and conclusions are weaker. A true generalization of a theorem is a new result for which the original theorem is a special case, generally consisting of obtaining the same, or stronger, conclusions under weaker hypotheses (here "weaker" means hypotheses which hold in actually or potentially more situations); obtaining stronger conclusions under the same hypotheses could also be considered a type of generalization, although such a result is usually just called a stronger theorem and not a generalization (() is a "generalization" of VIII.5.1.7. (in the case $r \geq 2$) in this sense). Thus VIII.5.3.12. is a true generalization of both VIII.5.3.4. and VIII.5.3.9., and VIII.5.4.2. a generalization of VIII.5.1.6. and VIII.5.1.7. ($\mathcal{C}^1$ version). The only other true generalizations I know of the Implicit and Inverse Function Theorems are extensions to maps between more general spaces like Banach spaces (cf. XXI.1.2.3.), or results like VIII.5.2.1..

VIII.5.8. The Domain and Range Straightening Theorems

From the Implicit and Inverse Function Theorems we can get a simple general local picture of a differentiable function, especially one of constant rank: up to a smooth change of coordinates, such a function of constant rank k from $\mathbb{R}^n$ to $\mathbb{R}^m$ locally consists simply of projection onto a k-dimensional subspace of $\mathbb{R}^n$ followed by a linear embedding of this subspace into $\mathbb{R}^m$.

The first result, a variation of VIII.5.2.1., is called the *Domain-Straightening Theorem* or *Local Submersion Theorem* in some references. If $\boldsymbol{f}$ is a smooth function from $U \subseteq \mathbb{R}^n$ to $\mathbb{R}^m$ and $\boldsymbol{a} \in U$, then $\boldsymbol{a}$ is called a *regular point* of $\boldsymbol{f}$ if the rank of $D\boldsymbol{f}(\boldsymbol{a})$ is m. (If $\boldsymbol{f}$ has a regular point, then necessarily $n \geq m$.) The set of regular points of $\boldsymbol{f}$ is an open set.

VIII.5.8.1. Theorem. [Domain-Straightening or Local Submersion Theorem] Let $\boldsymbol{f}$ be a $\mathcal{C}^r$ function ($1 \leq r \leq \infty$) from an open subset of $\mathbb{R}^n$ to $\mathbb{R}^m$, $n \geq m$, and $\boldsymbol{a}$ a regular point of $\boldsymbol{f}$. Then there is an open neighborhood U of $\boldsymbol{a}$ and a $\mathcal{C}^r$ diffeomorphism $\boldsymbol{g}$ from a neighborhood U' of $(\boldsymbol{b}, \boldsymbol{0})$ in $\mathbb{R}^n \cong \mathbb{R}^m \times \mathbb{R}^{n-m}$ to U with $\boldsymbol{g}(\boldsymbol{b}, \boldsymbol{0}) = \boldsymbol{a}$ and $\boldsymbol{f} \circ \boldsymbol{g}(\boldsymbol{x}, \boldsymbol{y}) = \boldsymbol{x}$ for all $(\boldsymbol{x}, \boldsymbol{y}) \in U'$, i.e.

$$\boldsymbol{f} \circ \boldsymbol{g}(x_1, \ldots, x_n) = (x_1, \ldots, x_m)$$

for all $(x_1, \ldots, x_n) \in U'$.

The name "Domain-Straightening Theorem" is appropriate since the theorem says that local coordinates can be chosen around $\boldsymbol{a}$ so that $\boldsymbol{f}$ just picks out the first m coordinates of a point, and thus the preimage of any point in $\mathbb{R}^m$ in a neighborhood of $\boldsymbol{b}$ is a piece of a vertical $(n-m)$-dimensional hyperplane. The case $n = m$ is just the Inverse Function Theorem. See () for an explanation of the name "Local Submersion Theorem."

Proof: By precomposing $\boldsymbol{f}$ with a translation, there is no loss of generality in assuming $\boldsymbol{a} = \boldsymbol{0}$. By assumption, the column rank of $D\boldsymbol{f}(\boldsymbol{0})$ is m, so the columns of $D\boldsymbol{f}(\boldsymbol{0})$ can be permuted so that the first m

columns are linearly independent. Thus $\boldsymbol{f}$ can be precomposed with a linear transformation T (permutation of coordinates) so that, if we write $\mathbb{R}^n$ as $\mathbb{R}^m \times \mathbb{R}^{n-m}$ and points in $\mathbb{R}^n$ as $(\boldsymbol{x}, \boldsymbol{y})$, with $\boldsymbol{x} \in \mathbb{R}^m$ and $\boldsymbol{y} \in \mathbb{R}^{n-m}$, we have $D_{\boldsymbol{x}}(\boldsymbol{f} \circ T)(\boldsymbol{0}, \boldsymbol{0})$ invertible. Thus applying VIII.5.2.1. with the roles of $\boldsymbol{x}$ and $\boldsymbol{y}$ interchanged, there is an open neighborhood V of $(\boldsymbol{b}, \boldsymbol{0})$ in $\mathbb{R}^n$ and a $\mathcal{C}^r$ function $\boldsymbol{h} : V \to \mathbb{R}^m$ such that $\boldsymbol{h}(\boldsymbol{b}, \boldsymbol{0}) = (\boldsymbol{0}, \boldsymbol{0})$ and $(\boldsymbol{f} \circ T)(\boldsymbol{h}(\boldsymbol{x}, \boldsymbol{y}), \boldsymbol{y}) = \boldsymbol{x}$ for all $(\boldsymbol{x}, \boldsymbol{y}) \in V$. The function $\phi : V \to \mathbb{R}^n$ defined by $\phi(\boldsymbol{x}, \boldsymbol{y}) = (\boldsymbol{h}(\boldsymbol{x}, \boldsymbol{y}), \boldsymbol{y})$ has $D\phi(\boldsymbol{0}, \boldsymbol{0})$ invertible, so by the Inverse Function Theorem there is an open neighborhood U' of $(\boldsymbol{b}, \boldsymbol{0})$ for which $\phi(U') \subseteq V$ and $\phi|_{U'}$ is a $\mathcal{C}^r$ diffeomorphism from U' to $\phi(U')$. Set $U = T(\phi(U'))$ and $\boldsymbol{g} = T \circ \phi$. 👍

VIII.5.8.2. Corollary. [Smooth Local Open Mapping Theorem] Let $\boldsymbol{f}$ be a $\mathcal{C}^r$ function ($r \geq 1$) from an open set in $\mathbb{R}^n$ to $\mathbb{R}^m$ ($n \geq m$), $\boldsymbol{a}$ a regular point of $\boldsymbol{f}$, and $\boldsymbol{b} = \boldsymbol{f}(\boldsymbol{a})$. Then $\boldsymbol{a}$ has an open neighborhood U such that every open neighborhood of $\boldsymbol{a}$ contained in U maps onto an open neighborhood of $\boldsymbol{b}$, and $\boldsymbol{f}^{-1}(\boldsymbol{b}) \cap U$ is an $(n-m)$-dimensional $\mathcal{C}^r$ hypersurface in U. In particular, the range of $\boldsymbol{f}$ contains an open set around $\boldsymbol{f}(\boldsymbol{a})$.

Proof: Let U and $\boldsymbol{g}$ be as in VIII.5.8.1.. Then

$$\boldsymbol{f}^{-1}(\boldsymbol{b}) \cap U = \boldsymbol{g}((\boldsymbol{f} \circ \boldsymbol{g})^{-1}(\boldsymbol{b})) = \boldsymbol{g}\left(\{(b_1, \ldots, b_m, x_{m+1}, \ldots, x_n) : x_{m+1}, \ldots, x_n \in \mathbb{R}\} \cap U'\right)$$

where $\boldsymbol{b} = (b_1, \ldots, b_m)$. 👍

VIII.5.8.3. Conversely, it is a remarkable fact (**??**, a consequence of Sard's Theorem) that if the range of $\boldsymbol{f}$ contains a nonempty open set in $\mathbb{R}^m$, and $\boldsymbol{f}$ is sufficiently smooth, then $\boldsymbol{f}$ has "many" regular points.

By straightening only some of the coordinates in the domain, we obtain:

VIII.5.8.4. Theorem. Let $\boldsymbol{f}$ be a $\mathcal{C}^r$ function ($1 \leq r \leq \infty$) from an open subset Ω of $\mathbb{R}^n$ to $\mathbb{R}^m$, and $\boldsymbol{a}$ a point of the domain of $\boldsymbol{f}$. Suppose $D\boldsymbol{f}(\boldsymbol{a})$ has rank $\geq k$, $k < m$. Then there is an open neighborhood U of $\boldsymbol{a}$, a point $\boldsymbol{b} \in \mathbb{R}^k$, and a $\mathcal{C}^r$ diffeomorphism $\boldsymbol{g}$ from a neighborhood U' of $(\boldsymbol{b}, \boldsymbol{0})$ in $\mathbb{R}^n \cong \mathbb{R}^k \times \mathbb{R}^{n-k}$ to U with $\boldsymbol{g}(\boldsymbol{b}, \boldsymbol{0}) = \boldsymbol{a}$, an invertible linear transformation $T : \mathbb{R}^m \to \mathbb{R}^m$ (permutation of coordinates) with $T \circ \boldsymbol{f}(\boldsymbol{a}) = (\boldsymbol{b}, \boldsymbol{c})$ for some $\boldsymbol{c} \in \mathbb{R}^{m-k}$, and a $\mathcal{C}^r$ function $\boldsymbol{f}_0 : \mathbb{R}^n \to \mathbb{R}^{m-k}$ defined on a neighborhood of $(\boldsymbol{b}, \boldsymbol{0})$ such that

$$T \circ \boldsymbol{f} \circ \boldsymbol{g}(\boldsymbol{x}, \boldsymbol{y}) = (\boldsymbol{x}, \boldsymbol{f}_0(\boldsymbol{x}, \boldsymbol{y}))$$

for all $(\boldsymbol{x}, \boldsymbol{y}) \in U' \subseteq \mathbb{R}^k \times \mathbb{R}^{n-k}$, i.e.

$$T \circ \boldsymbol{f} \circ \boldsymbol{g}(x_1, \ldots, x_k, x_{k+1}, \ldots, x_n) = (x_1, \ldots, x_k, \boldsymbol{f}_0(x_1, \ldots, x_n))$$

for all $(x_1, \ldots, x_n) \in U'$. We have $\boldsymbol{f}_0(\boldsymbol{b}, \boldsymbol{0}) = \boldsymbol{c}$.

Proof: The matrix $D\boldsymbol{f}(\boldsymbol{a})$ has rank at least k, so by permuting rows we may make the first k rows linearly independent. Let T be such a coordinate permutation, and let ϕ be the function from Ω to $\mathbb{R}^k$ whose coordinate functions are the first k coordinate functions of $T \circ \boldsymbol{f}$. Set $\boldsymbol{b} = \phi(\boldsymbol{a})$. Then ϕ is $\mathcal{C}^r$ and satisfies the hypotheses of VIII.5.8.1., so there is a $\mathcal{C}^r$ diffeomorphism $\boldsymbol{g}$ from a neighborhood U' of $(\boldsymbol{b}, \boldsymbol{0})$ in $\mathbb{R}^n \cong \mathbb{R}^k \times \mathbb{R}^{n-k}$ to a neighborhood U of $\boldsymbol{a}$ with $\phi \circ \boldsymbol{g}(\boldsymbol{x}, \boldsymbol{y}) = \boldsymbol{x}$ for all $(\boldsymbol{x}, \boldsymbol{y}) \in U'$. Then $T \circ \boldsymbol{f} \circ \boldsymbol{g}(\boldsymbol{x}, \boldsymbol{y})$ is of the form

$$(\phi \circ \boldsymbol{g}(\boldsymbol{x}, \boldsymbol{y}), \boldsymbol{f}_0(\boldsymbol{x}, \boldsymbol{y})) = (\boldsymbol{x}, \boldsymbol{f}_0(\boldsymbol{x}, \boldsymbol{y}))$$

for $(\boldsymbol{x}, \boldsymbol{y}) \in U'$, for some $\mathcal{C}^r$ function $\boldsymbol{f}_0 : U' \to \mathbb{R}^{m-k}$. 👍

VIII.5.8.5. Suppose $\boldsymbol{f}$ is as in the statement of the theorem. If the rank of $D\boldsymbol{f}(\boldsymbol{z})$ is exactly k for all $\boldsymbol{z}$ in a neighborhood of $\boldsymbol{a}$, we can say more. Set $\boldsymbol{h} = T \circ \boldsymbol{f} \circ \boldsymbol{g}$. Then $\boldsymbol{h}$ has rank exactly k in a neighborhood of $(\boldsymbol{b}, \boldsymbol{0})$. The derivative of $\boldsymbol{h}$ at $(\boldsymbol{x}, \boldsymbol{y})$ is of the form

$$\begin{bmatrix} I_k & 0 \\ B & A \end{bmatrix}$$

where $D\boldsymbol{f}_0(\boldsymbol{x}, \boldsymbol{y}) = [\, B \; A \,]$, B is $(m-k) \times k$, and A is $(m-k) \times (n-k)$. For such a matrix to have rank k, A must be 0: the first k columns are linearly independent, and if A has a nonzero entry the column it appears in will be linearly independent from the first k columns, a contradiction. Thus the partial derivatives of $\boldsymbol{f}_0$ in the $\boldsymbol{y}$ variables are identically zero near $(\boldsymbol{b}, \boldsymbol{0})$, i.e. $\boldsymbol{f}_0(\boldsymbol{x}, \boldsymbol{y})$ depends only on the $\boldsymbol{x}$ variables in a neighborhood of $(\boldsymbol{b}, \boldsymbol{0})$. Thus we obtain:

VIII.5.8.6. Theorem. [Rank Theorem] Let $\boldsymbol{f}$ be a $\mathcal{C}^r$ function $(1 \leq r \leq \infty)$ from an open subset of $\mathbb{R}^n$ to $\mathbb{R}^m$, and $\boldsymbol{a}$ a point of the domain of $\boldsymbol{f}$. Suppose $D\boldsymbol{f}$ has constant rank k in a neighborhood of $\boldsymbol{a}$. Then there is an open neighborhood U of $\boldsymbol{a}$, a point $\boldsymbol{b} \in \mathbb{R}^k$, a $\mathcal{C}^r$diffeomorphism $\boldsymbol{g}$ from an open neighborhood U' of $(\boldsymbol{b}, \boldsymbol{0})$ in $\mathbb{R}^n \cong \mathbb{R}^k \times \mathbb{R}^{n-k}$ to U, an open neighborhood W of $\boldsymbol{b}$ in $\mathbb{R}^k$ such that $\boldsymbol{x} \in W$ whenever $(\boldsymbol{x}, \boldsymbol{y}) \in U'$, and a $\mathcal{C}^r$ function $\tilde{\boldsymbol{f}} : W \to \mathbb{R}^m$ such that

$$\boldsymbol{f} \circ \boldsymbol{g}(\boldsymbol{x}, \boldsymbol{y}) = \tilde{\boldsymbol{f}}(\boldsymbol{x})$$

for all $(\boldsymbol{x}, \boldsymbol{y}) \in U'$.

In fact, since $\boldsymbol{f}_0(\boldsymbol{x}, \boldsymbol{y}) = \boldsymbol{f}_0(\boldsymbol{x}, \boldsymbol{0})$ for any $\boldsymbol{y}$, we can take $\tilde{\boldsymbol{f}}(\boldsymbol{x}) = T^{-1}(\boldsymbol{x}, \boldsymbol{f}_0(\boldsymbol{x}, \boldsymbol{0}))$.

In the case $k = n < m$ in VIII.5.8.4., the T is unnecessary and can be eliminated, and the Rank Theorem applies (the case $k = n = m$ is just the Inverse Function Theorem). In this case a better result holds, called the *Range-Straightening Theorem* or *Local Immersion Theorem*:

VIII.5.8.7. Theorem. [Range-Straightening or Local Immersion Theorem] Let $\boldsymbol{f}$ be a $\mathcal{C}^r$ function $(1 \leq r \leq \infty)$ from an open subset Ω of $\mathbb{R}^n$ to $\mathbb{R}^m$, and $\boldsymbol{a}$ a point of the domain of $\boldsymbol{f}$. Suppose $D\boldsymbol{f}(\boldsymbol{a})$ has rank n (then necessarily $n \leq m$). Set $\boldsymbol{b} = \boldsymbol{f}(\boldsymbol{a})$. Then there are open neighborhoods U of $\boldsymbol{a}$ in $\mathbb{R}^n$ and V of $\boldsymbol{b}$ in $\mathbb{R}^m$, and a $\mathcal{C}^r$ diffeomorphism $\boldsymbol{h}$ from V to a neighborhood V' of $(\boldsymbol{a}, \boldsymbol{0})$ in $\mathbb{R}^m$ with $\boldsymbol{h}(\boldsymbol{b}) = (\boldsymbol{a}, \boldsymbol{0})$, such that

$$\boldsymbol{h} \circ \boldsymbol{f}(\boldsymbol{x}) = (\boldsymbol{x}, \boldsymbol{0})$$

for all $\boldsymbol{x} \in U$, i.e.

$$\boldsymbol{h} \circ \boldsymbol{f}(x_1, \ldots, x_n) = (x_1, \ldots, x_n, 0, \ldots, 0)$$

for all $(x_1, \ldots, x_n) \in U$.

The name "Range-Straightening Theorem" means that a smooth function from $\mathbb{R}^n$ to $\mathbb{R}^m$ $(n < m)$ which has rank n at a point $\boldsymbol{a}$ has local range which up to a smooth change of coordinates is a piece of a horizontal n-dimensional hyperplane in $\mathbb{R}^m$. See VIII.5.8.10. for a precise and more general result. See () for an explanation of the name "Local Immersion Theorem."

Proof: Since $D\boldsymbol{f}(\boldsymbol{a})$ has row rank n, there is an invertible linear transformation $T : \mathbb{R}^m \to \mathbb{R}^m$ (permutation of coordinates) so that the first n rows of $D(T \circ \boldsymbol{f})(\boldsymbol{a})$ are linearly independent. Define $\boldsymbol{F} : \Omega \times \mathbb{R}^{m-n} \subseteq \mathbb{R}^m \to$

$\mathbb{R}^m$ by $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{z}) = T(\boldsymbol{f}(\boldsymbol{x}))+(\boldsymbol{0},\boldsymbol{z})$ (where $\boldsymbol{x} \in \mathbb{R}^n$, $\boldsymbol{z} \in \mathbb{R}^{m-n}$, and the last expression uses $\mathbb{R}^m \cong \mathbb{R}^n \times \mathbb{R}^{m-n}$). Then $D\boldsymbol{F}(\boldsymbol{a},\boldsymbol{0})$ is of the form

$$\begin{bmatrix} A & 0 \\ B & I_{m-n} \end{bmatrix}$$

where the first column is $D(T \circ \boldsymbol{f})(\boldsymbol{a})$; since A is invertible, $D\boldsymbol{F}(\boldsymbol{a},\boldsymbol{0})$ is invertible. Thus by the Inverse Function Theorem there is an inverse function $\boldsymbol{G}$ defined on a neighborhood V'' of $\boldsymbol{F}(\boldsymbol{a},\boldsymbol{0}) = T(\boldsymbol{f}(\boldsymbol{a}))$ to a neighborhood V' of $(\boldsymbol{a},\boldsymbol{0})$. Set $V = T^{-1}(V'')$ and $\boldsymbol{h} = \boldsymbol{G} \circ T$. If $U = \{\boldsymbol{x} \in \Omega : (\boldsymbol{x},\boldsymbol{0}) \in V'\}$, then

$$\boldsymbol{h} \circ \boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{G} \circ T \circ \boldsymbol{f}(\boldsymbol{x}) = \boldsymbol{G}(T(\boldsymbol{f}(\boldsymbol{x})) + (\boldsymbol{0},\boldsymbol{0})) = \boldsymbol{G}(\boldsymbol{F}(\boldsymbol{x},\boldsymbol{0})) = (\boldsymbol{x},\boldsymbol{0})$$

for all $\boldsymbol{x} \in U$. 👍

Putting together the Range-Straightening Theorem with the Rank Theorem (which depends on the Domain-Straightening Theorem), we obtain the ultimate result (this result is called the Rank Theorem or the Constant Rank Theorem in some references):

VIII.5.8.8. THEOREM. [STRAIGHTENING THEOREM] Let $\boldsymbol{f}$ be a $\mathcal{C}^r$ function ($1 \leq r \leq \infty$) from an open subset of $\mathbb{R}^n$ to $\mathbb{R}^m$, and $\boldsymbol{a}$ a point of the domain of $\boldsymbol{f}$. Suppose $D\boldsymbol{f}$ has constant rank k in a neighborhood of $\boldsymbol{a}$. Then there is an open neighborhood U of $\boldsymbol{a}$ and an open neighborhood V of $\boldsymbol{b} = \boldsymbol{f}(\boldsymbol{a})$ with $\boldsymbol{f}(U) \subseteq V$, and $\mathcal{C}^r$ diffeomorphisms $\boldsymbol{g}$ from a neighborhood U' of $(\boldsymbol{0},\boldsymbol{0})$ in $\mathbb{R}^n \cong \mathbb{R}^k \times \mathbb{R}^{n-k}$ to U and $\boldsymbol{h}$ from V to a neighborhood V' of $(\boldsymbol{0},\boldsymbol{0})$ in $\mathbb{R}^m \cong \mathbb{R}^k \times \mathbb{R}^{m-k}$ with $\boldsymbol{g}(\boldsymbol{0},\boldsymbol{0}) = \boldsymbol{a}$, $\boldsymbol{h}(\boldsymbol{b}) = (\boldsymbol{0},\boldsymbol{0})$, and

$$\boldsymbol{h} \circ \boldsymbol{f} \circ \boldsymbol{g}(x_1,\ldots,x_k,x_{k+1},\ldots,x_n) = (x_1,\ldots,x_k,0,\ldots,0) \ .$$

PROOF: By pre- and post-composing $\boldsymbol{f}$ with translations, there is no loss of generality in assuming that $\boldsymbol{a} = \boldsymbol{0}$ and that $\boldsymbol{b} = \boldsymbol{f}(\boldsymbol{0}) = \boldsymbol{0}$. By the Rank Theorem, there is a $\mathcal{C}^r$ diffeomorphism $\boldsymbol{g}$, defined on an open neighborhood U'' of $\boldsymbol{0}$ in $\mathbb{R}^n$, an open neighborhood W of $\boldsymbol{0}$ in $\mathbb{R}^k$, and a $\mathcal{C}^r$ function $\tilde{\boldsymbol{f}} : W \to \mathbb{R}^m$, such that $\boldsymbol{f} \circ \boldsymbol{g}(\boldsymbol{x},\boldsymbol{y}) = \tilde{\boldsymbol{f}}(\boldsymbol{x})$ for all $(\boldsymbol{x},\boldsymbol{y}) \in U''$. Then $\tilde{\boldsymbol{f}}$ satisfies the hypotheses of the Range-Straightening Theorem, so there is a neighborhood W' of $\boldsymbol{0}$ in $\mathbb{R}^k$, contained in W, an open neighborhood V of $\boldsymbol{0}$ in $\mathbb{R}^m$, and a $\mathcal{C}^r$ diffeomorphism $\boldsymbol{h}$ from V to an open neighborhood V' of $\boldsymbol{0}$ such that

$$\boldsymbol{h} \circ \tilde{\boldsymbol{f}}(\boldsymbol{x}) = (\boldsymbol{x},\boldsymbol{0})$$

for all $\boldsymbol{x} \in W'$. Set

$$U' = \{(\boldsymbol{x},\boldsymbol{y}) \in U'' : \boldsymbol{x} \in W'\} \ .$$

Then U' is an open neighborhood of $\boldsymbol{0}$ in $\mathbb{R}^n$, and

$$\boldsymbol{h} \circ \boldsymbol{f} \circ \boldsymbol{g}(\boldsymbol{x},\boldsymbol{y}) = (\boldsymbol{x},\boldsymbol{0})$$

for all $(\boldsymbol{x},\boldsymbol{y}) \in U'$. Set $U = \boldsymbol{g}(U')$. 👍

VIII.5.8.9. Note that this theorem automatically applies if the rank of $D\boldsymbol{f}(\boldsymbol{a})$ is m (i.e. $\boldsymbol{a}$ is a regular point of $\boldsymbol{f}$), since it is rank $\leq m$ everywhere and at least m in some neighborhood of $\boldsymbol{a}$ (). In this case the $\boldsymbol{h}$ can be simply be taken to be a translation. Thus the Straightening Theorem is a generalization of the Domain-Straightening Theorem VIII.5.8.1.. A similar observation holds if $D\boldsymbol{f}(\boldsymbol{a})$ has rank n, so the Range-Straightening Theorem VIII.5.8.7. is also a special case of the Straightening Theorem. (And the Inverse Function Theorem is the case $k = n = m$.)

VIII.5.8.10. Corollary. Let $\boldsymbol{f}$ be a $\mathcal{C}^r$ function $(1 \leq r \leq \infty)$ from an open subset of $\mathbb{R}^n$ to $\mathbb{R}^m$, and $\boldsymbol{a}$ a point of the domain of $\boldsymbol{f}$. Suppose $D\boldsymbol{f}$ has constant rank k in a neighborhood of $\boldsymbol{a}$. Then there is an open neighborhood U of $\boldsymbol{a}$ such that $\boldsymbol{f}(U)$ is a k-dimensional $\mathcal{C}^r$ hypersurface in $\mathbb{R}^m$ passing through $\boldsymbol{b} = \boldsymbol{f}(\boldsymbol{a})$.

Although the Straightening Theorem only applies at points where the function is locally of constant rank (i.e. has constant rank in a neighborhood of the point), this set of points is "generic":

VIII.5.8.11. Proposition. Let $\boldsymbol{f}$ be a $\mathcal{C}^r$ function $(1 \leq r \leq \infty)$ from an open subset U of $\mathbb{R}^n$ to $\mathbb{R}^m$. Then the set of points where $\boldsymbol{f}$ is locally of constant rank is a dense open subset of U.

Proof: For $0 \leq k \leq n$ let V_k be the set of points of U where $\boldsymbol{f}$ has rank $\geq k$. Then each V_k is open, and the set W of points where $\boldsymbol{f}$ is locally of constant rank is

$$W = \bigcup_{k=0}^{n} \left(V_k \setminus \bar{V}_{k+1}\right) \ .$$

Thus W is open, and $U \setminus W$ is

$$U \setminus W = U \cap \left[\bigcup_{k=0}^{n} \left(\bar{V}_k \setminus V_k\right)\right] \ .$$

Each $\bar{V}_k \setminus V_k = \partial V_k$ is closed and nowhere dense, hence its complement is dense and open; and a finite intersection of dense open sets is dense and open (XIII.2.3.10.). 👍

VIII.5.8.12. Remarks. (i) The only result in this section which applies to an $\boldsymbol{f}$ which is not necessarily of locally constant rank around $\boldsymbol{a}$ is VIII.5.8.4.. But the Straightening Theorem applies at "almost every" point by VIII.5.8.11..

(ii) The Domain-Straightening Theorem and Range-Straightening Theorem are stated in such a way that only composition of $\boldsymbol{f}$ on one side with a diffeomorphism is necessary. For the ultimate Straightening Theorem, composition on both sides is necessary in general.

(iii) Much of the notational complication of the results and proofs in this section comes from the need to carefully specify and name exact neighborhoods on which functions are defined and formulas are valid. It is probably a good idea for a reader to at first ignore these precise neighborhoods, replacing each instance simply by "on some neighborhood of $\boldsymbol{a}$ (etc.)" or just "near $\boldsymbol{a}$" (as is done in the text in a few places where precise specification of the neighborhood is unnecessary) to follow the essence of the argument without distraction; at the end of the day, the exact neighborhoods are unimportant, since the real conclusion is merely that there are *some* neighborhoods on which the results hold.

VIII.5.9. The Degenerate Case

We now put together the previous results to describe a common way the Implicit Function Theorem can be thought of and used. We will change notation a little at the beginning, and get back closer to the previous notation as we go. We will be a little informal during the discussion, but end up with a carefully stated theorem.

VIII.5.9.1. Suppose we have a general problem of solving a system of functional equations

$$\begin{aligned} F_1(u_1,\dots,u_q) &= v_1 \\ F_2(u_1,\dots,u_q) &= v_2 \\ &\vdots \\ F_m(u_1,\dots,u_q) &= v_m \end{aligned}$$

for some of the u's as functions of the v's and the other u's. The system can be abbreviated

$$\boldsymbol{F}(\boldsymbol{u}) = \boldsymbol{v}$$

where $\boldsymbol{u} = (u_1,\dots,u_q) \in \mathbb{R}^q$, $\boldsymbol{v} = (v_1,\dots,v_m) \in \mathbb{R}^m$, $\boldsymbol{F} = (F_1,\dots,F_m) : \mathbb{R}^q \to \mathbb{R}^m$. We suppose $\boldsymbol{F}$ is defined and $\mathcal{C}^r$ $(r \geq 1)$ on an open set $U \subseteq \mathbb{R}^q$, and $\boldsymbol{u}_0 \in U$ with $\boldsymbol{F}(\boldsymbol{u}_0) = \boldsymbol{v}_0$. We want a solution of $\boldsymbol{F}(\boldsymbol{u}) = \boldsymbol{v}$ near $(\boldsymbol{u}_0, \boldsymbol{v}_0)$.

VIII.5.9.2. We will assume that $D\boldsymbol{F}(\boldsymbol{u})$ has rank n at all points in a neighborhood of $\boldsymbol{u}_0$ (this entails $n \leq \min(q,m)$). By reducing the size of U, we may and will assume that the rank is n for all $\boldsymbol{u} \in U$. We may have $n = q$ and/or $n = m$; in these cases, the following discussion will have to be slightly modified (simplified) notationally. The case $n = m$ is exactly the nondegenerate case treated in VIII.5.2.1.. We will try to solve for n of the u's in terms of the v's and the rest of the u's (linear algebra results show that we cannot hope to solve for more than n of the u's even if $\boldsymbol{F}$ is linear).

VIII.5.9.3. We may then reorder the v's and rename them $(z_1,\dots,z_n,w_1,\dots,w_k)$ $(k = m-n)$, writing $\boldsymbol{z} = (z_1,\dots,z_n) \in \mathbb{R}^n$, $\boldsymbol{w} = (w_1,\dots,w_k) \in \mathbb{R}^k$, $\Phi(\boldsymbol{u}) = (F_1(\boldsymbol{u}),\dots,F_n(\boldsymbol{u})) : U \to \mathbb{R}^n$, $\Psi(\boldsymbol{u}) = (F_{n+1}(\boldsymbol{u}),\dots,F_m(\boldsymbol{u})) : U \to \mathbb{R}^k$, so $\boldsymbol{v} = (\boldsymbol{z},\boldsymbol{w})$, $\boldsymbol{F} = (\Phi,\Psi)$, in such a way that $D\Phi(\boldsymbol{u}_0)$ has rank n. This is simply a matter of choosing n linearly independent rows in $D\boldsymbol{F}(\boldsymbol{u}_0)$, which can be done in several ways in general but there is always at least one way. We then have that $D\Phi(\boldsymbol{u})$ has rank n in a neighborhood of $\boldsymbol{u}_0$, and by further reducing the size of U we may and will assume it has rank n at all points of U. Write $\boldsymbol{v}_0 = (\boldsymbol{c},\boldsymbol{d})$.

VIII.5.9.4. The system $\Phi(\boldsymbol{u}) = \boldsymbol{z}$ then essentially falls under the case of VIII.5.2.1., but one more notational choice is needed. We reorder and rename the u's as $(x_1,\dots,x_p,y_1,\dots,y_n)$ $(p = q-n)$ and write $\boldsymbol{x} = (x_1,\dots,x_p) \in \mathbb{R}^p$, $\boldsymbol{y} = (y_1,\dots,y_n) \in \mathbb{R}^n$, $\boldsymbol{u} = (\boldsymbol{x},\boldsymbol{y})$, in such a way that $D_{\boldsymbol{y}}\Phi(\boldsymbol{u}_0)$ has rank n, i.e. is invertible. (This amounts to choosing n linearly independent columns in $D\Phi(\boldsymbol{u}_0)$, which can always be done, in many ways in general.) Write $\boldsymbol{u}_0 = (\boldsymbol{a},\boldsymbol{b})$. We have that $D_{\boldsymbol{y}}\Phi(\boldsymbol{u})$ is invertible for all $\boldsymbol{u}$ in a neighborhood of $\boldsymbol{u}_0$; we may again reduce U so this is true for all $\boldsymbol{u} \in U$. Our system

$$\Phi(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{z}$$

then exactly satisfies the hypotheses of VIII.5.2.1..

VIII.5.9.5. There is thus a unique function $\boldsymbol{G}$, defined in a neighborhood of $(\boldsymbol{a}, \boldsymbol{c})$ with range in a suitable neighborhood of $\boldsymbol{b}$, such that $\boldsymbol{G}(\boldsymbol{a}, \boldsymbol{c}) = \boldsymbol{b}$ and $\Phi(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})) = \boldsymbol{z}$ for all $(\boldsymbol{x}, \boldsymbol{z})$ near $(\boldsymbol{a}, \boldsymbol{c})$. We have thus written $y_1, \ldots, y_n$ as functions of $\boldsymbol{x}$ and $\boldsymbol{z}$, i.e. as functions of $\boldsymbol{x}$ and $\boldsymbol{v}$, as desired.

VIII.5.9.6. We have so far not used the last k equations. So how do they come into the picture? For one thing, we could in general have chosen to use some of the w's in place of some of the z's, and if we did that we would have the y's (or, in general, possibly a different set of y's) written in a different way as functions of the x's and v's – in the degenerate case there is no uniqueness possible in general for how to "solve" the equations, even for a single choice of y's.

VIII.5.9.7. If we stick to the same choice of z's, w's, $x's$, and y's, though, the additional equations serve as a system of *constraints*: The equation $\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) = (\boldsymbol{z}, \boldsymbol{w})$ does not have a solution for all $(\boldsymbol{z}, \boldsymbol{w})$ near $(\boldsymbol{c}, \boldsymbol{d})$, only for $(\boldsymbol{z}, \boldsymbol{w})$ satisfying a relation. By the Straightening Theorem (), the range of $\boldsymbol{F}$ on a suitably small neighborhood of $(\boldsymbol{a}, \boldsymbol{b})$ (which we may take to be U by further reduction) is an n-dimensional $\mathcal{C}^r$-submanifold Γ of $\mathbb{R}^m$. For every $\boldsymbol{z}$ near $\boldsymbol{c}$ there is a unique point of Γ whose first n coordinates are $\boldsymbol{z}$; thus the last k coordinates $\boldsymbol{w}$ can be considered a function of $\boldsymbol{z}$, i.e. Γ is the graph of a function $\boldsymbol{H}$ from an open set in $\mathbb{R}^n$ containing $\boldsymbol{c}$ to $\mathbb{R}^k$, with $\boldsymbol{H}(\boldsymbol{c}) = \boldsymbol{d}$. Since Γ is a $\mathcal{C}^r$-manifold, it follows that $\boldsymbol{H}$ is also $\mathcal{C}^r$. We thus have the following theorem, leaving out the steps of choosing the x's, y's, z's, w's, in which nothing needs proof except some basic linear algebra facts, and the reductions in the size of U, which need ().

VIII.5.9.8. Theorem. [Implicit/Inverse Function Theorem, Degenerate Case] Let $n, r \in \mathbb{N}$, $p, k \in \mathbb{N} \cup \{0\}$, U an open set in $\mathbb{R}^{p+n}$, $\boldsymbol{F} = (\Phi, \Psi) : U \to \mathbb{R}^{n+k}$ with $\Phi : U \to \mathbb{R}^n$ and $\Psi : U \to \mathbb{R}^k$ $\mathcal{C}^r$ functions, $\boldsymbol{a} \in \mathbb{R}^p$, $\boldsymbol{b}, \boldsymbol{c} \in \mathbb{R}^n$, $\boldsymbol{d} \in \mathbb{R}^k$, $(\boldsymbol{a}, \boldsymbol{b}) \in U$, $\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b}) = (\boldsymbol{c}, \boldsymbol{d})$. Suppose $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y})$ and $D_{\boldsymbol{y}}\Phi(\boldsymbol{x}, \boldsymbol{y})$ have rank n for all $(\boldsymbol{x}, \boldsymbol{y}) \in U$. Then there are open neighborhoods $\mathcal{X}$ of $\boldsymbol{a}$, $\mathcal{Y}$ of $\boldsymbol{b}$, $\mathcal{Z}$ of $\boldsymbol{c}$, and $\mathcal{W}$ of $\boldsymbol{d}$, with $\mathcal{X} \times \mathcal{Y} \subseteq U$, and unique functions $\boldsymbol{G} : \mathcal{X} \times \mathcal{Z} \to \mathcal{Y}$ with $\boldsymbol{G}(\boldsymbol{a}, \boldsymbol{c}) = \boldsymbol{b}$, and $\boldsymbol{H} : \mathcal{Z} \to \mathcal{W}$ with $\boldsymbol{H}(\boldsymbol{c}) = \boldsymbol{d}$, such that the equation

$$\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) = (\boldsymbol{z}, \boldsymbol{w})$$

or, equivalently, the system of equations

$$\Phi(\boldsymbol{x}, \boldsymbol{y}) = \boldsymbol{z}$$
$$\Psi(\boldsymbol{x}, \boldsymbol{y}) = \boldsymbol{w}$$

is equivalent to the system

$$\boldsymbol{y} = \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})$$
$$\boldsymbol{w} = \boldsymbol{H}(\boldsymbol{z})$$

on $\mathcal{X} \times \mathcal{Y} \times \mathcal{Z} \times \mathcal{W}$, in the sense that if $(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{z}, \boldsymbol{w}) \in \mathcal{X} \times \mathcal{Y} \times \mathcal{Z} \times \mathcal{W}$, then $(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{z}, \boldsymbol{w})$ satisfies one system if and only if it satisfies the other. Additionally, $\boldsymbol{G}$ and $\boldsymbol{H}$ are $\mathcal{C}^r$ on their domains.
If $p = 0$ the $\boldsymbol{x}$ and $\boldsymbol{a}$ are omitted from the statement, and if $k = 0$ the $\boldsymbol{w}$, $\boldsymbol{d}$, and $\boldsymbol{H}$ are eliminated, with the statement notation adjusted accordingly.

VIII.5.9.9. The case $k = 0$ is exactly VIII.5.2.1., and the case $p = k = 0$ is exactly the Inverse Function Theorem.

VIII.5.9.10. In the situation of VIII.5.9.1., if the rank of $D\boldsymbol{F}$ is not locally constant around $\boldsymbol{u}_0$, there is no solution to the system in general, at least in the sense we have discussed.

VIII.5.10. Analytic Versions

There are analytic versions of most of the results of this section:

VIII.5.10.1. Theorem. [Implicit Function Theorem, Real Analytic Version] Let U be an open set in $\mathbb{R}^{p+n}$ and $(\boldsymbol{a},\boldsymbol{b}) \in U$. Let $\boldsymbol{F} : U \to \mathbb{R}^n$ with $\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b}) = \boldsymbol{0}$. Suppose $\boldsymbol{F}$ is analytic on U. If $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$ is invertible, i.e. $det(D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})) \neq 0$, then there are:

(i) An open set V in $\mathbb{R}^{p+n}$ containing $(\boldsymbol{a},\boldsymbol{b})$, with $V \subseteq U$, such that $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})$ is invertible for all $(\boldsymbol{x},\boldsymbol{y}) \in V$;

(ii) An open set W in $\mathbb{R}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $\boldsymbol{f} : W \to \mathbb{R}^n$ such that $\boldsymbol{f}(\boldsymbol{a}) = \boldsymbol{b}$ and, for all $\boldsymbol{x} \in W$, $(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) \in V$ and

$$\boldsymbol{F}(\boldsymbol{x}, f(\boldsymbol{x})) = \boldsymbol{0} \ .$$

Additionally, $\boldsymbol{f}$ is analytic on W, and for any $\boldsymbol{x} \in W$, we have

$$D\boldsymbol{f}(\boldsymbol{x}) = -D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))^{-1} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, f(\boldsymbol{x}))$$

(in particular, $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))$ is invertible for all $\boldsymbol{x} \in W$).

VIII.5.10.2. Theorem. [Real Analytic Inverse Function Theorem] Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{a} \in U$, and $\boldsymbol{f} : U \to \mathbb{R}^n$ an analytic function. If $D\boldsymbol{f}(\boldsymbol{a})$ is invertible, then there is a neighborhood V of $\boldsymbol{a}$, $V \subseteq U$, such that

(i) $\boldsymbol{f}$ is one-to-one on V.

(ii) $\boldsymbol{f}(V)$ is open in $\mathbb{R}^n$.

(iii) $D\boldsymbol{f}(\boldsymbol{x})$ is invertible for all $\boldsymbol{x} \in V$.

(iv) $\boldsymbol{f}^{-1}$ is analytic on $\boldsymbol{f}(V)$ and, for all $\boldsymbol{y} \in \boldsymbol{f}(V)$,

$$D(\boldsymbol{f}^{-1})(\boldsymbol{y}) = [D\boldsymbol{f}(\boldsymbol{f}^{-1}(\boldsymbol{y}))]^{-1} \ .$$

VIII.5.10.3. Theorem. [General Real Analytic Implicit/Inverse Function Theorem] Let $n \in \mathbb{N}$, $p \in \mathbb{N} \cup \{0\}$, $\boldsymbol{a} \in \mathbb{R}^p$, $\boldsymbol{b}, \boldsymbol{c} \in \mathbb{R}^n$, U an open neighborhood of $(\boldsymbol{a},\boldsymbol{b})$ in $\mathbb{R}^{p+n}$, $\boldsymbol{F} : U \to \mathbb{R}^n$ an analytic function with $\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b}) = \boldsymbol{c}$ and $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$ invertible. Then there are:

(i) An open neighborhood V of $(\boldsymbol{a},\boldsymbol{b})$ in $\mathbb{R}^{p+n}$, contained in U, such that $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})$ is invertible for all $(\boldsymbol{x},\boldsymbol{y}) \in V$;

(ii) An open neighborhood W of $(\boldsymbol{a},\boldsymbol{c})$ in $\mathbb{R}^{p+n}$;

(iii) A unique function $\boldsymbol{G} : W \to \mathbb{R}^n$ satisfying $\boldsymbol{G}(\boldsymbol{a}, \boldsymbol{c}) = \boldsymbol{b}$ and, for all $(\boldsymbol{x}, \boldsymbol{z}) \in W$, $(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})) \in V$ and

$$\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})) = \boldsymbol{z} \ .$$

Additionally, $\boldsymbol{G}$ is analytic on W, and for all $(\boldsymbol{x}, \boldsymbol{z}) \in V$,

$$D\boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z}) = \begin{bmatrix} & \vdots & \\ -D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z}))^{-1} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})) & \vdots & D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z}))^{-1} \\ & \vdots & \end{bmatrix} \ .$$

VIII.5.10.4. Theorem. [Implicit Function Theorem, Complex Analytic Version] Let U be an open set in $\mathbb{C}^{p+n}$ and $(\boldsymbol{a}, \boldsymbol{b}) \in U$. Let $\boldsymbol{F} : U \to \mathbb{C}^n$ with $\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b}) = \boldsymbol{0}$. Suppose $\boldsymbol{F}$ is analytic on U. If $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b})$ is invertible, i.e. $det(D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b})) \neq 0$, then there are:

(i) An open set V in $\mathbb{C}^{p+n}$ containing $(\boldsymbol{a}, \boldsymbol{b})$, with $V \subseteq U$, such that $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y})$ is invertible for all $(\boldsymbol{x}, \boldsymbol{y}) \in V$;

(ii) An open set W in $\mathbb{C}^p$ containing $\boldsymbol{a}$;

(iii) A unique function $\boldsymbol{f} : W \to \mathbb{C}^n$ such that $\boldsymbol{f}(\boldsymbol{a}) = \boldsymbol{b}$ and, for all $\boldsymbol{x} \in W$, $(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x})) \in V$ and

$$\boldsymbol{F}(\boldsymbol{x}, f(\boldsymbol{x})) = \boldsymbol{0} \ .$$

Additionally, $\boldsymbol{f}$ is analytic on W, and for any $\boldsymbol{x} \in W$, we have

$$D\boldsymbol{f}(\boldsymbol{x}) = -D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))^{-1} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, f(\boldsymbol{x}))$$

(in particular, $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{f}(\boldsymbol{x}))$ is invertible for all $\boldsymbol{x} \in W$).

VIII.5.10.5. Theorem. [Complex Analytic Inverse Function Theorem] Let U be an open set in $\mathbb{C}^n$, $\boldsymbol{a} \in U$, and $\boldsymbol{f} : U \to \mathbb{C}^n$ an analytic function. If $D\boldsymbol{f}(\boldsymbol{a})$ is invertible, then there is a neighborhood V of $\boldsymbol{a}$, $V \subseteq U$, such that

(i) $\boldsymbol{f}$ is one-to-one on V.

(ii) $\boldsymbol{f}(V)$ is open in $\mathbb{C}^n$.

(iii) $D\boldsymbol{f}(\boldsymbol{x})$ is invertible for all $\boldsymbol{x} \in V$.

(iv) $\boldsymbol{f}^{-1}$ is analytic on $\boldsymbol{f}(V)$ and, for all $\boldsymbol{y} \in \boldsymbol{f}(V)$,

$$D(\boldsymbol{f}^{-1})(\boldsymbol{y}) = [D\boldsymbol{f}(\boldsymbol{f}^{-1}(\boldsymbol{y}))]^{-1} \ .$$

VIII.5.10.6. Theorem. [General Complex Analytic Implicit/Inverse Function Theorem] Let $n \in \mathbb{N}$, $p \in \mathbb{N} \cup \{0\}$, $\boldsymbol{a} \in \mathbb{C}^p$, $\boldsymbol{b}, \boldsymbol{c} \in \mathbb{C}^n$, U an open neighborhood of $(\boldsymbol{a}, \boldsymbol{b})$ in $\mathbb{C}^{p+n}$, $\boldsymbol{F} : U \to \mathbb{C}^n$ an analytic function with $\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b}) = \boldsymbol{c}$ and $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{a}, \boldsymbol{b})$ invertible. Then there are:

(i) An open neighborhood V of $(\boldsymbol{a}, \boldsymbol{b})$ in $\mathbb{C}^{p+n}$, contained in U, such that $D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y})$ is invertible for all $(\boldsymbol{x}, \boldsymbol{y}) \in V$;

(ii) An open neighborhood W of $(\boldsymbol{a}, \boldsymbol{c})$ in $\mathbb{C}^{p+n}$;

(iii) A unique function $\boldsymbol{G} : W \to \mathbb{C}^n$ satisfying $\boldsymbol{G}(\boldsymbol{a}, \boldsymbol{c}) = \boldsymbol{b}$ and, for all $(\boldsymbol{x}, \boldsymbol{z}) \in W$, $(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})) \in V$ and

$$\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})) = \boldsymbol{z} \ .$$

Additionally, $\boldsymbol{G}$ is analytic on W, and for all $(\boldsymbol{x}, \boldsymbol{z}) \in V$,

$$D\boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z}) = \begin{bmatrix} & \vdots & \\ -D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z}))^{-1} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})) & \vdots & D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z}))^{-1} \\ & \vdots & \end{bmatrix} .$$

VIII.5.10.7. If $n = p = 1$, the unique analytic functions defined in VIII.5.10.1., VIII.5.10.2., VIII.5.10.4., and VIII.5.10.5. have Taylor series which, when relocated to 0, are the formal power series obtained in III.5.3.8. and III.5.3.7. respectively with $F = \mathbb{R}$ or $\mathbb{C}$. In other words, if the initial power series in III.5.3.8. and III.5.3.7. have positive radius of convergence, so does the power series in the conclusion. The same is true for general n and p, cf. III.5.3.8.(h). (There are also formal analogs of VIII.5.10.3. and VIII.5.10.6.; details are left to the reader.)

VIII.5.10.8. The complex analytic versions can be efficiently proved as follows. We outline the proof of VIII.5.10.6., of which VIII.5.10.4. and VIII.5.10.5. are corollaries. So begin with an analytic function $\boldsymbol{F} : U \to \mathbb{C}^n$ satisfying the hypotheses.

(1) Regard $\boldsymbol{F}$ as a $\mathcal{C}^\infty$ function from $\mathbb{R}^{2p+2n}$ to $\mathbb{R}^{2n}$.

(2) Apply VIII.5.2.1. to obtain the unique $\boldsymbol{G} : \mathbb{R}^{2p+2n} \to \mathbb{R}^{2n}$ with the right properties. Then $\boldsymbol{G}$ is $\mathcal{C}^\infty$.

(3) Check from the derivative formula of VIII.5.2.1. (cf. III.11.12.2.) that the partial derivatives of $\boldsymbol{G}$ with respect to any consecutive odd/even pair of coordinates satisfy the Cauchy-Riemann equations (XII.10.1.7.).

(4) Conclude from XII.10.1.6. that $\boldsymbol{G}$, regarded as a function from $\mathbb{C}^{p+n}$ to $\mathbb{C}^n$, is complex analytic.

VIII.5.10.9. The Taylor series of $\boldsymbol{G}$ around $(\boldsymbol{a}, \boldsymbol{c})$ can be computed by brute force algebraic manipulation of power series (there is a unique multivariable power series which formally satisfies the identity $\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{G}(\boldsymbol{x}, \boldsymbol{z})) = \boldsymbol{z}$ for all $\boldsymbol{x}, \boldsymbol{z}$; cf. VIII.5.11.10.), although the calculation becomes rather ghastly. This calculation can be used to give an alternate proof of most of VIII.5.10.6.. But the calculation is not sufficient by itself: it must also be shown that the resulting series converges in a neighborhood of $(\boldsymbol{a}, \boldsymbol{c})$. Then the function it converges to must satisfy the identity in the conclusion, and is the only analytic solution (). Thus there is a unique analytic function satisfying the conclusion. But to conclude there is a unique *function* satisfying the identity, additional argument is needed (such as an application of VIII.5.2.1.).

VIII.5.10.10. There is an alternate approach which avoids all use of VIII.5.2.1. (or the other smooth results). Begin by proving the Complex Analytic Inverse Function Theorem VIII.5.10.5., where uniqueness comes along essentially for free, using the method of VIII.5.10.9.. Then conclude VIII.5.10.6. as in VIII.5.2.3..

VIII.5.10.11. For the real analytic versions, the following procedure seems to suffice (we again outline the proof of VIII.5.10.3.). Let $\boldsymbol{F} : U \to \mathbb{R}^n$ satisfy the hypotheses.

(1) Complexify $\boldsymbol{F}$ to a complex analytic function $\boldsymbol{F}_{\mathbb{C}}$ from a neighborhood of $(\boldsymbol{a}, \boldsymbol{b})$ in $\mathbb{C}^{p+n}$ to $\mathbb{C}^n$, using the same power series centered at $(\boldsymbol{a}, \boldsymbol{b})$.

(2) Apply VIII.5.10.6. to $\boldsymbol{F}_{\mathbb{C}}$ to obtain a complex analytic function $\boldsymbol{G}_{\mathbb{C}} : \mathbb{C}^{p+n} \to \mathbb{C}^n$.

(3) Restrict $\boldsymbol{G}_{\mathbb{C}}$ to $\mathbb{R}^{p+n}$ to get $\boldsymbol{G}$.

There is, however, a technical subtlety: it must be shown that $\boldsymbol{G}$ takes values in $\mathbb{R}^n$, not just in $\mathbb{C}^n$. This can be done by computing the Taylor series for $\boldsymbol{G}_{\mathbb{C}}$ around $(\boldsymbol{a}, \boldsymbol{c})$ as in VIII.5.10.9. and verifying that all coefficients (partial derivatives) are real.

VIII.5.10.12. There is a better approach: as in VIII.5.10.10., first prove the Real Analytic Inverse Function Theorem VIII.5.10.2.. This can be done as follows. Suppose $\boldsymbol{f}$ satisfies the hypotheses of VIII.5.10.2..

(1) Apply the Inverse Function Theorem to show that $\boldsymbol{f}$ is one-to-one on a neighborhood V_r of $\boldsymbol{a}$ with $\mathcal{C}^\infty$ inverse function $\boldsymbol{f}^{-1}$ on the neighborhood $W_r = \boldsymbol{f}(V_r)$ of $\boldsymbol{b} = \boldsymbol{f}(\boldsymbol{a})$ in $\mathbb{R}^n$.

(2) Complexify $\boldsymbol{f}$ to $\boldsymbol{f}_{\mathbb{C}}$ on a neighborhood of $\boldsymbol{a}$ in $\mathbb{C}^n$ with the same Taylor series. Verify that $\boldsymbol{f}_{\mathbb{C}}$ satisfies the hypotheses of the Complex Analytic Inverse Function Theorem, hence is one-to-one on a neighborhood V_c of $\boldsymbol{a}$ in $\mathbb{C}^n$ with complex analytic inverse function $\boldsymbol{f}_{\mathbb{C}}^{-1}$ on the neighborhood $W_c = \boldsymbol{f}_{\mathbb{C}}(V_c)$ of $\boldsymbol{b}$ in $\mathbb{C}^n$.

(3) Use that $\boldsymbol{f}_{\mathbb{C}}$ is one-to-one and extends $\boldsymbol{f}$ to conclude that the restriction of $\boldsymbol{f}_{\mathbb{C}}^{-1}$ to the neighborhood $W = W_c \cap W_r$ of $\boldsymbol{b}$ in $\mathbb{R}^n$ agrees with the restriction of $\boldsymbol{f}^{-1}$ to W. Thus $\boldsymbol{f}^{-1}$ is real analytic on W.

Theorem VIII.5.10.2. can also be proved by the method of VIII.5.10.9. without any use of the usual Inverse Function Theorem.

Thus the real and complex analytic theorems are all proved (see Exercise VIII.5.11.20. for details). 👍

VIII.5.10.13. There are then real and complex analytic versions of the Straightening Theorems and the Rank Theorem; see Exercise VIII.5.11.20..

VIII.5.11. Exercises

VIII.5.11.1. Show that the hypothesis that $D_y\boldsymbol{F}(\boldsymbol{a},\boldsymbol{b})$ is invertible is not necessary for the conclusion of the Smooth Implicit Function Theorem, i.e. that the converse of the theorem does not hold. [Consider $F(x,y) = x^3 - y^3$.]

VIII.5.11.2. (a) If F is a function from $\mathbb{R}^2$ to $\mathbb{R}$, and the graph of the equation $F(x,y) = 0$ is a curve that crosses itself at $\boldsymbol{a}$ with different tangent lines, and F is differentiable at $\boldsymbol{a}$, show that $DF(\boldsymbol{a}) = 0$. [Consider directional derivatives.] This "explains" why the Implicit Function Theorem cannot apply at $\boldsymbol{a}$.

(b) If F is a $\mathcal{C}^1$-function from $\mathbb{R}^2$ to $\mathbb{R}$, and the graph of the equation $F(x,y) = 0$ is a curve with two segments passing through $\boldsymbol{a}$ with the same tangent line, not identically equal in any neighborhood of $\boldsymbol{a}$, show that $DF(\boldsymbol{a}) = 0$. [By making a linear change of variables, it may be assumed the tangent line at $\boldsymbol{a}$ is horizontal. Show that the Implicit Function Theorem cannot apply at $\boldsymbol{a}$.]

VIII.5.11.3. Let W be an open set in $\mathbb{R}^p$, and $\boldsymbol{f}$ a continuous function from W to $\mathbb{R}^n$. Define $\boldsymbol{F} : W \times \mathbb{R}^n \to \mathbb{R}^n$ by $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{y} - \boldsymbol{f}(\boldsymbol{x})$. Let $\boldsymbol{a} \in W$, and set $\boldsymbol{b} = \boldsymbol{f}(\boldsymbol{a})$.

(a) Show that $\boldsymbol{F}$, $\boldsymbol{a}$, $\boldsymbol{b}$ satisfy the hypotheses of VIII.5.1.6..

(b) Show that the implicitly defined function is $\boldsymbol{f}$ (possibly restricted to a smaller neighborhood of $\boldsymbol{a}$).

Thus every continuous function is defined implicitly by a function as in VIII.5.1.6.. Since $\boldsymbol{f}$ need not be differentiable anywhere, no stronger conclusion can be obtained in VIII.5.1.6. without additional hypotheses, even in the case $p = n = 1$.

VIII.5.11.4. Show that under the hypotheses of VIII.5.3.2., even if $p = 1$, there is not necessarily a continuous function f on a neighborhood W of $\boldsymbol{a}$ with $f(\boldsymbol{a}) = b$ and $F(\boldsymbol{x}, f(\boldsymbol{x})) = 0$ for all $\boldsymbol{x} \in W$. [Construct a pseudo-arc P in $[0,1] \times (0,1) \subseteq \mathbb{R}^2$ containing only one point $(0,c)$ on the left edge and one point on the right edge, whose complement in $[0,1]^2$ has exactly two components, and let F be a continuous function from $[0,1]^2$ to $\mathbb{R}$ with $F(0,y) = y - c$, $F(x,1) = 1 - c$, $F(x,0) = -c$, and which is zero precisely on P. Note that $\frac{\partial F}{\partial y}(0,c)$ exists and equals 1.]

VIII.5.11.5. (a) Assuming the Implicit Function Theorem, use the formula for $D\boldsymbol{F}$ in VIII.5.2.4. to deduce the formula for the total derivative of the inverse function to $\boldsymbol{f}$.

(b) Assuming the Inverse Function Theorem, use the formula for $D\tilde{\boldsymbol{F}}$ in VIII.5.2.3. and () to deduce the formula for the total derivative $D\boldsymbol{f} = -(D_{\boldsymbol{y}}\boldsymbol{F})^{-1} D_{\boldsymbol{x}}\boldsymbol{F}$ of the implicitly defined function $\boldsymbol{f}$.

VIII.5.11.6. Use VIII.5.3.9. and the argument of VIII.5.2.4. to obtain the version of the one-dimensional Inverse Function Theorem described in VIII.5.7.4..

VIII.5.11.7. (Newton; cf. [Edw79]) Let $F(x,y) = \sum_{j,k} a_{jk} x^j y^k$ be a polynomial. Suppose x and y are (differentiable) functions of t and write $\dot{x}$ and $\dot{y}$ for $x'(t)$ and $y'(t)$ respectively. Suppose x and y are related by the equation $F(x,y) = 0$, i.e. x and y give parametrized motion along the "curve" $F(x,y) = 0$.

(a) Using the power, product, and chain rules, deduce that

$$\sum_{j,k} \left(\frac{j\dot{x}}{x} + \frac{k\dot{y}}{y} \right) a_{jk} x^j y^k = 0 \ .$$

(b) Interpret this equation as

$$\dot{x}\frac{\partial F}{\partial x} + \dot{y}\frac{\partial F}{\partial y} = 0 \ .$$

(c) If $\dot{x}$ and $\frac{\partial F}{\partial y}$ are nonzero, deduce the formula

$$\frac{\dot{y}}{\dot{x}} = -\frac{\partial F/\partial x}{\partial F/\partial y} \ .$$

(d) Deduce the last two formulas if F is just a differentiable function of x and y.

(e) Is this a proof of the one-variable Implicit Function Theorem VIII.5.3.10.? Why or why not?

VIII.5.11.8. Recall the way the formula for $f'(x)$ is found by implicit differentiation in first-semester calculus from an equation $F(x, y) = 0$: differentiate $G(x) = F(x, f(x))$ by the Chain Rule and other differentiation rules, set it equal to 0, and solve for $f'(x)$ (streamlined notation is usually used which amounts to this). Show that the same formula as the one in VIII.5.3.10. is always obtained.

VIII.5.11.9. In VIII.5.3.7., assume that the first-order partials of F are defined on U and continuous at $(\boldsymbol{a}, b)$ (which implies that F is differentiable at $(\boldsymbol{a}, b)$), and that $\frac{\partial F}{\partial y}$ is nonzero on U (which can be automatically arranged in the continuous partial case if $\frac{\partial F}{\partial y}(\boldsymbol{a}, b) \neq 0$ by replacing U by a smaller neighborhood of $(\boldsymbol{a}, b)$). Give a simplified proof as follows (note that the f is unique and continuous in this case by VIII.5.3.4.):

(a) For notational simplicity, assume $p = 1$. If Δx is sufficiently small, write $\Delta y = f(a + \Delta x) - f(a) = f(a + \Delta x) - b$. Then

$$0 = F(a + \Delta x, b + \Delta y) = F(a, b) = F(a + \Delta x, b + \Delta y) - F(a, b)$$
$$= [F(a + \Delta x, b + \Delta y) - F(a, b + \Delta y)] + [F(a, b + \Delta y) - F(a, b)] \ .$$

(b) By two applications of the MVT, there are $0 < \alpha, \beta < 1$ (depending on Δx) such that

$$F(a + \Delta x, b + \Delta y) - F(a, b + \Delta y) = \frac{\partial F}{\partial x}(a + \alpha\Delta x, b + \Delta y)\Delta x$$

$$F(a, b + \Delta y) - F(a, b) = \frac{\partial F}{\partial y}(a, b + \beta\Delta y)\Delta y \ .$$

(c) From (a) and (b),

$$\frac{\partial F}{\partial x}(a + \alpha\Delta x, b + \Delta y)\Delta x + \frac{\partial F}{\partial y}(a, b + \beta\Delta y)\Delta y = 0$$

so

$$\frac{\Delta y}{\Delta x} = -\frac{\frac{\partial F}{\partial x}(a + \alpha\Delta x, b + \Delta y)}{\frac{\partial F}{\partial y}(a, b + \beta\Delta y)} \ .$$

(d) By continuity,

$$\lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \to 0} -\frac{\frac{\partial F}{\partial x}(a + \alpha\Delta x, b + \Delta y)}{\frac{\partial F}{\partial y}(a, b + \beta\Delta y)}$$

exists and equals $-\frac{\frac{\partial F}{\partial x}(a,b)}{\frac{\partial F}{\partial y}(a,b)}$.

(e) Adapt the argument notationally to the case $p > 1$.

VIII.5.11.10. Use the Chain Rule to find formulas for the higher-order derivatives of implicitly defined functions.

VIII.5.11.11. Give a direct argument proving the Continuous Implicit Function Theorem along the lines of the proof of VIII.5.5.1. by proving the following version first proved in [Gou03]:

THEOREM. Let U be an open set in $\mathbb{R}^{p+n}$ containing $(\mathbf{0},\mathbf{0})$, and $\boldsymbol{G} : U \to \mathbb{R}^n$ a continuous function with $\boldsymbol{G}(\mathbf{0},\mathbf{0}) = \mathbf{0}$, such that $D_{\boldsymbol{y}}\boldsymbol{G}$ is continuous on U and $D_{\boldsymbol{y}}\boldsymbol{G}(\mathbf{0},\mathbf{0}) = \mathbf{0}$. Then there are open sets V in $\mathbb{R}^{p+n}$, $V \subseteq U$, $(\mathbf{0},\mathbf{0}) \in V$, and W in $\mathbb{R}^p$, $\mathbf{0} \in W$, and Y in $\mathbb{R}^n$, $\mathbf{0} \in Y$, such that for every $\boldsymbol{y} \in Y$ there is a unique $\boldsymbol{x} \in W$ with $(\boldsymbol{x},\boldsymbol{y}) \in V$ and $\boldsymbol{G}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{y}$.

(a) Prove this theorem by using the Contraction Mapping Principle.

(b) If $U \subseteq \mathbb{R}^{p+n}$, $(\mathbf{0},\mathbf{0}) \in U$, and $\boldsymbol{F} : U \to \mathbb{R}^n$ is a continuous with $\boldsymbol{F}(\mathbf{0},\mathbf{0}) = \mathbf{0}$, such that $D_{\boldsymbol{y}}\boldsymbol{F}$ is continuous on U and $D_{\boldsymbol{y}}\boldsymbol{F}(\mathbf{0},\mathbf{0}) = I_n$, show that there is a unique implicitly defined function $\boldsymbol{f}$ on a neighborhood W of $\mathbf{0}$ in $\mathbb{R}^p$, taking values in a neighborhood Y of $\mathbf{0}$ in $\mathbb{R}^n$, such that $\boldsymbol{F}(\boldsymbol{x},\boldsymbol{f}(\boldsymbol{x})) = \mathbf{0}$ for all $\boldsymbol{x} \in W$. [Set $\boldsymbol{G}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{y} - \boldsymbol{F}(\boldsymbol{x},\boldsymbol{y})$.]

(c) Use an affine change of variables to deduce the existence of an implicit function under the hypotheses of VIII.5.1.6.. Conclude continuity of the implicit function from VIII.5.1.15..

See [**?**] for a nice geometric interpretation of this argument.

VIII.5.11.12. Define $F : \mathbb{R}^2 \to \mathbb{R}$ by

$$F(x,y) = \begin{cases} y + x^2 \cos\left(\frac{y}{x^4}\right) & \text{if} \quad x \neq 0 \\ y & \text{if} \quad x = 0 \end{cases} .$$

(a) Show that F is differentiable everywhere. In particular, F is continuous, and $\frac{\partial F}{\partial x}$ and $\frac{\partial F}{\partial y}$ exist everywhere.

(b) Show that $\frac{\partial F}{\partial y}$ is continuous in y for fixed x, and that $\frac{\partial F}{\partial y}(0,0) = 1$.

(c) Show that the equation $F(x,y) = 0$ cannot be uniquely solved for y as a differentiable function of x in any small neighborhood of $(0,0)$ (the smaller the neighborhood, the more differentiable solutions there are).

VIII.5.11.13. (a) Write a statement which is a common generalization of VIII.5.3.12. and VIII.5.7.7., along the lines of VIII.5.4.2..

***(b) Is this statement true? [cf. VIII.5.11.14.(b).]

VIII.5.11.14. (a) Show that under the hypotheses of VIII.5.7.5., if U is connected, then $det(D\boldsymbol{f}(\boldsymbol{x}))$ does not change sign on U, i.e. $\boldsymbol{f}$ either preserves or reverses orientation on all of U.

***(b) Is the assumption of a decreasing chain of minors as in VIII.5.4.3. automatic? (If so, an inductive proof of VIII.5.7.5. and the statement in VIII.5.11.13. can be given.)

VIII.5.11.15. Let U and V be open sets in $\mathbb{R}^n$, and $f : U \to V$ a bijection which is $\mathcal{C}^r$ $(1 \leq r \leq \infty)$. If f^{-1} is differentiable everywhere on V, show that f^{-1} is necessarily $\mathcal{C}^r$ on V.

VIII.5.11.16. Formulate and prove generalizations of the Continuous and Mixed Implicit Function Theorem similar to VIII.5.2.1..

VIII.5.11.17. Let $f : \mathbb{R} \to \mathbb{R}$ be given by $f(x) = x^2$. Around which points can f be straightened?

VIII.5.11.18. Let $\boldsymbol{f} : \mathbb{R} \to \mathbb{R}^2$ be given by $\boldsymbol{f}(x) = (x^3, x^2)$. Then $\boldsymbol{f}$ is $\mathcal{C}^\infty$. Show that the range of $\boldsymbol{f}$ can be topologically straightened but not smoothly straightened around 0.

VIII.5.11.19. Define $\boldsymbol{f} : \mathbb{R} \to \mathbb{R}^2$ by

$$\boldsymbol{f}(x) = \left(e^{-1/x^2} \left[1 - \cos \frac{2\pi}{x} \right], e^{-1/x^2} \sin \frac{2\pi}{x} \right)$$

for $x \neq 0$, and $\boldsymbol{f}(0) = (0, 0)$.

(a) Show that $\boldsymbol{f}$ is a $\mathcal{C}^\infty$ function.

(b) Show that the image of $\left(-\frac{1}{n}, \frac{1}{n}\right)$ is topologically a Hawaiian earring (XIII.19.5.8.) for any $n \in \mathbb{N}$. Thus the range cannot even be topologically straightened around 0.

(c) Discuss straightening of the function $\boldsymbol{g} : \mathbb{R}^2 \to \mathbb{R}^2$ given by

$$\boldsymbol{g}(x, y) = \left(e^{-1/x^2} \left[1 - \cos \frac{2\pi}{x} \right], y + e^{-1/x^2} \sin \frac{2\pi}{x} \right)$$

for $x \neq 0$ and $\boldsymbol{g}(0, y) = (0, y)$.

VIII.5.11.20. (a) Write out the details of the proofs of the real and complex analytic versions of the Implicit and Inverse Function Theorems.

(b) Compute enough terms of the Taylor series of the implicitly defined function to indicate the general procedure and the proof of uniqueness.

(c) Verify by calculation the derivative formulas for the complex analytic versions (for the real analytic versions, these formulas are trivial from the smooth versions).

(d) Formulate and prove real and complex analytic versions of the Straightening Theorems and the Rank Theorem.

VIII.5.11.21. Formulate and prove precise versions, both real and complex, of the statement that the roots of an n'th degree polynomial are continuous, and in fact analytic, functions of the coefficients, except at multiple roots. [Fix n, and consider the function

$$F(a_0, \ldots, a_n, x) = a_0 + a_1 x + \cdots + a_n x^n$$

and solve $F(a_0, \ldots, a_n, x) = 0$ for x.]

This suggests there are analytic formulas for the roots of a general n'th degree polynomial, although explicit expressions for the formulas may not be possible in general. There cannot be explicit formulas just involving finitely many algebraic operations, including roots, if $n \geq 5$.

Note that this argument applies to polynomials of degree $\leq n$, for any fixed n. Thus the analytic functions obtained are compatible for different n. Illustrate this explicitly for $n = 2$.

VIII.5.11.22. Let U be an open set in $\mathbb{R}^3$, and $F : U \to \mathbb{R}$ be a $\mathcal{C}^1$ function with $\frac{\partial F}{\partial x}$, $\frac{\partial F}{\partial y}$, and $\frac{\partial F}{\partial z}$ nonzero on U. Then the equation $F(x, y, z) = 0$ can be locally solved for each of x, y, z as functions of the other two. Show that

$$\frac{\partial x}{\partial y}\frac{\partial y}{\partial z}\frac{\partial z}{\partial x} = -1 \ .$$

(Give a careful explanation of what this equation means.) Thus algebraic manipulations of Leibniz notation must be done carefully. See also VIII.2.4.2..

VIII.5.11.23. Let K be the Cantor set, and let ϕ be a nonnegative $\mathcal{C}^\infty$ function from $\mathbb{R}$ to $\mathbb{R}$ which is zero exactly on $K \cup (-K)$ (V.17.2.9.). Set

$$F(x, y, z) = x^2 + y^2 - \phi(z)$$

$$G(x, y, z) = x^2 + y^2 + \phi(z)$$

and let $\Gamma = \{(x, y, z) : F(x, y, z) = 0\}$ and $\Delta = \{(x, y, z) : G(x, y, z) = 0\}$.

(a) Show that F and G are $\mathcal{C}^\infty$ on all of $\mathbb{R}^3$.

(b) Discuss the local structure of Γ and Δ around $\mathbf{0}$. Are they surfaces in any sense?

VIII.5.11.24. Formulate and prove the general version of VIII.5.1.25. for arbitrary $k, n, p \in \mathbb{N}$, $k \leq n$.

VIII.5.11.25. Deduce the following result from VIII.5.8.2.:

Corollary. [Smooth Open Mapping Theorem] Let $\boldsymbol{f}$ be a $\mathcal{C}^r$ function ($r \geq 1$) from an open set U in $\mathbb{R}^n$ to $\mathbb{R}^m$. Suppose $D\boldsymbol{f}$ has rank m at all points of U (this entails that $n \geq m$). Then $\boldsymbol{f}$ is an open mapping, i.e. if V is an open set in $\mathbb{R}^n$ contained in U, then $\boldsymbol{f}(V)$ is open in $\mathbb{R}^m$.

Compare with ().

VIII.5.11.26. Show that if $f : \mathbb{R}^n \to \mathbb{R}^m$ is linear (and hence differentiable), the Rank Theorem for f follows easily from (and is in fact equivalent to) the following facts from linear algebra:

(i) Every subspace of a vector space has a complementary subspace ().

(ii) If $\mathcal{W}$ is a subspace of $\mathbb{R}^n$ complementary to the null space $\mathcal{N}(f)$, then the restriction of f to $\mathcal{W}$ is a linear isomorphism of $\mathcal{W}$ onto the range of f ().

(iii) Two vector spaces of the same dimension are isomorphic.

VIII.6. Constrained Extrema and Lagrange Multipliers

It is often necessary to find the extrema of a function over a surface in $\mathbb{R}^3$, or a higher-dimensional version of the situation. There is a clever way to do this in many cases, using the method of *Lagrange multipliers*. The theory is related to the Implicit Function Theorem.

VIII.6.1. The Two-Dimensional Case

VIII.6.2. The Higher-Dimensional Case with One Constraint

VIII.6.3. The Higher-Dimensional Case with Multiple Constraints

VIII.6.4. Degenerate Cases

VIII.6.5. Exercises

VIII.6.5.1. Consider the following problem treated in first-semester calculus courses:

> Find the most economical shape of a cylindrical can, i.e. the shape making the surface area as small as possible for a fixed volume.

In other words, if r is the radius of the base and h the height, minimize

$$S = 2\pi r^2 + 2\pi r h$$

subject to the constraint

$$V = \pi r^2 h = \text{ constant }.$$

(a) The standard way to do it is to solve the constraint equation for h and then find the minimum of

$$S(r) = 2\pi r^2 + 2\pi r \left(\frac{V}{\pi r^2}\right) = 2\pi r^2 + \frac{2V}{r}$$

for $r > 0$. Solve the problem this way and show that h must be $2r$.

(b) Solve the problem somewhat more easily using Lagrange multipliers (this cannot be done in first-semester calculus!)

(c) Critique the following alternate solution which appeared in [Gri27]:

"[Implicitly] Differentiate both of these equations at once with respect to r [regarding h as a function of r].

$$\frac{dS}{dr} = 4\pi r + 2\pi h + 2\pi r \frac{dh}{dr} = 0,$$

$$\frac{dV}{dr} = 2\pi r h + \pi r^2 \frac{dh}{dr} = 0.$$

[$\frac{dV}{dr} = 0$ since V is constant, and $\frac{dS}{dr} = 0$ at a minimum.] From [the second] we find

$$\frac{dh}{dr} = -\frac{2h}{r}.$$

This substituted in [the first] gives

$$4\pi r + 2\pi h - 4\pi h = 0;$$

whence $h = 2r$. The height must equal the diameter."

This is the correct answer. When does this method work?

VIII.7. Surface Area and Surface Integrals

VIII.7.1. Surface Area

Giving a proper definition of area for a surface in $\mathbb{R}^3$ is much trickier than defining arc length of a curve. The roughly analogous process simply does not work.

VIII.7.1.1. To define the arc length of a curve, one chooses a large number of closely spaced points along the curve, approximates the curve by the straight line segments between consecutive points, and adds up the lengths of these segments to give an approximation to the arc length. As the lengths of these approximating segments approaches zero uniformly, the approximations to the arc length approach a limit (actually the supremum) which is the reasonable candidate for the arc length of the curve. See ().

We could try to do something similar with a surface. Choose a lot of closely spaced points which can be connected by straight line segments forming planar triangles, and use these triangles as a piecewise-linear approximation to the surface and the sum of the areas as an approximation to the area of the surface, and then take the limit as the diameters of the triangles approach zero.

VIII.7.1.2. There are two potential problems:

(i) It is not obvious that such triangular approximations can be made for any surface. This turns out not to be a serious problem, since it is a (nontrivial) theorem that every surface can be triangulated ().

(ii) It is not obvious that the limit exists in this case.

In fact, the limit does *not* exist in general! So this method of defining surface area is doomed to failure.

VIII.7.1.3. Example. We describe the standard example where things go terribly wrong. This phenomenon was discovered by Archimedes in ancient Greece.

We want to find the surface area of a (right) cylinder of height h whose base has radius r. By cutting the cylinder along a vertical line and "unrolling" it, we can easily guess that the surface area should be $2\pi rh$.

Instead, we try the procedure described above. To make calculations easier, take the case $r = h = 1$. Fix two large natural numbers m and n. Draw $m+1$ evenly spaced horizontal circles on the cylinder including the two end circles, and on each place n evenly spaced points so alternate circles have the points placed halfway between the ones on the adjacent circles. Approximate by triangles whose vertices are two consecutive points on one circle and the point halfway between on an adjacent circle. This approximates the cylinder by an "accordion" surface (Figure VIII.20), which is sometimes called a *Schwarz lantern* since it was described by H. Schwarz.

Let the sum of the areas of the triangles be $A_{m,n}$. Do we have that

$$\lim_{m,n\to\infty} A_{m,n} = 2\pi \ ?$$

(This means: for any $\epsilon > 0$, is there an N such that $|A_{m,n} - 2\pi| < \epsilon$ whenever $m, n > N$.)

It is easy to see that the answer is no. Fix m and n. Each triangle is isosceles, with a base of length $2\sin\frac{\pi}{n}$ and altitude greater than $1 - \cos\frac{\pi}{n}$. Since there are $2mn$ triangles, we have that

$$A_{m,n} > 2mn \sin\frac{\pi}{n}\left(1 - \cos\frac{\pi}{n}\right) \ .$$

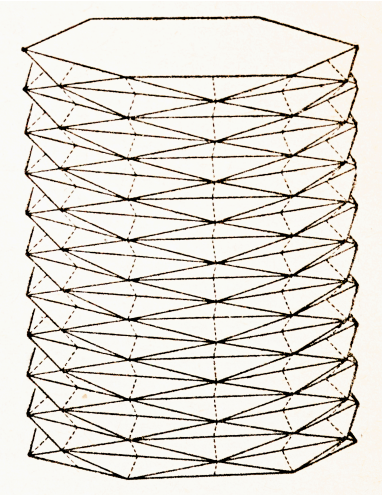

Figure VIII.20: Schwarz lantern.

If n is large, we have $\sin\frac{\pi}{n} \approx \frac{\pi}{n}$ and $1-\cos\frac{\pi}{n} \approx \frac{\pi^2}{2n^2}$, so the area of each triangle is roughly at least $\frac{\pi^3}{2n^3}$. Thus, if $m \gg n^2$, $A_{m,n}$ is large, so cannot approach 2π.

In fact, with slightly more care the altitude of each triangle can be computed to be $\sqrt{(1-\cos\frac{\pi}{n})^2+\frac{1}{m^2}}$, so we have an exact formula

$$A_{m,n} = 2mn\sin\frac{\pi}{n}\sqrt{\left(1-\cos\frac{\pi}{n}\right)^2+\frac{1}{m^2}}\ .$$

Suppose m and n go to infinity in such a way that

$$\lim_{m,n\to\infty}\frac{m}{n^2} = q$$

(this can be arranged for any $q \in [0,+\infty]$). Then

$$\lim_{m,n\to\infty} A_{m,n} = \lim_{m,n\to\infty} 2mn\sin\frac{\pi}{n}\sqrt{\left(1-\cos\frac{\pi}{n}\right)^2+\frac{1}{m^2}}$$

$$= \lim_{m,n\to\infty} 2\pi\left[\frac{n}{\pi}\sin\frac{\pi}{n}\right]\sqrt{m^2\frac{\pi^4}{4n^4}\left[\frac{4n^4}{\pi^4}\left(1-\cos\frac{\pi}{n}\right)^2\right]+1} = 2\pi\sqrt{\frac{\pi^4}{4}q^2+1}$$

since the limit of the expressions in square brackets is 1. Thus the area $A_{m,n}$ approaches the right answer 2π if and only if $q=0$, i.e. if and only if $m \to \infty$ more slowly than n^2. The limit can be anything in $[2\pi,+\infty]$ by choosing q properly.

VIII.7.1.4. It is actually possible to compute the surface area of any surface, or surfacelike subset, of $\mathbb{R}^3$ as a limit, although in a more complicated way. Indeed, the area of such a set is just its 2-dimensional Hausdorff measure (XVII.6.3.). But for smooth or piecewise-smooth surfaces, we will proceed in a different way which not only gives a workable definition, but also a practical method of calculation in reasonable cases.

VIII.8. Power Series and Analytic Functions of Several Variables

The theory of power series and analytic functions in several variables is similar to the theory in one variable with some technical complications. In this section, we will take the path of least resistance to the most important aspects of the theory, avoiding some of the (sometimes interesting) technicalities that arise. As in the one-variable case, we can do the real and complex theories in parallel; we let $\mathbb{F}$ stand for either $\mathbb{R}$ or $\mathbb{C}$.

VIII.8.1. Multivariable Power Series

VIII.8.1.1. In general, we want to consider power series of the form

$$\sum_{k_1=0}^{\infty}\sum_{k_2=0}^{\infty}\cdots\sum_{k_n=0}^{\infty} a_{k_1,\ldots,k_n}x_1^{k_1}x_2^{k_2}\cdots x_n^{k_n}$$

where the $a_{k_1,\ldots,k_n}$ are scalars (real or complex) and $x_1,\ldots,x_n$ are independent variables. The notation can become oppressive working with a general n, although multiindex notation (VIII.8.1.5.) can help, so sometimes we will notationally stick to the case $n=2$, writing x and y (or z and w in the complex case) for the independent variables. Just as in multivariable calculus, the case $n=2$ exhibits all the essential features of the theory for general n in contrast with the case $n=1$. Thus a power series in two variables will be written

$$\sum_{j=0}^{\infty}\sum_{k=0}^{\infty} a_{jk}x^j y^k$$

or more generally

$$\sum_{j=0}^{\infty}\sum_{k=0}^{\infty} a_{jk}(x-x_0)^j(y-y_0)^k\ .$$

VIII.8.1.2. Even in the two-variable case, there is no natural ordering on the terms, so we will regard the infinite series as an unordered sum

$$\sum_{(j,k)} a_{jk}(x-x_0)^j(y-y_0)^k$$

where the sum is over $\mathbb{N}_0^2$ (recall the notation $\mathbb{N}_0=\mathbb{N}\cup\{0\}$). In general, we will have an unordered sum over $\mathbb{N}_0^n$. Regarding multivariable power series as unordered sums means that we will only consider absolute convergence, and leads to technical simplifications in the theory without essential loss of generality.

VIII.8.1.3. Since we are considering multivariable power series as unordered sums, there is no harm in allowing more than one term with the same powers $(x-x_0)^j(y-y_0)^k$; we may even have infinitely many terms with the same pair (j,k) of powers, and it is convenient to allow this. Any such sum can be converted to *standard form* by first summing together all terms with powers a fixed (j,k), and then summing over (j,k); the standard form is a drastic revision of the original power series. As long as the original power series converges (as an unordered sum, i.e. converges absolutely), the standard form conversion and series will also converge (IV.2.10.20.). So we can make a formal definition:

VIII.8.1.4. DEFINITION. Let Ω be an index set, and $\phi = (\phi_1, \ldots, \phi_n) : \Omega \to \mathbb{N}_0^n$ a function. A *multivariable power series* in variables $X_1, \ldots, X_n$ indexed by Ω is an unordered sum

$$\sum_{\omega \in \Omega} a_\omega X_1^{\phi_1(\omega)} X_2^{\phi_2(\omega)} \cdots X_n^{\phi_n(\omega)}$$

where the a_ω are scalars. If $(c_1, \ldots, c_n)$ is an n-tuple of scalars, a multivariable power series in $x_1, \ldots, x_n$ centered at $(c_1, \ldots, c_n)$, indexed by Ω, is an unordered sum

$$\sum_{\omega \in \Omega} a_\omega (x_1 - c_1)^{\phi_1(\omega)} (x_2 - c_2)^{\phi_2(\omega)} \cdots (x_n - c_n)^{\phi_n(\omega)} \ .$$

If $n = 2$, a multivariable power series in x and y centered at (x_0, y_0), indexed by Ω, is an unordered sum

$$\sum_{\omega \in \Omega} a_\omega (x - x_0)^{\phi_1(\omega)} (y - y_0)^{\phi_2(\omega)} \ .$$

The multivariable power series is in *standard form* if ϕ is one-to-one; in this case, we may take $\Omega = \mathbb{N}_0^n$ and write the power series as

$$\sum_{(k_1, \ldots, k_n) \in \mathbb{N}_0^n} a_{k_1, \ldots, k_n} (x_1 - c_1)^{k_1} \cdots (x_n - c_n)^{k_n} \ .$$

Any convergent multivariable power series has a unique drastic revision which is in standard form.

VIII.8.1.5. It is convenient to use *multi-index notation*: if $\alpha = (m_1, \ldots, m_n) \in \mathbb{N}_0^n$, and $\boldsymbol{x} = (x_1, \ldots, x_n)$, write $\boldsymbol{x}^\alpha = x_1^{m_1} x_2^{m_2} \cdots x_n^{m_n}$. We can then write the series

$$\sum_{\omega \in \Omega} a_\omega (x_1 - c_1)^{\phi_1(\omega)} (x_2 - c_2)^{\phi_2(\omega)} \cdots (x_n - c_n)^{\phi_n(\omega)}$$

centered at $\boldsymbol{c} = (c_1, \ldots, c_n)$ as

$$\sum_{\omega \in \Omega} a_\omega (\boldsymbol{x} - \boldsymbol{c})^{\phi(\omega)}$$

and a standard form multivariable power series as

$$\sum_{\alpha \in \mathbb{N}_0^n} a_\alpha (\boldsymbol{x} - \boldsymbol{c})^\alpha \ .$$

VIII.8.1.6. If $\boldsymbol{c} = (c_1, \ldots, c_n) \in \mathbb{F}^n$, the power series

$$\sum_{\omega \in \Omega} a_\omega (\boldsymbol{x} - \boldsymbol{c})^{\phi(\omega)}$$

converges at $\boldsymbol{b} = (b_1, \ldots, b_n) \in \mathbb{F}^n$ if the unordered sum

$$\sum_{\omega \in \Omega} a_\omega (\boldsymbol{b} - \boldsymbol{c})^{\phi(\omega)}$$

converges (i.e. converges absolutely). We then have by comparison:

VIII.8.1.7. PROPOSITION. Let

$$\sum_{\omega\in\Omega} a_\omega(\boldsymbol{x}-\boldsymbol{c})^{\phi(\omega)}$$

be a multivariable power series. If the series converges at $\boldsymbol{b} = (b_1,\ldots,b_n)$, then it converges at $\boldsymbol{x} = (x_1,\ldots,x_n)$ for any $(x_1,\ldots,x_n) \in \mathbb{F}^n$ with $|x_1-c_1| \le |b_1-c_1|,\ldots,|x_n-c_n| \le |b_n-c_n|$.

VIII.8.1.8. Thus, if the series converges for some $\boldsymbol{b}$ with $b_k \ne c_k$ for all k, then it converges at all points of the rectangle (or *polydisk* if $\mathbb{F} = \mathbb{C}$)

$$R = \{\boldsymbol{x} : |x_k - c_k| \le |b_k - c_k| \text{ for all } 1 \le k \le n\}$$

centered at $\boldsymbol{c}$, and thus defines a function from R to $\mathbb{F}$.

VIII.8.1.9. EXAMPLE. A one-variable power series converges precisely on an interval (or disk in the complex case). But the situation is more complicated with multivariable power series: the set of convergence need not be a rectangle (or polydisk). For example, consider the real 2-variable power series

$$\sum_{k=0}^{\infty} x^k y^k \ .$$

This series converges (to $\frac{1}{1-xy}$) if and only if $|xy| < 1$, i.e. on the open subset of $\mathbb{R}^2$ containing $(0,0)$ bounded by the hyperbolas $y = \pm\frac{1}{x}$.

The best simple general statement we can make is that for any fixed y, a 2-variable power series converges at (x,y) exactly for all x in a (possibly degenerate or empty) interval (disk) centered at x_0, and similarly for fixed x. Thus if S is the set of convergence, every horizontal cross section is an interval (disk) centered at x_0, and every vertical cross section is an interval (disk) centered at y_0. These statements are true since if one variable is fixed, the series is an ordinary power series in the other variable. A similar statement holds in higher dimensions (fixing all but one variable). Thus, in general, the set of convergence is a union of rectangles (polydisks) centered at $\boldsymbol{c}$.

VIII.8.1.10. PROPOSITION. Let

$$\sum_{\omega\in\Omega} a_\omega(\boldsymbol{x}-\boldsymbol{c})^{\phi(\omega)}$$

be a multivariable power series which converges on a rectangle (polydisk)

$$R = \{\boldsymbol{x} : |x_k - c_k| \le r_k \text{ for all } 1 \le k \le n\}$$

centered at $\boldsymbol{c}$, where $r_1,\ldots,r_n > 0$. Let f be the function on R defined by the power series. For each finite $E \subseteq \Omega$, define

$$f_E(\boldsymbol{x}) = \sum_{\omega\in E} a_\omega(\boldsymbol{x}-\boldsymbol{c})^{\phi(\omega)}$$

for $\boldsymbol{x} \in R$. Then $f_E \to f$ uniformly on R, i.e. for every $\epsilon > 0$ there is a finite subset F of Ω such that, whenever E is a finite subset of Ω containing F,

$$|f(\boldsymbol{x}) - f_E(\boldsymbol{x})| < \epsilon$$

for all $\boldsymbol{x} \in R$.

PROOF: This is essentially the Weierstrass M-test (). Set $\boldsymbol{r} = (r_1, \ldots, r_n)$. The unordered sum

$$\sum_{\omega \in \Omega} a_\omega \boldsymbol{r}^{\phi(\omega)}$$

converges; hence for $\epsilon > 0$ there is a finite subset $F \subseteq \Omega$ such that

$$\sum_{\omega \in \Omega \setminus F} |a_\omega| \boldsymbol{r}^{\phi(\omega)} < \epsilon \ .$$

Thus, if E is a finite subset of Ω containing F, we have

$$|f(\boldsymbol{x}) - f_E(\boldsymbol{x})| = \left| \sum_{\omega \in \Omega \setminus E} a_\omega (\boldsymbol{x} - \boldsymbol{c})^{\phi(\omega)} \right|$$

$$\leq \sum_{\omega \in \Omega \setminus E} |a_\omega| |x_1 - c_1|^{\phi_1(\omega)} |x_2 - c_2|^{\phi_2(\omega)} \cdots |x_n - c_n|^{\phi_n(\omega)} \leq \sum_{\omega \in \Omega \setminus F} |a_\omega| \boldsymbol{r}^{\phi(\omega)} < \epsilon \ .$$

VIII.8.1.11. COROLLARY. If a multivariable power series converges on a rectangle (polydisk) R, it defines a continuous function on R.

We now show that a multivariable power series can be differentiated term-by-term.

VIII.8.1.12. THEOREM. Let

$$\sum_{\omega \in \Omega} a_\omega (\boldsymbol{x} - \boldsymbol{c})^{\phi(\omega)}$$

be a multivariable power series which converges on a rectangle (polydisk)

$$R = \{\boldsymbol{x} : |x_k - c_k| \leq r_k \text{ for all } 1 \leq k \leq n\}$$

centered at $\boldsymbol{c}$, where $r_1, \ldots, r_n > 0$. Let f be the function on R defined by the power series. Then, for each k, $1 \leq k \leq n$, the unordered sum

$$\sum_{\omega \in \Omega} a_\omega \frac{\partial}{\partial x_k} \left((\boldsymbol{x} - \boldsymbol{c})^{\phi(\omega)} \right) = \sum_{\omega \in \Omega} \phi_k(\omega) a_\omega (x_1 - c_1)^{\phi_1(\omega)} (x_2 - c_2)^{\phi_2(\omega)} \cdots (x_k - c_k)^{\phi_k(\omega) - 1} \cdots (x_n - c_n)^{\phi_n(\omega)} \tag{VIII.2}$$

converges u.c. to $\frac{\partial f}{\partial x_k}$ on the open rectangle (polydisk)

$$R^\circ = \{\boldsymbol{x} : |x_k - c_k| < r_k \text{ for all } 1 \le k \le n\} .$$

PROOF: This can be quickly reduced to the one-variable case. Fix k. For each $j \neq k$, fix x_j with $|x_j - c_j| \le r_j$. For any x_k, $|x_k - c_k| \le r_k$, the unordered sum

$$\sum_{\omega \in \Omega} a_\omega (\boldsymbol{x} - \boldsymbol{c})^{\phi(\omega)}$$

converges; hence it can be computed by summing in any manner. Form the drastic revision

$$\sum_{m \in \mathbb{N}_0} b_m (x_k - c_k)^m$$

obtained by first summing all terms with factor $(x_k - c_k)^m$ for fixed m. This is an unordered power series in one variable $x_k - c_k$ which converges for $|x_k - c_k| \le r_k$; thus the associated ordinary power series

$$\sum_{m=0}^{\infty} b_m (x - c_k)^m \tag{VIII.3}$$

has radius of convergence at least r_k, and converges to $f(x_1, \ldots, x_{k-1}, x, x_{k+1}, \ldots, x_n)$ for $|x - c_k| \le r_k$. Thus, by V.15.3.23., the series of term-by-term derivatives converges absolutely to

$$\frac{d}{dx}\left(f(x_1, \ldots, x_{k-1}, x, x_{k+1}, \ldots, x_n)\right) = \frac{\partial f}{\partial x_k}(x_1, \ldots, x_{k-1}, x, x_{k+1}, \ldots, x_n)$$

for $|x - c_k| < r_k$, i.e. VIII.3 converges to $\frac{\partial f}{\partial x_k}$ on R°.

We have not yet shown that the original multivariable series VIII.2 converges. But this can be shown by a majorization argument. The above argument can be used starting with the series of absolute values

$$\sum_{\omega \in \Omega} |a_\omega| (\boldsymbol{x} - \boldsymbol{c})^{\phi(\omega)}$$

which converges on R to a function F. If we choose the x_j so that $x_j - c_j \ge 0$ for all j, then the unordered sum

$$\sum_{\omega \in \Omega} \phi_k(\omega) |a_\omega| (x_1 - c_1)^{\phi_1(\omega)} (x_2 - c_2)^{\phi_2(\omega)} \cdots (x_k - c_k)^{\phi_k(\omega) - 1} \cdots (x_n - c_n)^{\phi_n(\omega)} \tag{VIII.4}$$

has a drastic revision which converges (to $\frac{\partial F}{\partial x_k}$); thus the series VIII.4 also converges since all the terms are nonnegative. This implies that VIII.2 converges on R° by comparison. Since it has a drastic revision which converges to $\frac{\partial f}{\partial x_k}$ on R°, VIII.2 also converges to $\frac{\partial f}{\partial x_k}$ on R°.

This argument shows pointwise convergence of VIII.2 on R°; u.c. convergence is then automatic by VIII.8.1.10.. 👍

VIII.8.1.13. Corollary. Let

$$\sum_{\omega\in\Omega} a_\omega(\boldsymbol{x}-\boldsymbol{c})^{\phi(\omega)}$$

be a multivariable power series which converges on an open rectangle (polydisk)

$$R^\circ = \{\boldsymbol{x} : |x_k - c_k| < r_k \text{ for all } 1 \le k \le n\}$$

centered at $\boldsymbol{c}$, where $r_1, \dots, r_n > 0$. Let f be the function on R° defined by the power series. Then f is $\mathcal{C}^\infty$ on R°, and the partial derivatives of all orders of f are obtained by term-by-term partial differentiation, i.e. for any $m_1, \dots, m_n \ge 0$ the unordered sum

$$\sum_{\omega\in\Omega} a_\omega \frac{\partial^{m_1+\cdots+m_n}}{\partial x_1^{m_1}\cdots\partial x_n^{m_n}}\left((\boldsymbol{x}-\boldsymbol{c})^{\phi(\omega)}\right)$$

converges u.c. to $\dfrac{\partial^{m_1+\cdots+m_n} f}{\partial x_1^{m_1}\cdots\partial x_n^{m_n}}$ on R°.

Proof: Every point of R° is contained in the interior of a closed polydisc centered at $(c_1, \dots, c_n)$ contained in R°. Apply VIII.8.1.12. repeatedly, shrinking the polydisk slightly each time. 👍

VIII.8.1.14. We extend the multi-index notation: if $\alpha = (m_1, \dots, m_n) \in \mathbb{N}_0^n$, write

$$|\alpha| = m_1 + \cdots + m_n$$

$$\alpha! = m_1! m_2! \cdots m_n!$$

$$\frac{\partial^\alpha}{\partial x_\alpha} = \frac{\partial^{|\alpha|}}{\partial x_\alpha} = \frac{\partial^{m_1+\cdots+m_n}}{\partial x_1^{m_1}\cdots\partial x_n^{m_n}} .$$

We can then rephrase VIII.8.1.13.: under the hypotheses, for every α the series

$$\sum_{\omega\in\Omega} a_\omega \frac{\partial^\alpha}{\partial x_\alpha}\left((\boldsymbol{x}-\boldsymbol{c})^{\phi(\omega)}\right)$$

converges u.c. on R° to $\dfrac{\partial^\alpha f}{\partial x_\alpha}$.

VIII.8.1.15. Equality of mixed partials (VIII.2.2.2.) for functions defined by convergent power series is an immediate corollary of VIII.8.1.13., giving a simpler alternate proof in this case.

VIII.8.1.16. Note that when $\mathbb{F} = \mathbb{C}$, these partial derivatives are interpreted in the complex sense: fix the remaining variables and take the derivative as in XII.1.1.2.. Thus a complex-valued function defined on a polydisk by a multivariable power series has partial derivatives of all orders in the complex sense, which are also given by multivariable power series obtained by term-by-term differentiation.

VIII.8.2. Analytic Functions of Several Variables

In this section, we describe some of the basics of the theory of real and complex analytic functions of several variables. Some aspects of the theory are virtually identical to the one-variable case, but there are also significant differences.

VIII.8.2.1. DEFINITION. Let U be an open set in $\mathbb{F}^n$. A function $f : U \to \mathbb{F}$ is *analytic* if, for every $\boldsymbol{c} \in U$, f is represented in a neighborhood of $\boldsymbol{c}$ by a multivariable power series centered at $\boldsymbol{c}$. A function $\boldsymbol{f} = (f_1, \ldots, f_m) : U \to \mathbb{F}^m$ is analytic if each f_k is analytic.

VIII.8.2.2. As in the one-variable case, this definition is a local one: a function f on an open set U is analytic on U if and only if it is analytic on a neighborhood of $\boldsymbol{c}$ for each $\boldsymbol{c} \in U$. In particular, if $U = \cup_j U_j$ is a union of open sets, then f is analytic on U if and only if it is analytic on each U_j.

An immediate corollary of VIII.8.1.13. is:

VIII.8.2.3. COROLLARY. Let U be an open set in $\mathbb{F}^n$, and f analytic on U. Then f is $\mathcal{C}^\infty$ on U, and for any multi-index α, $\frac{\partial^\alpha f}{\partial x_\alpha}$ is analytic on U.

VIII.8.2.4. An analytic function f is "jointly analytic" in its variables. If all but one variable is fixed, it is analytic in the remaining variable in the usual sense of (), since the multivariable power series for f around any point has a drastic revision obtained by collecting together all terms of like power in the remaining variable, which will converge in a neighborhood of the point in $\mathbb{F}$. (More generally, if some of the variables are fixed, the function is analytic in the remaining variables.) Thus an analytic function is "separately analytic" in its variables. But a separately real analytic function is not (jointly) analytic in general. For example,

$$f(x,y) = \begin{cases} \frac{xy}{x^2+y^2} & \text{if} \quad (x,y) \neq (0,0) \\ 0 & \text{if} \quad (x,y) = (0,0) \end{cases}$$

is separately analytic, but not even continuous at $(0,0)$ (). This function is analytic on $\mathbb{R}^2 \setminus \{(0,0)\}$. The function

$$g(x,y) = \begin{cases} xye^{-1/(x^2+y^2)} & \text{if} \quad (x,y) \neq (0,0) \\ 0 & \text{if} \quad (x,y) = (0,0) \end{cases}$$

is separately analytic, $\mathcal{C}^\infty$ on $\mathbb{R}^2$, and analytic on $\mathbb{R}^2 \setminus \{(0,0)\}$, but not analytic on any neighborhood of $(0,0)$.

The situation is completely different in the complex case: a complex-valued function on an open subset of $\mathbb{C}^n$ which is separately analytic is in fact analytic (XII.10.1.5.).

As in the one-variable case, the definition of analytic function is hard to check, since the condition of the definition must be verified for every $\boldsymbol{c} \in U$. Thus the next result is crucial in obtaining a useful theory:

VIII.8.2.5. THEOREM. Let U be an open set in $\mathbb{F}^n$. Then any multivariable power series which converges on U defines an analytic function on U.

PROOF: Let

$$\sum_{\omega\in\Omega} a_\omega(\boldsymbol{x}-\boldsymbol{c})^{\phi(\omega)}$$

be a multivariable power series which converges on U. We may assume that U is the interior of the set on which the series converges, which is a union of polydisks centered at $\boldsymbol{c}$ (since this is an open set containing U), and in particular that $\boldsymbol{c}\in U$. 👍

Chapter IX

Riemann Integration

There are four general approaches to integration: the Riemann integral and the "modern" approaches of Lebesgue, Daniell, and Denjoy-Perron-Henstock-Kurzweil. In this chapter, we discuss the first; the others are treated in Chapter XVIII. The idea is to associate to a real- (or complex)-valued function f defined on a set X, and a subset A of X, a number $\mathcal{I}_A(f)$, usually denoted by some version of the notation $\int_A f$, reflecting the "contribution" of the function f on the set A.

IX.1. Introduction

Integration is a basic component of real analysis. The goal of integration is to systematically assign to a real-valued function f on a set X, and a subset A of X, a number $\mathcal{I}_A(f)$ called the *integral of f over A* (the notation $\int_A f$, or some variation, is usually used; the symbol $\int$ is called the *integral sign*), which is usually thought of as a "normalized sum" of the values of f on the points of the subset A. This number has various interpretations in applied situations as total distance (regarding f as giving instantaneous velocity), total mass (regarding f as giving density), etc. Integration in analysis is thus almost always (and always in this book) a generalization or analog of what in elementary calculus is called the "definite integral." (We will also have occasion to consider analogs of the "indefinite integral" of calculus, but these will have different names and will not be called integrals.)

IX.1.1. Origin of Integration Theories

IX.1.1.1. All modern theories of integration are in a sense outgrowths of the so-called Riemann integral (actually developed first by Cauchy for continuous functions and generalized by Riemann to also handle moderately discontinuous functions), the type of integration treated in elementary calculus. The Riemann integral was the first reasonably satisfactory theory of integration, and is still by far the theory most widely used in applications.

IX.1.1.2. For theoretical purposes, Riemann integration has two serious inadequacies:

1. The class of Riemann integrable functions is too small. For a function to be Riemann integrable on an interval, it must be bounded and "almost continuous" (see () for a precise statement). It is particularly useful to be able to integrate certain unbounded functions. This is reasonably, but not entirely, satisfactorily

achieved by using various notions of improper Riemann integrals and principal values. It is also important to be able to integrate over unbounded intervals, which can be done through other types of improper integrals, although not in an entirely satisfactory way. At least for theoretical purposes, it is also important to be able to integrate functions which are too discontinuous to be Riemann integrable, and to be able to integrate functions over subsets of the real numbers more general than intervals or finite unions of intervals (although the practical value of this type of integration is sometimes somewhat overemphasized as an inadequacy of Riemann integration).

2. It is crucial in many settings to have limit and approximation theorems, i.e. to know that under reasonable conditions, if $f_n \to f$ in some sense, we have $\mathcal{I}_A(f_n) \to \mathcal{I}_A(f)$. It is quite difficult to establish good theorems of this sort for Riemann integration which are applicable even if we know that the limit function is Riemann integrable (which is often not the case due to the limitations described above). It turns out that to get reasonable convergence theorems, more general integration theories are needed.

IX.1.1.3. Another limitation of Riemann integration is that it only (directly) works on $\mathbb{R}$, or on $\mathbb{R}^n$. It is very important to have integration theories which work on more general spaces, and it turns out that modern approaches give this flexibility with essentially no additional work.

IX.1.1.4. There are three principal modern approaches to integration, each with many variations. We first discuss the basics of Riemann integration in a form allowing the various generalizations to be made naturally.

IX.1.1.5. The Riemann integral has gotten somewhat of a bad rap: it is fashionable in some circles to downplay or even ignore Riemann integration in favor of more modern integration theories. There are certainly inadequacies in Riemann integration which must be addressed, and there will be no suggestion here that modern integration theories are not important. However, Riemann integration is far from obsolete! Here are some senses in which Riemann integration (and even pre-Riemann Cauchy integration) is still central:

(i) Although there are versions of the Fundamental Theorem of Calculus for more general types of integration, it is still really a theorem about Riemann (or Cauchy) integration, and most applications are to computing Riemann integrals.

(ii) All numerical integration is based on the Riemann integral.

(iii) Integrals in vector calculus, complex analysis, and differential geometry (e.g. line and surface integrals, contour integrals, integrals of differential forms) are Riemann integrals.

(iv) Many, if not most, integrals arising in physics and engineering are Riemann integrals.

(v) It is often pointed out that one rarely if ever actually computes a Lebesgue (or other modern) integral; the integral is approximated by a Riemann integral which is computed either by the Fundamental Theorem of Calculus or by numerical integration techniques.

Thus it is worthwhile to give a full treatment of the Riemann integral as well as more modern theories.

IX.1.2. The Cauchy Integral for Continuous Functions

IX.1.2.1. Actually, we will begin with a sort of "pre-Riemann integral," due to CAUCHY, in which there seems to be only one natural approach, which is fairly simple: the case of integrating a continuous function on a closed bounded interval. All theories of integration essentially reduce to the same thing in this case. Actually this case, although quite special, is by far the most important one in a practical sense – most integrals encountered in practice are of this form, or slight variations of it which can be treated on an *ad hoc* basis. In fact, although the integral in this form was not given a rigorous approach until CAUCHY'S work, it had been used by mathematicians dating back at least to ARCHIMEDES in ancient Greece; the fundamental and brilliant insight of both NEWTON and LEIBNIZ which got the whole subject of calculus off the ground was the inverse relation between integration and differentiation.

IX.1.2.2. The integral is intended to denote the "area" of the region under the graph and above the x-axis, between the lines $x = a$ and $x = b$ (Figure IX.1). To obtain an integral with good properties, the parts of the region below the axis, where the function is negative, must be interpreted as "negative area"; such regions are shown in tan. The integral thus denotes a "signed area."

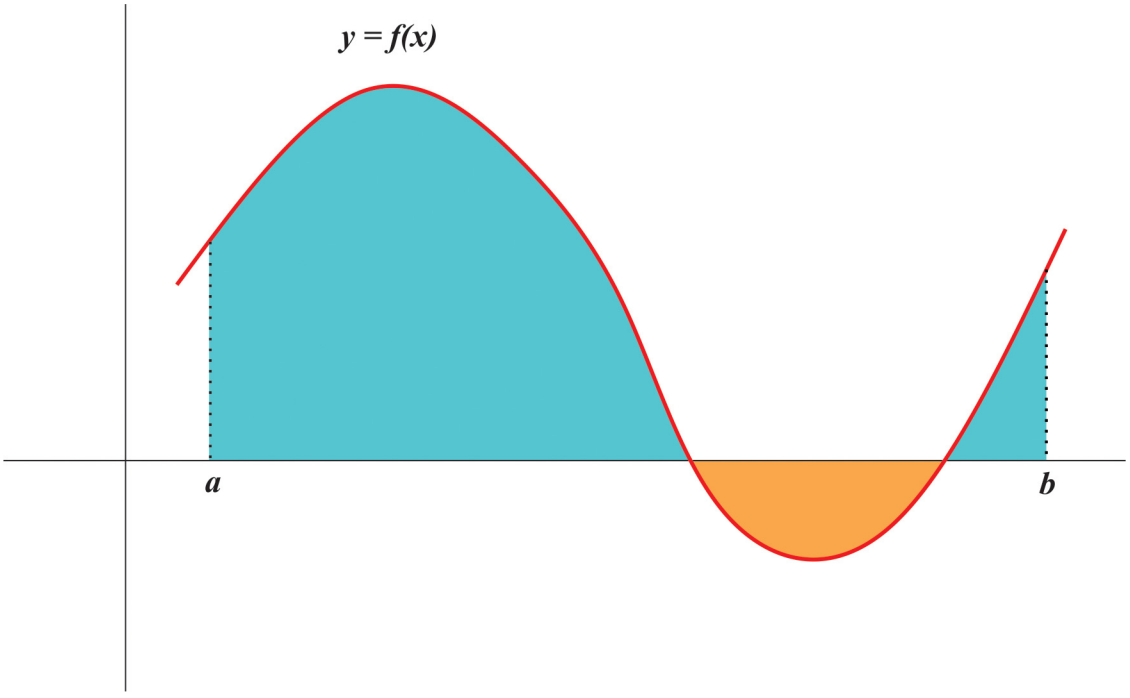

Figure IX.1: The Integral of a Continuous Function

IX.1.2.3. Suppose f is a continuous real-valued function on a closed bounded interval $J = [a, b]$. Write $\ell(J) = b - a$ for the length of J. We want to define the integral $\mathcal{I}_J(f)$ of f over J. There are three fundamental properties the integral ought to have:

(i) If $f \le g$ on J, then $\mathcal{I}_J(f) \le \mathcal{I}_J(g)$.

(ii) If f takes the constant value c on J, then $\mathcal{I}_J(f) = c \cdot \ell(J) = c(b-a)$.

(iii) If J is partitioned into nonoverlapping intervals $J_1, \dots, J_n$ ("nonoverlapping" means the subintervals only have endpoints in common), then

$$\mathcal{I}_J(f) = \sum_{k=1}^{n} \mathcal{I}_{J_k}(f) \ .$$

These three properties are enough to completely characterize the integral in this case, and to suggest an explicit method of defining and calculating its value.

IX.1.2.4. The continuity of f means that if $\mathcal{P} = \{J_1, \dots, J_n\}$ is a sufficiently fine partition of J into nonoverlapping subintervals, then f is almost constant on each J_k; thus, if t_k is any number (*tag*) in J_k, we must have

$$\mathcal{I}_J(f) \approx \sum_{k=1}^{n} f(t_k)\ell(J_k)$$

(such a sum is called a *Riemann sum* for $\mathcal{I}_J(f)$, although they were introduced by Cauchy, and Riemann did not even make extensive use of them) with the approximation becoming better and better as the partition becomes finer no matter how the t_k are chosen (within J_k). See Figure IX.2.

IX.1.2.5. This can be described more carefully in a slightly different way (this was in effect Riemann's general approach, although he phrased things somewhat differently; this formulation was explicitly introduced by Darboux after Riemann's death): if m_k and M_k are the infimum and supremum of f on J_k (in this case actually the minimum and maximum on J_k respectively), and $\omega(f, J_k) = M_k - m_k$ is the *oscillation* of f over J_k, then we define the *upper and lower estimates* $\overline{\mathcal{I}}(f, \mathcal{P})$ and $\underline{\mathcal{I}}(f, \mathcal{P})$ by

$$\overline{\mathcal{I}}(f, \mathcal{P}) = \sum_{k=1}^{n} M_k \ell(J_k) \quad \text{and} \quad \underline{\mathcal{I}}(f, \mathcal{P}) = \sum_{k=1}^{n} m_k \ell(J_k)$$

and we have that

$$\underline{\mathcal{I}}(f, \mathcal{P}) \le \mathcal{I}_J(f) \le \overline{\mathcal{I}}(f, \mathcal{P})$$

and

$$\overline{\mathcal{I}}(f, \mathcal{P}) - \underline{\mathcal{I}}(f, \mathcal{P}) = \sum_{k=1}^{n} \omega(f, J_k)\ell(J_k) \ .$$

(See Figures IX.3 and IX.4.) As the partition $\mathcal{P}$ becomes finer, we have that the $\underline{\mathcal{I}}(f, \mathcal{P})$ increase, the $\overline{\mathcal{I}}(f, \mathcal{P})$ decrease, and the $\omega(f, J_k)$ approach 0, so the upper and lower estimates approach the same limiting value (there are of course some technicalities to check here), which is the only reasonable value for $\mathcal{I}_J(f)$. We also have

$$\underline{\mathcal{I}}(f, \mathcal{P}) \le \sum_{k=1}^{n} f(x_k)\ell(J_k) \le \overline{\mathcal{I}}(f, \mathcal{P})$$

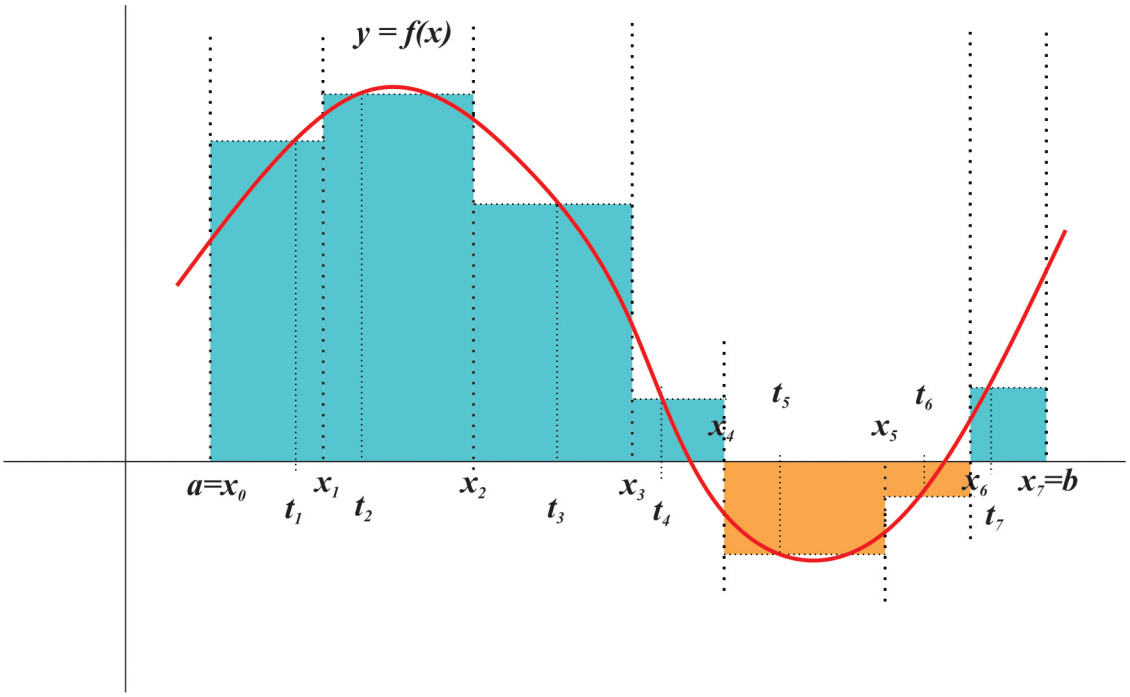

Figure IX.2: The Riemann Sum for a Tagged Partition

for any Riemann sum, so we have

$$\left|\mathcal{I}_J(f) - \sum_{k=1}^{n} f(x_k)\ell(J_k)\right| \leq \overline{\mathcal{I}}(f,\mathcal{P}) - \underline{\mathcal{I}}(f,\mathcal{P}) = \sum_{k=1}^{n} \omega(f,J_k)\ell(J_k)$$

for any Riemann sum, and thus the Riemann sums converge to $\mathcal{I}_J(f)$ as the partitions become arbitrarily fine (in the sense that the *mesh* of the partition, defined as the maximum of the lengths of the J_k, goes to 0).

IX.1.2.6. Before the rigor introduced in the nineteenth century, and informally still to this day, instead of an actual (finite) partition of J one would think of "partitioning" the interval J into an infinite number of subintervals of "infinitesimal" length dx (Figure IX.5). Then on the infinitesimal interval containing the number x, the function value would differ only infinitesimally from the number $f(x)$, so the integral over this infinitesimal subinterval would be $f(x) \cdot dx$ (up to a "second-order infinitesimal"). The total integral would then be the "sum" of these. This approach was taken by Leibniz, who developed the standard notation used for the integral even today: he denoted this "sum" $\mathbf{S}$, and wrote

$$\mathcal{I}_J(f) = \mathbf{S}_a^b f(x)\,dx\ .$$

He actually used a "long S" and almost immediately elongated it further to the familiar integral sign $\int$. (Summation notation using $\sum$ was introduced by Euler, and did not exist in Leibniz's time.)

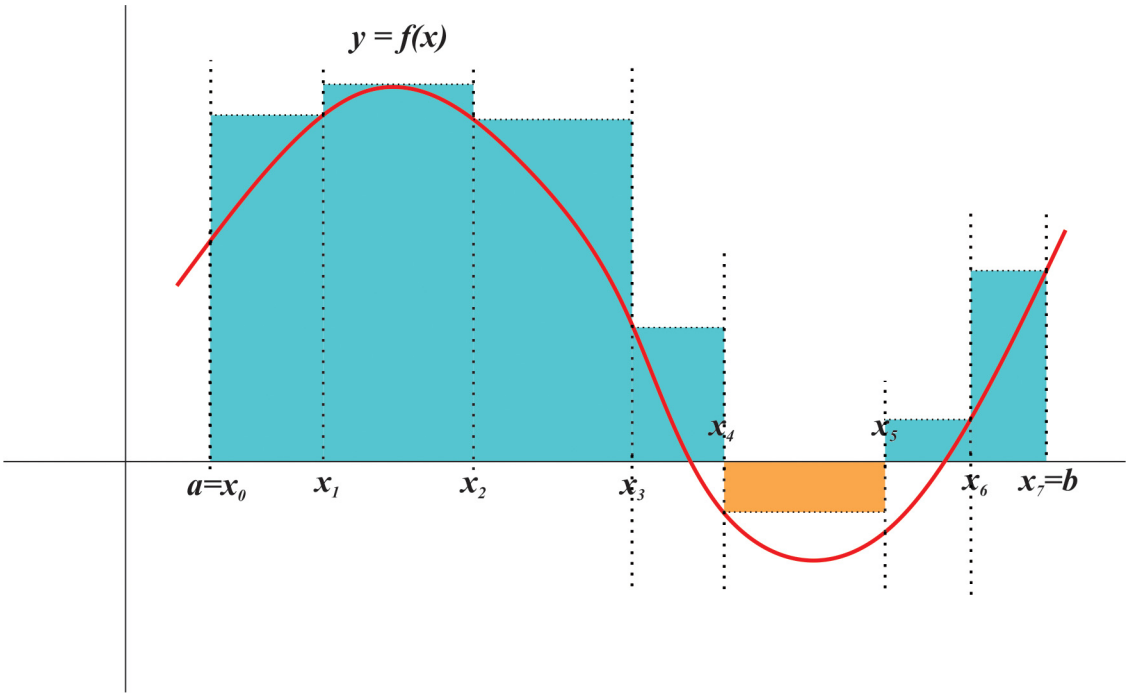

Figure IX.3: The Upper Estimate $\overline{\mathcal{I}}(f, \mathcal{P})$ for a Partition $\mathcal{P}$

IX.1.3. The Riemann Integral

IX.1.3.1. CAUCHY'S approach works in somewhat greater generality, as developed by RIEMANN. In order to have the upper and lower estimates converge together, we do not actually have to have the oscillations $\omega(f, J_k)$ approach zero as the partitions become fine; we need only that the sum ("weighted local oscillation")

$$\sum_{k=1}^{n} \omega(f, J_k)\ell(J_k)$$

becomes small, which only requires that the oscillation $\omega(f, J_k)$ be small for "most" k. See Figures IX.6 and IX.7. If f has isolated discontinuities, the weighted local oscillation is still small for fine partitions (Figure IX.8).

IX.1.3.2. Thus, if f is bounded, and continuous except at finitely many points (or, more generally, except on a set of Lebesgue measure 0), the Cauchy approach works perfectly well, either via the weighted local oscillation idea or via Riemann sums. (If f is unbounded, the weighted local oscillation approach does not make sense, and it is also easily seen that the Riemann sum approach cannot work either, at least the way we have done it using the mesh of the partitions.) The functions for which the approach works are called *Riemann-integrable functions* on J; it turns out that they are precisely the bounded functions which are continuous "almost everywhere" (except on a set of Lebesgue measure 0).

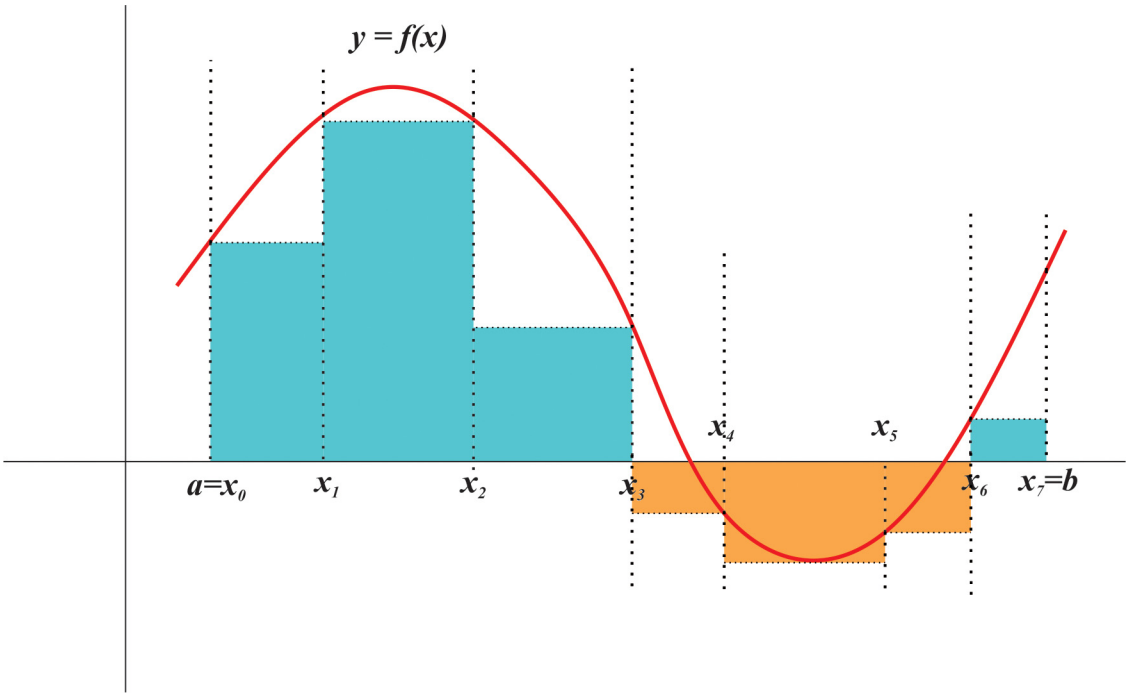

Figure IX.4: The Lower Estimate $\underline{\mathcal{I}}(f, \mathcal{P})$ for a Partition $\mathcal{P}$

IX.1.4. The Lebesgue Approach

IX.1.4.1. The first and most widely used modern approach began with LEBESGUE'S work in the early twentieth century. LEBESGUE'S idea was to consider more general partitions of the interval J on which the integral is to be defined, where the subsets A_k are not necessarily subintervals but can be more complicated, but where as in the Cauchy approach the function is almost constant on each A_k. The integral $\mathcal{I}_J(f)$ is then approximated by a sum over the sets in the partition, where the term corresponding to A_k is the almost constant value of f on A_k times the "size" of A_k.

IX.1.4.2. It is easy to find such sets A_k for any bounded function. (For motivational purposes, we will consider only bounded functions, although the actual development of the theory outlined below works equally well for unbounded functions and even extended real-valued functions.) In fact, it is not important that the domain of the function be an interval or even a set of real numbers; we can consider a bounded function f from any set X to $\mathbb{R}$ (bounded just means the range is a bounded subset of $\mathbb{R}$). Suppose $|f(x)| \leq M$ for all $x \in X$. Then, for any natural number n, we set

$$A_k = \left\{ x \in X : \frac{k-1}{n} < f(x) \leq \frac{k}{n} \right\}$$

for integers k with $|k| \leq nM$. This is a finite partition of X into pairwise disjoint subsets, and $\omega(f, A_k) \leq \frac{1}{n}$.

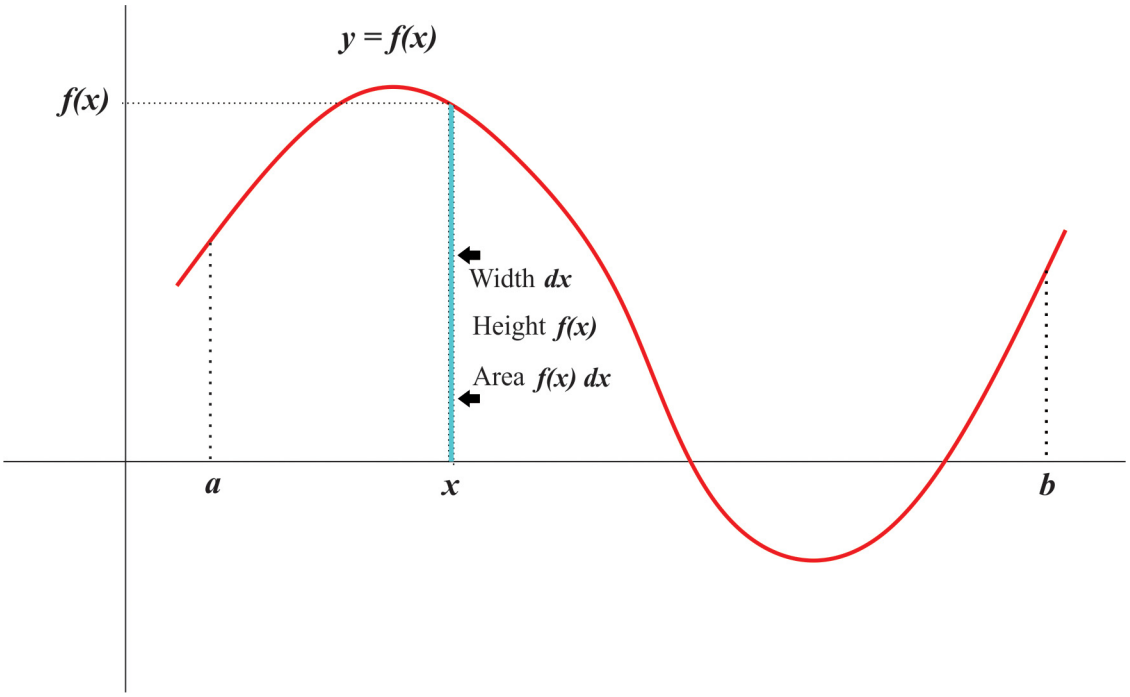

Figure IX.5: Partition into Rectangles of "Infinitesimal" Width

IX.1.4.3. We need one more ingredient, though: a "size" for each A_k. The reasonable way to do this is to require the A_k to be measurable sets for a measure μ on X; then $\mu(A_k)$ can be taken to be the "size" of A_k, and we get an approximation

$$\mathcal{I}_X(f,\mu) \approx \sum_k \frac{k}{n}\mu(A_k)$$

(the notation reflects the fact that the integral is with respect to the measure μ) which should become exact in the limit as $n \to \infty$. The restriction on f is then that the sets A_k must be μ-measurable for any choices of n and k; such an f is called a *μ-measurable function*. In most applications, including Lebesgue measure on $\mathbb{R}$, μ-measurability is a very mild restriction on f and is satisfied by any function which can be explicitly described. (There is an additional technicality: the sum may not be well defined if $\mu(A_k)$ is infinite for both positive and negative k's. This technicality forces a slightly different approach to the actual integral.)

IX.1.4.4. So in this approach, one begins with a measure space (LEBESGUE at first only considered Lebesgue measure on $\mathbb{R}$, but the general theory is nearly identical). As mentioned, for technical reasons, we will not proceed exactly as above, but the motivational description is an accurate reflection of the essence of the process.

IX.1.4.5. If μ is a measure on a set X, we build up the integral corresponding to μ in stages. We first consider indicator functions (often called characteristic functions, but this term also has other uses in

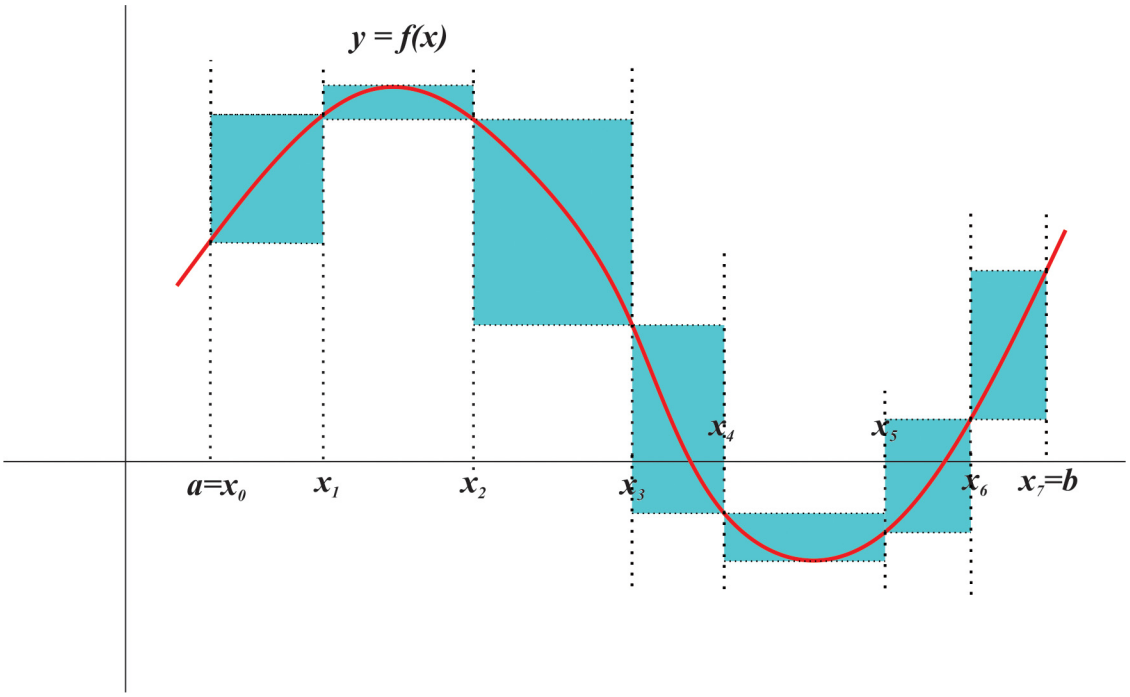

Figure IX.6: The Weighted Local Oscillation for a Partition

analysis). If $A \subseteq X$, let χ_A denote the function from X to $\mathbb{R}$ defined by

$$\chi_A(x) = \begin{cases} 1 & \text{if} \quad x \in A \\ 0 & \text{if} \quad x \notin A \end{cases} .$$

This χ_A is called the *indicator function* of the set A. It is reasonable to define the integral of χ_A to be the measure $\mu(A)$ of the set A (provided, of course, that A is a μ-measurable set, or equivalently that χ_A is a μ-measurable function).

IX.1.4.6. Next, we consider *simple functions*, finite nonnegative linear combinations of indicator functions of μ-measurable sets. Such a function has a representation

$$s = \sum_{k=1}^{n} a_k \chi_{A_k}$$

where the A_k are μ-measurable sets and the a_k are nonnegative real numbers. These are precisely the nonnegative μ-measurable functions taking only finitely many values. It then makes sense to define the integral by

$$\mathcal{I}_X(s, \mu) = \sum_{k=1}^{n} a_k \mu(A_k)$$

and indeed this is the only possible definition to obtain a linear integral. (There is a technicality here: it must be shown that this number is well defined by s, since the representation $s = \sum a_k \chi_{A_k}$ is not unique.)

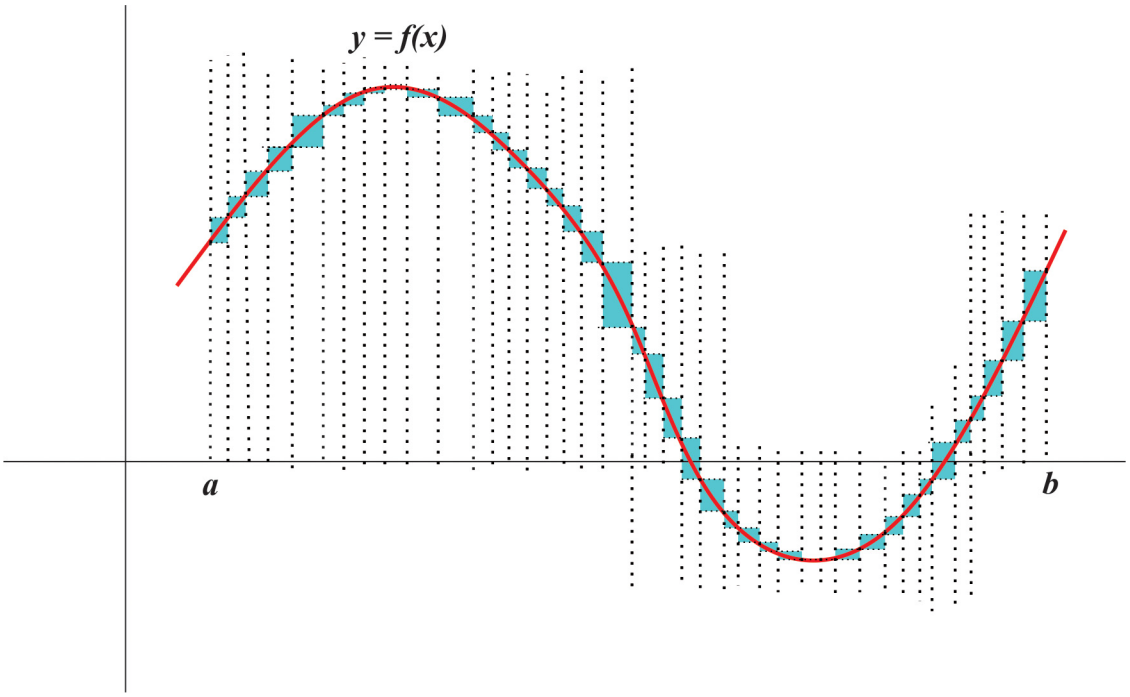

Figure IX.7: The Weighted Local Oscillation for a Finer Partition

IX.1.4.7. If f is a nonnegative μ-measurable function, we then define

$$\mathcal{I}_X(f,\mu) = \sup\{\mathcal{I}_X(s,\mu) : s \text{ simple}, 0 \le s \le f\} .$$

This definition even makes sense for extended real-valued functions. Even if f is real-valued, $\mathcal{I}_X(f,\mu)$ can equal $+\infty$. We say a nonnegative function f is μ-*integrable* if f is μ-measurable and $\mathcal{I}_X(f,\mu) < \infty$.

IX.1.4.8. Finally, if f is a real-valued μ-measurable function, and there are nonnegative μ-integrable functions g and h with $f = g - h$, we say f is μ-integrable and set

$$\mathcal{I}_X(f,\mu) = \mathcal{I}_X(g,\mu) - \mathcal{I}_X(h,\mu)$$

(it must be shown that this is well defined by f independent of the choices of g and h).

IX.1.4.9. We can extend the notion of integration over the whole measure space X to integration over any μ-measurable set A by setting

$$\mathcal{I}_A(f,\mu) = \mathcal{I}_X(f\chi_A,\mu)$$

where $f\chi_A$ is the function which is equal to f on A and is identically zero outside A; this definition even makes sense if f is only defined on the subset A.

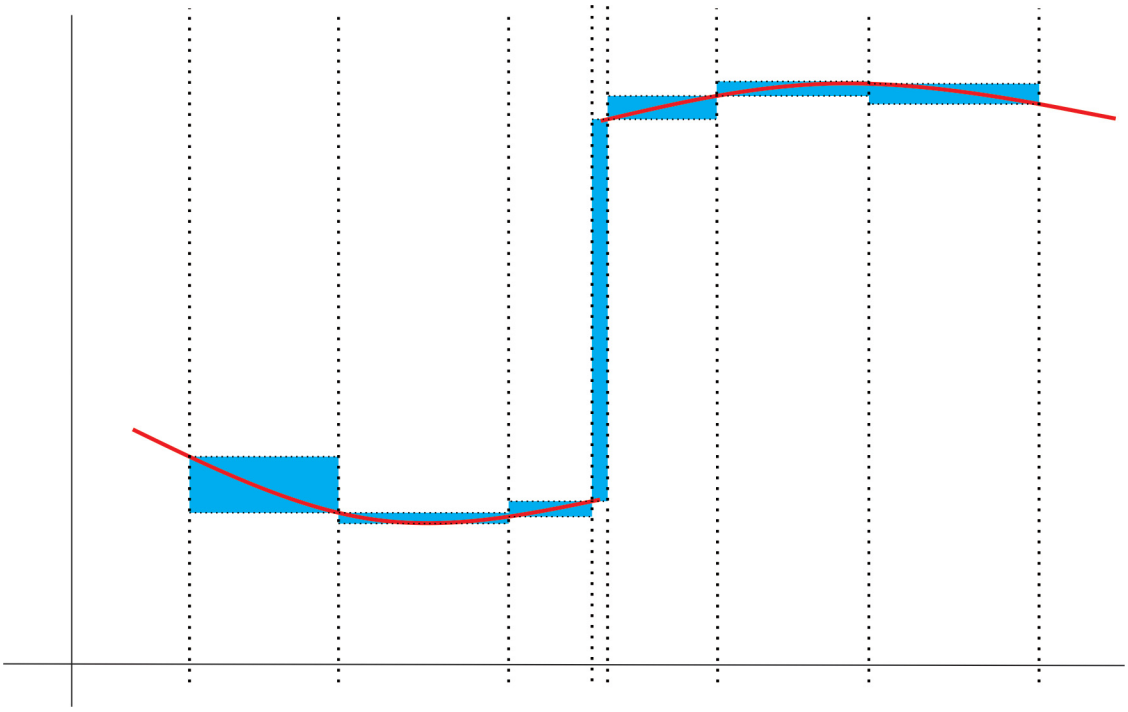

Figure IX.8: The Weighted Local Oscillation Around an Isolated Discontinuity

IX.1.4.10. It turns out that this integral $\mathcal{I}_X$ has all the nice properties one would expect, and almost all one might hope for, in an integral. In the case where μ is Lebesgue measure λ on $\mathbb{R}$, this integral extends the Riemann integral in the sense that any Riemann-integrable function f on a closed bounded interval J is Lebesgue-integrable (λ-integrable) on J and the the Riemann integral $\mathcal{I}_J(f)$ of f over J agrees with the Lebesgue integral $\mathcal{I}_J(f, \lambda)$ of f over J. But many more functions are Lebesgue integrable than are Riemann-integrable, including many unbounded functions.

IX.1.4.11. The Lebesgue approach to integration on a general measure space is also very important. For example, if $(\Omega, \mathcal{E}, \mathbf{P})$ is a probability space, a $\mathbf{P}$-measurable real-valued function X on Ω is called a *random variable*, and if X is nonnegative or $\mathbf{P}$-integrable, its integral is called the *expected value* of the random variable X.

IX.1.4.12. There are a couple of drawbacks to the Lebesgue approach, however. In order to define the Lebesgue integral on $\mathbb{R}$, Lebesgue measure must first be constructed, which is a moderately complicated task. The Lebesgue integral on a general measure space is somewhat simpler, but preliminaries are not completely avoided: besides the simple basics of the theory of measure spaces from (), one needs to know about measurable functions, where the details () are somewhat more challenging.

IX.1.4.13. The other drawback of Lebesgue integration from a certain point of view is that it is an "absolute" theory of integration: if f is measurable, then f is integrable if and only if $|f|$ is integrable.

Roughly, this means that both the positive and negative parts of f are not too large. There are situations where the improper Riemann integral of a function f taking both positive and negative values is defined, yet f is not Lebesgue integrable. On the other hand, the "absolute" property is what makes Lebesgue integration well-behaved; it is a sort of analog of absolute convergence of infinite series, which forces all sorts of nice behavior which does not carry over to conditionally convergent series. (The connection between integration and infinite series is much more than just an analog; the theory of infinite series can be interpreted as a special case of the theory of measure and integration – see ().)

IX.1.5. The Daniell Approach

IX.1.5.1. Either measure or integration can be regarded as the primitive notion, and the other one can be derived from it. We have seen how integration can be derived from measure via the Lebesgue approach. In Euclidean space, there is a more direct approach simply consisting of increasing dimension by one: if f is a nonnegative real-valued function on a subset E of $\mathbb{R}^n$, the integral $\int_E f\, d\lambda^{(n)}$ is simply the $(n+1)$-dimensional Lebesgue measure of the "subgraph"

$$\{(x_1, \ldots, x_n, y) : (x_1, \ldots, x_n) \in E, 0 \leq y \leq f(x_1, \ldots, x_n)\} \subseteq \mathbb{R}^{n+1}$$

(in particular, the integral of a nonnegative measurable function over a subset of $\mathbb{R}$ is just the measure of a corresponding subset of the plane). Conversely, measure can be recovered from integration: the measure of a subset E of $\mathbb{R}^n$ (or of a general measure space) is just the integral of the indicator function χ_E over $\mathbb{R}^n$.

IX.1.5.2. Taking integration as the primitive concept and defining measure from it is the approach taken by Daniell. In this approach, we begin with a sufficiently large supply of real-valued functions on a set X for which there is an "integral" defined having reasonable linearity, positivity, and continuity properties. The actual mechanism by which the integral is defined is unimportant; it can even just be an abstract real-valued functional defined on the set of functions. If necessary, the integral is then extended in a systematic way to a larger class of real-valued functions on X including indicator functions of enough subsets of X. A measure μ on X can then be defined by setting $\mu(E)$ for a subset E of X to be the integral of χ_E. A good motivating example (which was Daniell's own starting point) is to take X to be an interval $[a, b]$ in $\mathbb{R}$, the functions to be the real-valued continuous functions on $[a, b]$, and the integral the Cauchy integral. The measure obtained by the Daniell process is then just Lebesgue measure on $[a, b]$. This turns out to actually be a rather painless way to define Lebesgue measure.

IX.1.5.3. An important generalization of the motivating example is the *Riesz Representation Theorem*: if X is a compact Hausdorff space and ϕ is a positive linear functional on the set $C(X)$ of real-valued (or complex-valued) continuous functions on X, i.e. an assignment of a number $\phi(f)$ to each continuous function f with the properties that

(i) $\phi(f + g) = \phi(f) + \phi(g)$ for all $f, g \in C(X)$.

(ii) $\phi(\alpha f) = \alpha\phi(f)$ for every $f \in C(X)$ and every scalar α.

(iii) $\phi(f) \geq 0$ if f takes only nonnegative real values.

then there is a finite measure μ on the σ-algebra of subsets of X generated by the open sets (the *Borel sets*) such that $\phi(f) = \int_X f\, d\mu$ for all f. The measure μ is constructed by the Daniell process of extending the integral (linear functional) to a larger class of functions including indicator functions of Borel sets.

IX.1.6. Direct Generalizations of Riemann Integration

IX.1.6.1. A third approach to generalizing Riemann integration is to directly modify the definition of the Riemann integral to obtain a more-inclusive integral on $\mathbb{R}$. This approach was notably used by DENJOY and PERRON, and culminated relatively recently (1957) in the so-called HENSTOCK-KURZWEIL (H-K) integral, which agrees with the integrals of DENJOY and PERRON but has a much better definition.

IX.1.6.2. The H-K integral is easier to define than the Lebesgue integral (Lebesgue measure is not needed), and almost as easy as the Riemann integral; and it remedies both shortcomings of the Riemann integral. In fact, it turns out to be almost the same as the Lebesgue integral, and even slightly more general: a nonnegative function is H-K integrable if and only if it is Lebesgue integrable, but a function taking both positive and negative values can be H-K integrable but not Lebesgue integrable if its positive and negative parts are too big but "cancel out" in a suitable way.

IX.1.6.3. The H-K integral is defined using the Riemann sum approach. The main difference from Riemann integration is a much more delicate notion of the "fineness" of a partition into subintervals than just its mesh. We will not give a precise description here (see ()), but the fineness of a partition depends not only on the intervals J_k but also on which tags $t_k \in J_k$ are chosen. It is then a somewhat subtle matter to show that arbitrarily fine partitions exist. Once this has been done, the rest of the development formally follows the theory of Riemann integration very closely. But many more functions turn out to be H-K integrable.

IX.1.6.4. The H-K integral is nice to work with in many ways. For example, integrals which would naturally be called "improper H-K integrals" turn out to be honest H-K integrals. One of the nicest properties of H-K integration is that the following version of the Fundamental Theorem of Calculus, which fails spectacularly for Riemann integration and even fails for Lebesgue integration, holds for H-K integration:

IX.1.6.5. THEOREM. Let f be a differentiable function on a closed bounded interval $[a, b]$. Then f' is H-K integrable on $[a, b]$ (and hence on any subinterval), and for every $x \in [a, b]$ we have

$$f(x) = f(a) + \int_a^x f'(t)\, dt$$

where the integral is the H-K integral of f' over $[a, x]$.

IX.1.6.6. On the other hand, the H-K integral is strictly an extension of Riemann integration on $\mathbb{R}$, and does not generalize the way Lebesgue integration does to other measure spaces. (There is a version of H-K integration on $\mathbb{R}^n$, which is not nearly as satisfactory as on $\mathbb{R}$, but nothing more general.)

IX.1.7. Oriented and Unoriented Integration

IX.1.7.1. There are two general kinds of integration: oriented integration and unoriented integration (they are not very different, differing only in sign, but the sign is often crucial in applications). The two types both appear in Riemann integration: if I is a closed bounded interval $[a, b]$, with $a < b$, then the integral

$$\int_a^b f(x)\,dx$$

of a function f from I to $\mathbb{R}$ can be regarded either as an integral *over* I ("unoriented") or as an integral *from* a *to* b ("oriented"). The expression

$$\int_b^a f(x)\,dx$$

appears to be rather artificial and intrinsically meaningless, and the definition

$$\int_b^a f(x)\,dx = -\int_a^b f(x)\,dx$$

is seemingly arbitrary, although it is useful in a number of natural contexts, for example making the formula

$$\int_a^c f(x)\,dx = \int_a^b f(x)\,dx + \int_b^c f(x)\,dx$$

valid for any a, b, c no matter what their order (so long as they are all contained in some interval on which f is integrable). Another important use of this convention is that if f is continuous on an interval I and $x_0 \in I$, not necessarily the left endpoint, then the formula

$$F(x) = \int_{x_0}^x f(t)\,dt$$

defines the unique antiderivative of f on I satisfying $F(x_0) = 0$.

IX.1.7.2. Integrating from right to left in $\mathbb{R}$ seems unnatural since there is a natural orientation of $\mathbb{R}$. However, in Euclidean space there is no natural orientation; there are two equally natural possibilities (choice of a coordinate system specifies one of the two orientations; cf. VI.3.1.1., ()). Complicated subsets of $\mathbb{R}^n$ do not have any obvious intrinsic notion of orientation. Thus in the Lebesgue approach to integration it is natural to use unoriented integration. And when the generalization to abstract measure spaces is made, there is no notion of orientation available at all, so unoriented integration is the only possibility. Thus the theory of integration in measure theory is (almost) exclusively unoriented integration.

IX.1.7.3. On the other hand, in vector calculus and analysis such integrals as line and surface integrals are important, and in Complex Analysis contour integrals are basic; such integrals incorporate a natural orientation, and the orientation is crucial in many results. In fact, any result relating integration and differentiation along the lines of the Fundamental Theorem of Calculus, e.g. the various versions of Stokes' Theorem, necessarily involves oriented integration, since differentiation itself requires orientation (this is obscured for functions from $\mathbb{R}$ to $\mathbb{R}$ since $\mathbb{R}$ has a natural orientation, but orientations must be chosen to define the derivative of a real-valued function on a one-dimensional Euclidean space or a function between two one-dimensional Euclidean spaces). It turns out that many deep results in geometry and topology involve oriented integration.

IX.1.7.4. As a general (but not universal) rule, oriented integration is usually done only for smooth objects and is primarily used in geometry, while unoriented integration is done for not necessarily smooth or even continuous objects and is primarily used in analysis. That these statements are not categorically true is partly due to the fact that the boundary between analysis and geometry is quite blurred. We will examine important examples of both types of integration.

IX.2. The Riemann Integral

We first examine the integral commonly called the Riemann integral. This integral was actually developed informally by NEWTON and LEIBNIZ (based in part on ideas going back to ancient Greece), and formally developed by CAUCHY for continuous functions and expanded and put on a "modern" foundation by RIEMANN, with important contributions by others, notably DIRICHLET and DARBOUX. See [**?**] for a detailed historical account of the development of this integral.

It is a curious fact that there is no consensus among mathematicians at the present time about the proper definition of the Riemann integral and of Riemann-integrable functions. Several rather different-looking (but equivalent) definitions can be found in standard references and texts, with other variations given as theorems. While it is pretty easy to see that any two of these definitions give the same *value* for the integral of any function satisfying both definitions, it is not entirely obvious that they apply to exactly the same functions (i.e. give the same class of integrable functions). We will discuss the various definitions and show that they are actually all equivalent. A normal pedagogical approach would be to pick one definition as *the* definition, and prove that the others are equivalent characterizations; but the lack of a standard definition makes the several-definition approach more reasonable in this case.

The multitude of definitions can be somewhat of a conceptual obstacle to focusing on the essential nature of the Riemann integral. However, the situation can, and should, be viewed positively: the fact that Riemann-integrability can be viewed in a number of ways is of theoretical importance and an indication that it is a natural concept. And the large supply of equivalent definitions is very useful in practice: in any situation, we are free to use whichever definition is most convenient to work with at the moment.

The various definitions are all precise versions of the following informal definition:

DEFINITION. (INFORMAL) Let f be a real-valued function on a closed bounded interval $J = [a, b]$. Then f is Riemann-integrable on J if the sums

$$\sum_{k=1}^{n} c_k \ell(J_k)$$

where $\{J_1, \ldots, J_n\}$ is a partition of J into subintervals and c_k is an approximation to the value of f on J_k, converge to a limiting value L as the partition becomes sufficiently fine. The limiting value L is called the *(Riemann) integral of f over J*, denoted

$$\int_a^b f(x)\,dx \ .$$

There are, of course, several aspects of this "definition" which must be made precise to have a real definition. It is not entirely clear how to make some parts of the definition precise, particularly the part about the partition becoming "sufficiently fine." (With the right interpretation of this phrase, the statement actually becomes a definition of the Henstock-Kurzweil integral.)

The integral can be interpreted as the "area" of the region under the graph and above the x-axis, between the lines $x = a$ and $x = b$. Parts of the region below the axis, where the function is negative, are interpreted as "negative area"; such regions are shown in tan. The integral thus denotes a "signed area."

IX.2.1. Partitions, Tags, Riemann and Darboux Sums

In this subsection we make a number of definitions and set up the notation we will use for Riemann integration.

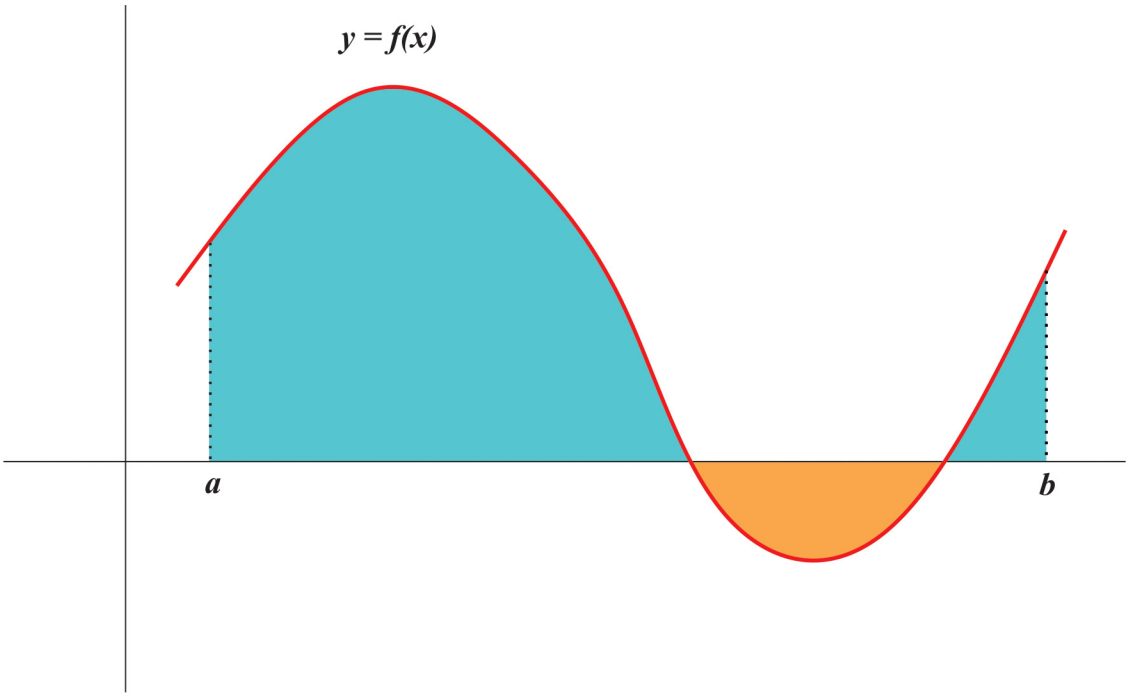

Figure IX.9: The Integral of a Continuous Function

Partitions

IX.2.1.1. DEFINITION. Let $[a, b]$ be a closed bounded interval in $\mathbb{R}$. A *partition* of $[a, b]$ is a division of $[a, b]$ into a finite number of subintervals $\{[x_{k-1}, x_k] : 1 \leq k \leq n\}$ with only endpoints in common. A partition $\mathcal{P}$ is usually described by its set of endpoints $\{x_0, x_1, \ldots, x_n\}$, where $a = x_0 < x_1 < \cdots < x_n = b$. We can also write $\mathcal{P} = \{J_1, \ldots, J_n\}$, where $J_k = [x_{k-1}, x_k]$ is the k'th subinterval. We sometimes write Δx_k for $\ell(J_k) = x_k - x_{k-1}$, the length of the k'th subinterval of the partition.

The *norm* or *mesh* of a partition $\mathcal{P} = \{x_0, x_1, \ldots, x_n\}$ is

$$\|\mathcal{P}\| = \max\{x_k - x_{k-1} : 1 \leq k \leq n\}.$$

If $\mathcal{P} = \{x_0, \ldots, x_n\}$ and $\mathcal{Q} = \{x'_0, \ldots, x'_m\}$ are partitions of $[a, b]$, we say that $\mathcal{Q}$ is *finer* than $\mathcal{P}$, or a *refinement* of $\mathcal{P}$, if $\mathcal{P} \subseteq \mathcal{Q}$, i.e. if each x_k is one of the x'_j, or equivalently if each interval in the partition $\mathcal{Q}$ is a subinterval of one of the intervals in $\mathcal{P}$.

A *tag* in an interval $[c, d]$ is a specified number in $[c, d]$. A *tagged partition* is a partition $\{x_0, x_1, \ldots, x_n\}$ with a specified tag t_i in $[x_{i-1}, x_i]$ for each i. A tagged partition is usually denoted by

$$\dot{\mathcal{P}} = \{x_0, x_1, \ldots, x_n; t_1, \ldots, t_n\} .$$

The norm or mesh of a partition is a measure of how fine the partition is. There is a more sophisticated and flexible notion of fineness of a partition based on gauges ().

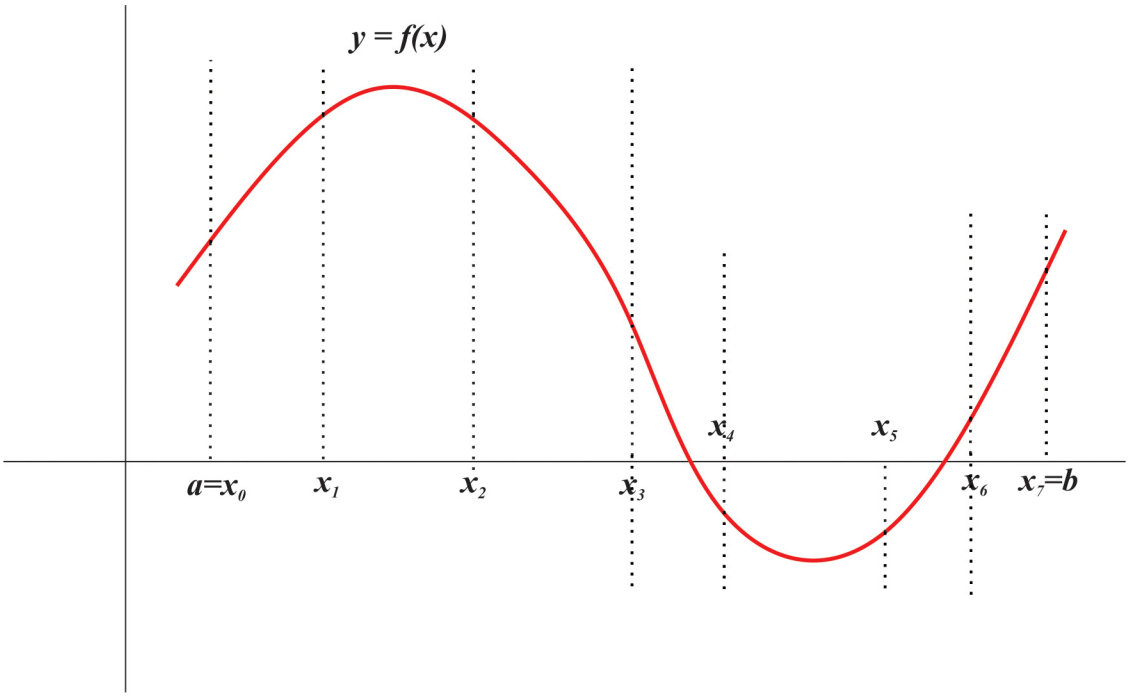

Figure IX.10: A partition with Seven Subintervals

Note that if $\mathcal{P}$ and $\mathcal{Q}$ are two partitions of $[a, b]$, neither is a refinement of the other in general. But:

IX.2.1.2. PROPOSITION. Two partitions $\mathcal{P}$ and $\mathcal{Q}$ of an interval $[a, b]$ have a common refinement.

PROOF: Just take $\mathcal{P} \cup \mathcal{Q}$, the partition obtained by using all the endpoints in both partitions. 👍

Riemann Sums

IX.2.1.3. DEFINITION. Let f be a real-valued function on an interval $[a, b]$, and let

$$\dot{\mathcal{P}} = \{x_0, x_1, \ldots, x_n; t_1, \ldots, t_n\}$$

be a tagged partition of $[a, b]$. The *Riemann sum* for f with respect to $\dot{\mathcal{P}}$ is

$$\mathcal{R}(f, \dot{\mathcal{P}}) = \sum_{k=1}^{n} f(t_k)(x_k - x_{k-1}) = \sum_{k=1}^{n} f(t_k)\,\Delta x_k \ .$$

Note that Riemann sums are only defined for tagged partitions, and the numerical value depends on the choice of tags as well as the partition.

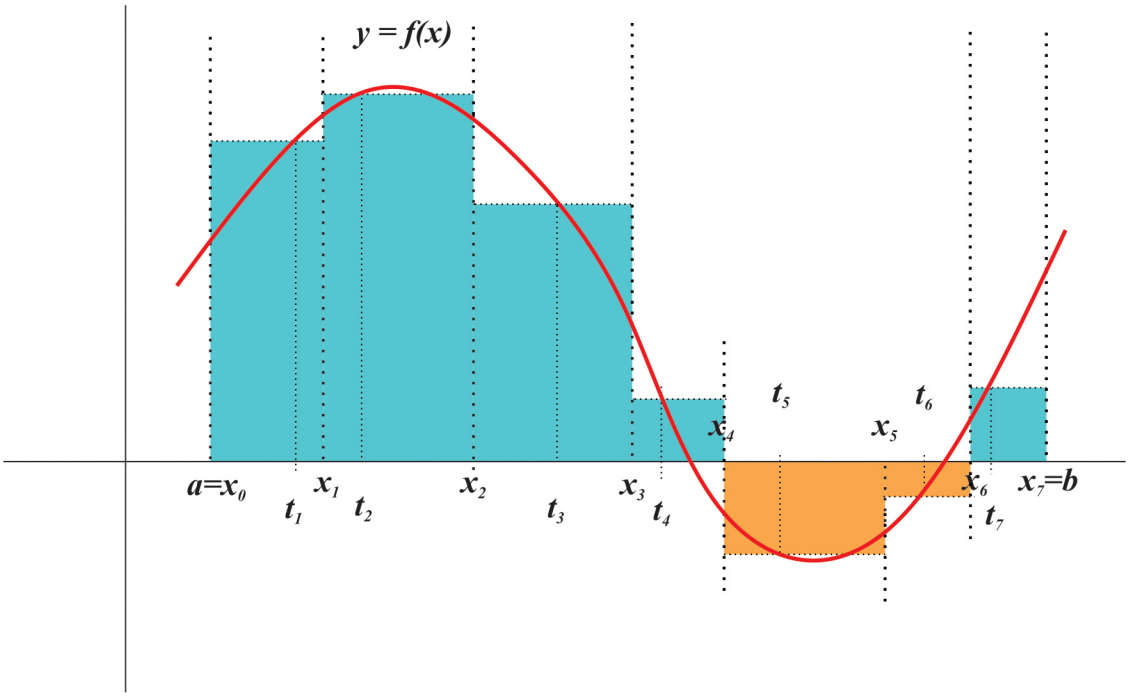

Figure IX.11: The Riemann Sum for a Tagged Partition

Darboux Sums and Oscillation

Two closely related sums which do not depend on tags are the upper and lower Darboux sums:

IX.2.1.4. DEFINITION. Let f be a bounded function on an interval $[a,b]$. If $\mathcal{P} = \{x_0, \ldots, x_n\}$ is a partition of $[a,b]$, for $1 \le k \le n$ set

$$M_k = \sup_{x_{k-1} \le x \le x_k} f(x) \text{ and } m_k = \inf_{x_{k-1} \le x \le x_k} f(x) \ .$$

Then the *upper and lower Darboux sums* for f with respect to $\mathcal{P}$ are

$$\overline{\mathcal{S}}(f,\mathcal{P}) = \sum_{k=1}^{n} M_k(x_k - x_{k-1}) = \sum_{k=1}^{n} M_k \, \Delta x_k$$

$$\underline{\mathcal{S}}(f,\mathcal{P}) = \sum_{k=1}^{n} m_k(x_k - x_{k-1}) = \sum_{k=1}^{n} m_k \, \Delta x_k$$

(written $U(f,\mathcal{P})$ and $L(f,\mathcal{P})$ in many references).

The relation between Darboux and Riemann sums is:

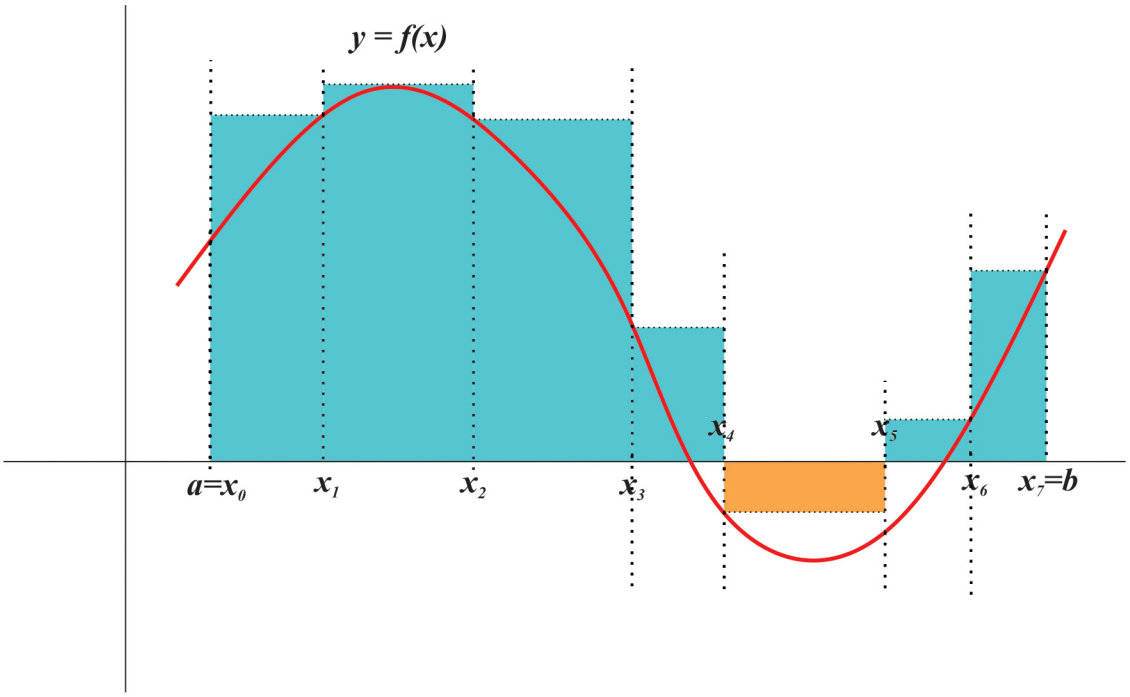

Figure IX.12: The Upper Darboux Sum for a Partition

IX.2.1.5. PROPOSITION. Let f be a bounded function on an interval $[a,b]$, and let $\mathcal{P}$ be a partition of $[a,b]$. Then

(i) If $\dot{\mathcal{P}}$ is any tagging of $\mathcal{P}$, then

$$\underline{\mathcal{S}}(f,\mathcal{P}) \leq \mathcal{R}(f,\dot{\mathcal{P}}) \leq \overline{\mathcal{S}}(f,\mathcal{P}) \ .$$

(ii) For any $\epsilon > 0$ there are taggings $\dot{\mathcal{P}}$ and $\ddot{\mathcal{P}}$ of $\mathcal{P}$ such that

$$\mathcal{R}(f,\dot{\mathcal{P}}) > \overline{\mathcal{S}}(f,\mathcal{P}) - \epsilon$$

$$\mathcal{R}(f,\ddot{\mathcal{P}}) < \underline{\mathcal{S}}(f,\mathcal{P}) + \epsilon \ .$$

PROOF: Part (i) is obvious. For (ii), let $\mathcal{P} = \{x_0,\ldots,x_n\}$. For each k, choose $t_k \in [x_{k-1},x_k]$ with

$$f(t_k) > M_k - \frac{\epsilon}{n\Delta x_k}$$

and set $\dot{\mathcal{P}} = \{x_0,\ldots,x_k;t_1,\ldots,t_k\}$. The construction of $\ddot{\mathcal{P}}$ is similar. 👍

As the partition $\mathcal{P}$ becomes finer, the upper Darboux sums decrease and the lower Darboux sums decrease:

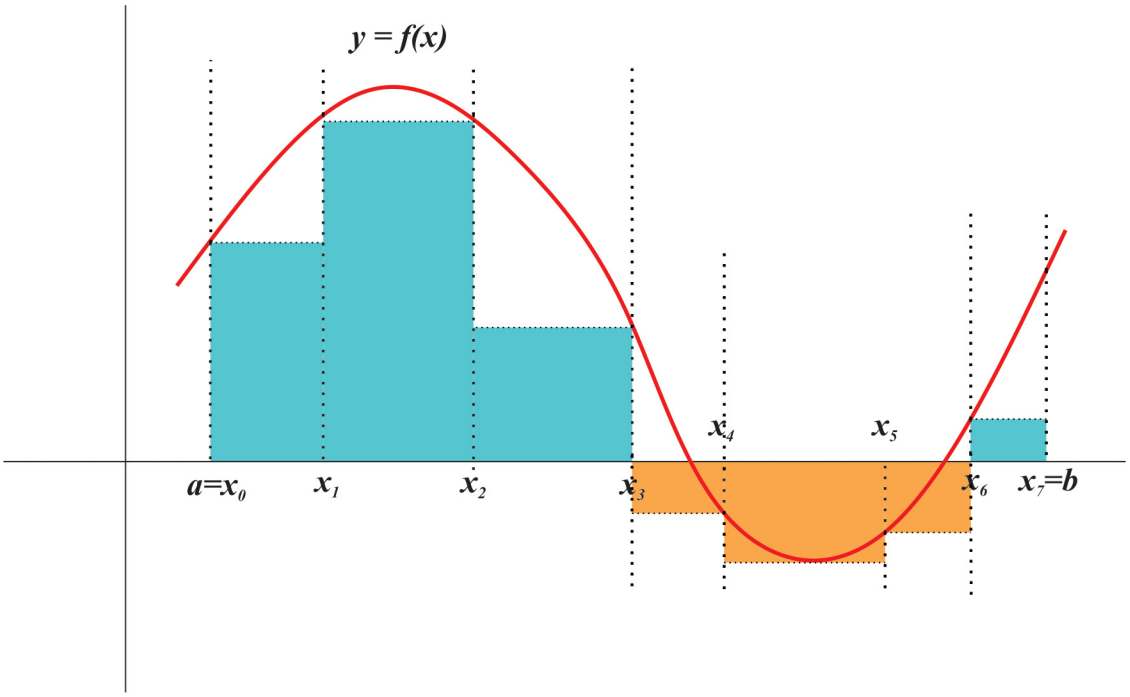

Figure IX.13: The Lower Darboux Sum for a Partition

IX.2.1.6. PROPOSITION. Let f be a bounded function on an interval $[a, b]$, and $\mathcal{P}$ and $\mathcal{Q}$ partitions of $[a, b]$. If $\mathcal{Q}$ is finer than $\mathcal{P}$, then

$$\underline{\mathcal{S}}(f, \mathcal{P}) \leq \underline{\mathcal{S}}(f, \mathcal{Q}) \leq \overline{\mathcal{S}}(f, \mathcal{Q}) \leq \overline{\mathcal{S}}(f, \mathcal{P}) \ .$$

There is no such simple relation for Riemann sums.

Interior Darboux Sums

For technical purposes, there is a useful variation on the notion of a Darboux sum:

IX.2.1.7. DEFINITION. Let f be a bounded function on an interval $[a, b]$. If $\mathcal{P} = \{x_0, \ldots, x_n\}$ is a partition of $[a, b]$, for $1 \leq k \leq n$ set

$$M_k^\circ = \sup_{x_{k-1} < x < x_k} f(x) \text{ and } m_k^\circ = \inf_{x_{k-1} < x < x_k} f(x) \ .$$

Then the *upper and lower interior Darboux sums* for f with respect to $\mathcal{P}$ are

$$\overline{\mathcal{S}}_\circ(f, \mathcal{P}) = \sum_{k=1}^{n} M_k^\circ (x_k - x_{k-1}) = \sum_{k=1}^{n} M_k^\circ \, \Delta x_k$$

$$\underline{\mathcal{S}}_\circ(f,\mathcal{P}) = \sum_{k=1}^{n} m_k^\circ(x_k - x_{k-1}) = \sum_{k=1}^{n} m_k^\circ\,\Delta x_k\ .$$

The difference is that M_k° and m_k° are the supremum and infimum of f on the *interior* of the k'th subinterval.

IX.2.1.8. For any f and $\mathcal{P}$, we obviously have $m_k \le m_k^\circ \le M_k^\circ \le M_k$, so

$$\underline{\mathcal{S}}(f,\mathcal{P}) \le \underline{\mathcal{S}}_\circ(f,\mathcal{P}) \le \overline{\mathcal{S}}_\circ(f,\mathcal{P}) \le \overline{\mathcal{S}}(f,\mathcal{P})\ .$$

If f is continuous on $[a,b]$, then $M_k^\circ = M_k$ and $m_k^\circ = m_k$ for all k, so we have equality at the ends, but the interior Darboux sums for step functions often differ from the usual Darboux sums. We will obtain an approximate equivalence between the notions in ().

The Metaprinciple

There is a simple but useful observation about the behavior of Riemann sums, Darboux sums, and interior Darboux sums:

IX.2.1.9. Proposition. Let f be a bounded function on an interval $[a,b]$, $\mathcal{P}$ a partition of $[a,b]$, and $\dot{\mathcal{P}}$ any tagging of $\mathcal{P}$. We have the following relations for any constant c:

$$\begin{aligned}
\mathcal{R}(f+c,\dot{\mathcal{P}}) &= \mathcal{R}(f,\dot{\mathcal{P}}) + c(b-a)\\
\overline{\mathcal{S}}(f+c,\mathcal{P}) &= \overline{\mathcal{S}}(f,\mathcal{P}) + c(b-a)\\
\underline{\mathcal{S}}(f+c,\mathcal{P}) &= \underline{\mathcal{S}}(f,\mathcal{P}) + c(b-a)\\
\overline{\mathcal{S}}_\circ(f+c,\mathcal{P}) &= \overline{\mathcal{S}}_\circ(f,\mathcal{P}) + c(b-a)\\
\underline{\mathcal{S}}_\circ(f+c,\mathcal{P}) &= \underline{\mathcal{S}}_\circ(f,\mathcal{P}) + c(b-a)\\
\mathcal{R}(-f,\dot{\mathcal{P}}) &= -\mathcal{R}(f,\dot{\mathcal{P}})\\
\overline{\mathcal{S}}(-f,\mathcal{P}) &= -\underline{\mathcal{S}}(f,\mathcal{P})\\
\underline{\mathcal{S}}(-f,\mathcal{P}) &= -\overline{\mathcal{S}}(f,\mathcal{P})\\
\overline{\mathcal{S}}_\circ(-f,\mathcal{P}) &= -\underline{\mathcal{S}}_\circ(f,\mathcal{P})\\
\underline{\mathcal{S}}_\circ(-f,\mathcal{P}) &= -\overline{\mathcal{S}}_\circ(f,\mathcal{P})\ .
\end{aligned}$$

IX.2.1.10. Thus, in analyzing and comparing such sums, it suffices to consider nonnegative functions by adding a suitable constant; and results about upper Darboux sums have an exact analog for lower Darboux sums which do not have to be proved separately, but simply follow by taking negations.

Relation between Darboux Sums and Interior Darboux Sums

The next result is a good example of the metaprinciple in action.

IX.2.1.11. PROPOSITION. Let f be a bounded function on an interval $[a,b]$, and $\mathcal{P}$ a partition of $[a,b]$. Then for every $\epsilon > 0$ there is a partition $\mathcal{Q}$ of $[a,b]$ such that

$$\underline{\mathcal{S}}_\circ(f,\mathcal{P}) - \epsilon \le \underline{\mathcal{S}}(f,\mathcal{Q}) \le \overline{\mathcal{S}}(f,\mathcal{Q}) \le \overline{\mathcal{S}}_\circ(f,\mathcal{P}) + \epsilon \ .$$

PROOF: By the Metaprinciple, we need show there is a $\mathcal{Q}$ giving the last inequality: then by negation, there is a $\mathcal{Q}'$ giving the first inequality, and a common refinement of $\mathcal{Q}$ and $\mathcal{Q}'$ gives both. Furthermore, in finding $\mathcal{Q}$ for the last inequality we may assume that f is nonnegative.

Let $\mathcal{P} = \{x_0, \dots, x_n\}$. We will obtain $\mathcal{Q}$ by shortening each interval in $\mathcal{P}$ and adding additional small intervals around x_k for each k: given $\epsilon > 0$, choose $\delta > 0$ small enough that $\delta < \ell(J_k)/2$ for all k, and so that $\delta < \frac{\epsilon}{2M(n+1)}$, where M is a bound for f on $[a,b]$, and let

$$\mathcal{Q} = \{x_0, x_0+\delta, x_1-\delta, x_1+\delta, \dots, x_n-\delta, x_n\} \ .$$

Then for each k we have

$$\sup_{x_{k-1}+\delta \le x \le x_k - \delta} f(x) \le M_k^\circ$$

and so by adding up separately over the truncated original intervals and the new intervals we have

$$\overline{\mathcal{S}}(f,\mathcal{Q}) \le \sum_{k=1}^n M_k^\circ[\ell(J_k) - 2\delta] + \sum_{k=0}^n M(2\delta) \le \overline{\mathcal{S}}_\circ(f,\mathcal{P}) + \epsilon \ .$$

Oscillation

The oscillation of a bounded real-valued function on any set can be defined:

IX.2.1.12. DEFINITION. Let f be a real-valued function on a set X, and $S \subseteq X$. If f is bounded on S, the number

$$\omega(f,S) = \sup_S f - \inf_S f$$

is called the *oscillation* of f on S.

IX.2.1.13. More generally, if f is a function from a set X to a metric space (Y,ρ), and f is bounded on a subset S of X, then we can define

$$\omega(f,S) = \sup\{\rho(f(s),f(t)) : s,t \in S\} \ .$$

If X is a topological space and $x_0 \in X$, then f is continuous at x_0 if and only if

$$\lim \omega(f,\mathcal{U}) = 0$$

as $\mathcal{U}$ ranges over the directed set of neighborhoods of x_0. In particular, if $X \subseteq \mathbb{R}$, then $f : X \to \mathbb{R}$ is continuous at $x_0 \in X$ if and only if

$$\lim_{\epsilon \to 0} \omega(f, X \cap (x-\epsilon, x+\epsilon)) = 0 \ .$$

IX.2.1.14. The connection with integration is that if f is a bounded function on an interval $[a, b]$, and $\mathcal{P}$ is a partition of $[a, b]$, with M_k and m_k defined as in IX.2.1.4., then

$$\omega(f, J_k) = M_k - m_k$$

and so we have

$$\overline{\mathcal{S}}(f, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P}) = \sum_{k=1}^{n} \omega(f, J_k)\ell(J_k) \ .$$

The last number is called the *weighted local oscillation* of f with respect to $\mathcal{P}$.

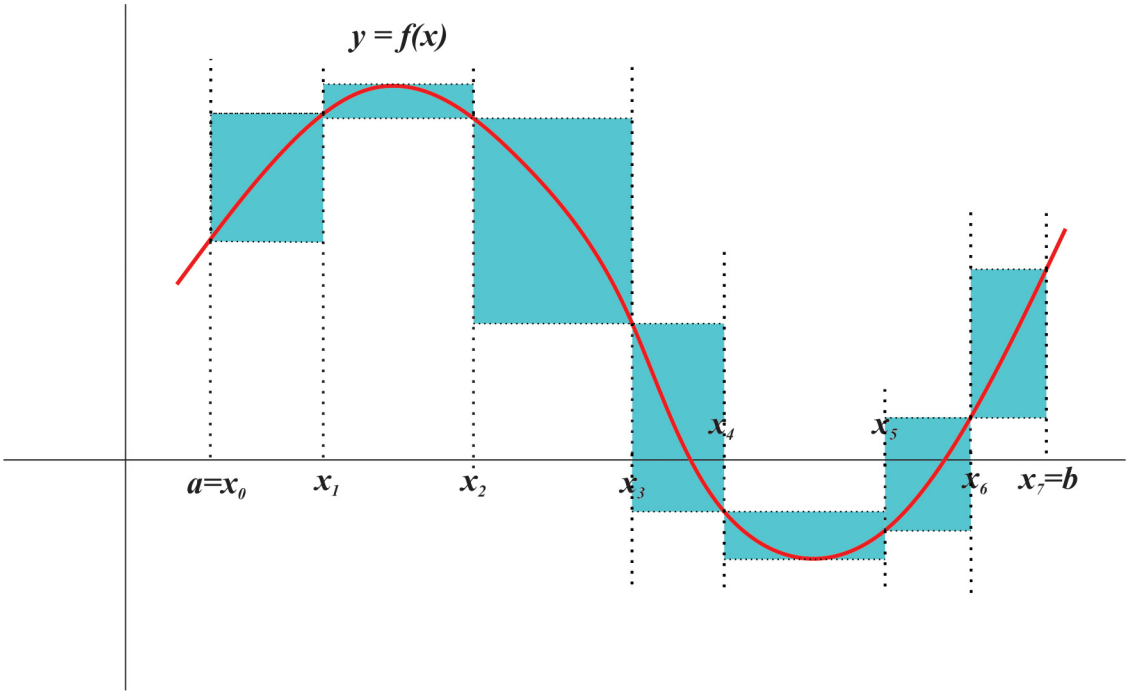

Figure IX.14: The Weighted Local Oscillation for a Partition

IX.2.1.15. The weighted local oscillation does not increase, and typically decreases, as the partition becomes finer (Figure IX.15).

IX.2.2. Step Functions and their Integrals

IX.2.3. Definitions of the Riemann Integral

We will give five definitions of Riemann integrability. All have slight rephrasings which are easily seen to be equivalent to the basic definition. There are other definitions which can be found in the literature, but the ones we give are the "extreme" ones and others can be seen to fit between our definitions.

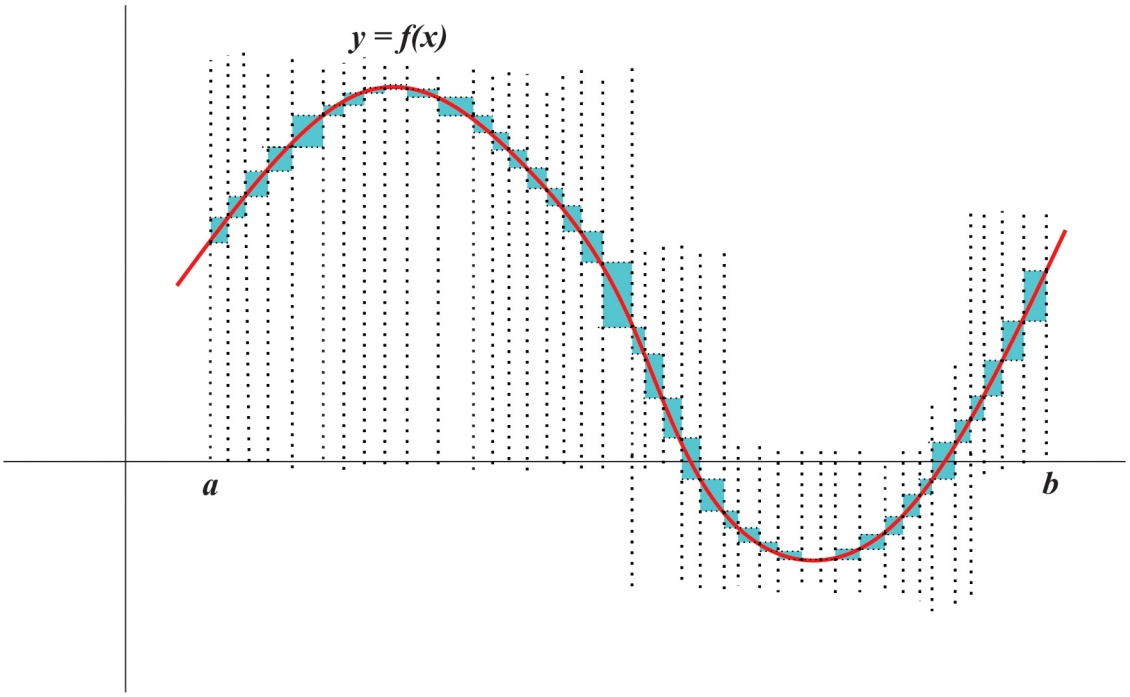

Figure IX.15: The Weighted Local Oscillation for a Finer Partition

The basic definitions are in terms of (1) Riemann sums, (2) upper and lower Darboux sums (or oscillation), or (3) approximation above and below by step functions. The other variation is (A) requiring existence of one partition forcing good approximation or (B) requiring good approximation for all sufficiently fine partitions.

Definition 1

IX.2.3.1. DEFINITION. [DEFINITION 1A] Let f be a function on a closed bounded interval $J = [a, b]$. Then f is Riemann-integrable on J in sense 1A, with Riemann integral $R \in \mathbb{R}$, if for every $\epsilon > 0$ there is a partition $\mathcal{P} = \{x_0, \ldots, x_n\}$ of J such that, for every choice of tags $t_1, \ldots, t_n$ for $\mathcal{P}$, we have

$$\left| R - \sum_{k=1}^{n} f(t_k)(x_k - x_{k-1}) \right| < \epsilon \ .$$

IX.2.3.2. DEFINITION. [DEFINITION 1B] Let f be a function on a closed bounded interval $J = [a, b]$. Then f is Riemann-integrable on J in sense 1B, with Riemann integral $R \in \mathbb{R}$, if for every $\epsilon > 0$ there is a $\delta > 0$ such that, for every tagged partition $\dot{\mathcal{P}} = \{x_0, \ldots, x_n; t_1, \ldots, t_n\}$ of J with $\|\mathcal{P}\| < \delta$, we have

$$\left| R - \sum_{k=1}^{n} f(t_k)(x_k - x_{k-1}) \right| < \epsilon \ .$$

Definition 2

IX.2.3.3. DEFINITION. [DEFINITION 2A] Let f be a bounded function on a closed bounded interval $J = [a, b]$. Then f is Riemann-integrable on J in sense 2A if for every $\epsilon > 0$ there is a partition $\mathcal{P}$ of J such that

$$\overline{\mathcal{S}}(f, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P}) < \epsilon \ .$$

IX.2.3.4. DEFINITION. [DEFINITION 2B] Let f be a bounded function on a closed bounded interval $J = [a, b]$. Then f is Riemann-integrable on J in sense 2B if for every $\epsilon > 0$ there is a $\delta > 0$ such that, for every partition $\mathcal{P}$ of J with $\|\mathcal{P}\| < \delta$, we have

$$\overline{\mathcal{S}}(f, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P}) < \epsilon \ .$$

Definitions 2A and 2B can be rephrased in terms of "weighted local oscillations":

IX.2.3.5. DEFINITION. [DEFINITION 2A′] Let f be a bounded function on a closed bounded interval $J = [a, b]$. Then f is Riemann-integrable on J in sense 2A′ if for every $\epsilon > 0$ there is a partition $\mathcal{P}$ of J such that

$$\sum_{k=1}^{n} \omega(f, J_k)\ell(J_k) < \epsilon$$

where J_k is the k'th subinterval of $\mathcal{P}$.

IX.2.3.6. DEFINITION. [DEFINITION 2B′] Let f be a bounded function on a closed bounded interval $J = [a, b]$. Then f is Riemann-integrable on J in sense 2B′ if for every $\epsilon > 0$ there is a $\delta > 0$ such that, for every partition $\mathcal{P}$ of J with $\|\mathcal{P}\| < \delta$, we have

$$\sum_{k=1}^{n} \omega(f, J_k)\ell(J_k) < \epsilon$$

where J_k is the k'th subinterval of $\mathcal{P}$.

The fact that Definitions 2A′ and 2B′ are equivalent to 2A and 2B respectively is obvious.

There is a less obvious rephrasing of Definition 2A using interior Darboux sums (IX.2.1.7.) which also turns out to be equivalent and technically useful:

IX.2.3.7. DEFINITION. [DEFINITION 2A″] Let f be a bounded function on a closed bounded interval $J = [a, b]$. Then f is Riemann-integrable on J in sense 2A″ if for every $\epsilon > 0$ there is a partition $\mathcal{P}$ of J such that

$$\overline{\mathcal{S}}_\circ(f, \mathcal{P}) - \underline{\mathcal{S}}_\circ(f, \mathcal{P}) < \epsilon \ .$$

IX.2.3.8. Since for any f and any partition $\mathcal{P}$ we have

$$\underline{\mathcal{S}}(f,\mathcal{P}) \le \underline{\mathcal{S}}_\circ(f,\mathcal{P}) \le \overline{\mathcal{S}}_\circ(f,\mathcal{P}) \le \overline{\mathcal{S}}(f,\mathcal{P})$$

it follows that if f is Riemann-integrable in sense 2A, then it is Riemann-integrable in sense 2A$''$. The converse implication follows easily from IX.2.1.11., so we have:

IX.2.3.9. PROPOSITION. Let f be a bounded function on a closed bounded interval $[a,b]$. Then f is Riemann-integrable in sense 2A$''$ if and only if f is Riemann-integrable in sense 2A.

IX.2.3.10. We could also give an obvious similar version 2B$''$ of 2B. However, although 2B $\Rightarrow$ 2B$''$ is obvious, it is difficult to prove directly that 2B$''$ $\Rightarrow$ 2B. After the fact it will be seen to be true since we will have 2B$''$ $\Rightarrow$ 2A$''$ $\Rightarrow$ 2A $\Rightarrow$ 2B.

Definition 3

IX.2.3.11. DEFINITION. [DEFINITION 3A] Let f be a function on a closed bounded interval $J=[a,b]$. Then f is Riemann-integrable on J in sense 3A if for every $\epsilon>0$ there are step functions ϕ and ψ on J such that $\phi \le f \le \psi$ on J and

$$\int_a^b (\psi-\phi) = \int_a^b \psi - \int_a^b \phi < \epsilon\ .$$

IX.2.3.12. One could give a corresponding Definition 3B, but the statement is awkward and does not appear in the literature to my knowledge. But there is a commonly used rephrasing of Definition 3A, which is fairly obviously equivalent to 3A. First note that since a step function is bounded, any function satisfying Definition 3A is automatically bounded. Then make the following definition:

IX.2.3.13. DEFINITION. Let f be a bounded function on a closed bounded interval $J=[a,b]$. Define

$$\underline{\int_a^b} f(x)\,dx = \sup\left\{\int_a^b \phi : \phi \text{ step},\ \phi \le f\right\}$$

$$\overline{\int_a^b} f(x)\,dx = \inf\left\{\int_a^b \psi : \psi \text{ step},\ f \le \psi\right\}\ .$$

IX.2.3.14. DEFINITION. [DEFINITION 3A$'$] Let f be a function on a closed bounded interval $J=[a,b]$. Then f is Riemann-integrable on J in sense 3A$'$ if

$$\underline{\int_a^b} f(x)\,dx = \overline{\int_a^b} f(x)\,dx\ .$$

The common value is called the *Riemann integral* of f from a to b.

IX.2.3.15. To see that Definitions 3A and 3A′ are equivalent, note first that if f is any bounded function on J and ϕ, ψ are step functions with $\phi \le f \le \psi$, then $\int_a^b \phi \le \int_a^b \psi$, and thus by () we have

$$\int_a^b \phi \le \underline{\int_a^b} f(x)\,dx \le \bar{\int_a^b} f(x)\,dx \le \int_a^b \psi\ .$$

Thus, if f is Riemann integrable in sense 3A, then for any $\epsilon > 0$ we have

$$0 \le \bar{\int_a^b} f(x)\,dx - \underline{\int_a^b} f(x)\,dx < \epsilon$$

so f is Riemann integrable in sense 3A′. Conversely, if f is Riemann integrable in sense 3A′, and $\epsilon > 0$, choose step functions ϕ and ψ on J with $\phi \le f \le \psi$ and

$$\int_a^b \phi > \underline{\int_a^b} f(x)\,dx - \frac{\epsilon}{2} \quad \text{and} \quad \int_a^b \psi < \bar{\int_a^b} f(x)\,dx + \frac{\epsilon}{2}\ .$$

Then

$$\int_a^b \psi - \int_a^b \phi < \epsilon$$

so f is Riemann integrable in sense 3A.

One useful technical fact is the invariance of all the definitions under adding constants:

IX.2.3.16. Proposition. Let f be a function on a closed bounded interval $J = [a, b]$, let c be a constant, and $g = f + c$. If f is Riemann-integrable in any of the senses, then g is also Riemann-integrable in the same sense, and the Riemann integral of g is the Riemann integral of f plus $c(b-a)$. Riemann and Darboux sums for g are also the same as for f, plus $c(b-a)$.

Using this proposition, the theory of Riemann integration can be reduced to the case of nonnegative functions, since any function which is bounded below can be converted to a nonnegative function by adding a constant.

IX.2.4. Comparing the Definitions

The main result is:

IX.2.4.1. Theorem. Let f be a function on a closed bounded interval $J = [a, b]$. Then

(i) If f is Riemann-integrable on J in sense 1A or 1B, then f is bounded on J.

(ii) If f is Riemann-integrable in sense 2A or 2B, there is a unique real number I such that

$$\underline{\mathcal{S}}(f, \mathcal{P}) \le I \le \overline{\mathcal{S}}(f, \mathcal{P})$$

for every partition $\mathcal{P}$ of J.

(iii) If f is Riemann-integrable on J in any of the senses 1A, 1B, 2A, 2B, 2A′, 2B′, 3A, or 3A′, it is Riemann-integrable on J in all these senses, and the Riemann integral of f over J is well defined. In particular, the number R in definitions 1A and 1B is unique, and coincides with the number I of (ii) and with $\int_a^b f(x)\,dx$ of 3A′.

IX.2.4.2. A few implications are obvious. If f is Riemann-integrable in sense 1B, it is clearly Riemann-integrable in sense 1A. Similarly, if f is Riemann-integrable in sense 2B, it is also Riemann-integrable in sense 2A. And the obvious equivalence of 2A and 2A′, and of 2B and 2B′, has already been noted, as was the slightly less obvious equivalence between 3A and 3A′.

Thus, to prove (i), it suffices to consider an f which is Riemann-integrable in sense 1A.

IX.2.4.3. LEMMA. Suppose f is Riemann-integrable on J in sense 1A. Then f is bounded on J.

PROOF: Let R be the Riemann integral of f, and let $\mathcal{P} = \{J_1, \ldots, J_n\}$ be a partition such that for any choice of tags $t_k \in J_k$, we have

$$\left| R - \sum_{k=1}^{n} f(t_k)\ell(J_k) \right| < 1 \ .$$

If f is not bounded above, then there is a k_0 such that f is not bounded above on J_{k_0}. Let $t_1, \ldots, t_n$ be a choice of tags, and choose $s_{k_0} \in J_{k_0}$ with $f(s_{k_0}) > f(t_{k_0}) + \frac{2}{\ell(J_{k_0})}$. Set $s_k = t_k$ for $k \neq k_0$. We then have

$$\left| R - \sum_{k=1}^{n} f(t_k)\ell(J_k) \right| < 1$$

$$\left| R - \sum_{k=1}^{n} f(s_k)\ell(J_k) \right| < 1$$

so we have

$$[f(s_{k_0}) - f(t_{k_0})]\ell(J_{k_0}) = \left| \sum_{k=1}^{n} f(s_k)\ell(J_k) - \sum_{k=1}^{n} f(t_k)\ell(J_k) \right|$$

$$\leq \left| \sum_{k=1}^{n} f(s_k)\ell(J_k) - R \right| + \left| R - \sum_{k=1}^{n} f(t_k)\ell(J_k) \right| < 2$$

which is a contradiction. The proof that f is bounded below is almost identical. 👍

Next we compare definitions 1A and 2A, and 1B and 2B.

IX.2.4.4. LEMMA. Suppose f is a bounded function on J, and $\mathcal{P} = \{J_1, \ldots, J_n\}$ is a partition of J. Then $\underline{\mathcal{S}}(f, \mathcal{P})$ and $\overline{\mathcal{S}}(f, \mathcal{P})$ are the infimum and supremum, respectively, of the Riemann sums corresponding to all choices of tags for $\mathcal{P}$.

PROOF: It is clear that if $t_1, \ldots, t_n$ is any choice of tags for $\mathcal{P}$, then

$$\underline{\mathcal{S}}(f, \mathcal{P}) \leq \sum_{k=1}^{n} f(t_k)\ell(J_k) \leq \overline{\mathcal{S}}(f, \mathcal{P}) \ .$$

Fix $\epsilon > 0$. For each k, choose $t_k \in J_k$ with $f(t_k) > M_k - \frac{\epsilon}{\ell(J)}$. Then

$$\sum_{k=1}^{n} f(t_k)\ell(J_k) > \sum_{k=1}^{n} M_k\ell(J_k) - \frac{\epsilon}{\ell(J)} \sum_{k=1}^{n} \ell(J_k) = \overline{\mathcal{S}}(f, \mathcal{P}) - \epsilon \ .$$

The argument for the infimum is almost identical. 👍

IX.2.4.5. Now let f be a (necessarily bounded) function which is Riemann-integrable on J in sense 1A with Riemann integral R, $\epsilon > 0$, and $\mathcal{P} = \{J_1, \ldots, J_k\}$ a partition of J such that

$$\left| R - \sum_{k=1}^{n} f(t_k)\ell(J_k) \right| < \frac{\epsilon}{3}$$

for any choice of tags $t_k \in J_k$. Then

$$\left|R - \overline{\mathcal{S}}(f, \mathcal{P})\right| \leq \frac{\epsilon}{3} \quad \text{and} \quad |R - \underline{\mathcal{S}}(f, \mathcal{P})| \leq \frac{\epsilon}{3}$$

so we have

$$\overline{\mathcal{S}}(f, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P}) \leq |\overline{\mathcal{S}}(f, \mathcal{P}) - R| + |R - \underline{\mathcal{S}}(f, \mathcal{P})| \leq \frac{2\epsilon}{3} < \epsilon$$

and so f is Riemann-integrable in sense 2A. An almost identical argument shows that if f is Riemann-integrable in sense 1B, then it is also Riemann-integrable in sense 2B.

For the other direction, note that there is no explicitly given value for the Riemann integral in definitions 2A or 2B, or in 2A′ or 2B′ (or in 3A, but there is one in the equivalent definition 3A′.) The essential point of (ii) is to provide a value for the Riemann integral in case 2A or 2B. To prove (ii), we first make an important observation:

IX.2.4.6. LEMMA. If f is a bounded function on J, and $\mathcal{P}$ and $\mathcal{Q}$ are any partitions of J, then

$$\underline{\mathcal{S}}(f, \mathcal{P}) \leq \overline{\mathcal{S}}(f, \mathcal{Q}) \ .$$

PROOF: The key is that there is a partition $\mathcal{R}$ which is a refinement of both $\mathcal{P}$ and $\mathcal{Q}$ (IX.2.1.2.). Then, by IX.2.1.6.,

$$\underline{\mathcal{S}}(f, \mathcal{P}) \leq \underline{\mathcal{S}}(f, \mathcal{R}) \leq \overline{\mathcal{S}}(f, \mathcal{R}) \leq \overline{\mathcal{S}}(f, \mathcal{Q}) \ .$$

👍

We then conclude from () that

IX.2.4.7. COROLLARY. Let f be a bounded function on J. Then

$$\sup_{\mathcal{P}}\{\underline{\mathcal{S}}(f,\mathcal{P})\} \le \inf_{\mathcal{P}}\{\overline{\mathcal{S}}(f,\mathcal{P})\}$$

where the supremum and infimum are taken over all partitions of J.

IX.2.4.8. Thus, if f is Riemann-integrable in sense 2A, then we have

$$\sup_{\mathcal{P}}\{\underline{\mathcal{S}}(f,\mathcal{P})\} = \inf_{\mathcal{P}}\{\overline{\mathcal{S}}(f,\mathcal{P})\}\ .$$

Call this number I. Then we have

$$\underline{\mathcal{S}}(f,\mathcal{P}) \le I \le \overline{\mathcal{S}}(f,\mathcal{P})$$

for any partition $\mathcal{P}$, and I is clearly the only number with this property, proving (ii). Also, if $\epsilon > 0$ and $\mathcal{P} = \{J_1,\dots,J_n\}$ is a partition with $\overline{\mathcal{S}}(f,\mathcal{P}) - \underline{\mathcal{S}}(f,\mathcal{P}) < \epsilon$, then for any choice of tags $t_1,\dots,t_n$ with $t_k \in J_k$ we have

$$\left| I - \sum_{k=1}^{n} f(t_k)\ell(J_k) \right| < \epsilon$$

so f is Riemann-integrable in sense 1A with Riemann integral I. If f is Riemann-integrable in sense 2B, it follows almost identically that f is Riemann-integrable in sense 1B.

IX.2.4.9. Now let us compare definitions 2A and 3A. Let f be a bounded function on J. If $\mathcal{P} = \{J_1,\dots,J_n\}$ is a partition of J, and M_k and m_k the supremum and infimum of f on J_k as usual, define step functions ϕ and ψ by setting $\phi(x) = m_k$ and $\psi(x) = M_k$ for $x \in J_k$. If $x = x_k$ is the common endpoint of J_k and J_{k+1}, set $\phi(x)$ to be the smaller of m_k and m_{k+1}, and $\psi(x)$ the larger of M_k and M_{k+1}. Then ϕ and ψ are step functions, $\phi \le f \le \psi$, and $\int_a^b \phi = \underline{\mathcal{S}}(f,\mathcal{P})$, $\int_a^b \psi = \overline{\mathcal{S}}(f,\mathcal{P})$.

IX.2.4.10. So if f is Riemann-integrable in sense 2A, and $\epsilon > 0$, let $\mathcal{P}$ be a partition for which $\overline{\mathcal{S}}(f,\mathcal{P}) - \underline{\mathcal{S}}(f,\mathcal{P}) < \epsilon$. Define ϕ and ψ as above for this $\mathcal{P}$; then

$$\int_a^b \psi - \int_a^b \phi = \overline{\mathcal{S}}(f,\mathcal{P}) - \underline{\mathcal{S}}(f,\mathcal{P}) < \epsilon$$

so f is Riemann-integrable in sense 3A. We also conclude that the number I from (ii) is exactly $\int_a^b f(x)\,dx$.

IX.2.4.11. Going from 3A to 2A is equally straightforward except for an annoying technicality. Suppose f is a bounded function on $J = [a,b]$, which we may assume to be nonnegative by IX.2.3.16.. We want to show that

$$\inf_{\mathcal{P}}\{\overline{\mathcal{S}}(f,\mathcal{P})\} = \inf\left\{ \int_a^b \psi : \psi \text{ step}, f \le \psi \right\}$$

and similarly for lower estimates. (We have $\ge$ by the previous argument.) Let ψ be a step function for which $f \le \psi$, and $\mathcal{P}$ the partition consisting of $x_0 = a$, $x_n = b$, and the jump discontinuities $x_1,\dots,x_{n-1}$

of ψ in (a,b). Let c_k be the value of ψ on (x_{k-1},x_k), and $d_k = f(x_k)$. If M_k is the supremum of f on $J_k = [x_{k-1},x_k]$, we have $M_k \le \max(c_k,d_k,d_{k-1})$. So if $d_{k-1},d_k \le c_k$ for all k, we have

$$\overline{\mathcal{S}}(f,\mathcal{P}) \le \int_a^b \psi$$

but this fails if $d_k > c_k$ or $d_{k-1} > c_k$ for some k. To get around this problem, use definition 2A″ instead: we have

$$\overline{\mathcal{S}}_\circ(f,\mathcal{P}) \le \int_a^b \psi$$

for any such ψ. We thus get the desired inequality

$$\inf_{\mathcal{P}}\{\overline{\mathcal{S}}(f,\mathcal{P})\} = \inf_{\mathcal{P}}\{\overline{\mathcal{S}}_\circ(f,\mathcal{P})\} \le \inf\left\{\int_a^b \psi : \psi \text{ step}, \ f \le \psi\right\}$$

where the first equality is from IX.2.1.11.. By a similar argument we obtain

$$\sup_{\mathcal{P}}\{\underline{\mathcal{S}}(f,\mathcal{P})\} \ge \sup\left\{\int_a^b \phi : \phi \text{ step}, \ \phi \le f\right\}$$

(the opposite inequality follows from the previous argument).

IX.2.4.12. Thus, if f is Riemann-integrable in sense 3A, it is Riemann-integrable in sense 2A, and the number I of (ii) is exactly $\int_a^b f(x)\,dx$.

IX.2.4.13. We have now shown that definitions 1A, 2A, and 3A (hence also 2A′ and 3A′) define the same class of Riemann-integrable functions, and the Riemann integrals coincide (using (ii) in case 2A). We will say that a function Riemann-integrable in any of these senses is Riemann-integrable in sense A. Similarly, definitions 1B and 2B (hence also 2B′) define the same class of Riemann-integrable functions, with a well-defined Riemann integral, called the functions Riemann-integrable in sense B. Also, a function Riemann-integrable in sense B is Riemann-integrable in sense A, and the Riemann integrals coincide. Thus, finish the proof of the theorem, we need to show that a function which is Riemann-integrable in sense A is Riemann-integrable in sense B. This is the least obvious part of the proof of the theorem.

IX.2.4.14. So suppose f is Riemann-integrable on J in sense A, and let $\epsilon > 0$. Let $\mathcal{P} = \{x_0,x_1,\dots,x_n\}$ be a partition satisfying

$$\overline{\mathcal{S}}(f,\mathcal{P}) - \underline{\mathcal{S}}(f,\mathcal{P}) < \frac{\epsilon}{2}\,.$$

Let M be a bound for f on J, and set $g = f + M$, $h = f - M$. Then $0 \le g \le 2M$ and $-2M \le h \le 0$. Let $\delta < \frac{\epsilon}{4(n-1)M}$. If $\mathcal{Q} = \{I_1,\dots,I_m\}$ is a partition of J with $\|\mathcal{Q}\| < \delta$, then $\mathcal{Q}$ might not quite be a refinement of $\mathcal{P}$ since some or all of the x_k might be interior points of intervals of $\mathcal{Q}$. But there are at most $n-1$ of these intervals; let N_1 be the set of r such that I_r is one of these, and let N_2 be the rest of the indices. Then

$$\overline{\mathcal{S}}(g,\mathcal{Q}) = \sum_{r\in N_1} M_r\ell(I_r) + \sum_{r\in N_2} M_r\ell(I_r)$$

where M_r is the supremum of g on I_r. Since for each $r \in N_2$ we have that I_r is contained in one of the J_k, and the supremum of g over I_r is less than or equal to the supremum of g over the corresponding J_k, we have that

$$\sum_{r \in N_2} M_r \ell(I_r) \leq \overline{\mathcal{S}}(g, \mathcal{P}) \ .$$

Since each I_r has length $< \delta$, and N_1 contains at most $n-1$ indices, we have

$$\sum_{r \in N_1} M_r \ell(I_r) \leq 2(n-1)M\delta < \frac{\epsilon}{2} \ .$$

Thus we have

$$\overline{\mathcal{S}}(g, \mathcal{Q}) < \overline{\mathcal{S}}(g, \mathcal{P}) + \frac{\epsilon}{2} \ .$$

By translation (IX.2.3.16.), we thus have

$$\overline{\mathcal{S}}(f, \mathcal{Q}) < \overline{\mathcal{S}}(f, \mathcal{P}) + \frac{\epsilon}{2} \ .$$

Applying a similar argument to h using infima, we have

$$\underline{\mathcal{S}}(h, \mathcal{Q}) > \underline{\mathcal{S}}(h, \mathcal{P}) - \frac{\epsilon}{2}$$

and so by linearity we have

$$\underline{\mathcal{S}}(f, \mathcal{Q}) > \underline{\mathcal{S}}(f, \mathcal{P}) - \frac{\epsilon}{2} \ .$$

Combining the two estimates, we get

$$\overline{\mathcal{S}}(f, \mathcal{Q}) - \underline{\mathcal{S}}(f, \mathcal{Q}) < \epsilon$$

and so f is Riemann-integrable in sense 2B (i.e. in sense B).

IX.2.4.15. There is one last loose end. We must show that the number R in Definition 1A is unique. Let f be Riemann-integrable in sense 1A, and R a number satisfying Definition 1A. Fix $\epsilon > 0$, and let $\mathcal{P}$ be a partition such that

$$\left| R - \sum_{k=1}^{n} f(t_k)\ell(J_k) \right| < \epsilon$$

for any choice of tags. Then by IX.2.4.4., we have

$$|R - \underline{\mathcal{S}}(f, \mathcal{P})| \leq \epsilon$$

$$|R - \overline{\mathcal{S}}(f, \mathcal{P})| \leq \epsilon$$

and so, since the number I of (ii) is between $\underline{\mathcal{S}}(f, \mathcal{P})$ and $\overline{\mathcal{S}}(f, \mathcal{P})$, we have

$$|R - I| \leq \epsilon \ .$$

since $\epsilon > 0$ is arbitrary, we have $R = I$ and R is uniquely determined.

This completes the proof of IX.2.4.1..

In light of Theorem IX.2.4.1., we can make the definitive definition of Riemann-integrability:

IX.2.4.16. Definition. Let f be a bounded function on a closed bounded interval $J = [a, b]$. Then f is *Riemann-integrable* on J if it is Riemann-integrable in any of the senses 1A-B, 2A-B, 2A′-B′, or 3A-A′. The Riemann integral of f over J, or from a to b, denoted $\int_a^b f(x)\,dx$, is the number defined in IX.2.3.1.–IX.2.3.14..

Additivity of the Riemann Integral

A simple consequence of the equivalence of the definitions is:

IX.2.4.17. Proposition. Let f be a function on $[a, b]$, and let $\{\mathcal{P}_n\}$ be a sequence of partitions of $[a, b]$ with $\lim_{n\to\infty} \|\mathcal{P}_n\| = 0$. Then f is Riemann-integrable on $[a, b]$ if and only if

$$\lim_{n\to\infty} \left[\overline{\mathcal{S}}(f, \mathcal{P}_n) - \underline{\mathcal{S}}(f, \mathcal{P}_n)\right] = 0 \ .$$

If f is Riemann-integrable, then, for any taggings $\dot{\mathcal{P}}_n$ of the $\mathcal{P}_n$, we have

$$\int_a^b f(x)\,dx = \lim_{n\to\infty} \overline{\mathcal{S}}(f, \mathcal{P}_n) = \lim_{n\to\infty} \underline{\mathcal{S}}(f, \mathcal{P}_n) = \lim_{n\to\infty} \mathcal{R}(f, \dot{\mathcal{P}}_n) \ .$$

IX.2.4.18. This is useful in many ways. For example, it allows Riemann-integrability to be checked and the Riemann integral to be computed using only partitions of $[a, b]$ into subintervals of equal length $\frac{b-a}{n}$ for any sequence of n's going to infinity (e.g. powers of 2). Another important consequence is:

IX.2.4.19. Corollary. Let f be a function on $[a, b]$, and $\mathcal{P}_0$ a fixed partition of $[a, b]$. In checking Riemann-integrability of f on $[a, b]$ and in computing the integral, it suffices to consider only partitions of $[a, b]$ refining $\mathcal{P}_0$.

IX.2.4.20. Corollary. [Additivity of the Riemann Integral] Let f be a function on $[a, b]$, and $\mathcal{P}_0 = \{a = c_0, \ldots, c_n = b\}$ a partition of $[a, b]$. Then f is Riemann-integrable on $[a, b]$ if and only if it is Riemann-integrable on $[c_{k-1}, c_k]$ for $1 \le k \le n$, and

$$\int_a^b f(x)\,dx = \sum_{k=1}^{n} \int_{c_{k-1}}^{c_k} f(x)\,dx \ .$$

In particular, if $a < c < b$, then f is Riemann-integrable on $[a, b]$ if and only if it is Riemann-integrable on both $[a, c]$ and $[c, b]$, and

$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx \ .$$

IX.2.4.21. This property of the Riemann integral is called "additivity" and is not the same as the property in IX.2.6.1.(i) which is called "linearity." (The two are related: additivity is the case of linearity using $f\chi_{[a,b]} = f\chi_{[a,c]} + f\chi_{(c,b]}$.)

IX.2.5. Integrals of Continuous and Monotone Functions

Let $\chi_{\mathbb{Q}}$ be the indicator function of $\mathbb{Q}$.

IX.2.6. Properties of the Riemann Integral

The following result summarizes some of the most important properties of the Riemann integral:

IX.2.6.1. THEOREM. Let $[a,b]$ be a closed bounded interval in $\mathbb{R}$, and f and g real-valued functions on $[a,b]$, and $c \in \mathbb{R}$. Then

(i) (*Linearity*) If f and g are Riemann-integrable on $[a,b]$, then $f+g$ and cf are Riemann-integrable on $[a,b]$, and

$$\int_a^b [f(x)+g(x)]\,dx = \int_a^b f(x)\,dx + \int_a^b g(x)\,dx$$
$$\int_a^b (cf)(x)\,dx = c\int_a^b f(x)\,dx\ .$$

(ii) (*Monotonicity*) If f and g are Riemann-integrable on $[a,b]$, and if $f(x) \le g(x)$ for all $x \in [a,b]$, then

$$\int_a^b f(x)\,dx \le \int_a^b g(x)\,dx\ .$$

(iii) The constant function c is Riemann-integrable on $[a,b]$, and

$$\int_a^b c\,dx = c(b-a)\ .$$

PROOF: For (i), note that for any tagged partition $\dot{\mathcal{P}}$ of $[a,b]$, we have

$$\mathcal{R}(f+g,\dot{\mathcal{P}}) = \mathcal{R}(f,\dot{\mathcal{P}}) + \mathcal{R}(g,\dot{\mathcal{P}})$$
$$\mathcal{R}(cf,\dot{\mathcal{P}}) = c\mathcal{R}(f,\dot{\mathcal{P}})\ .$$

For (ii), if $f \le g$, for any tagged partition $\dot{\mathcal{P}}$ of $[a,b]$ we have

$$\mathcal{R}(f,\dot{\mathcal{P}}) \le \mathcal{R}(g,\dot{\mathcal{P}})\ .$$

For (iii), for any tagged partition $\dot{\mathcal{P}}$ of $[a,b]$ we have

$$\mathcal{R}(c,\dot{\mathcal{P}}) = c(b-a)\ .$$

Apply Definition 1. 👍

The following crude estimate is surprisingly useful:

IX.2.6.2. Corollary. Let f be Riemann-integrable on $[a,b]$. If $m \le f(x) \le M$ for all $x \in [a,b]$, then

$$m(b-a) \le \int_a^b f(x)\,dx \le M(b-a)\ .$$

In particular, if $|f(x)| \le M$ for all $x \in [a,b]$, then

$$\left| \int_a^b f(x)\,dx \right| \le M(b-a)\ .$$

This Corollary can be proved more easily by simply noting that if $\mathcal{P}$ is the partition of $[a,b]$ consisting of one interval, then

$$m(b-a) \le \underline{\mathcal{S}}(f,\mathcal{P}) \le \int_a^b f(x)\,dx \le \overline{\mathcal{S}}(f,\mathcal{P}) \le M(b-a)\ .$$

Here is a simple but important consequence:

IX.2.6.3. Corollary. Let f be a nonnegative continuous function on $[a,b]$. If

$$\int_a^b f(t)\,dt = 0$$

then f is identically 0 on $[a,b]$.

Proof: Suppose there is an $x_0 \in [a,b]$ with $f(x_0) > 0$. Then by continuity there is a subinterval $[c,d]$ of $[a,b]$ containing x_0 such that $f(x) \ge m := \frac{f(x_0)}{2} > 0$ for all $x \in [c,d]$. Then

$$\int_c^d f(t)\,dt \ge m(d-c)$$

$$0 = \int_a^b f(t)\,dt = \int_a^c f(t)\,dt + \int_c^d f(t)\,dt + \int_d^b f(t)\,dt \ge m(d-c) > 0$$

since the first and third integrals are nonnegative, a contradiction. 👍

See IX.2.7.9. and XVIII.1.3.11. for generalizations.

Another closely related inequality, an integral version of the Triangle Inequality (), is also used regularly:

IX.2.6.4. Corollary. Let f be Riemann-integrable on $[a,b]$. Then $|f|$ is also Riemann-integrable on $[a,b]$, and

$$\left|\int_a^b f(x)\,dx\right| \leq \int_a^b |f(x)|\,dx\ .$$

Proof: We only need to see that $|f|$ is Riemann-integrable. But if $\mathcal{P}$ is any partition of $[a,b]$, then

$$\overline{\mathcal{S}}(|f|,\mathcal{P}) - \underline{\mathcal{S}}(|f|,\mathcal{P}) \leq \overline{\mathcal{S}}(f,\mathcal{P}) - \underline{\mathcal{S}}(f,\mathcal{P})$$

since $\omega(|f|,I) \leq \omega(f,I)$ for any interval I. 👍

IX.2.6.5. In the context of Figure IX.9, this is really a triangle inequality: if A_1 and A_3 are the areas of the two blue regions and A_2 the area of the tan region, then $\left|\int_a^b f(x)\,dx\right| = |A_1 - A_2 + A_3|$ and $\int_a^b |f(x)|\,dx = A_1 + A_2 + A_3$.

In connection with this, a product of Riemann integrable functions is Riemann integrable. This follows immediately from the characterization of (), but there is a slick elementary proof.

IX.2.6.6. Lemma. Let f be a bounded function on a set I, with $|f| \leq M$ on I. Then the oscillation

$$\omega(f^2,I) \leq 2M\omega(f,I)\ .$$

Proof: If $s,t \in I$, then

$$|[f(s)]^2 - [f(t)]^2| = |f(s)+f(t)||f(s)-f(t)| \leq 2M|f(s)-f(t)|\ .$$

👍

IX.2.6.7. Lemma. Let f be a Riemann integrable function on an interval $[a,b]$. Then f^2 is also Riemann integrable on $[a,b]$.

Proof: Since f is Riemann integrable on $[a,b]$, it is bounded. Fix M with $|f| \leq M$ on $[a,b]$. If $\mathcal{P}$ is any partition of $[a,b]$, then by IX.2.6.6.

$$\overline{\mathcal{S}}(f^2,\mathcal{P}) - \underline{\mathcal{S}}(f^2,\mathcal{P}) \leq 2M|\overline{\mathcal{S}}(f,\mathcal{P}) - \underline{\mathcal{S}}(f,\mathcal{P})|\ .$$

👍

IX.2.6.8. PROPOSITION. Let f and g be Riemann integrable on $[a,b]$. Then fg is Riemann integrable on $[a,b]$.

PROOF: We have that $f+g$ is Riemann integrable on $[a,b]$. Hence f^2, g^2, and $(f+g)^2$ are Riemann integrable on $[a,b]$ by IX.2.6.7., and

$$fg = \frac{1}{2}\left[(f+g)^2 - f^2 - g^2\right] \ .$$

The Mean Value Theorem for Integrals

Here is a version of the Mean Value Theorem for integrals. It is an immediate consequence of the FTC1 and the ordinary MVT, but it has a simple direct proof from the Intermediate Value Theorem.

IX.2.6.9. THEOREM. [MEAN VALUE THEOREM FOR INTEGRALS, VERSION 1] Let f be a continuous function on $[a,b]$. Then f is Riemann integrable on $[a,b]$, and there is a $c \in [a,b]$ for which

$$f(c)(b-a) = \int_a^b f(t)\,dt \ .$$

PROOF: By (), f is Riemann integrable on $[a,b]$. If M and m are the maximum and minimum values f takes on $[a,b]$ (), then

$$m(b-a) \leq \int_a^b f(t)\,dt \leq M(b-a)$$

(), and so by the Intermediate Value Theorem () there is a $c \in [a,b]$ with

$$f(c) = \frac{1}{b-a}\int_a^b f(t)\,dt \ .$$

Here is a generalized version:

IX.2.6.10. THEOREM. [MEAN VALUE THEOREM FOR INTEGRALS, VERSION 2] Let f and g be continuous functions on $[a,b]$, with g nonnegative. Then f, g, and fg are Riemann integrable on $[a,b]$, and there is a $c \in [a,b]$ for which

$$f(c)\int_a^b g(t)\,dt = \int_a^b f(t)g(t)\,dt \ .$$

PROOF: If g is identically 0, then fg is also identically 0 and there is nothing to prove. If g is not identically 0, then $\int_a^b g(t)\,dt > 0$ (IX.2.6.3.). Then, if M and m are the maximum and minimum values of f on $[a,b]$, we have $mg \le fg \le Mg$ on $[a,b]$, so

$$m\int_a^b g(t)\,dt \le \int_a^b f(t)g(t)\,dt \le M\int_a^b g(t)\,dt$$

and thus by the Intermediate Value Theorem there is a $c \in [a,b]$ with

$$f(c) = \frac{\int_a^b f(t)g(t)\,dt}{\int_a^b g(t)\,dt}\ .$$

See IX.2.7.14. and XIX.1.3.2. for more general versions.

Continuity of the Integral

One must be quite careful about interchanging integrals and limits: the Riemann integral is not continuous for all types of limits. In fact, obtaining good limit theorems was one of the main goals of developing modern integration theories.

There is one simple but important situation where Riemann integration is continuous:

IX.2.6.11. PROPOSITION. Let $[a,b]$ be a closed bounded interval, and (f_n) a sequence of functions on $[a,b]$ converging uniformly on $[a,b]$ to a function f. If each f_n is Riemann-integrable on $[a,b]$, then f is Riemann-integrable on $[a,b]$ and

$$\int_a^b f_n(x)\,dx \to \int_a^b f(x)\,dx\ .$$

(Informally, the integral of a uniform limit is the limit of the integrals.)

PROOF: If we know f is Riemann-integrable (e.g. if the f_n are continuous), this follows immediately from IX.2.6.1., IX.2.6.2., and IX.2.6.4.: if $\epsilon > 0$, choose N so that $|f_n(x) - f(x)| < \frac{\epsilon}{b-a}$ for all $n \ge N$ and all $x \in [a,b]$; then

$$\left|\int_a^b f_n(x)\,dx - \int_a^b f(x)\,dx\right| = \left|\int_a^b (f_n(x) - f(x))\,dx\right| \le \int_a^b |f_n(x) - f(x)|\,dx \le \frac{\epsilon}{b-a}(b-a) = \epsilon$$

for all $n \ge N$.

The argument that f is Riemann-integrable is very similar to the proof that a uniform limit of continuous functions is continuous (). Note that if $|f_n(x) - f(x)| < \epsilon$ for all $x \in [a,b]$, then for any partition $\mathcal{P}$ we have

$$|\underline{\mathcal{S}}(f_n,\mathcal{P}) - \underline{\mathcal{S}}(f,\mathcal{P})| \le \epsilon(b-a)$$

$$|\overline{\mathcal{S}}(f_n,\mathcal{P}) - \overline{\mathcal{S}}(f,\mathcal{P})| \le \epsilon(b-a)$$

so, if $\epsilon > 0$, and N is such that

$$|f_n(x) - f(x)| < \frac{\epsilon}{3(b-a)}$$

for all $n \geq N$ and $x \in [a,b]$, and $\mathcal{P}$ is a partition such that

$$\overline{\mathcal{S}}(f_N, \mathcal{P}) - \underline{\mathcal{S}}(f_N, \mathcal{P}) < \frac{\epsilon}{3}$$

we have that

$$\begin{aligned}\overline{\mathcal{S}}(f, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P}) &\leq |\overline{\mathcal{S}}(f, \mathcal{P}) - \overline{\mathcal{S}}(f_N, \mathcal{P})| + [\overline{\mathcal{S}}(f_N, \mathcal{P}) - \underline{\mathcal{S}}(f_N, \mathcal{P})] + |\underline{\mathcal{S}}(f_N, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P})| \\ &< \frac{\epsilon}{3(b-a)}(b-a) + \frac{\epsilon}{3} + \frac{\epsilon}{3(b-a)}(b-a) = \epsilon \ .\end{aligned}$$

Since $\epsilon > 0$ is arbitrary, f is Riemann-integrable by Definition 2A. 👍

Dense Sets and Integrability

IX.2.6.12. PROPOSITION. If f_1 and f_2 are Riemann-integrable on $[a,b]$ and agree on a dense subset D, then

$$\int_a^b f_1(x)\,dx = \int_a^b f_2(x)\,dx \ .$$

PROOF: If $\mathcal{P}$ is any partition of $[a,b]$, then Riemann sums for f_1 and f_2 with respect to $\mathcal{P}$ can be chosen with the tags in D, so these Riemann sums coincide. 👍

We can use this fact to give a definition of Riemann-integrability and the Riemann integral for certain functions which are not defined everywhere.

IX.2.6.13. DEFINITION. Let f be a real-valued function defined on a dense subset D of $[a,b]$. Then f is Riemann-integrable on $[a,b]$ if there is a Riemann-integrable function g on $[a,b]$ whose restriction to A is f. The Riemann integral $\int_a^b f(x)\,dx$ is defined to be $\int_a^b g(x)\,dx$.

IX.2.6.14. The Riemann integral of f is well defined independent of the choice of g by IX.2.6.12., and any two choices for g actually agree almost everywhere (IX.2.12.1.). An f which is Riemann-integrable in this extended sense is necessarily bounded.

The simplest situation is when f is defined except at finitely many points. Such a function can be changed, defined, or left undefined at finitely many points without changing its Riemann-integrability or its Riemann integral:

IX.2.6.15. PROPOSITION. Let f be a function defined at all but finitely many points of $[a,b]$. If f is Riemann-integrable, then any function g defined on all but finitely many points and agreeing with f at all but finitely many points is also Riemann-integrable, with

$$\int_a^b g(x)\,dx = \int_a^b f(x)\,dx\ .$$

PROOF: If $\mathcal{P}$ is a partition fine enough that it includes all the points where f or g is undefined and the points where they have unequal values, we have

$$\overline{\mathcal{S}}_\circ(f,\mathcal{P}) = \overline{\mathcal{S}}_\circ(g,\mathcal{P}) \text{ and } \underline{\mathcal{S}}_\circ(f,\mathcal{P}) = \underline{\mathcal{S}}_\circ(g,\mathcal{P})$$

and we can apply Definition 2A″. 👍

IX.2.6.16. Changing a function on even countably many points can affect its Riemann-integrability, e.g. changing the constant function 0 to $\chi_{\mathbb{Q}}$. (But if the new function is Riemann-integrable, the value of the integral is the same.)

IX.2.7. Null Sets and Almost Everywhere

We need to introduce here an important concept from measure theory. This discussion can serve as a preparatory introduction to measure theory.

IX.2.7.1. DEFINITION. Let A be a subset of $\mathbb{R}$. A has *measure zero*, or is a *null set*, if for every $\epsilon > 0$ there is a sequence (I_k) of finite intervals (which may be degenerate) such that $A \subseteq \cup_{k=1}^{\infty} I_k$ and $\sum_{k=1}^{\infty} \ell(I_k) < \epsilon$.
A has *zero content* if for each $\epsilon > 0$ there is a finite set $\{I_1, \ldots, I_n\}$ of finite intervals such that $A \subseteq \cup_{k=1}^{n} I_k$ and $\sum_{k=1}^{n} \ell(I_k) < \epsilon$.

IX.2.7.2. The term "null set" is often used as a synonym for "empty set", but in analysis it is more useful to use the definition we have given. (Note that the empty set is a null set by the analysis definition, but so are many nonempty sets, such as any finite set; in fact finite sets have zero content.)

Any subset of a null set (resp. a set of zero content) is a null set (resp. a set of zero content).

A set with zero content is obviously a null set (since $\emptyset$ is a degenerate interval); the converse is false:

IX.2.7.3. EXAMPLES. (i) Any countable set is a null set. [If A is countable, say $A = \{x_n : n \in \mathbb{N}\}$, and $\epsilon > 0$, let I_k be the open interval centered at x_k of length $\frac{\epsilon}{2^k}$.] Thus, for example, $\mathbb{Q}$ is a null set. But $\mathbb{Q}$ does not have zero content since a set with zero content is clearly bounded.

(ii) Even a bounded null set need not have zero content. For example, $A = \mathbb{Q} \cap [0, 1]$ is a null set by (i), but if $\{I_1, \ldots, I_n\}$ is a finite set of intervals containing A, then $\cup_{k=1}^{n} I_k$ contains all but finitely many points of $[0, 1]$. It follows that $\sum_{k=1}^{n} \ell(I_k) \geq 1$ (this seems obvious, but is actually somewhat tricky to prove; see (). This argument can be used to show that a true interval cannot be a null set, but this can be otherwise proved; see IX.2.7.12.. Thus the complement of a null set is dense.)

(iii) There are uncountable sets which have measure zero, e.g. the Cantor set K (). In fact, K has zero content.

In testing whether a set is a null set or has zero content, it suffices to use open intervals:

IX.2.7.4. PROPOSITION. Let A be a subset of $\mathbb{R}$. Then A is a null set if and only if there is a sequence (J_k) of bounded *open* intervals with $A \subseteq \cup_{k=1}^{\infty} J_k$ and $\sum_{k=1}^{\infty} \ell(J_k) < \epsilon$. A has zero content if and only if for every $\epsilon > 0$ there is a finite sequence (J_k) of bounded open intervals with the same properties.

PROOF: Suppose A has measure zero, and $\epsilon > 0$. There is a sequence (I_k) of bounded intervals such that $A \subseteq \cup_{k=1}^{\infty} I_k$ and $\sum_{k=1}^{\infty} \ell(I_k) < \frac{\epsilon}{2}$. For each k let J_k be the open interval with the same midpoint as I_k with $\ell(J_k) = 2\ell(I_k)$; then $I_k \subseteq J_k$, and the J_k work. The same argument works for finitely many intervals in the zero content case. The converse implication is trivial. 👍

IX.2.7.5. COROLLARY. A subset A has zero content if and only if it is bounded and its closure has measure zero. In particular, a closed bounded null set has zero content.

PROOF: Suppose A has zero content. Then A is bounded. Let $\epsilon > 0$, and let $\{I_1, \ldots, I_n\}$ be a finite set of bounded intervals with $A \subseteq \cup_{k=1}^n I_k$ and $\sum_{k=1}^n \ell(I_k) < \epsilon$. Replacing each I_k by its closure if necessary, we may assume each I_k is closed. But then $\cup_{k=1}^n I_k$ is closed, so $\bar{A} \subseteq \cup_{k=1}^n I_k$ and $\bar{A}$ is a null set (in fact, has zero content).

Conversely, suppose A is bounded and $\bar{A}$ is a null set. Fix $\epsilon > 0$, and let (I_k) be a sequence of bounded open intervals such that $\bar{A} \subseteq \cup_{k=1}^\infty I_k$ and $\sum_{k=1}^\infty \ell(I_k) < \epsilon$. The I_k cover $\bar{A}$, and since $\bar{A}$ is compact there is a finite subcover, i.e. $\bar{A} \subseteq \cup_{k=1}^n I_k$ for some n. Since $\sum_{k=1}^n \ell(I_k) < \epsilon$, it follows that $\bar{A}$, and hence A, has zero content. 👍

Unions of Null Sets

A finite union of null sets is a null set, and a finite union of sets of zero content has zero content. For null sets, we have a better result:

IX.2.7.6. PROPOSITION. A countable union of null sets is a null set.

PROOF: Let A_n be a null set for each n, and $A = \cup_{n=1}^\infty$. Fix $\epsilon > 0$. For each n, let $\{I_{n,k}\}$ be a sequence of bounded intervals such that $A_n \subseteq \cup_{k=1}^\infty I_{n,k}$ and $\sum_{k=1}^\infty \ell(I_{n,k}) < \frac{\epsilon}{2^n}$. Then the set $\{I_{n,k} : n, k \in \mathbb{N}\}$ is a countable set of bounded intervals with $A \subseteq \cup_{n,k} I_{n,k}$ and $\sum_{n,k} \ell(I_{n,k}) < \epsilon$. Since $\epsilon > 0$ is arbitrary, A is a null set. 👍

IX.2.7.7. This result gives another proof that every countable set is a null set, since it is a countable union of singletons.

It is not true that countable unions of sets of zero content have zero content (e.g. $\mathbb{Q}$). Closure of the null sets under countable unions indicates that the notion of null set is a more flexible one than that of a set of zero content. Good behavior under countable unions turns out to be necessary for a good theory of measure and advanced integration.

Almost Everywhere

IX.2.7.8. It is convenient to use the phrase *almost everywhere*, abbreviated *a.e.*, to mean "except on a null set." Thus, for example, if we say "the functions f and g agree almost everywhere," we mean "the set of all x for which $f(x) = g(x)$ does not hold (i.e. one or both of $f(x)$ and $g(x)$ is undefined, or both are defined but unequal) has measure zero."

Nonnegative Riemann-Integrable Functions

Using the language of null sets and almost everywhere, we can give an important fact about nonnegative Riemann-integrable functions:

IX.2.7.9. PROPOSITION. Let f be a nonnegative function on an interval $[a,b]$. If f is Riemann-integrable on $[a,b]$ and $\int_a^b f(x)\,dx = 0$, then $f = 0$ a.e. on $[a,b]$.

PROOF: For each n, let

$$A_n = \left\{ x \in [a,b] : f(x) \geq \frac{1}{n} \right\} .$$

We will show that each A_n has zero content, hence is a null set. This will suffice, since then

$$\{x \in [a,b] : f(x) \neq 0\} = \bigcup_{n=1}^{\infty} A_n$$

will be a null set by IX.2.7.6..

Fix n, and then fix $\epsilon > 0$. Let $\mathcal{P} = \{x_0, \ldots, x_m\}$ be a partition with $\overline{\mathcal{S}}(f,\mathcal{P}) < \frac{\epsilon}{n}$. Let K be the set of all k such that $A_n \cap [x_{k-1}, x_k]$ is nonempty. Then $A_n \subseteq \cup_{k\in K}[x_{k-1}, x_k]$. If M_k is the supremum of f on $[x_{k-1}, x_k]$, we have

$$\frac{1}{n}\sum_{k\in K}(x_k - x_{k-1}) \leq \sum_{k\in K} M_k(x_k - x_{k-1}) \leq \sum_{k=1}^{m} M_k(x_k - x_{k-1}) = \overline{\mathcal{S}}(f,\mathcal{P}) < \frac{\epsilon}{n}$$

and so $\sum_{k\in K}(x_k - x_{k-1}) < \epsilon$. Since $\epsilon > 0$ is arbitrary, A_n has zero content. 👍

IX.2.7.10. IX.2.6.12. gives a strong converse: if f is Riemann-integrable on $[a,b]$ and equal to zero on a dense subset, then $\int_a^b f(x)\,dx = 0$.

One direction of the next proposition is a corollary of the proof of IX.2.7.9.:

IX.2.7.11. PROPOSITION. Let A be a subset of $[a,b]$. Then A has zero content if and only if the indicator function χ_A is Riemann-integrable on $[a,b]$ and $\int_a^b \chi_A(x)\,dx = 0$.

IX.2.7.12. COROLLARY. No interval is a null set.

PROOF: First let $[a,b]$ be a closed bounded interval (with $a < b$). If $[a,b]$ is a null set, it has zero content by IX.2.7.5.. But $\int_a^b \chi_{[a,b]}(x)\,dx = b - a > 0$, so $[a,b]$ does not have zero content by IX.2.7.11..

Now let I be an arbitrary interval, and let $a, b \in I$, $a < b$. If I is a null set, then its subset $[a,b]$ is also a null set, a contradiction. 👍

Almost the same result as IX.2.6.15. holds if "finite set" is replaced by "set of zero content," but boundedness of the modified function is not automatic and must be assumed:

IX.2.7.13. PROPOSITION. Let f be a function defined on $[a,b]$ except on a set of zero content. If f is Riemann-integrable, then any bounded function g defined except on a set of zero content and agreeing with f except on a set of zero content is also Riemann-integrable, with

$$\int_a^b g(x)\,dx = \int_a^b f(x)\,dx\ .$$

PROOF: Let h be a Riemann-integrable function on $[a,b]$ agreeing with f where f is defined. Extend g in any manner to a bounded function defined everywhere on $[a,b]$; we will from now on assume g is defined everywhere.

Let A be a set of zero content such that f and g are defined and equal on $[a,b]\setminus A$, and let $M>0$ be a bound for both g and h on $[a,b]$. Fix $\epsilon>0$. Let $\{I_1,\dots,I_n\}$ be a set of bounded intervals with $A\subseteq\cup_{k=1}^n I_k$ and $\sum_{k=1}^n \ell(I_k)<\frac{\epsilon}{4M}$. Let $\mathcal{P}$ be a partition of $[a,b]$ such that $\overline{\mathcal{S}}_\circ(h,\mathcal{P})-\underline{\mathcal{S}}_\circ(h,\mathcal{P})<\frac{\epsilon}{2}$ and such that $\mathcal{P}$ includes all endpoints of $I_1,\dots,I_n$ which are in $[a,b]$. Let M_j and m_j be the supremum and infimum of g on (x_{j-1},x_j).

Let J be the set of all indices j such that $(x_{j-1},x_j)\subseteq\cup_{k=1}^n I_k$. Then

$$\overline{\mathcal{S}}_\circ(g,\mathcal{P})-\underline{\mathcal{S}}_\circ(g,\mathcal{P})=\sum_{j=1}^m (M_j-m_j)(x_j-x_{j-1})$$

$$=\sum_{j\in J}(M_j-m_j)(x_j-x_{j-1})+\sum_{j\notin J}(M_j-m_j)(x_j-x_{j-1})<2M\frac{\epsilon}{4M}+\frac{\epsilon}{2}=\epsilon\ .$$

Since $\epsilon>0$ is arbitrary, g is Riemann-integrable on $[a,b]$ by Definition 2A″, and

$$\int_a^b g(x)\,dx=\int_a^b h(x)\,dx\ .$$

The Mean Value Theorem Again

Using IX.2.7.9., we get a slight extension of the Mean Value Theorem for Integrals IX.2.6.10.:

IX.2.7.14. THEOREM. [MEAN VALUE THEOREM FOR INTEGRALS, VERSION 3] Let f be a continuous function on $[a,b]$, and g a nonnegative Riemann integrable function on $[a,b]$. Then fg is Riemann integrable on $[a,b]$, and there is a $c\in[a,b]$ for which

$$f(c)\int_a^b g(t)\,dt=\int_a^b f(t)g(t)\,dt\ .$$

PROOF: The product fg is Riemann integrable on $[a,b]$ by IX.2.6.8.. If $\int_a^b g(t)\,dt=0$, then g is 0 a.e., so fg is also 0 a.e. and there is nothing to prove. Otherwise, the proof of IX.2.6.10. works verbatim. 

Note that g need not be continuous, but f must be continuous for the proof to work, and in fact the result fails in general if f is not continuous (consider the case where f is the indicator function of a proper subinterval).

IX.2.8. The Upper and Lower Envelope of a Riemann-Integrable Function

We continue somewhat in the spirit of IX.2.3.11., in a sense carrying it to its logical conclusion.

IX.2.8.1. DEFINITION. Let f be a bounded function on an interval $[a,b]$. Define

$$\underline{f} = \sup\{\phi : [a,b] \to \mathbb{R} \ : \ \phi \text{ lower semicontinuous, } \phi \le f\}$$

$$\overline{f} = \inf\{\psi : [a,b] \to \mathbb{R} \ : \ \psi \text{ upper semicontinuous, } f \le \psi\} \ .$$

The functions $\overline{f}$ and $\underline{f}$ are called the *upper* and *lower envelopes* of f on $[a,b]$.

We have that $\overline{f}$ and $\underline{f}$ are bounded, and $\underline{f} \le f \le \overline{f}$. By (), $\overline{f}$ is upper semicontinuous and $\underline{f}$ is lower semicontinuous.

IX.2.8.2. PROPOSITION. Let f be a bounded function on $[a,b]$, and $\overline{f}$ and $\underline{f}$ its upper and lower envelopes. If J is any open subinterval of $[a,b]$, then

$$\sup_{x\in J} \overline{f}(x) = \sup_{x\in J} f(x) \quad \text{and} \quad \inf_{x\in J} \underline{f}(x) = \inf_{x\in J} f(x) \ .$$

PROOF: It is clear that $\sup_{x\in J} \overline{f}(x) \ge \sup_{x\in J} f(x)$. Conversely, let $M = \sup_{x\in J} f(x)$. Then there is an upper semicontinuous step function ψ on $[a,b]$, which is constant on J and two other subintervals of $[a,b]$, with $\psi = M$ on J and $f \le \psi$. Thus

$$\sup_{x\in J} \overline{f}(x) \le \sup_{x\in J} \psi(x) = M = \sup_{x\in J} f(x) \ .$$

The argument for $\underline{f}$ is nearly identical. 👍

IX.2.8.3. COROLLARY. Let f be a bounded function on $[a,b]$, and $\overline{f}$ and $\underline{f}$ its upper and lower envelopes. For each $x \in [a,b]$, we have

$$\overline{f}(x) = \max\{f(x), \limsup_{y\to x} f(y)\} \quad \text{and} \quad \underline{f}(x) = \min\{f(x), \liminf_{y\to x} f(y)\} \ .$$

IX.2.8.4. COROLLARY. Let f be a bounded function on $[a,b]$, and $\overline{f}$ and $\underline{f}$ its upper and lower envelopes. If $\mathcal{P}$ is any partition of $[a,b]$, then

$$\overline{\mathcal{S}}_\circ(\overline{f}, \mathcal{P}) = \overline{\mathcal{S}}_\circ(f, \mathcal{P}) \quad \text{and} \quad \underline{\mathcal{S}}_\circ(\underline{f}, \mathcal{P}) = \underline{\mathcal{S}}_\circ(f, \mathcal{P}) \ .$$

Thus we have

$$\overline{\int_a^b} \overline{f}(x)\,dx = \overline{\int_a^b} f(x)\,dx \quad \text{and} \quad \underline{\int_a^b} \underline{f}(x)\,dx = \underline{\int_a^b} f(x)\,dx \ .$$

Using these results, we can prove the fundamental characterization of Riemann integrability:

IX.2.8.5. THEOREM. Let f be a function on an interval $[a,b]$. Then f is Riemann-integrable on $[a,b]$ if and only if it is bounded, and continuous almost everywhere.

PROOF: We have already shown that a Riemann-integrable function must be bounded. Suppose f is Riemann-integrable on $[a,b]$. Let $\overline{f}$ and $\underline{f}$ be its upper and lower envelopes, and set $g = \overline{f} - \underline{f}$. Then $g \geq 0$. Fix $\epsilon > 0$, and choose a partition $\mathcal{P}$ such that $\overline{\mathcal{S}}_\circ(f,\mathcal{P}) - \underline{\mathcal{S}}_\circ(f,\mathcal{P}) < \epsilon$. Then we have

$$\overline{\mathcal{S}}_\circ(g,\mathcal{P}) = \overline{\mathcal{S}}_\circ(\overline{f},\mathcal{P}) - \underline{\mathcal{S}}_\circ(\underline{f},\mathcal{P}) = \overline{\mathcal{S}}_\circ(f,\mathcal{P}) - \underline{\mathcal{S}}_\circ(f,\mathcal{P}) < \epsilon$$

and, since g is nonnegative and hence $0 \leq \underline{\mathcal{S}}_\circ(g,\mathcal{P}) \leq \overline{\mathcal{S}}_\circ(g,\mathcal{P}) < \epsilon$, we have that g is Riemann-integrable on $[a,b]$ and $\int_a^b g(x)\,dx = 0$. Thus $g = 0$ a.e. (IX.2.7.9.), i.e. $\underline{f} = f = \overline{f}$ a.e. If x is such that $\underline{f}(x) = f(x) = \overline{f}(x)$, then f is both upper semicontinuous and lower semicontinuous at x, hence continuous at x (). (The conclusion also follows immediately from IX.2.8.3..)

Conversely, suppose f is bounded and continuous a.e. on $[a,b]$. Let $M > 0$ be a bound for f on $[a,b]$, and A the set of discontinuities of f in $[a,b]$. Fix $\epsilon > 0$. Let (I_k) be a sequence of open intervals with $A \subseteq \cup_{k=1}^\infty I_k$ and $\sum_{k=1}^\infty \ell(I_k) < \frac{\epsilon}{4M}$. For each $x \in [a,b]\setminus A$ there is an open interval J_x around x with $|f(y)-f(z)| < \frac{\epsilon}{2(b-a)}$ for all $y,z \in J_x$, since f is continuous at x. The collection $\{I_k : k \in N\} \cup \{J_x : x \in [a,b] \setminus A\}$ is an open cover of $[a,b]$. By compactness, there is a finite subcover, so there is a partition $\mathcal{P} = \{x_0,\ldots,x_n\}$ of $[a,b]$ such that each interval $[x_{j-1},x_j]$ is contained either in one of the I_k or one of the J_x. Let K be the set of j such that $[x_{j-1},x_j]$ is contained in one of the I_k. Then, if M_j and m_j are the supremum and infimum of f on $[x_{j-1},x_j]$, we have

$$\overline{\mathcal{S}}(f,\mathcal{P}) - \underline{\mathcal{S}}(f,\mathcal{P}) = \sum_{j=1}^n (M_j - m_j)(x_j - x_{j-1})$$

$$= \sum_{j\in K}(M_j - m_j)(x_j - x_{j-1}) + \sum_{j\notin K}(M_j - m_j)(x_j - x_{j-1}) < 2M\frac{\epsilon}{4M} + \frac{\epsilon}{2(b-a)}(b-a) = \epsilon\ .$$

Since $\epsilon > 0$ is arbitrary, f is Riemann-integrable on $[a,b]$. 👍

IX.2.9. Differentiation and the Fundamental Theorem of Calculus

In this section, we establish the fundamental results that integration and differentiation are inverse processes.

IX.2.9.1. Let f be a Riemann-integrable function on $[a, b]$. Then, for any $x \in [a, b]$, f is Riemann-integrable on $[a, x]$ (). For $a \leq x \leq b$, define

$$A(x) = \int_a^x f(t)\, dt \ .$$

$A(x)$ is called the *cumulative area* of f from a to x; this can be regarded as a function A from $[a, b]$ to $\mathbb{R}$, called the *cumulative area function* of f from a to b. (If f is nonnegative, $A(x)$ can be truly regarded as the "area" of the region below the graph of f and above the x-axis, between the vertical lines at a and x. Rigorously, this is backward: the area of this region can be *defined* to be this integral – see (). For a general f, $A(x)$ gives the "signed area" under the graph from a to x, with regions below the x-axis having negative "area.")

IX.2.9.2. Proposition. If f is a Riemann-integrable function on $[a, b]$, then its cumulative area function is Lipschitz () on $[a, b]$, and hence (uniformly) continuous on $[a, b]$.

Proof: Since f is Riemann-integrable on $[a, b]$, it is bounded; let M be a bound for $|f|$ on $[a, b]$. Then, for every $x, y \in [a, b]$, $x < y$, we have

$$|A(y) - A(x)| = \left| \int_a^y f(t)\, dt - \int_a^x f(t)\, dt \right| = \left| \int_x^y f(t)\, dt \right| \leq \int_x^y |f(t)|\, dt \leq M(y - x)$$

by (). 👍

The next theorem is the main result of this section and, as the name suggests, one of the most important theorems in elementary analysis:

IX.2.9.3. Theorem. [Fundamental Theorem of Calculus, Version 1] Let f be Riemann-integrable on $[a, b]$, and A its cumulative area function. If f is continuous at $x_0 \in [a, b]$, then A is differentiable at x_0 and $A'(x_0) = f(x_0)$.

Before giving the proof of this theorem, we give some simple consequences. The first is the same as V.8.5.9.:

IX.2.9.4. Corollary. If f is continuous on $[a, b]$, then there is a function F, unique up to addition of a constant, which is differentiable on $[a, b]$ and for which $F'(x) = f(x)$ for all $x \in [a, b]$.

The uniqueness of the antiderivative up to a constant follows immediately from V.8.2.5..

The next variation gives the common procedure for calculating the value of the integral:

IX.2.9.5. Corollary. If f is continuous on $[a,b]$, and F is any antiderivative for f on $[a,b]$, then

$$\int_a^b f(x)\,dx = F(b) - F(a)\ .$$

Proof: Let A be the cumulative area function of f. Then we have that A is an antiderivative for f by IX.2.9.3., and that

$$\int_a^b f(x)\,dx = A(b)$$

and $A(a) = 0$. Also, by IX.2.9.4., there is a constant C such that $F(x) = A(x) + C$ for all $x \in [a,b]$. We then have

$$F(b) - F(a) = [A(b) + C] - [A(a) + C] = A(b) - A(a) = A(b) = \int_a^b f(x)\,dx\ .$$

IX.2.9.6. Extensive and detailed applications of this version of the Fundamental Theorem of Calculus to evaluating definite integrals can be found in any Calculus text. Since this is not a Calculus text, we omit discussion of these applications.

IX.2.9.7. We now give the proof of IX.2.9.3..
Proof: We have, for $x \in [a,b]$, $x \neq x_0$,

$$A(x) - A(x_0) = \int_a^x f(t)\,dt - \int_a^{x_0} f(t)\,dt = \int_{x_0}^x f(t)\,dt$$

$$\frac{A(x) - A(x_0)}{x - x_0} = \frac{1}{x - x_0}\int_{x_0}^x f(t)\,dt\ .$$

We also have

$$f(x_0) = \frac{1}{x - x_0}\int_{x_0}^x f(x_0)\,dt$$

(since $f(x_0)$ is just a constant), and so

$$\frac{A(x) - A(x_0)}{x - x_0} - f(x_0) = \frac{1}{x - x_0}\int_{x_0}^x [f(t) - f(x_0)]\,dt\ .$$

Let $\epsilon > 0$. Since f is continuous at x_0, there is a $\delta > 0$ such that, whenever $x \in [a,b]$ and $|x - x_0| < \delta$, $|f(x) - f(x_0)| < \epsilon$. If $x \in [a,b]$ and $|x - x_0| < \delta$, then $|t - x_0| < \delta$ for all t between x_0 and x, and hence

$$\left|\int_{x_0}^x [f(t) - f(x_0)]\,dt\right| < \epsilon|x - x_0|$$

by (); so we have

$$\left|\frac{A(x) - A(x_0)}{x - x_0} - f(x_0)\right| = \frac{1}{|x - x_0|}\left|\int_{x_0}^x [f(t) - f(x_0)]\,dt\right| < \epsilon$$

and therefore

$$A'(x_0) = \lim_{x \to x_0} \frac{A(x) - A(x_0)}{x - x_0} = f(x_0) \ .$$

IX.2.9.8. EXAMPLES. If f is Riemann-integrable on $[a, b]$, A is its cumulative area function, and f is not continuous at $x_0 \in [a, b]$, then A may or may not be differentiable at x_0, and if it is we may or may not have $A'(x_0) = f(x_0)$:

(i) Let $f(x) = 0$ for $x < 0$ and $f(x) = 1$ for $x \geq 0$. Then f is Riemann-integrable on $[-1, 1]$, and its cumulative area function A is given by $A(x) = 0$ if $-1 \leq x \leq 0$ and $A(x) = x$ if $0 \leq x \leq 1$. A is not differentiable at 0.

(ii) Let $f(x) = 0$ for $x \neq 0$ and $f(0) = 1$. Then f is Riemann-integrable on $[-1, 1]$, and A is identically 0. We have that A is differentiable at 0, but $A'(0) \neq f(0)$.

(iii) [vRS82, p. 3-4] Let $f(x) = \sin\left(\frac{1}{x}\right)$ for $x \neq 0$ and $f(0) = 0$. Then f is bounded, and continuous except at 0, so f is Riemann-integrable on $[-1, 1]$ (or any other closed bounded interval). If A is its cumulative area function, we will show that A is differentiable at 0 and $A'(0) = 0 = f(0)$ even though f is discontinuous at 0. This can be shown directly by brute force, but we can get it more easily indirectly.

We first show that f has an antiderivative F. Let

$$G(x) = \begin{cases} x^2 \cos\left(\frac{1}{x}\right) & \text{if} \quad x \neq 0 \\ 0 & \text{if} \quad x = 0 \end{cases} \ .$$

Then G is differentiable everywhere, and

$$G'(x) = g(x) = \left\{ \begin{array}{cc} 2x \cos\left(\frac{1}{x}\right) + \sin\left(\frac{1}{x}\right) & \text{if} \quad x \neq 0 \\ 0 & \text{if} \quad x = 0 \end{array} \right\} = h(x) + f(x)$$

where

$$h(x) = \begin{cases} 2x \cos\left(\frac{1}{x}\right) & \text{if} \quad x \neq 0 \\ 0 & \text{if} \quad x = 0 \end{cases} \ .$$

Since h is continuous, it has an antiderivative H (IX.2.9.4.). Then $f = g - h$ also has an antiderivative $F = G - H$.

We then have that $A - F$ is continuous everywhere, differentiable everywhere except possibly at 0, and $(A - F)'(x) = 0$ for all $x \neq 0$. Thus by V.8.4.1.(iii) $A - F$ is constant, hence differentiable also at 0; so A is differentiable at 0 and $A'(0) = F'(0) = 0 = f(0)$.

More dramatic versions of this example exist: see Exercise V.12.4.3.. For a related example, if f is a Lebesgue integrable function on $[a, b]$ and A is its cumulative area function (i.e. $A(x)$ is the Lebesgue integral of f from a to x), then A is continuous, differentiable almost everywhere, and $A' = f$ almost everywhere (XIX.5.2.15.). Such an f need not be continuous anywhere and need not be equal almost everywhere to a function which is Riemann integrable on any subinterval ().

IX.2.9.9. Version IX.2.9.3. of the Fundamental Theorem of Calculus roughly says that the derivative of the integral is the original function. What about the integral of the derivative? One problem is that the derivative of a differentiable function on an interval need not be Riemann-integrable:

IX.2.9.10. EXAMPLES. (i) Let F be the function

$$F(x) = \left\{ \begin{array}{cc} x^2 \sin\left(\frac{1}{x^2}\right) & \text{if} \quad x \neq 0 \\ 0 & \text{if} \quad x = 0 \end{array} \right. .$$

Then F is differentiable everywhere, and

$$F'(x) = f(x) = \left\{ \begin{array}{cc} 2x \sin\left(\frac{1}{x^2}\right) - \frac{2}{x} \cos\left(\frac{1}{x^2}\right) & \text{if} \quad x \neq 0 \\ 0 & \text{if} \quad x = 0 \end{array} \right\}$$

which is unbounded near 0 and hence not Riemann-integrable in any interval containing 0 (in fact, it is not even Lebesgue integrable in any interval containing 0).

(ii) Let F be the function of (). Then F is differentiable on $[0, 1]$, and $F' = f$ is bounded there. Since f is 0 on a dense subset of $[0, 1]$, the Riemann integral of f on any subinterval, if it existed, would have to be 0 (IX.2.6.12.). Since F is not constant on any subinterval, it follows from IX.2.9.11. below that f is not Riemann-integrable on any subinterval. It even turns out that f is not equal almost everywhere to a Riemann-integrable function ().

We do, however, have the following theorem, which extends IX.2.9.5.:

IX.2.9.11. THEOREM. [FUNDAMENTAL THEOREM OF CALCULUS, VERSION 2] Let F be a function which is continuous on $[a, b]$ and differentiable except possibly at finitely many points, with derivative f. If f is Riemann-integrable on $[a, b]$, then for all $x \in [a, b]$ we have

$$F(x) = F(a) + \int_a^x f(t)\, dt$$

and so, in particular,

$$\int_a^b f(t)\, dt = F(b) - F(a) .$$

PROOF: It suffices to prove the second statement; the first statement then results from applying the second to the interval $[a, x]$.

Let $\epsilon > 0$, and let $\mathcal{P} = \{a = x_0, x_1, \ldots, x_n = b\}$ be a partition satisfying Definition 1A for this ϵ, and fine enough that $\mathcal{P}$ contains all points where F is not differentiable (such a partition exists by Definition 1B). By the Mean Value Theorem (), for each k choose $t_k \in (x_{k-1}, x_k)$ so that

$$F(x_k) - F(x_{k-1}) = f(t_k)(x_k - x_{k-1}) .$$

Then, by telescoping, we have

$$F(b) - F(a) = \sum_{k=1}^{n} (F(x_k) - F(x_{k-1})) = \sum_{k=1}^{n} f(t_k)(x_k - x_{k-1})$$

and so, since the right side is a Riemann sum for f with respect to $\mathcal{P}$, we have

$$\left|(F(b) - F(a)) - \int_a^b f(t)\,dt\right| < \epsilon\ .$$

Since $\epsilon > 0$ is arbitrary, the result follows. 👍

This result generalizes to the case in which f is only required to be Lebesgue integrable (XIX.5.2.22.).

The hypothesis can be relaxed to allow F to be nondifferentiable at countably many points (if it is continuous) (XIX.5.2.22.), but not just differentiable almost everywhere ().

More general versions of the Fundamental Theorem of Calculus will be discussed in XVIII.4.2.1., XIX.5.2.15., XIX.5.2.21., ...

The Average Value of a Function

IX.2.9.12. DEFINITION. Let f be Riemann-integrable on $J = [a, b]$. Then the *average value* of f on J is

$$av(f, J) = \frac{1}{b-a}\int_a^b f(x)\,dx\ .$$

(Note that this definition also makes sense if $b < a$, and gives the same value if a and b are interchanged.)

It is not hard to motivate this definition as a reasonable version of the average value of a function on an interval, e.g. by considering Riemann sums corresponding to a subdivision of the interval into a large number of subintervals of equal length. One interpretation which is reasonable motivation is that $av(f, J)$ is the value of a constant function on J which has the same integral over J as f.

IX.2.9.13. Using this notion of average value, we have an interesting relation between average and instantaneous rates of change. If f is differentiable on $[a, b]$ and f' is Riemann integrable on $[a, b]$, then by IX.2.9.11. we have

$$\frac{1}{b-a}\int_a^b f'(t)\,dt = \frac{f(b) - f(a)}{b-a}$$

i.e. the average rate of change of f over $[a, b]$ (the right-hand side) is equal to the average value of the instantaneous rate of change of f over $[a, b]$ (the left-hand side). This can be thought of as a variant of the Mean Value Theorem: If f is differentiable on $[a, b]$ and f' is Riemann integrable on $[a, b]$, the difference quotient of f over $[a, b]$ is the average value of f' over $[a, b]$ (the MVT asserts it is the value of f' at some particular point of $[a, b]$).

We then have the following analog of the Mean Value Theorem (actually more than an analog, in light of IX.2.9.3.).

IX.2.9.14. PROPOSITION. [MEAN VALUE THEOREM FOR INTEGRALS] Let f be a continuous function on a closed bounded interval $J = [a, b]$. Then there is at least one $c \in (a, b)$ with $f(c) = av(f, J)$.

PROOF: Let m and M be the minimum and maximum of f on $[a, b]$ (). Then, if $\mathcal{P} = \{a, b\}$ is the partition with one subinterval, we have $\underline{\mathcal{S}}(f, \mathcal{P}) = m(b - a)$ and $\overline{\mathcal{S}}(f, \mathcal{P}) = M(b - a)$, so we have

$$m(b - a) \leq \int_a^b f(x)\, dx \leq M(b - a)$$

so, dividing through by $b - a$, we have

$$m \leq av(f, J) \leq M \ .$$

If $m = M$, then f is constant on $[a, b]$, and we can take c to be any number in (a, b). If $m < M$, we have $m < av(f, J) < M$ [if $m = av(f, J)$, set $g(x) = f(x) - m$; then $g \geq 0$ is continuous and $\int_a^b g(x)\, dx = 0$, so g is identically 0 (), a contradiction. A similar argument using $h(x) = M - f(x)$ shows that we cannot have $av(f, J) = M$.] Choose $x_1, x_2 \in [a, b]$ with $f(x_1) = m$, $f(x_2) = M$ (). Then by the Intermediate Value Theorem () there is a c in the open interval between x_1 and x_2 with $f(c) = av(f, J)$. 👍

Note that this result can fail if f is not continuous, e.g. if f is a step function taking only the values 0 and 1.

Derivatives and Limits

We can use the FTC plus properties of the Riemann integral to give a simpler proof of a crucial special case of V.8.5.5.:

IX.2.9.15. THEOREM. Let (F_n) and (f_n) be sequences of functions on an interval I. Suppose

(a) Each f_n is continuous on I.

(b) Each F_n is differentiable on I, with $F_n' = f_n$.

(c) The sequence (f_n) converges u.c. on I to a function f.

(d) There is an $x_0 \in I$ such that the sequence $(F_n(x_0))$ converges.

Then:

(i) The sequence (F_n) converges u.c. on I to a function F.

(ii) F is differentiable on I and $F' = f$.

PROOF: Set $L = \lim_{n\to\infty} F_n(x_0)$. By the FTC2, we have, for each n and each $x \in I$,

$$F_n(x) = F_n(x_0) + \int_{x_0}^x f_n(t)\, dt \ .$$

For each fixed $x \in I$, since $f_n \to f$ uniformly on the interval between x_0 and x,

$$F_n(x) = F_n(x_0) + \int_{x_0}^x f_n(t)\, dt \to L + \int_{x_0}^x f(t)\, dt$$

by IX.2.6.11.; so, if we define, for $x \in I$,

$$F(x) = L + \int_{x_0}^{x} f(t)\,dt$$

we have by the FTC1 that F is differentiable on I and $F' = f$; and $F_n \to F$ pointwise on I. It remains to show that $F_n \to F$ u.c. on I. Let $[a,b]$ be a closed bounded subinterval of I containing x_0. Fix $\epsilon > 0$, and choose N so that $|f_n(x) - f(x)| < \frac{\epsilon}{2(b-a)}$ for all $n \geq N$ and all $x \in [a,b]$, and $|F_n(x_0) - L| < \frac{\epsilon}{2}$ for all $n \geq N$. Then, for $n \geq N$ and $x \in [a,b]$,

$$|F_n(x) - F(x)| \leq |F_n(x_0) - L| + \left| \int_{x_0}^{x} [f_n(t) - f(t)]\,dt \right| \leq |F_n(x_0) - L| + \int_{x_0}^{x} |f_n(t) - f(t)|\,dt$$

$$< \frac{\epsilon}{2} + \frac{\epsilon}{2(b-a)}|x - x_0| \leq \epsilon\ .$$

IX.2.10. Integration by Substitution and Integration by Parts

IX.2.10.1. Integration (antidifferentiation) is harder than differentiation. Differentiation of functions composed of standard algebraic, exponential, logarithm, trigonometric, inverse trigonometric, etc., functions can be done more or less mechanically by repeated application of the rules of differentiation. But there is no systematic procedure to find antiderivatives. A number of techniques have been developed to find antiderivatives of certain kinds of functions (a considerable portion of most university calculus sequences is devoted to "techniques of integration"), but no technique or procedure works in general; indeed, there are even functions with standard formulas, such as $f(x) = e^{-x^2}$, which are important in applications but which have no antiderivative formula in terms of standard functions (XII.12.3.18.). Thus there is no systematic technique to evaluate Riemann integrals via the Fundamental Theorem of Calculus in general.

Any differentiation rule can be turned around to give an antiderivative rule (although some care must be exercised to get precise and valid statements in general). Antiderivatives of certain specific functions can be found this way. And the Product Rule and Chain Rule can be turned around to give two of the most basic techniques of integration, Integration by Substitution and Integration by Parts.

Integration by Substitution or Change of Variable

Informally, the Chain Rule says that if F and ϕ are differentiable functions, with $F' = f$, then

$$\frac{d}{dx}\left(F(\phi(x))\right) = f(\phi(x))\phi'(x)$$

so $F \circ \phi$ is an antiderivative for $(f \circ \phi)\phi'$. To make a statement valid for Riemann integrals, we have to be a little careful with hypotheses. We will not state the most general result possible here (see IX.2.12.9.–IX.2.12.10. and XIX.5.5.6. for other results).

IX.2.10.2. THEOREM. [INTEGRATION BY SUBSTITUTION OR CHANGE OF VARIABLE, RIEMANN VERSION] Let I and J be intervals, ϕ a differentiable function on I, $\phi(I) \subseteq J$, and f a continuous function on J. Let $a, b \in I$, $a < b$. If $(f \circ \phi)\phi'$ is Riemann integrable on $[a, b]$, then

$$\int_a^b f(\phi(x))\phi'(x)\,dx = \int_{\phi(a)}^{\phi(b)} f(u)\,du \ .$$

By IX.2.12.7., the hypothesis that $(f \circ \phi)\phi'$ is Riemann integrable on $[a, b]$ is satisfied if ϕ' is Riemann integrable on $[a, b]$, since ϕ is continuous on I and f is continuous on J, so $f \circ \phi$ is continuous on I and thus on $[a, b]$. In particular, the hypothesis is satisfied if ϕ' is continuous on $[a, b]$, i.e. ϕ is $\mathcal{C}^1$ on $[a, b]$.

PROOF: Since f is continuous on J and $\phi(a), \phi(b) \in J$, the Riemann integral

$$\int_{\phi(a)}^{\phi(b)} f(u)\,du$$

is defined (we should not talk about the interval $[\phi(a), \phi(b)]$ since we could have $\phi(b) < \phi(a)$; nonetheless the integral is defined in this case too). Let F be an antiderivative for f on J (); then by the Chain Rule, $F \circ \phi$ is differentiable on I, with derivative $(f \circ \phi)\phi'$. By two applications of the FTC2,

$$\int_{\phi(a)}^{\phi(b)} f(u)\,du = F(\phi(b)) - F(\phi(a)) = \int_a^b f(\phi(x))\phi'(x)\,dx \ .$$

IX.2.10.3. Note that there is no requirement in this result that ϕ is monotone, or even that $\phi([a, b])$ is contained in the interval between $\phi(a)$ and $\phi(b)$ - it just has to be contained in the interval J on which f is defined and continuous. Thus XIX.5.5.6., which has a monotonicity hypothesis on ϕ, is not strictly a generalization of IX.2.10.2. (see IX.2.12.9.–IX.2.12.10. for special cases of XIX.5.5.6. for Riemann integration).

IX.2.10.4. This result is called "Integration by Substitution" or "Change of Variable" since in its applications we usually think of making the "substitution" $u = \phi(x)$, so notationally we have

$$\frac{du}{dx} = \phi'(x)$$

$$du = \phi'(x)\,dx$$

even though both sides of the last equation are "meaningless." We then have

$$f(u)\,du = f(\phi(x))\phi'(x)\,dx$$

so their integrals should be equal. But we must change the limits from the extreme values of x to the corresponding extreme values of u:

$$\int_{u=\phi(a)}^{u=\phi(b)} f(u)\,du = \int_{x=a}^{x=b} f(\phi(x))\phi'(x)\,dx \ .$$

This way of writing the "substitution" highlights the utility of the Leibniz notation for integrals.

IX.2.10.5. Thus we convert an integral in x which is possibly difficult to evaluate directly into an integral in u which may be simpler. The substitution of course depends on the choice of ϕ; there may be more than one way to choose ϕ to rewrite the integrand as $(f \circ \phi)\phi'$ for some f, and the most useful choice of ϕ may not be obvious. Calculus courses extensively discuss the types of integrals for which this technique is successful, and the proper choice of ϕ in various situations. But of course this technique is only applicable to certain kinds of integrals where the integrand can be put into the form $(f \circ \phi)\phi'$ for some choice of f and ϕ.

IX.2.10.6. Example. Although this is not a calculus text and we will not discuss techniques of integration in any detail, we give one simple typical example illustrating the technique. To compute

$$\int_1^4 2x\sqrt{x^2+1}\,dx$$

we make the substitution $u = x^2 + 1$, i.e. $\phi(x) = x^2 + 1$. Then $\phi'(x) = 2x$, i.e. $du = 2x\,dx$. (The hypotheses are satisfied since ϕ is $\mathcal{C}^1$ on all of $\mathbb{R}$ and its range is $[1, +\infty)$, on which $f(u) = \sqrt{u}$ is continuous.) Since $\phi(1) = 2$ and $\phi(4) = 17$, we have

$$\int_1^4 2x\sqrt{x^2+1}\,dx = \int_1^4 \sqrt{x^2+1}\cdot 2x\,dx = \int_2^{17} \sqrt{u}\,du = \frac{2}{3}u^{3/2}\Big|_2^{17} = \frac{2}{3}(17^{3/2} - 2^{3/2})\ .$$

To illustrate the comment in IX.2.10.3., instead compute

$$\int_{-1}^1 2x\sqrt{x^2+1}\,dx$$

in the same way. This time $\phi(-1) = \phi(1) = 2$, so

$$\int_{-1}^1 2x\sqrt{x^2+1}\,dx = \int_2^2 \sqrt{u}\,du = 0\ .$$

This integral could have been evaluated without calculation, since the integrand is an odd function so its integral over any (bounded) interval centered at 0 is 0.

Integration by Parts

IX.2.10.7. If F and G are differentiable on an interval I with $F' = f$ and $G' = g$, then by the Product Rule FG is differentiable on I and

$$\frac{d}{dx}\left(F(x)G(x)\right) = F(x)g(x) + f(x)G(x)$$

so FG is an antiderivative for $Fg + fG$ on I. We thus obtain:

IX.2.10.8. Theorem. [Integration by Parts, Riemann Version] Let F and G be differentiable on $[a, b]$, with $F' = f$ and $G' = g$. If Fg and fG are Riemann integrable on $[a, b]$, then

$$\int_a^b F(x)g(x)\,dx = F(b)G(b) - F(a)G(a) - \int_a^b f(x)G(x)\,dx\ .$$

The hypotheses are satisfied if f and g are Riemann integrable on $[a,b]$, and in particular if they are continuous, i.e. if F and G are $\mathcal{C}^1$ on $[a,b]$.

PROOF: By the FTC2, we have

$$\int_a^b F(x)g(x)\,dx + \int_a^b f(x)G(x)\,dx = \int_a^b [F(x)g(x) + f(x)G(x)]\,dx = F(b)G(b) - F(a)G(a)\ .$$

IX.2.10.9. This result is often efficiently written notationally by setting $u = F(x)$ and $v = G(x)$, so $du = f(x)\,dx$ and $dv = g(x)\,dx$. The statement is then

$$\int_a^b u\,dv = uv\big|_a^b - \int_a^b v\,du\ .$$

IX.2.10.10. This technique is useful in integrating products, which are generally hard to integrate. The integral of Fg, which may be hard to evaluate directly, is converted into the integral of fG, which may be easier. To be successful on a particular problem, the technique requires the proper choice of F and G, which may not always be obvious.

IX.2.10.11. EXAMPLE. We again give a simple typical example. To evaluate

$$\int_0^{\pi/2} x\cos x\,dx$$

we may choose $F(x) = x$ and $g(x) = \cos x$. Thus $f(x) = 1$ and $G(x) = \sin x$ (or, in the alternate notation, $u = x$ and $dv = \cos x\,dx$, so $du = dx$ and $v = \sin x$), so

$$\int_0^{\pi/2} x\cos x\,dx = (x\sin x)\big|_0^{\pi/2} - \int_0^{\pi/2} 1\cdot\sin x\,dx$$

$$= (x\sin x)\big|_0^{\pi/2} - (-\cos x)\big|_0^{\pi/2} = \left(\frac{\pi}{2}\cdot 1 - 0\cdot 0\right) - (0-(-1)) = \frac{\pi}{2} - 1\ .$$

If we had made a bad choice of F and g, say $F(x) = \cos x$ and $g(x) = x$, so $f(x) = -\sin x$ and $G(x) = \frac{1}{2}x^2$, we would obtain the formula

$$\int_0^{\pi/2} x\cos x\,dx = \left(\frac{1}{2}x^2\cos x\right)\Big|_0^{\pi/2} - \int_0^{\pi/2} -\frac{1}{2}x^2\sin x\,dx = \int_0^{\pi/2} \frac{1}{2}x^2\sin x\,dx$$

which is correct but not useful since the new integral is even harder than the original one (in fact, to evaluate it one must do integration by parts twice, first converting it back to the original integral!).

IX.2.11. Improper Riemann Integration

The fact that unbounded functions cannot be Riemann integrable is partially compensated by the various forms of improper Riemann integration.

IX.2.11.1. DEFINITION. If f is a real-valued function defined on $(a, b]$, and Riemann integrable on $[a + \epsilon, b]$ for every $\epsilon > 0$, then f is *improperly Riemann integrable* from a to b if

$$\lim_{\epsilon \to 0+} \left[\int_{a+\epsilon}^{b} f(x)\, dx \right]$$

exists (in the usual sense, as a real number). We then define the *improper Riemann integral* to be

$$\int_a^b f(x)\, dx = \lim_{\epsilon \to 0+} \left[\int_{a+\epsilon}^{b} f(x)\, dx \right] .$$

If f is nonnegative on $(a, b]$, then

$$\lim_{\epsilon \to 0+} \left[\int_{a+\epsilon}^{b} f(x)\, dx \right] = \sup_{\epsilon > 0} \left[\int_{a+\epsilon}^{b} f(x)\, dx \right]$$

always exists (in the regular or extended sense), and in this case, we define

$$\int_a^b f(x)\, dx = \lim_{\epsilon \to 0+} \left[\int_{a+\epsilon}^{b} f(x)\, dx \right] .$$

A nonnegative function is then improperly Riemann integrable from a to b if $\int_a^b f(x)\, dx < \infty$.

IX.2.12. Exercises

IX.2.12.1. (a) Show that a function which is continuous almost everywhere and zero on a dense set is zero almost everywhere. [Show it is zero wherever it is continuous.]

(b) If f and g are functions which are each continuous almost everywhere, and f and g agree on a dense set, then $f = g$ a.e.

IX.2.12.2. Show that a finite union of sets of zero content has zero content. [You can mimic the proof of IX.2.7.6., but there is an easier argument.]

IX.2.12.3. Prove Proposition IX.2.7.11..

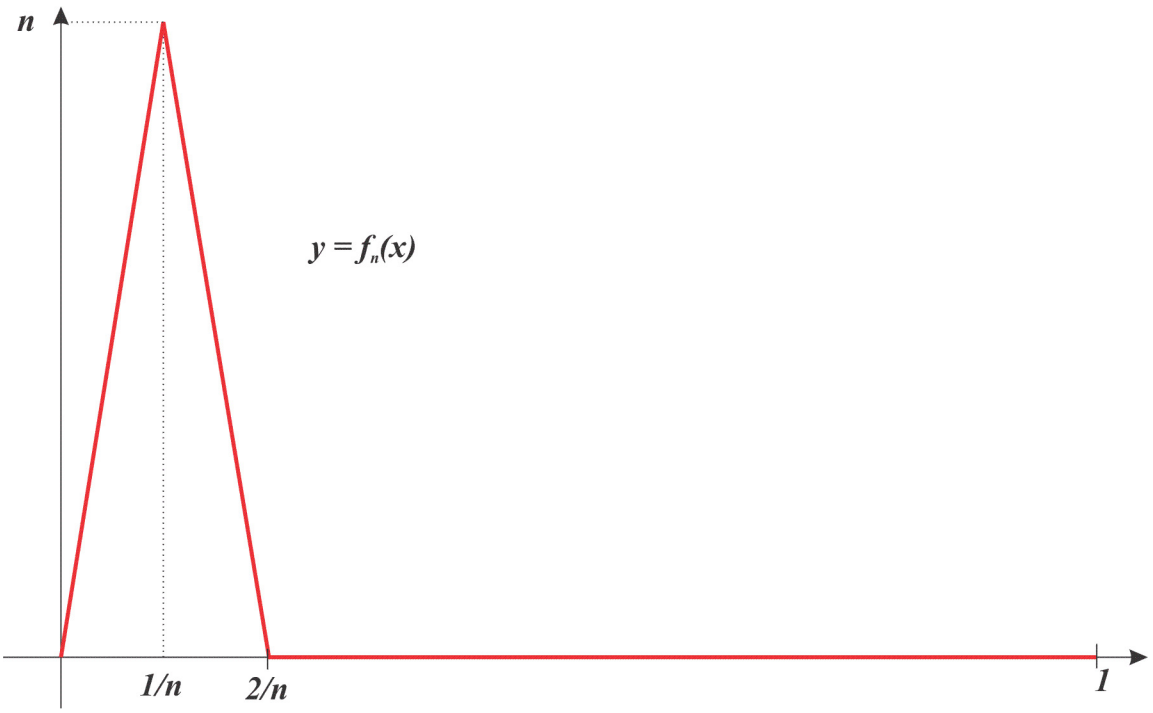

Figure IX.16: Graph of a Function

IX.2.12.4. This problem is a continuation of V.8.6.7..

(a) Show that every regulated function on an interval I is Riemann-integrable on any closed bounded subinterval of I. Then deduce V.8.6.7.(c) from IX.2.9.3..

(b) Let $g(x) = \sin(1/x)$ for $x \neq 0$, and $g(0) = 0$. Let (r_n) be an enumeration of $\mathbb{Q}$, and set

$$f(x) = \sum_{n=1}^{\infty} 2^{-n} g(x - r_n) \ .$$

Show that f is discontinuous at every point of $\mathbb{Q}$ and continuous at every point of $\mathbb{J}$.

(c) Show that f is Riemann-integrable over every closed bounded subinterval of $\mathbb{R}$ (give two proofs, one using IX.2.8.5. and one using ()), but f is not regulated on any interval.

(d) Show using IX.2.9.8.(iii) and V.8.5.5. that f has an antiderivative on $\mathbb{R}$.

IX.2.12.5. Let f be a bounded function on an interval $[a,b]$, and $\overline{f}$ its upper envelope (IX.2.8.1.).

(a) Show that

$$\overline{f} = \inf\{\psi : \psi \geq f, \psi \text{ an upper semicontinuous step function}\} .$$

[Use the argument of the proof of IX.2.8.2..]

(b) Show that, for every $x_0 \in [a,b]$,

$$\overline{f}(x_0) = \max\left(f(x_0), \limsup_{x \to x_0} f(x)\right) .$$

(c) Give similar characterizations of $\underline{f}$.

IX.2.12.6. Let E be a subset of $[a,b]$, and consider the indicator function χ_E.

(a) Show that the upper envelope (IX.2.8.1.) $\overline{\chi_E}$ is $\chi_{\bar{E}}$, and the lower envelope $\underline{\chi_E}$ is χ_{E°.

(b) Show that χ_E is Riemann-integrable on $[a,b]$ if and only if ∂E has zero content (), i.e. E is a Jordan region () in $\mathbb{R}$.

IX.2.12.7. (a) Use Theorem IX.2.8.5. to prove that if f and g are Riemann integrable on $[a,b]$, so is fg.

(b) To obtain a direct low-tech proof of (a), suppose f is a bounded function on an interval I, say $|f(x)| \leq M$ for all $x \in I$. Show that

$$|f(x)^2 - f(y)^2| \leq 2M|f(x) - f(y)|$$

for all $x, y \in I$.

(c) If f is a bounded function on $[a,b]$, say $|f(x)| \leq M$ for all $x \in [a,b]$, and if $\mathcal{P}$ is any partition of $[a,b]$, then

$$\overline{\mathcal{S}}(f^2, \mathcal{P}) - \underline{\mathcal{S}}(f^2, \mathcal{P}) \leq 2M[\overline{\mathcal{S}}(f, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P})] .$$

(d) Conclude from (c) that if f is Riemann integrable on $[a,b]$, so is f^2.

(e) Use the identity

$$4fg = (f+g)^2 - (f-g)^2$$

for functions f, g on $[a,b]$ to prove (a).

(f) Give a similar proof using the triangle inequality that if f is Riemann integrable on $[a,b]$, so is $|f|$. What about the converse? (cf. ())

IX.2.12.8. Let ϕ be a differentiable function on an interval $[a,b]$. Suppose there are constants m, M with $0 < m \le M$ such that $m \le |\phi'(x)| \le M$ for all $x \in [a,b]$.

(a) Show that ϕ is strictly monotone on $[a,b]$, that $\phi([a,b])$ is an interval $[c,d]$, and that $\phi^{-1} : [c,d] \to [a,b]$ is differentiable with

$$\frac{1}{M} \le (\phi^{-1})'(x) \le \frac{1}{m}$$

for all $x \in [c,d]$.

(b) If $A \subseteq [a,b]$, show that A has measure 0 [resp. content 0] if and only if $\phi(A)$ has measure 0 [resp. content 0].

(c) Show that if f is a function on $[c,d]$, then f is Riemann integrable on $[c,d]$ if and only if $f \circ \phi$ is Riemann integrable on $[a,b]$.

The result in (b) can be extended to the case where ϕ is differentiable and ϕ' is never 0 (XIX.5.1.16.).

IX.2.12.9. (a) Extend the result of IX.2.10.2. to the case where f is bounded and has countably many discontinuities, provided ϕ is injective (i.e. strictly monotone).

(b) What is the difficulty in (a) if ϕ is not one-to-one (i.e. strictly monotone)? Is there a weaker restriction on ϕ which suffices?

(c) What is the difficulty in (a) if f is just assumed to be Riemann integrable on $[c,d]$, even if ϕ is strictly monotone? See IX.2.12.8..

IX.2.12.10. Use IX.2.12.8.(c) and IX.2.12.7. to prove the following theorem, which is a special case of XIX.5.5.6.. [Mimic the proof of IX.2.10.2..]

THEOREM. Let ϕ be a differentiable function on an interval $[a,b]$. Suppose there are constants m, M with $0 < m \le M$ such that $m \le |\phi'(x)| \le M$ for all $x \in [a,b]$, and that ϕ' is Riemann integrable on $[a,b]$. Set $[c,d] = \phi([a,b])$. If f is Riemann integrable on $[c,d]$, then $(f \circ \phi)|\phi'|$ is Riemann integrable on $[a,b]$, and

$$\int_a^b f(\phi(x))|\phi'(x)|\,dx = \int_c^d f(u)\,du \ .$$

Note that the hypotheses on ϕ' imply that ϕ is strictly monotone of $[a,b]$, and are automatically satisfied if ϕ' is continuous and nonzero on $[a,b]$. What is the (modest) significance of the absolute value on the ϕ'? [Hint: how are c and d related to $\phi(a)$ and $\phi(b)$?]

IX.2.12.11. The result of this problem may be "geometrically obvious," but requires proof. Let $a > 0$ and f an odd function () on $[-a,a]$ which is Riemann integrable on $[-a,a]$.

(a) Show that if $\mathcal{P}$ is a partition of $[-a,a]$ which is symmetric around 0, then 0 is a Riemann sum for $\int_{-a}^{a} f(x)\,dx$ subordinate to $\mathcal{P}$.

(b) Conclude that $\int_{-a}^{a} f(x)\,dx = 0$.

(c) Use IX.2.12.10. to show that

$$\int_{-a}^{a} f(x)\,dx = -\int_{-a}^{a} f(x)\,dx$$

to obtain an alternate proof of (b).

IX.2.13. Numerical Integration and Simpson's Rule

Usually the best way to compute the exact value of a Riemann integral is via the Fundamental Theorem of Calculus. But sometimes integrals are encountered where this approach is not possible or feasible, and to calculate the integral we need to return to the definition and compute the integral directly as a limit.

We know in theory that if a function is Riemann integrable on an interval, then the Riemann sums for the integral converge to the exact integral as the partitions become sufficiently fine. But how can we choose a Riemann sum, or similar sum, which gives the integral to within a specified accuracy, and how do we know how accurate an approximation we get from a given sum? Numerical integration theory is the study of these problems.

Numerical methods for integration are essentially based on Riemann integration, and do not work satisfactorily unless the function being integrated is well-behaved (piecewise-continuous at the least, and usually with some smoothness). Thus numerical integration is really a part of the theory of Riemann integration and not more advanced integration theories. Numerical integration is frequently used in situations where function values can only be calculated easily at certain points, and even then sometimes only to a certain accuracy, or to functions whose values are known only from data sets.

Numerical integration is an important part of the subject of *numerical analysis*, a part of mathematics (usually regarded as part of "applied mathematics") which seeks to develop efficient ways to numerically calculate or approximate various important mathematical quantities, e.g. integrals, sums of infinite series, zeroes of functions, eigenvalues and eigenvectors, solutions to differential equations. Much of numerical analysis has a very different character than the type of analysis developed in this book, but the word *analysis* is appropriately used for this subject since (among other things) analytic techniques are used in determining the accuracy and efficiency of the numerical algorithms developed. We will only scratch the surface of numerical integration here; books such as [Hil87] or [IK94] have a far more thorough treatment.

Quadrature Procedures

IX.2.13.1. Suppose we have a fixed interval, which we will for simplicity take to be a closed bounded interval $[a, b]$, and we want to have a fixed procedure for estimating integrals

$$\int_a^b f(x)\,dx$$

for continuous functions f. The obvious procedure is to fix points $x_0, \ldots, x_n$ in $[a, b]$ (which we will always take to be in increasing order). These will typically be a partition of $[a, b]$, but not necessarily, i.e. the endpoints need not be among the x_k. We will then fix real constants $\alpha_0, \ldots, \alpha_n$, usually positive (a *nonnegative procedure*, cf. IX.2.13.4.). The procedure $Q = Q(x_0, \ldots, x_n; \alpha_0, \ldots, \alpha_n)$ then gives the approximation

$$\int_a^b f(x)\,dx \approx Q(f) = \sum_{k=0}^{n} \alpha_k f(x_k)\ .$$

IX.2.13.2. The first obvious property we should have is that the approximation should be exact for constant functions. This translates into the restriction

$$\sum_{k=0}^{n} \alpha_k = b - a\ .$$

IX.2.13.3. Another more restrictive condition which is natural is that for any continuous f,

$$\underline{\mathcal{S}}(f,\mathcal{P}) \leq Q(f) \leq \overline{\mathcal{S}}(f,\mathcal{P})$$

for some partition $\mathcal{P}$ of $[a,b]$, where $\underline{\mathcal{S}}(f,\mathcal{P})$ and $\overline{\mathcal{S}}(f,\mathcal{P})$ are the lower and upper Darboux sums (). A procedure satisfying this condition is called *regular* with respect to $\mathcal{P}$. If Q is regular with respect to the partition of $[a,b]$ given by $x_0,\ldots,x_n$ and the endpoints of the interval if not included among the x_k, then Q is called *regular*.

Some quadrature procedures considered in numerical analysis are regular, but many are not, although most are regular with respect to a coarser partition. The condition $\sum \alpha_k = b-a$ insures that all nonnegative procedures are regular with respect to the trivial partition, since any nonnegative procedure is monotone.

IX.2.13.4. In numerical work, subtraction, or addition of numbers of different magnitudes, can lead to a serious loss of precision; thus the most useful quadrature procedures are ones where the α_n are all the same sign (positive) and approximately the same size, although these restrictions are not necessary in principle.

IX.2.13.5. Definition. A *quadrature procedure*, or *numerical integration procedure*, on an interval $[a,b]$ is a choice of points $x_0,\ldots,x_n \in [a,b]$ and real numbers $\alpha_0,\ldots,\alpha_n$ with $\sum_{k=0}^{n} \alpha_k = b-a$. For any real-valued function f, the application of the procedure $Q = Q(x_0,\ldots,x_n;\alpha_0,\ldots,\alpha_n)$ to f is the sum

$$Q(f) = \sum_{k=0}^{n} \alpha_k f(x_k) \ .$$

$Q(f)$ is called the *approximation to the integral of f over $[a,b]$ by the procedure Q*.

Definite integration, especially numerical integration, is often called *quadrature* because of the standard interpretation of integrals as areas.

IX.2.13.6. We could also consider more general quadrature procedures of the form

$$Q(f) = \sum_{k=0}^{n} \alpha_k f(x_k) + \sum_{k=0}^{n} \beta_k f'(x_k) + \sum_{k=0}^{n} \gamma_k f''(x_k) + \cdots$$

which are sometimes used in numerical analysis (cf. IX.2.13.19., IX.2.13.39., IX.2.13.51.).

IX.2.13.7. A *procedure* by this definition must be carefully distinguished from a numerical integration *process* or *scheme*, which is a sequence of quadrature procedures converging to the exact integral for all, or at least nicely behaved, functions. For example, the standard procedures like Simpson's rule begin by partitioning the interval into n subintervals in some specific way. There is thus one procedure for each fixed n, and they form a process as $n \to \infty$.

Note that any sequence (Q_n) of quadrature procedures regular with respect to partitions $\mathcal{P}_n$ with $\|\mathcal{P}_n\| \to 0$ as $n \to \infty$ will converge to the exact integral for all continuous functions (in fact for all Riemann-integrable functions), i.e. will form a numerical integration process. However, for practical reasons the *rate* of convergence is a critical consideration in numerical analysis.

IX.2.13.8. It is easily checked that any quadrature procedure Q is linear, i.e.

$$Q(cf+g) = cQ(f) + Q(g)$$

for any functions f, g and scalar c; a procedure with all $\alpha_k > 0$ is also monotone, i.e. $Q(f) \le Q(g)$ if $f \le g$.

IX.2.13.9. EXAMPLES. (i) The simplest quadrature procedures are the left and right estimates for the Riemann integral (): if $\{x_0, \dots, x_n\}$ is a partition of $[a,b]$, set $\alpha_k = x_{k+1} - x_k$ for $0 \le k < n$ and $\alpha_n = 0$. Then the estimate

$$\sum_{k=0}^{n} \alpha_k f(x_k)$$

is the left estimate L_n for the integral of f. If we instead take $\alpha_0 = 0$ and $\alpha_k = x_k - x_{k-1}$ for $1 \le k \le n$, we get the right estimate R_n.

(ii) More generally, if $\{x_0, \dots, x_n; t_1, \dots, t_n\}$ is a tagged partition of $[a,b]$, set $\alpha_k = \Delta x_k = x_k - x_{k-1}$ for $1 \le k \le n$. Then $Q(t_1, \dots, t_n; \alpha_1, \dots, \alpha_n)$ gives the Riemann sum approximation to the integral for this tagged partition:

$$Q(f) = \sum_{k=1}^{n} f(t_k)\Delta x_k \ .$$

A numerically good procedure is to take the x_k to be evenly spaced and t_k the midpoint of the k'th interval. This procedure is called the *midpoint rule* with n intervals, denoted M_n. Note that in this procedure the points where the function is evaluated do not form a partition of the interval, i.e. the endpoints are not included.

(iii) Here is a quadrature procedure which is not just a Riemann sum. We average the left and right estimates from (i), normally using n subintervals of equal length $h = \frac{b-a}{n}$. In this case $\alpha_0 = \alpha_n = \frac{h}{2}$ and $\alpha_k = h$ for $1 \le k \le n-1$.

This procedure is called the *trapezoid rule* with n intervals, for the following reason. It is also obtained by approximating the function within each subinterval by a linear (affine) function, so that the integral is approximated by a sum of areas of trapezoids (Figure IX.17, from http://tutorial.math.lamar.edu/Classes/CalcII/ApproximatingDefIntegrals.aspx). We call this procedure T_n.

An alternate formula for T_n is

$$T_n(f) = \frac{h}{2}\left[f(x_0) + 2f(x_1) + 2f(x_2) + \cdots + 2f(x_{n-1}) + f(x_n)\right]$$

where $h = \frac{b-a}{n}$ and $x_k = x_0 + kh$ for $0 \le k \le n$.

All these quadrature procedures are regular, as is easily verified.

Simpson's Rule

IX.2.13.10. If the graph of f is concave up on $[a,b]$, it is clear that the trapezoid estimate is too large and the midpoint estimate is too small, for any fixed n, and vice versa if the graph of f is concave down. Thus we would expect the errors to tend to have opposite sign. And experiments with calculable integrals suggest that the absolute error from the midpoint estimate for a given n is typically about half the absolute

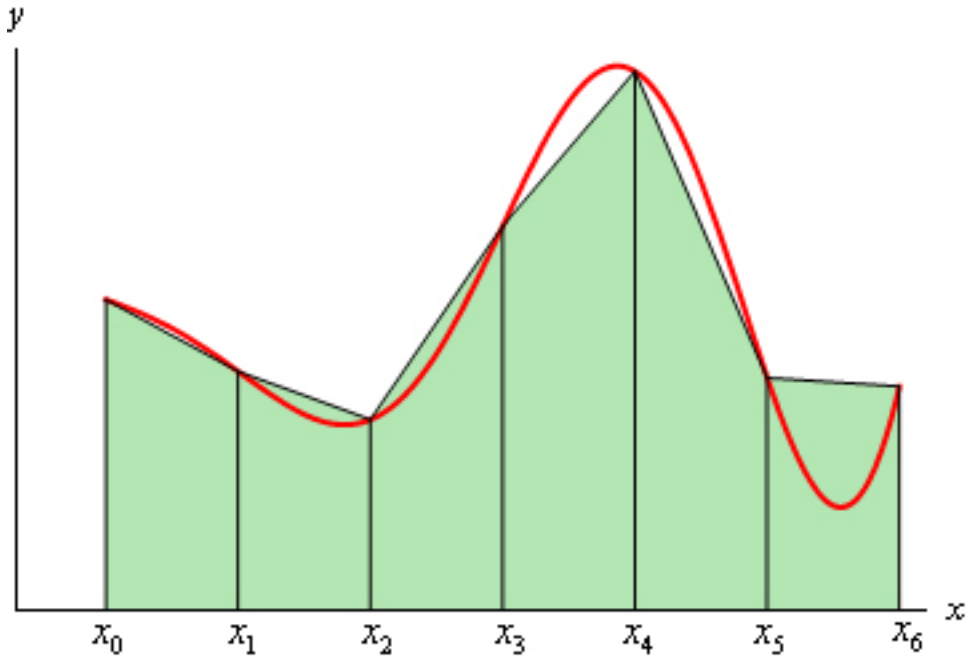

Figure IX.17: The trapezoid rule

error of the trapezoid estimate for the same n – see IX.2.13.44. for a precise statement along these lines. (Some unsophisticated references assert or suggest the absolute midpoint error is exactly half the absolute trapezoid error, but in fact it is rarely exactly half, and in some cases is not even approximately half; cf. Exercise IX.2.14.2..)

IX.2.13.11. These statements suggest that in many cases, twice the midpoint error should largely cancel with the trapezoid error; thus a weighted average of the two should often be much better than either. So we define

$$S_{2n}(f) = \frac{2}{3}M_n(f) + \frac{1}{3}T_n(f)$$

which is *Simpson's rule* with $2n$ intervals.

To put Simpson's rule into the standard form of a quadrature procedure and explain the use of the index $2n$, note that in evaluating $M_n(f)$ and $T_n(f)$, the function f must be evaluated at $2n+1$ points, the $n+1$ points of the partition and the n midpoints. These points form a partition of the interval $[a,b]$ into $2n$ subintervals of equal length.

IX.2.13.12. Changing notation slightly, if n is an even number and $\{x_0,\dots,x_n\}$ is a partition of $[a,b]$ into n subintervals of equal length $h = \frac{b-a}{n}$, we have $\alpha_0 = \alpha_n = \frac{h}{3}$, $\alpha_k = \frac{2h}{3}$ for k even, $0 < k < n$, and

$\alpha_k = \frac{4h}{3}$ for k odd. Thus

$$S_n(f) = \frac{h}{3}\left[f(x_0) + 4f(x_1) + 2f(x_2) + 4f(x_3) + \cdots + 2f(x_{n-2}) + 4f(x_{n-1}) + f(x_n)\right]$$

where $x_k = x_0 + kh$ for $0 \leq k \leq n$.

IX.2.13.13. The Simpson's rule approximation with $2n$ intervals is indeed typically (but not always!) *much* better than the trapezoid or midpoint approximations with n intervals. The function must, of course, be evaluated at about twice as many points. But $S_{2n}(f)$ is typically even considerably more accurate than $T_{2n}(f)$ or $M_{2n}(f)$. See IX.2.13.36.–IX.2.13.52. for an error analysis.

Simpson's rule S_{2n} is not a regular quadrature procedure, but it is regular with respect to the partition of $[a, b]$ into n equal subintervals; hence $S_{2n}(f) \to \int_a^b f(x)\,dx$ as $n \to \infty$ for any continuous f (even every Riemann-integrable f), as does $T_n(f)$ and $M_n(f)$.

IX.2.13.14. There is a quite different way of motivating and arriving at Simpson's rule; see IX.2.13.24. and IX.2.13.26..

Is There a "Best" Quadrature Procedure?

IX.2.13.15. We would like to find and use the "best" quadrature procedure. However, it appears obvious that we run into a tradeoff between accuracy and complexity, since it stands to reason (and is "generally" correct) that procedures using more points would tend to be more accurate; thus we should not expect a universal procedure which is "best" in all respects.

But there is a more fundamental sense in which there is no "best" procedure. Given *any* two quadrature procedures Q_1 and Q_2, a continuous function f_1, even a polynomial, can be constructed such that $Q_1(f_1)$ is a better approximation to the true integral of f_1 than $Q_2(f_1)$, and another continuous function (polynomial) f_2 such that $Q_2(f_2)$ is better than $Q_1(f_2)$. So even beyond questions of complexity of computation there is no universally "best" quadrature procedure.

IX.2.13.16. We will appear to argue that Simpson's rule is generally the best rule to use for numerical integration, and within the shallow limits of our numerical analysis work here this statement is defensible for many typically encountered integrals, and Simpson's rule is the most widely used quadrature procedure. However, the reader should be aware that it is much too simplistic to tout Simpson's rule as the ultimate quadrature procedure; there are many others (e.g. Romberg integration, cf. IX.2.14.7., or Clenshaw-Curtis Integration, cf. ()) which are better in certain circumstances. See IX.2.13.61. for further comments.

Simple and Composite Quadrature Procedures

One fairly good measure of the accuracy of a quadrature procedure is how well it approximates the exact integral for polynomials of small order.

IX.2.13.17. Definition. Let Q be a quadrature procedure on $[a, b]$. Then Q has *order of precision* m if

$$Q(f) = \int_a^b f(x)\,dx$$

(i.e. Q is exactly correct) whenever f is a polynomial of degree $\leq m$, but not for polynomials of degree $m+1$.

The term *order of precision* is standard, but some references use *order of exactness* which seems more descriptive.

We have built into our definition that a quadrature procedure always has order of precision at least 0.

IX.2.13.18. A quadrature procedure is *simple* if it has high order of precision for the number of nodes used. A *composite* quadrature procedure is one which consists of first dividing the interval $[a,b]$ into a number of smaller intervals and applying a simple quadrature procedure on each subinterval (the simple procedures used on the subintervals are usually, but not always, the same on all subintervals). The order of precision of a composite procedure is at least as great as (usually exactly equal to) the minimum of the order of precision of the simple procedures used on the subintervals. A composite procedure is always regular with respect to the partition into the subintervals on which the simple procedures are applied.

For reasons described in IX.2.13.4., as well as considerations of efficiency, composite procedures using a simple procedure of lower order on each subinterval are often better in practice than simple procedures of higher order.

Simple quadrature procedures are almost always interpolatory or osculatory:

IX.2.13.19. Definition. Let $x_0,\dots,x_n$ be points of $[a,b]$. The *interpolatory quadrature procedure* on $[a,b]$ for the nodes $x_0,\dots,x_n$ is the procedure Q defined by

$$Q(f)=\int_a^b p_{0,\dots,n}(x)\,dx$$

where $p_{0,\dots,n}$ is the interpolating polynomial of f on $[a,b]$ for these nodes (V.11.1.1.).

It follows easily from the Lagrange or Newton form of the interpolating polynomial that an interpolatory quadrature procedure is indeed a quadrature procedure of the form of IX.2.13.5..

This definition can be extended to the situation where the $x_0,\dots,x_n$ are not necessarily distinct by using the osculating polynomial (V.11.6.4.); such a quadrature procedure is called *osculatory*. (An osculatory procedure is of the generalized form of IX.2.13.6., and can only be used for functions which are sufficiently differentiable.)

IX.2.13.20. It is immediate that an interpolatory or osculatory quadrature procedure using $n+1$ nodes has order of precision at least n. (Conversely, a quadrature procedure using $n+1$ nodes of order of precision at least n must by interpolatory or osculatory; but cf. IX.2.14.6..) If the nodes are well chosen, the order of precision can be greater than n (IX.2.13.30., IX.2.13.46.).

IX.2.13.21. There are thus two general strategies for developing simple quadrature procedures:

(1) First pick nodes $x_0,\dots,x_n$ in a convenient way, e.g. evenly spaced, and use the interpolatory or osculatory procedure for these nodes.

(2) Fix n and choose the x_k carefully to maximize the order of precision of the corresponding interpolatory or osculatory procedure.

The Newton-Cotes Formulas

IX.2.13.22. We first examine the procedure obtained by choosing a partition of $[a,b]$ into n subintervals of equal length $h = \frac{b-a}{n}$, i.e. $x_k = a + kh$ for $0 \le k \le n$. The corresponding interpolatory procedure is called the *Newton-Cotes procedure* (or *Newton-Cotes formula*) of order n, denoted NC_n.

Since an explicit formula for the interpolating polynomial can be obtained, a formula for the procedure NC_n can be found by integrating this polynomial. The calculation is straightforward but tedious, and we carry it out only for $n = 1$ and $n = 2$.

IX.2.13.23. First consider the case $n = 1$, i.e. $x_0 = a$, $x_1 = b$. The interpolating polynomial is

$$p_{0,1}(x) = f(a) + \frac{f(b) - f(a)}{b - a}(x - a)$$

so we have

$$NC_1(f) = \int_a^b \left[f(a) + \frac{f(b) - f(a)}{b - a}(x - a) \right] dx$$
$$= f(a)(b - a) + \frac{1}{2}\frac{f(b) - f(a)}{b - a}(b - a)^2 = \frac{h}{2}[f(a) + f(b)]$$

which is just the trapezoid rule for $n = 1$, i.e. $NC_1 = T_1$.

IX.2.13.24. Now consider the case $n = 2$, i.e. $x_0 = a$, $x_1 = \frac{a+b}{2}$, $x_2 = b$. The interpolating polynomial is

$$p_{0,1,2}(x) = f(a) + \frac{f(b) - f(a)}{b - a}(x - a) + \frac{f[b, x_1] - f[a, b]}{x_1 - a}(x - a)(x - b)$$
$$= f(a) + \frac{f(b) - f(a)}{2h}(x - a) + \frac{1}{2h}\left[\frac{f(b) - f(x_1)}{h} - \frac{f(b) - f(a)}{2h} \right](x - a)(x - b)$$
$$= f(a) + \frac{f(b) - f(a)}{2h}(x - a) + \frac{1}{4h^2}\left[f(b) - 2f(x_1) + f(a) \right](x - a)(x - b)$$

so we have

$$NC_2(f) = \int_a^b \left[f(a) + \frac{f(b) - f(a)}{2h}(x - a) + \frac{1}{4h^2}\left[f(b) - 2f(x_1) + f(a) \right](x - a)(x - b) \right] dx \ .$$

We have

$$\int_a^b (x - a)(x - b)\, dx = -\frac{(2h)^3}{6}$$

by making the substitution $x = a + th$; thus

$$NC_2(f) = f(a)(2h) + \frac{f(b) - f(a)}{2h}\left(\frac{1}{2}(2h)^2 \right) - \frac{8h^3}{6}\frac{1}{4h^2}[f(b) - 2f(x_1) + f(a)] = \frac{h}{3}[f(a) + 4f(x_1) + f(b)]$$

which is exactly $S_2(f)$ (IX.2.13.12.), i.e. NC_2 is exactly the simple Simpson's rule for $n = 2$: Simpson's rule is obtained by approximating the graph of f by a parabola through the endpoints and midpoint, cf. Figure IX.18, from http://en.wikipedia.org/wiki/Simpson's_rule. (In fact, this is how SIMPSON came up with the rule in the first place in 1743; the simple Simpson's rule was previously essentially known to others, including NEWTON and KEPLER, and was apparently first described by CAVALIERI in 1639.)

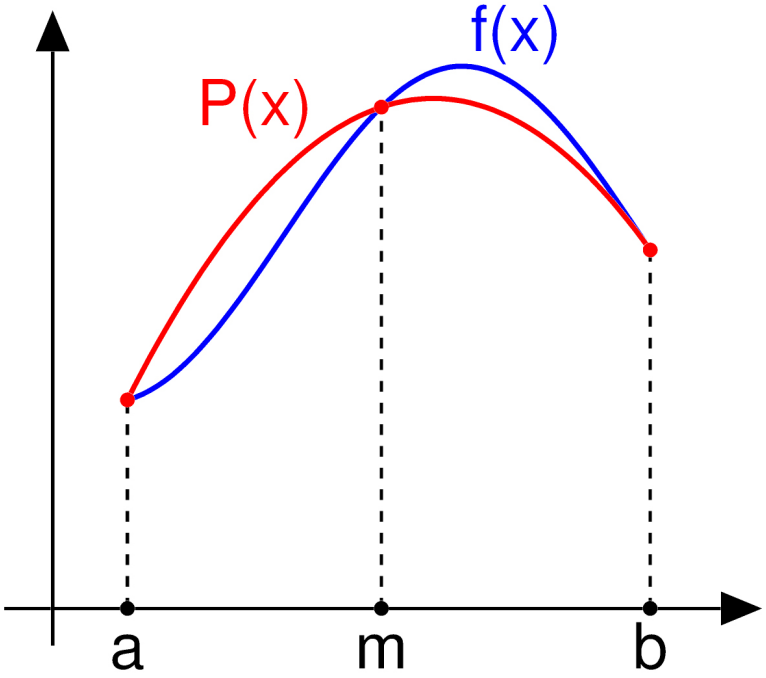

Figure IX.18: The simple Simpson's rule

IX.2.13.25. We list without proof a few more of the Newton-Cotes formulas:

$$NC_3(f) = \frac{3h}{8}[f(x_0) + 3f(x_1) + 3f(x_2) + f(x_3)]$$

$$NC_4(f) = \frac{2h}{45}[7f(x_0) + 32f(x_1) + 12f(x_2) + 32f(x_3) + 7f(x_4)]$$

$$NC_5(f) = \frac{5h}{288}[19f(x_0) + 75f(x_1) + 50f(x_2) + 50f(x_3) + 75f(x_4) + 19f(x_5)]$$

$$NC_8(f) = \frac{4h}{14175}[989f(x_0)+5888f(x_1)-928f(x_2)+10496f(x_3)-4540f(x_4)+10496f(x_5)-928f(x_6)+5888f(x_7)+989f(x_8)]$$

IX.2.13.26. As n increases, the coefficients in NC_n vary more greatly. More problematically, if $n \geq 8$ the coefficients are not all positive. Thus, for reasons described in IX.2.13.4., higher Newton-Cotes formulas are not well suited for numerical work. Composite procedures using Newton-Cotes formulas of smaller degree on the subintervals generally work better numerically.

It turns out that if n is even, NC_n generally gives almost as good an approximation as NC_{n+1} (and sometimes better), for reasons described in IX.2.13.57.. In particular, NC_2 (simple Simpson's rule) is generally nearly as good as NC_3 (*Simpson's three-eighths rule*), which requires more arithmetic. (In fact, the

composite Simpson's rule is generally even better than the composite three-eighths rule for the *same* overall number of subintervals; cf. Exercise IX.2.14.4..)

The ordinary Simpson's rule S_{2n} of IX.2.13.12. is nothing but the composite procedure consisting of dividing $b-a$ into n subintervals of equal length and then applying the simple Simpson's rule S_2 on each subinterval; for this reason, Simpson's rule is sometimes called the *parabolic rule*. In part for the reasons in the last two paragraphs, Simpson's rule is a popular and generally very good procedure.

IX.2.13.27. As a variation, given n we can divide $[a,b]$ into $n+2$ subintervals of equal length $h=\frac{b-a}{n+2}$, and not use the two endpoints but only the $n+1$ interior points $x_1,\dots,x_{n+1}$, where $x_k = a+kh$ for $1\le k\le n+1$. The resulting formulas are the *open Newton-Cotes formulas*, written NC_n^o. The only one of interest to us is NC_0^o, which is just the simple midpoint rule M_1. We list a couple more:

$$NC_1^o(f) = \frac{3h}{2}[f(x_1)+f(x_2)]$$

$$NC_2^o(f) = \frac{4h}{3}[2f(x_1)-f(x_2)+2f(x_3)]$$

Already the coefficients in NC_2^o are not all positive. NC_n^o is again of order of precision at least n.

Gaussian Quadrature

IX.2.13.28. We now change indexing convention slightly, beginning with $k=1$ instead of $k=0$. The quadrature formula

$$Q(f) = \sum_{k=1}^{n} \alpha_k f(x_k)$$

has $2n$ unknowns, the coefficients α_k and the nodes x_k. If we fix the x_k, there is a unique choice of the α_k giving a Q of maximum order of precision, which is necessarily the interpolatory procedure and has order of precision $\ge n-1$ (these α_k can be found by solving a system of linear equations; the technique is called the *method of undetermined coefficients*). The Newton-Cotes approach was of this form. We could alternately fix the α_k and find the x_k for which the procedure has maximum order of precision, or we could vary both the α_k and x_k, keeping only n fixed.

IX.2.13.29. First consider fixing the α_k. For reasons discussed in IX.2.13.4. (a more detailed analysis justifies this further), a good choice is to take all the α_k equal (to $\frac{b-a}{n}$). This problem can be solved and gives a procedure of order of precision $\ge n$ only for $n\le 7$ and $n=9$; if n is even the order of precision is actually $n+1$. The case $n=1$ gives the midpoint rule. If $[a,b]=[-1,1]$ and $n=2$, the optimal notes are at $\pm\frac{1}{\sqrt{3}} = 0.577\cdots$. Tables giving the nodes for other n can be found in [IK94] and other references.

IX.2.13.30. Now consider varying both the α_k and the x_k. It can be shown that the maximum order of precision is obtained by taking the nodes to be the roots of the unique (up to constant multiple) polynomial p_n of degree n which is orthogonal to the subspace of polynomials of degree $\le n-1$ with respect to the usual real inner product

$$\langle f,g\rangle = \int_a^b f(x)g(x)\,dx\ .$$

If $[a,b]=[-1,1]$, the p_n are the *Legendre polynomials* (); other intervals can be handled via affine transformations. The α_k are then chosen so the procedure is interpolatory. The resulting procedure is called *Gaussian quadrature*, or *Legendre-Gauss quadrature*, with n nodes, denoted G_n. The procedure G_n has order $2n-1$. Here are formulas for small $n>1$ for the interval $[-1,1]$ (the case $n=1$ is just the midpoint rule):

$$G_2(f)=f\left(-\frac{1}{\sqrt{3}}\right)+f\left(\frac{1}{\sqrt{3}}\right)=f(-.577350\cdots)+f(.577350\cdots)$$

$$G_3=\frac{5}{9}f(-\sqrt{0.6})+\frac{8}{9}f(0)+\frac{5}{9}f(\sqrt{0.6})=\frac{1}{9}[5f(-0.774597\cdots)+8f(0)+5f(0.774597\cdots)]$$

$$G_4(f)=(0.347855\cdots)f(-0.861136\cdots)+(0.652145\cdots)f(-0.339981\cdots)$$
$$+(0.652145\cdots)f(0.339981\cdots)+(0.347855\cdots)f(0.861136\cdots)$$

The coefficients and nodes are algebraic numbers, but irrational in general and must be computed by a numerical procedure; see e.g. http://mathworld.wolfram.com/Legendre-GaussQuadrature.html. There are tables available online for at least up to $n=64$.

IX.2.13.31. Advantages of Gaussian quadrature are that it is usually very accurate for modest n if f is sufficiently smooth (cf. IX.2.13.60.), and the coefficients are all positive, although not too close to the same magnitude if n is large (cf. IX.2.13.4.). Disadvantages are that it can be difficult to calculate the nodes and coefficients for n large (although there are tables for reasonable n), and if the process is repeated for a larger n all the coefficients and nodes must be recalculated (unlike, say, Simpson's rule if n is doubled). A method like this also cannot be easily applied to functions arising from data sets.

Weight Functions and Chebyshev Quadrature

IX.2.13.32. It is often important to consider a more general version of quadrature, to estimate integrals of the form

$$I(f)=\int_a^b f(x)w(x)\,dx$$

where w is a fixed weight function on $[a,b]$. Here w can be any nonnegative function which is Riemann-integrable or improperly Riemann-integrable (or, more generally, Lebesgue integrable) on $[a,b]$, but in applications w is usually a simple smooth function. We want a quadrature procedure Q of the form

$$Q(f)=\sum_{k=1}^{n}\alpha_k f(x_k)$$

for constants α_k and nodes x_k. The basic restriction now is

$$\sum_{k=1}^{n}\alpha_k=\int_a^b w(x)\,dx\ .$$

Usual quadrature is the special case where w is the constant function 1.

IX.2.13.33. Gaussian quadrature works similarly in this setting: the optimal nodes are the roots of the polynomial of degree n which is orthogonal to all polynomials of smaller degree with respect to the real inner product

$$\langle f, g\rangle = \int_a^b f(x)g(x)w(x)\,dx$$

and the weights are then found by the method of undetermined coefficients. This works because of the result of Exercise IX.2.14.5..

IX.2.13.34. More generally, a Radon measure μ () can be used on $[a, b]$, and the integrals

$$\int_{[a,b]} f\,d\mu$$

approximated by quadrature procedures as above. The optimal polynomial of degree n is the one orthogonal to the polynomials of smaller degree for the inner product

$$\langle f, g\rangle = \int_{[a,b]} fg\,d\mu\ .$$

It can be shown using the Krein-Milman theorem () that such quadrature procedures must converge for any continuous f as $n \to \infty$. However, this generality is of little or no practical use in numerical analysis.

IX.2.13.35. A particularly important case is the weight function $w(x) = \frac{1}{\sqrt{1-x^2}}$on $[-1, 1]$. Making the substitution $x = \cos\theta$, we have

$$\int_{-1}^{1} \frac{f(x)}{\sqrt{1-x^2}}\,dx = \int_0^{\pi} f(\cos(\theta))\,d\theta$$

and the optimal nodes are the Chebyshev nodes (). This case is called *Chebyshev quadrature*.

Error Analysis of the Trapezoid Rule

IX.2.13.36. We begin with an analysis of the accuracy of the simple trapezoid rule

$$T_1(f) = \frac{h}{2}[f(a) + f(b)]$$

where $h = b - a$. The technique in the other error analyses will be similar. We want to calculate the error

$$E_1^T(f) = \int_a^b f(x)\,dx - T_1(f) = \int_a^b [f(x) - p_{0,1}(x)]\,dx = \int_a^b (x-a)(x-b)f[a, b, x]\,dx$$

by ().

Assume f is $\mathcal{C}^2$ on $[a, b]$. Then $g(x) = f[a, b, x]$ is continuous on $[a, b]$ (), and for each $x \in (a, b)$ we can write

$$f[a, b, x] = \frac{f''(\xi(x))}{2}$$

for some $\xi(x) \in (a,b)$ (V.11.5.9.). Since $(x-a)(x-b)$ does not change sign on $[a,b]$, and $f[a,b,x]$ is continuous on $[a,b]$, we can apply the Mean Value Theorem for integrals () to obtain

$$E_1^T(f) = \int_a^b (x-a)(x-b) f[a,b,x]\,dx = f[a,b,c] \int_a^b (x-a)(x-b)\,dx = \frac{f''(\xi)}{2} \int_a^b (x-a)(x-b)\,dx$$

for some $c \in (a,b)$, where $\xi = \xi(c) \in (a,b)$. We calculate

$$\int_a^b (x-a)(x-b) = -\frac{h^3}{6}$$

(cf. the proof of IX.2.13.24.), so we get

$$E_1^T(f) = -\frac{h^3}{12} f''(\xi)$$

for some $\xi \in (a,b)$.

IX.2.13.37. Now suppose we do the composite trapezoid rule with n subintervals, each of length $h = \frac{b-a}{n}$. Using the previous analysis on each subinterval, we have

$$E_n^T(f) = -\frac{h^3}{12} f''(\xi_1) - \frac{h^3}{12} f''(\xi_2) - \cdots - \frac{h^3}{12} = -\frac{(b-a)^3}{12n^3} \left[f''(\xi_1) + \cdots + f''(\xi_n)\right]$$

for some $\xi_k \in (x_{k-1}, x_k)$. If f is $\mathcal{C}^2$, we can apply the Intermediate Value Theorem to f'' to obtain a $\xi \in (a,b)$ with

$$f''(\xi_1) + \cdots + f''(\xi_n) = n f''(\xi)$$

so we obtain a simplified form of the error:

$$E_n^T(f) = -\frac{(b-a)^3}{12n^2} f''(\xi)$$

for some $\xi \in (a,b)$. If $|f''|$ is bounded by K on $[a,b]$, we have

$$|E_n^T(f)| \leq \frac{(b-a)^3}{12n^2} K\ .$$

IX.2.13.38. Thus, as n increases, the error in the trapezoid rule is $O(n^{-2})$, so decreases fairly rapidly. The error bound at the end of IX.2.13.37. is actually conservative in many cases: the sum

$$|f''(\xi_1) + \cdots + f''(\xi_n)|$$

is often much less than $n \cdot \max_{[a,b]} |f''|$, especially if f'' varies significantly or changes sign on $[a,b]$; in fact,

$$f''(\xi_1) + \cdots + f''(\xi_n)$$

is close to n times the *average* value of f'' on $[a,b]$, i.e.

$$n \frac{f'(b) - f'(a)}{b-a}$$

for n large. Thus

$$E_n^T(f) \approx -\frac{(b-a)^2}{12n^2} [f'(b) - f'(a)]$$

for n large.

IX.2.13.39. We can thus add a correction term to the trapezoid rule: set

$$\tilde{T}_n(f) = T_n(f) + \frac{(b-a)^2}{12n^2}[f'(b) - f'(a)] \ .$$

The error for this quadrature rule is $o(n^{-2})$, and $O(n^{-4})$ if f is $\mathcal{C}^4$. (It is not always practical to compute $f'(a)$ and $f'(b)$, e.g. if f is given only by a data set. There are approximations possible using higher-order differences which can be used as a substitute.)

IX.2.13.40. If $f'(a) = f'(b)$, e.g. if f is periodic and the integration is over an entire period, then the correction term is zero and we have that the error $E_n^T(f)$ is $o(n^{-2})$ if f is $\mathcal{C}^2$, and $O(n^{-4})$ if f is $\mathcal{C}^4$. Thus the trapezoid rule is especially accurate for periodic functions. In fact, using the Euler-Maclaurin formula () it can be shown that if f is $\mathcal{C}^r$ and periodic with period $b-a$, then there is a constant C_r depending only on r such that

$$E_n^T(f) = C_r \frac{(b-a)^{r+1}}{n^r} f^{(r)}(\xi)$$

for some $\xi \in (a,b)$, and thus $E_n^T(f)$ is $O(n^{-r})$. See [IK94] for details.

Error Analysis of the Midpoint Rule

IX.2.13.41. Let us examine the error in the simple midpoint rule

$$M_1(f) = f(x_1)h$$

where $h = b-a$ and x_1 is the midpoint of $[a,b]$. The key trick in getting a good error formula is to note that not only is M_1 the interpolatory quadrature rule for the set $\{x_1\}$, but, if f is $\mathcal{C}^1$, it is also the osculatory quadrature rule for the nodes (x_1, x_1): the osculating polynomial is $p(x) = f(x_1) + f'(x_1)(x - x_1)$, and

$$\int_a^b [f(x_1) + f'(x_1)(x-x_1)]\,dx = f(x_1)(b-a) + \frac{1}{2}f'(x_1)[(b-x_1)^2 - (a-x_1)^2]$$

and the second term is zero. Thus the error is

$$E_1^M(f) = \int_a^b f(x)\,dx - M_1(f) = \int_a^b (x-x_1)^2 f[x_1, x_1, x]\,dx \ .$$

Assume f is $\mathcal{C}^2$ on $[a,b]$. Then $g(x) = f[x_1, x_1, x]$ is continuous on $[a,b]$ so by the MVT for integrals, there is a $c \in (a,b)$ such that

$$\int_a^b (x-x_1)^2 f[x_1, x_1, x]\,dx = f[x_1, x_1, c] \int_a^b (x-x_1)^2\,dx \ .$$

We also have by () that

$$f[x_1, x_1, c] = \frac{f''(\xi)}{2}$$

for some $\xi \in (a,b)$. We calculate

$$\int_a^b (x-x_1)^2\,dx = \frac{1}{3}[(b-x_1)^3 - (a-x_1)^3] = \frac{1}{3} \cdot 2\left(\frac{h}{2}\right)^3 = \frac{h^3}{12}$$

so we have

$$E_1^M(f) = \frac{h^3}{24} f''(\xi)$$

for some $\xi \in (a, b)$.

IX.2.13.42. Now consider the composite midpoint rule with n subintervals of length $h = \frac{b-a}{n}$. If f is $\mathcal{C}^2$ on $[a, b]$, we have

$$E_n^M(f) = \frac{h^3}{24} f''(\xi_1) + \cdots + \frac{h^3}{24} f''(\xi_n) = \frac{(b-a)^3}{24n^3}[f''(\xi_1) + \cdots + f''(\xi_n)]$$

for some $\xi_k \in (x_{k-1}, x_k)$. By the Intermediate Value Theorem there is a $\xi \in (a, b)$ with $f''(\xi_1)+\cdots+f''(\xi_n) = nf''(\xi)$, so we get the clean formula

$$E_n^M(f) = \frac{(b-a)^3}{24n^2} f''(\xi)$$

for some $\xi \in (a, b)$. If $|f''|$ is bounded by K on $[a, b]$, we get

$$|E_n^M(f)| \leq \frac{(b-a)^3}{24n^2} K \ .$$

IX.2.13.43. As with the trapezoid rule, the absolute error estimate for the midpoint rule is conservative, and we may add a correction term: set

$$\tilde{M}_n(f) = M_n(f) - \frac{(b-a)^2}{24n^2}[f'(b) - f'(a)] \ .$$

This has error $O(n^{-4})$ if f is $\mathcal{C}^4$. If $f'(a) = f'(b)$, e.g. if f is periodic and the integration is over an entire period, then the correction term is zero and we have that the error $E_n^M(f)$ is $O(n^{-4})$ if f is $\mathcal{C}^4$. (In the periodic case, the midpoint rule, the trapezoid rule, and the left and right approximations are effectively all the same procedure.)

IX.2.13.44. Comparing IX.2.13.41. with IX.2.13.36. and IX.2.13.42. with IX.2.13.37., we see that if f is $\mathcal{C}^2$, the error in the midpoint rule is indeed approximately of opposite sign and half the absolute value of the error in the trapezoid rule for the same n (cf. IX.2.13.10.). The statement is not exactly true since the ξ's are not the same in general; but if n is chosen large enough that f'' varies little over each subinterval, the $f''(\xi_k)$'s are almost equal for each k, so the statement is very nearly true. Thus for such an n we have that Simpson's rule S_{2n} is an extremely good approximation to the integral. See IX.2.13.49..

IX.2.13.45. Another consequence of the error formula (which is pretty obvious just from the definition) is that even though the simple midpoint rule is an interpolatory procedure with only one node, it has order of precision 1, not 0: it gives the exact answer for linear functions, not just constant functions. The simple trapezoid rule also has order of precision 1, as expected since it is an interpolatory procedure with two nodes. The composite procedures also have order of precision 1.

Error Analysis of Simpson's Rule

IX.2.13.46. Consider the simple Simpson's rule S_2, where $h = \frac{b-a}{2}$. We first observe that S_2 actually has order of precision ≥ 3 instead of the expected 2. To show this, by linearity it suffices to show that $S_2(f) = \int_a^b f(x)\,dx$ for $f(x) = x^3$, which is a simple calculation:

$$S_2(f) = \frac{h}{3}[a^3 + 4x_1^3 + b^3] = \frac{b-a}{6}\left[a^3 + 4\left(\frac{a+b}{2}\right)^3 + b^3\right]$$

$$= \frac{b-a}{6}\left[a^3 + \frac{1}{2}(a+b)^3 + b^3\right] = \frac{1}{6}(b-a)\left[a^3 + \frac{1}{2}a^3 + \frac{3}{2}a^2b + \frac{3}{2}ab^2 + \frac{1}{2}b^3 + b^3\right]$$

$$= \frac{1}{4}(b-a)(a^3 + a^2b + ab^2 + b^3) = \frac{1}{4}(b^4 - a^4) = \int_a^b x^3\,dx\ .$$

(It is easily checked the same way that S_2 is not exact on $f(x) = x^4$, so the order of precision of S_2 is exactly 3.)

IX.2.13.47. Now suppose f is $\mathcal{C}^1$, and let p be the osculating polynomial for f with nodes x_0, x_1, x_1, x_2. Then the interpolating polynomial for p for the nodes x_0, x_1, x_2 is the same polynomial q as the interpolating polynomial for f with these same nodes. Since p is cubic, we have

$$\int_a^b p(x)\,dx = S_2(p) = \int_a^b q(x)\,dx = S_2(f)\ .$$

Thus, for $\mathcal{C}^1$ functions, S_2 is the osculating quadrature procedure with nodes x_0, x_1, x_1, x_2.

IX.2.13.48. As a result, if f is $\mathcal{C}^1$ we get a formula for the error in S_2:

$$E_2^S(f) = \int_a^b [f(x) - p(x)]\,dx = \int_a^b (x-x_0)(x-x_1)^2(x-x_2)f[x_0, x_1, x_1, x_2, x]\,dx\ .$$

We proceed as before. Suppose f is $\mathcal{C}^1$ on $[a,b]$. The function $g(x) = f[x_0, x_1, x_1, x_2, x]$ is continuous on $[a,b]$, and $(x-x_0)(x-x_1)^2(x-x_2)$ does not change sign on $[a,b]$, so by the MVT for integrals we have

$$E_2^S(f) = \int_a^b (x-x_0)(x-x_1)^2(x-x_2)f[x_0, x_1, x_1, x_2, x]\,dx = f[x_0, x_1, x_1, x_2, c]\int_a^b (x-x_0)(x-x_1)^2(x-x_2)\,dx$$

for some $c \in (a,b)$.

Next we calculate

$$\int_a^b (x-a)(x-x_1)^2(x-b)\,dx\ .$$

Make the substitution $x = x_0 + th$; then

$$\int_a^b (x-a)(x-x_1)^2(x-b)\,dx = h^5\int_0^2 t(t-1)^2(t-2)\,dt = -\frac{4h^5}{15}\ .$$

Now suppose f is $\mathcal{C}^4$ on $[a,b]$. Then

$$f[x_0,x_1,x_1,x_2,c] = \frac{f^{(4)}(\xi)}{4!}$$

for some $\xi \in (a,b)$. Thus we obtain

$$E_2^S(f) = -\frac{4h^5}{15}\frac{f^{(4)}(\xi)}{24} = -\frac{h^5}{90}f^{(4)}(\xi)$$

for some $\xi \in (a,b)$.

IX.2.13.49. Now consider the composite Simpson's rule with n subintervals of length $h = \frac{b-a}{n}$, where $n = 2m$ is even. If f is $\mathcal{C}^4$ on $[a,b]$, we have, applying S_2 on each pair of successive intervals,

$$E_n^S(f) = -\frac{h^5}{90}f^{(4)}(\xi_1) - \cdots - \frac{h^5}{90}f^{(4)}(\xi_m) = -\frac{(b-a)^5}{90n^5}[f^{(4)}(\xi_1) + \cdots + f^{(4)}(\xi_m)]$$

for some $\xi_k \in (x_{2k-2}, x_{2k})$. By the Intermediate Value Theorem there is a $\xi \in (a,b)$ with $f^{(4)}(\xi_1) + \cdots + f^{(4)}(\xi_m) = mf^{(4)}(\xi)$, so we get the clean formula

$$E_n^M(f) = -\frac{(b-a)^5}{180n^4}f^{(4)}(\xi)$$

for some $\xi \in (a,b)$. If $|f^{(4)}|$ is bounded by K on $[a,b]$, we get

$$|E_n^S(f)| \leq \frac{(b-a)^5}{180n^4}K\ .$$

IX.2.13.50. Thus, as n increases, the error in Simpson's rule is $O(n^{-4})$, so decreases rapidly. The error bound at the end of IX.2.13.49. is actually conservative in many cases: the sum

$$|f^{(4)}(\xi_1) + \cdots + f^{(4)}(\xi_m)|$$

is often much less than $m \cdot \max_{[a,b]} |f^{(4)}|$, especially if $f^{(4)}$ varies significantly or changes sign on $[a,b]$; in fact,

$$f^{(4)}(\xi_1) + \cdots + f^{(4)}(\xi_m)$$

is close to m times the *average* value of $f^{(4)}$ on $[a,b]$, i.e.

$$m\frac{f^{(3)}(b) - f^{(3)}(a)}{b-a}$$

for n large. Thus

$$E_n^S(f) \approx -\frac{(b-a)^4}{180n^4}[f^{(3)}(b) - f^{(3)}(a)]$$

for n large. See also IX.2.13.44..

IX.2.13.51. We can thus add a correction term to Simpson's rule: if n is even, set

$$\tilde{S}_n(f) = S_n(f) + \frac{(b-a)^4}{180n^4}[f^{(3)}(b) - f^{(3)}(a)] \ .$$

The error for this quadrature rule is $o(n^{-4})$ if f is $\mathcal{C}^4$, and $O(n^{-6})$ if f is $\mathcal{C}^6$. (It is not always practical to compute $f^{(3)}(a)$ and $f^{(3)}(b)$, e.g. if f is given only by a data set. There are approximations possible using higher-order differences which can be used as a substitute.)

IX.2.13.52. If $f^{(3)}(a) = f^{(3)}(b)$, e.g. if f is periodic and the integration is over an entire period, then the correction term is zero and we have that the error $E_n^S(f)$ is $O(n^{-6})$ if f is $\mathcal{C}^6$. Thus, like the trapezoid rule, Simpson's rule is especially accurate for periodic functions. But because of IX.2.13.40., there is little practical reason to use Simpson's rule instead of the trapezoid rule for periodic functions.

IX.2.13.53. For functions which are not smooth, the trapezoid rule is actually often a little better than Simpson's rule for the same number of subintervals. See [CUN02] for a detailed analysis of the errors for both methods for classes of nonsmooth functions.

Error Analysis for Newton-Cotes Procedures

IX.2.13.54. Error formulas for the higher-order Newton-Cotes formulas and open Newton-Cotes formulas can be obtained by essentially the same arguments, although the details are more complicated beyond Simpson's rule; see e.g. [IK94]. The result is:

IX.2.13.55. THEOREM. Let f be a function on $[a,b]$, and $n \in \mathbb{N}$. Set $h = \frac{b-a}{n}$.
(i) Suppose n is odd and f is $\mathcal{C}^{n+1}$ on $[a,b]$. Then

$$E_n^{NC}(f) = \int_a^b f(x)\,dx - NC_n(f) = \frac{M_n}{(n+1)!}h^{n+2}f^{(n+1)}(\xi)$$

for some $\xi \in (a,b)$, where

$$M_n = \int_0^n \pi_n(t)\,dt = \int_0^n t(t-1)\cdots(t-n)\,dt < 0 \ .$$

(ii) Suppose n is even and f is $\mathcal{C}^{n+2}$ on $[a,b]$. Then

$$E_n^{NC}(f) = \int_a^b f(x)\,dx - NC_n(f) = \frac{M_n}{(n+2)!}h^{n+3}f^{(n+2)}(\xi)$$

for some $\xi \in (a,b)$, where

$$M_n = \int_0^n t\pi_n(t) = \int_0^n t^2(t-1)\cdots(t-n)\,dt < 0 \ .$$

These formulas are consistent with the cases $n = 1$ (trapezoid rule) and $n = 2$ (Simpson's rule) developed in IX.2.13.36. and IX.2.13.46..

IX.2.13.56. COROLLARY. If n is even, the Newton-Cotes procedure NC_n has order of precision $n+1$; if n is odd, NC_n has order of precision n.

IX.2.13.57. Thus, if n is even, The Newton-Cotes procedure NC_n has essentially the same accuracy as NC_{n+1} (the accuracy of NC_{n+1} is roughly better by a constant factor). Thus Newton-Cotes procedures are "better" for even n. The "explanation" is that if n is even, the procedure NC_n, which is the interpolatory procedure for the evenly spaced nodes $x_0, \ldots, x_n$, turns out to be also the osculatory procedure for the $n+2$ nodes $x_0, \ldots, x_{n/2}, x_{n/2}, \ldots, x_n$, with $x_{n/2}$ repeated, as in the case of the midpoint rule and Simpson's rule.

IX.2.13.58. There are similar results for the open Newton-Cotes formulas NC_n^o, which also gain an extra order of precision for n even (e.g. for the midpoint rule NC_0^o). In this case the constants are positive.

IX.2.13.59. These error formulas are for simple Newton-Cotes procedures. Similar error formulas for compound Newton-Cotes procedures can be obtained in exactly the same manner as for the trapezoid, midpoint, and Simpson's rule cases.

Error Analysis for Gaussian Quadrature

IX.2.13.60. The error for Gaussian quadrature G_n on $[a,b]$ may be calculated in a similar manner: if f is $\mathcal{C}^{2n}$ on $[a,b]$, then

$$E_n^G(f) = \int_a^b f(x)\,dx - G_n(f) = \frac{2}{(2n+1)!}\left[\frac{2^n(n!)^2}{(2n)!}\right]^2 (b-a)^{2n+1} f^{(2n)}(\xi)$$

for some $\xi \in (a,b)$. Using Stirling's formula () to approximate the factorials, we get, for n large,

$$E_n^G(f) \approx \frac{\pi n (b-a)^{2n+1}}{2^{2n-1}(2n+1)!} f^{(2n)}(\xi)$$

for some $\xi \in (a,b)$. Thus if the derivatives of f do not grow too rapidly (e.g. if f is complex-analytic on a large enough region containing $[a,b]$), the Gaussian quadrature approximations converge rapidly as $n \to \infty$. See e.g. [IK94] for details.

IX.2.13.61. In practice, knowing when a procedure gives a sufficiently accurate estimate is not easy. There are procedures which carefully combine results of a standard procedure done twice for different partitions to greatly improve accuracy and make it easier to know when to stop. A theoretically and computationally appealing such improvement of the trapezoid rule is *Romberg integration* (Exercise IX.2.14.7.). A widely-used similar variation of Gaussian quadrature is *Gauss-Kronrod integration*.

There are also *adaptive procedures* for numerical integration, where the interval lengths and procedures are not fixed in advance but the details vary according to properties of the function being integrated. These are generally the best numerical procedures when feasible. Most software packages for numerical integration use some combination or variation of these procedures; further discussion is beyond our scope, but can be found in numerical analysis texts.

IX.2.14. Exercises

IX.2.14.1. Here are some additional relations among standard integration procedures on a fixed interval $[a, b]$.

(a) Show that $T_{2n} = \frac{1}{2}(T_n + M_n)$ for any n.

(b) Show that $S_{2n} = \frac{1}{3}(4T_{2n} - T_n)$ for any n.

IX.2.14.2. (a) Consider

$$\int_{-m}^{m} \frac{1}{x^2+1}\, dx \ .$$

Compute the exact value, and the trapezoid and midpoint estimates using one subinterval. Show that the absolute trapezoid error is less than the absolute midpoint error if $m > 1.44$, and the trapezoid estimate is *much* better than the midpoint estimate for m large.

(b) Consider

$$\int_{0}^{1} x^m\, dx \ .$$

Compute the exact value, and the trapezoid and midpoint estimates using one subinterval. Show that the midpoint estimate is *much* better than the trapezoid estimate for m large.

Actually, none of the estimates are very good in these cases, as may be expected when only one interval is used. In (b), at least the midpoint errors approach 0 as $m \to +\infty$, while the absolute trapezoid error increases as m increases. In (a), both the absolute trapezoid and midpoint errors increase as m increases, but the trapezoid errors are bounded and the midpoint errors unbounded as $m \to +\infty$.

IX.2.14.3. Consider the integral

$$\int_{-1}^{1} |x|\, dx \ .$$

Show that either the trapezoid rule or the midpoint rule for n subintervals gives the exact answer if n is even (even $n = 2$), and not if n is odd. Thus the approximations do not necessarily become monotonically better as n increases (although they do converge to the exact integral as $n \to \infty$).

This function is not differentiable everywhere. But it can be uniformly approximated arbitrarily closely by a polynomial () for which the same statements are approximately true; in particular, approximations using a relatively small even number of intervals, even 2, are better than approximations of the same kind using a larger odd number of subintervals.

It can be shown that if f is a polynomial, then the absolute error $|E_n^T(f)|$ monotonically decreases for sufficiently large n, but this is not always true if f is merely smooth. See http://mathoverflow.net/questions/180542/monotonicity-of-trapezoid-approximations.

IX.2.14.4. **Simpson's Three-Eighths Rule.** Fix an interval $[a, b]$.

(a) Show that if f is a function on $[a, b]$, then

$$NC_3(f) = \frac{3h}{8}[f(x_0) + 3f(x_1) + 3f(x_2) + f(x_3)]$$

where $h = \frac{b-a}{3}$.

(b) Show that if f is $\mathcal{C}^4$ on $[a,b]$, then

$$E_3^{NC}(f) = -\frac{3}{80}h^5 f^{(4)}(\xi)$$

for some $\xi \in (a,b)$.

(c) Compare $E_3^{NC}(f)$ with $E_2^{NC}(f) = E_2^S(f)$ (IX.2.13.46.). [Caution: the h's are different in the two cases, and the ξ's are also normally different.]

(d) If $n = 3m$ is divisible by 3, let R_n be the composite quadrature procedure obtained by dividing $[a,b]$ into m equal subintervals and applying NC_3 on each (so $[a,b]$ is divided into n equal subintervals of length $h = \frac{b-a}{n}$). Show that if f is $\mathcal{C}^4$ on $[a,b]$, then

$$E_n^R(f) = \int_a^b f(x)\,dx - R_n(f) = -\frac{3}{80}\frac{(b-a)^5}{n^5}[f^{(4)}(\xi_1) + \cdots + f(\xi_m)] = -\frac{1}{80}\frac{(b-a)^5}{n^4}f^{(4)}(\xi)$$

for some $\xi_k \in (x_{3k-3}, x_{3k})$ and some $\xi \in (a,b)$.

(e) Suppose f is $\mathcal{C}^4$ on $[a,b]$, and n is divisible by 6 and large enough that $f^{(4)}$ is almost constant on each subinterval. Show that $|E_n^S(f)|$ is "typically" smaller than $|E_n^R(f)|$.

IX.2.14.5. Let w be a nonnegative Riemann-integrable function on $[a,b]$ with $\int_a^b w(x)\,dx > 0$. Define a real inner product on the set of polynomials (with real coefficients) by

$$\langle p, q\rangle = \int_a^b p(x)q(x)w(x)\,dx\ .$$

(a) Show that for each $n \in \mathbb{N}$ there is a unique (up to scalar multiple) nonzero polynomial p of degree n which is orthogonal to all polynomials of degree $\leq n-1$ under this inner product.

(b) Suppose p changes sign exactly m times in $[a,b]$, at $x_1, \ldots, x_m$ in (a,b), i.e. $x_1, \ldots, x_m$ are the distinct roots of p of odd order in (a,b). Show that p cannot be orthogonal to

$$q(x) = (x - x_1)(x - x_2)\cdots(x - x_m)$$

($q(x) = 1$ if $m = 0$) since pq does not change sign on $[a,b]$. Thus $m = deg(q) \geq n$.

(c) Conclude that all the roots of p are real and distinct and lie in (a,b).

IX.2.14.6. [Ham86, 17.7] Consider the following quadrature procedure for twice-differentiable functions on $[-1,1]$:

$$Q(f) = \frac{1}{21}[5f(-1) + 32f(0) + 5f(1)] - \frac{1}{315}[f''(-1) + 32f''(0) + f''(1)]\ .$$

(a) Show that Q has order of precision 6.

(b) Show that Q is not an osculating procedure.

IX.2.14.7. Romberg Integration. Fix an interval $[a,b]$. Let T_n^0 be the trapezoid rule T_n for any n. Recursively define

$$T_{2n}^k = \frac{1}{4^k-1}\left(4^k T_{2n}^{k-1} - T_n^{k-1}\right)$$

for all n and k.

(a) Show that $T_{2n}^1 = S_{2n}$ for any n.

(b) Show that T_{4n}^2 is $NC_{4,n}$, the process of dividing $[a,b]$ into n subintervals of equal length and applying NC_4 on each subinterval.

(c) The simple relation of (a) and (b) with the Newton-Cotes formulas does not persist. Show that

$$T_8^3 = \frac{4h}{2835}\left(217f(x_0) + 1024f(x_1) + 352f(x_2) + 1024f(x_3) + 436f(x_4) + 1024f(x_5) + 352f(x_6) + 1024f(x_7) + 217f(x_8)\right)$$

($h = \frac{b-a}{8}$) which is not the same as NC_8 (however, the coefficients of T_8^3 are all positive, which is desirable computationally, and the sizes of the coefficients do not vary greatly).

The Romberg integration procedure is as follows. Fix an n (in practice $n = 1$ is often used). Successively calculate $T_{2^m n}^k$ for $k \le 2^m$. The results can be conveniently collected in a triangular array

$$\begin{array}{cccc} T_n^0 & & & \\ T_{2n}^0 & T_{2n}^1 & & \\ T_{4n}^0 & T_{4n}^1 & T_{4n}^2 & \\ \vdots & \vdots & \vdots & \ddots \end{array}$$

where each entry is computed from the one to the left and the one diagonally above to the left (the entries in the first column are computed from the trapezoid rule using additional function evaluations; note that $T_{2^{m+1}n}^0$ can be calculated from $T_{2^m n}^0$ by only $2^m n$ additional function evaluations). In practice the entries are rounded to the desired accuracy and the process stops when two identical numbers to the desired accuracy are obtained. The process is computationally efficient and frequently produces the desired accuracy with fewer function evaluations than Simpson's Rule. The convergence rate is comparable to the rate using correction terms (IX.2.13.39.), and is more computationally efficient and avoids making a careful estimate of the starting n needed. See books on Numerical Analysis for details and error analyses.

IX.3. Jordan Content and Riemann Integration in $\mathbb{R}^n$

Generalization of Riemann integration to $\mathbb{R}^n$ is in many ways straightforward, but there are some significant technicalities to overcome. One is to nail down what kinds of sets functions can be reasonably integrated over, and the answer is considerably more complicated than in the one-dimensional case where intervals are the obvious answer. There is a natural collection of subsets called *Jordan regions* which work nicely for Riemann integration and which are general enough to cover most cases of practical interest. As a special case of integration, we also have a natural notion of "volume," called *Jordan content*, for Jordan regions.

IX.3.1. Integration over Rectangles

It is most straightforward to integrate over rectangles in $\mathbb{R}^n$ whose edges are parallel to the axes. The following definition will be used throughout this section (a more general definition is used in ()).

IX.3.1.1. Definition. A *rectangle* in $\mathbb{R}^n$ is a set R of the form $I_1 \times \cdots \times I_n$, where each I_k is a closed bounded interval $[a_k, b_k]$ or degenerate interval (if $a_k = b_k$) in $\mathbb{R}$, i.e.

$$R = \{(x_1, \ldots, x_n) : a_k \leq x_k \leq b_k \text{ for all } k\} .$$

The rectangle is *degenerate* if I_k is degenerate for at least one k. The *content* (*n-dimensional content*), or *volume* (*n-dimensional volume*) of R is

$$V(R) = \prod_{k=1}^{n} \ell(I_k) = \prod_{k=1}^{n} (b_k - a_k) .$$

Such rectangles should more properly be called closed coordinate rectangles or closed aligned rectangles, since there are more general sets which can be called rectangles. However, rectangles as defined in IX.3.1.1. are exclusively used in developing Riemann integration and it is pedantic to have to constantly qualify them.

IX.3.1.2. We use the term "rectangle" in any number of dimensions even though it is only geometrically accurate if $n = 2$; in $\mathbb{R}^3$ a rectangle by our definition is what is usually called a rectangular solid, and for $n > 3$ there is not a standard geometric name. Note that the case $n = 1$ is not excluded; a rectangle in $\mathbb{R}$ is just a closed bounded interval or single point. Similarly, "volume" is only strictly appropriate if $n = 3$, which is why we prefer the term "content": if $n = 2$ content is usually called "area" (and for $n = 1$ it is "length"). We will, however, use the notation $V(R)$ which suggests the term "volume" no matter what n is. To emphasize the dimension, we can (but rarely will) write V_n in place of V.

Note that the n-dimensional content of a degenerate rectangle is always 0. A degenerate rectangle is geometrically m-dimensional for some $m < n$ (the number of nondegenerate coordinate intervals) and so has an m-dimensional "content"; thus we must exercise some care in fixing n and interpreting "content" to be n-dimensional content for this n.

It is a matter of taste whether to regard $\emptyset$ as a rectangle; whether we do or not necessarily leads to some notational complications, which are greater if we do. We will not.

The next observation is obvious from the fact that the intersection of two intervals in $\mathbb{R}$ is an interval or degenerate interval.

IX.3.1.3. PROPOSITION. If R and S are rectangles in $\mathbb{R}^n$, and $R \cap S \neq \emptyset$, then $R \cap S$ is also a rectangle.

PROOF: If $R = I_1 \times \cdots \times I_n$ and $S = J_1 \times \cdots \times J_n$, then $R \cap S = (I_1 \cap J_1) \times \cdots \times (I_n \cap J_n)$. 👍

IX.3.1.4. DEFINITION. Let R and S be rectangles in $\mathbb{R}^n$. Then R and S are *nonoverlapping* if either $R \cap S = \emptyset$ or $R \cap S$ is a degenerate rectangle.

Partitions and Grids

IX.3.1.5. DEFINITION. Let R be a rectangle in $\mathbb{R}^n$. A *partition* of R is a set $\mathcal{P} = \{R_1, \ldots, R_m\}$ of pairwise nonoverlapping rectangles in $\mathbb{R}^n$ with $R = \cup_{k=1}^m R_k$.

A partition $\mathcal{Q}$ is a *refinement* of $\mathcal{P}$ if every rectangle in $\mathcal{Q}$ is contained in a rectangle of $\mathcal{P}$.

A *grid* in R is a partition of $R = I_1 \times \cdots \times I_n$ of the form $\mathcal{G} = \mathcal{P}_1 \times \cdots \times \mathcal{P}_n$, where $\mathcal{P}_k$ is a partition of I_k.

Note that a partition of a rectangle is not necessarily a grid. See Figure IX.19. It is convenient to allow degenerate rectangles in partitions, as our definition does; thus a partition of an interval in $\mathbb{R}$ by this definition is slightly more general than the definition in (), since repeated points are allowed. This will make no practical difference but simplifies some notation. We could develop the whole theory just using grids, but it is convenient to allow partitions which are not grids. Every partition has a refinement which is a grid (see the proof of IX.3.1.6.).

By IX.3.1.3., any two partitions of a rectangle have a common refinement obtained by intersecting the subrectangles. If the partitions are grids, so is the common refinement constructed in this way.

Note that there is no natural ordering of the rectangles in a partition, even a grid, if $n > 1$. We have notationally fixed an ordering, but the ordering is not part of the definition of the partition.

Here is a technicality which may be considered geometrically "obvious" (but see the discussion in I.6.1.3.); however, it needs proof (if $n > 1$). This is one of the fundamental observations which gets Jordan content and Riemann integration theory in $\mathbb{R}^n$ off the ground.

IX.3.1.6. PROPOSITION. Let R be a rectangle in $\mathbb{R}^n$. Suppose R is a union of a finite number of pairwise nonoverlapping subrectangles $R = \cup_{k=1}^m R_k$. Then

$$V(R) = \sum_{k=1}^{m} V(R_k) \ .$$

To prove IX.3.1.6., we will first prove a special case where the subdivision is a grid:

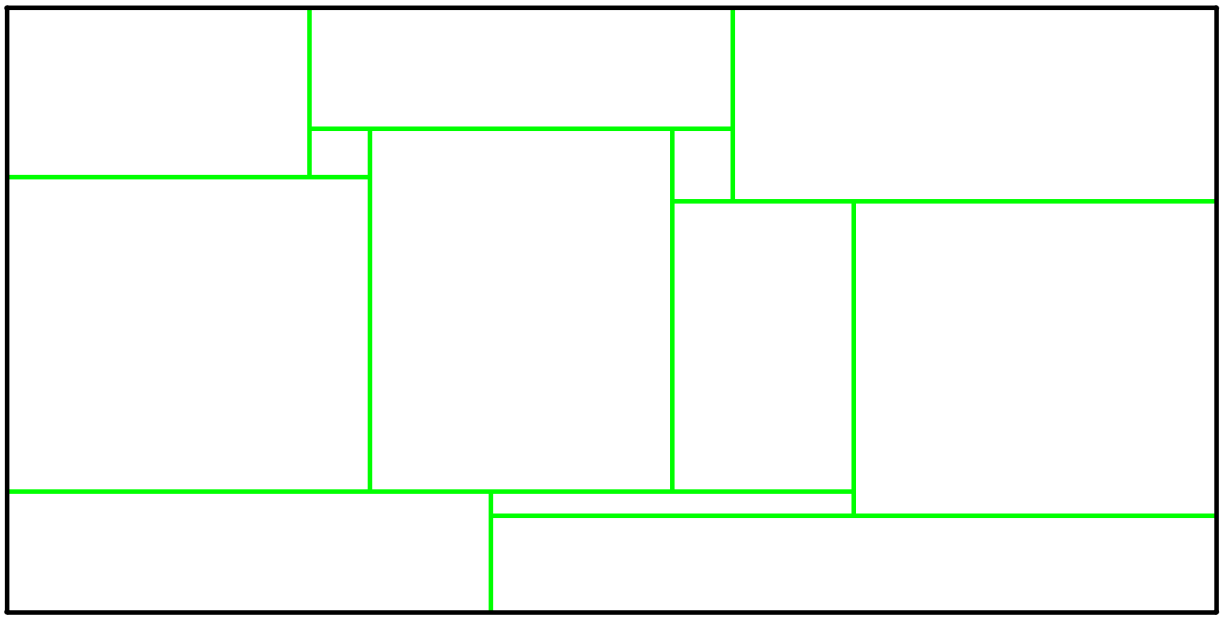

Figure IX.19: Subdivision of a Rectangle

IX.3.1.7. LEMMA. Let $R = [a_1, b_1] \times \cdots \times [a_n, b_n]$ be a rectangle in $\mathbb{R}^n$. For each k let $\mathcal{P}_k$ be a partition of $[a_k, b_k]$, and let $\mathcal{G} = \mathcal{P}_1 \times \cdots \times \mathcal{P}_n$ be the corresponding grid. Let $\{R_1, \ldots, R_p\}$ be the subrectangles in the grid. Then

$$V(R) = \sum_{k=1}^{p} V(R_k) \ .$$

PROOF: We write the proof for $n = 2$; the proof for general $n > 1$ is nearly identical but notationally offensive. So we have $R = [a_1, b_1] \times [a_2, b_2]$, $\mathcal{P}_1 = \{c_0, \ldots, c_r\}$, $\mathcal{P}_2 = \{d_0, \ldots, d_s\}$. Set

$$R_{jk} = [c_{j-1}, c_j] \times [d_{k-1}, d_k]$$

so

$$V(R_{jk}) = (c_j - c_{j-1})(d_k - d_{k-1}) \ .$$

We then have

$$\sum_{j,k} V(R_{jk}) = \sum_{j=1}^{r} \left[\sum_{k=1}^{s} (c_j - c_{j-1})(d_k - d_{k-1}) \right]$$

$$= \sum_{j=1}^{r} \left[(c_j - c_{j-1}) \sum_{k=1}^{s} (d_k - d_{k-1}) \right] = \sum_{j=1}^{r} (c_j - c_{j-1})(b_2 - a_2)$$

$$= (b_2 - a_2)\sum_{j=1}^{r}(c_j - c_{j-1}) = (b_2 - a_2)(b_1 - a_1) = V(R) \ .$$

We now give the proof of IX.3.1.6..

PROOF: Let $R = [a_1, b_1] \times \cdots \times [a_n, b_n]$ and $R_k = [a_{k,1}, b_{k,1}] \times \cdots \times [a_{k,n}, b_{k,n}]$. For each j, let $\mathcal{P}_j$ be the partition of $[a_j, b_j]$ consisting of all the $a_{k,j}$ and $b_{k,j}$. Let $\mathcal{G}$ be the corresponding grid, and let $\{R_{j_1,\ldots,j_n}\}$ be the rectangles in the grid. Then, by IX.3.1.7.,

$$V(R) = \sum_{j_1,\ldots,j_n} V(R_{j_1,\ldots,j_n}) \ .$$

For each k, set

$$I_k = \{(j_1, \ldots, j_n) : R_{j_1,\ldots,j_n} \subseteq R_k\} \ .$$

Every $(j_1, \ldots, j_n)$ for which $R_{j_1,\ldots,j_n}$ is nondegenerate is in exactly one I_k. For each k, the $R_{j_1,\ldots,j_n}$ for $(j_1, \ldots, j_n) \in I_k$ form a grid subdivision of R_k, so again by IX.3.1.7. we have

$$V(R_k) = \sum_{(j_1,\ldots,j_n)\in I_k} V(R_{j_1,\ldots,j_n})$$

for each k, and thus we have

$$V(R) = \sum_{j_1,\ldots,j_n} V(R_{j_1,\ldots,j_n}) = \sum_{k=1}^{m}\left[\sum_{(j_1,\ldots,j_n)\in I_k} V(R_{j_1,\ldots,j_n})\right] = \sum_{k=1}^{m} V(R_k) \ .$$

See Figure IX.20.

Upper and Lower Integrals over a Rectangle

We now proceed just as we did to define the integral of a bounded function over an interval in $\mathbb{R}$:

IX.3.1.8. DEFINITION. Let R be a rectangle in $\mathbb{R}^n$, and $f : R \to \mathbb{R}$ a bounded function. If $\mathcal{P} = \{R_1, \ldots, R_m\}$ is a partition of R, for each k set $M_k = \sup\{f(\boldsymbol{x}) : \boldsymbol{x} \in R_k\}$ and $m_k = \inf\{f(\boldsymbol{x}) : \boldsymbol{x} \in R_k\}$. Then the *upper and lower sums for f with respect to $\mathcal{P}$* are

$$\overline{\mathcal{S}}(f, \mathcal{P}) = \sum_{k=1}^{m} M_k \cdot V(R_k)$$

$$\underline{\mathcal{S}}(f, \mathcal{P}) = \sum_{k=1}^{m} m_k \cdot V(R_k) \ .$$

This definition agrees with the one in () if $n = 1$. Note that it does not make sense unless f is bounded.

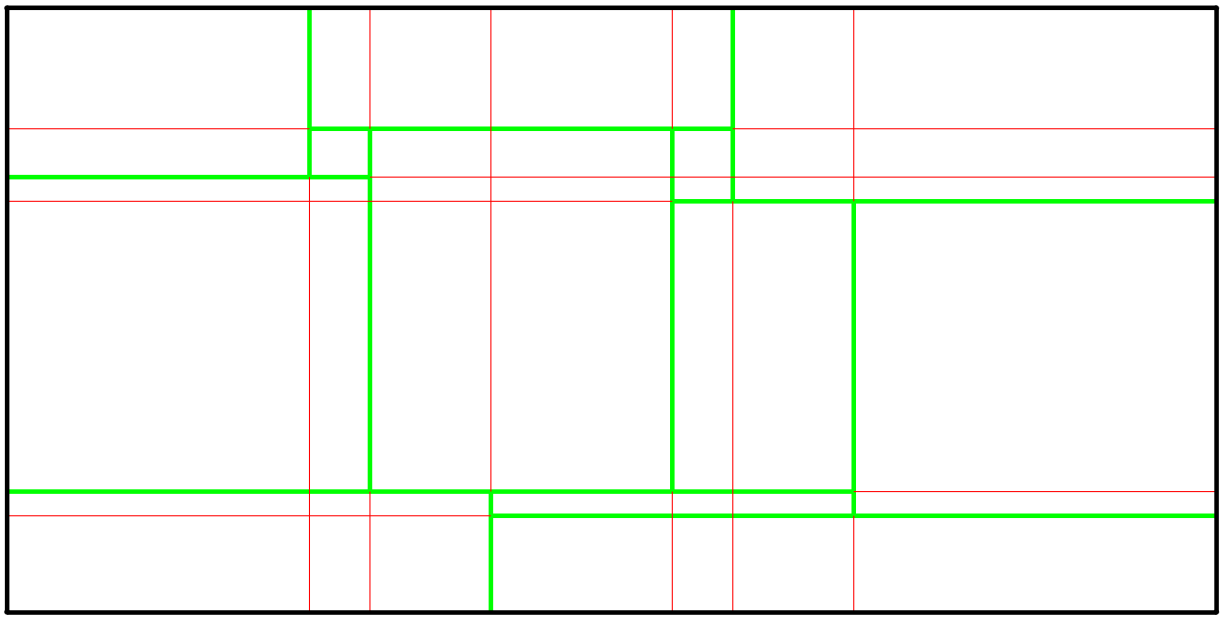

Figure IX.20: Grid Refinement of a Rectangle Subdivision

IX.3.1.9. It is clear that if $\mathcal{Q}$ is a refinement of $\mathcal{P}$, then

$$\underline{\mathcal{S}}(f,\mathcal{P}) \le \underline{\mathcal{S}}(f,\mathcal{Q}) \le \overline{\mathcal{S}}(f,\mathcal{Q}) \le \overline{\mathcal{S}}(f,\mathcal{P})$$

for any bounded function f. Thus the following definition is reasonable:

IX.3.1.10. Definition. Let R be a rectangle in $\mathbb{R}^n$, and $f : R \to \mathbb{R}$ a bounded function. The *upper and lower integrals* of f over R are

$$\overline{\int_R} f\,dV = \inf_{\mathcal{P}} \overline{\mathcal{S}}(f,\mathcal{P})$$

$$\underline{\int_R} f\,dV = \sup_{\mathcal{P}} \underline{\mathcal{S}}(f,\mathcal{P})\ .$$

The function f is *(Riemann) integrable over* R if $\overline{\int_R} f\,dV = \underline{\int_R} f\,dV$; in this case, the common value is the *integral of* f *over* R, denoted $\int_R f\,dV$.

IX.3.1.11. If $n = 1$, this definition is consistent with (): If $R = [a,b]$ and $f : R \to \mathbb{R}$ is bounded, then f is integrable over R if and only if it is Riemann integrable in the sense of (), and we have

$$\int_R f\,dV = \int_{[a,b]} f\,dV = \int_a^b f(x)\,dx\ .$$

IX.3.1.12. Of course we have $\underline{\int_R} f\,dV \le \overline{\int_R} f\,dV$ for any R and f. As in () we have:

IX.3.1.13. Proposition. Let R be a rectangle in $\mathbb{R}^n$, and $f : R \to \mathbb{R}$ a bounded function. Then f is integrable on R if and only if, for every $\epsilon > 0$, there is a partition $\mathcal{P}$ of R such that

$$\overline{\mathcal{S}}(f, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P}) < \epsilon \ .$$

Reasonable functions turn out to be Riemann integrable. Most importantly, we have the following higher-dimensional version of (), which is proved almost identically. We omit the proof since we will obtain a more general result in IX.3.2.21. with almost the same proof.

IX.3.1.14. Theorem. Let R be a rectangle in $\mathbb{R}^n$, and $f : R \to \mathbb{R}$ a continuous function. Then f is integrable over R.

However, functions which are too discontinuous are not integrable:

IX.3.1.15. Example. Let A be a subset of $\mathbb{R}^n$ which is dense and has dense complement, e.g. the set of points with rational coordinates. If R is any rectangle in $\mathbb{R}^n$ and $\mathcal{P}$ is any partition of R, then $\overline{\mathcal{S}}(\chi_A, \mathcal{P}) = V(R)$ and $\underline{\mathcal{S}}(\chi_A, \mathcal{P}) = 0$. Thus $\overline{\int_R} \chi_A\,dV = V(R)$ and $\underline{\int_R} \chi_A\,dV = 0$, so χ_A is not integrable on R unless R is degenerate.

Additivity of Upper and Lower Integrals

IX.3.1.16. Proposition. Let R be a rectangle in $\mathbb{R}^n$, and $f : R \to \mathbb{R}$ a bounded function. If $\mathcal{P} = \{R_1, \ldots, R_m\}$ is a partition of R, then we have

$$\overline{\int_R} f\,dV = \sum_{k=1}^{m} \overline{\int_{R_k}} f\,dV \text{ and } \underline{\int_R} f\,dV = \sum_{k=1}^{m} \underline{\int_{R_k}} f\,dV \ .$$

Proof: In calculating $\overline{\int_R} f\,dV$, only partitions of R refining $\mathcal{P}$ need be considered. Each such partition $\mathcal{Q}$ splits into partitions $\mathcal{Q}_k$ of R_k for each k, so we obtain

$$\overline{\mathcal{S}}(f, \mathcal{Q}) = \sum_{k=1}^{m} \overline{\mathcal{S}}(f, \mathcal{Q}_k) \ .$$

Conversely, if $\mathcal{Q}_k$ is a partition of R_k for each k, the union of the $\mathcal{Q}_k$ is a partition of R refining $\mathcal{P}$. So the infimum over partitions can be taken separately in each term. The argument for $\underline{\int_R} f\,dV$ is essentially identical. 👍

IX.3.1.17. Also note that if R is a degenerate rectangle and f is any bounded function on R, then f is integrable on R and $\int_R f\,dV = 0$.

Linearity of the Integral

IX.3.1.18. PROPOSITION. Let R be a rectangle in $\mathbb{R}^n$, $f : R \to \mathbb{R}$ a bounded function, and $\alpha \in \mathbb{R}$. Then

$$\overline{\int_R} \alpha f\,dV = \begin{cases} \alpha \overline{\int_R} f\,dV & \text{if} \quad \alpha \geq 0 \\ \alpha \underline{\int_R} f\,dV & \text{if} \quad \alpha < 0 \end{cases}$$

$$\underline{\int_R} \alpha f\,dV = \begin{cases} \alpha \underline{\int_R} f\,dV & \text{if} \quad \alpha \geq 0 \\ \alpha \overline{\int_R} f\,dV & \text{if} \quad \alpha < 0 \end{cases}$$

In particular, if f is integrable over R, then so is αf, and

$$\int_R \alpha f\,dV = \alpha \int_R f\,dV\ .$$

PROOF: This is obvious from the fact that if $\mathcal{P} = \{R_1, \ldots, R_m\}$ is any partition of R, then, for $1 \leq k \leq m$, $M_k(\alpha f) = \alpha M_k(f)$ if $\alpha \geq 0$ and $M_k(\alpha f) = \alpha m_k(f)$ if $\alpha < 0$, so that $\overline{\mathcal{S}}(\alpha f, \mathcal{P}) = \alpha \overline{\mathcal{S}}(f, \mathcal{P})$ if $\alpha \geq 0$ and $\overline{\mathcal{S}}(\alpha f, \mathcal{P}) = \alpha \underline{\mathcal{S}}(f, \mathcal{P})$ if $\alpha < 0$, and similarly for the other. 👍

IX.3.1.19. PROPOSITION. Let R be a rectangle in $\mathbb{R}^n$, and f and g bounded functions on R. Then

$$\overline{\int_R} (f+g)\,dV \leq \overline{\int_R} f\,dV + \overline{\int_R} g\,dV$$

$$\underline{\int_R} (f+g)\,dV \geq \underline{\int_R} f\,dV + \underline{\int_R} g\,dV\ .$$

In particular, if f and g are integrable over R, then so is $f + g$, and

$$\int_R (f+g)\,dV = \int_R f\,dV + \int_R g\,dV\ .$$

PROOF: This is similar to the previous proposition, noting that if $\mathcal{P} = \{R_1, \ldots, R_m\}$ is any partition of R, then, for $1 \leq k \leq m$, $M_k(f+g) \leq M_k(f) + M_k(g)$ and $m_k(f+g) \geq m_k(f) + m_k(g)$ (). 👍

IX.3.1.20. Thus the integral over a fixed rectangle is linear: if f and g are integrable over a rectangle R, and $\alpha, \beta \in \mathbb{R}$, then $\alpha f + \beta g$ is integrable over R and

$$\int_R (\alpha f + \beta g)\, dV = \alpha \int_R f\, dV + \beta \int_R g\, dV \ .$$

However, the upper and lower integrals are not linear for functions which are not integrable. For example, A is a dense set with dense complement, then for any nondegenerate R we have

$$V(R) = \overline{\int_R} 1\, dV = \overline{\int_R} (\chi_A + \chi_{A^c})\, dV < \overline{\int_R} \chi_A\, dV + \overline{\int_R} \chi_{A^c}\, dV = 2V(R)$$

and similarly for the lower integral for $-\chi_A - \chi_{A^c}$.

Order Properties of the Integral

The order properties of the integral are obvious (consider partitions):

IX.3.1.21. Proposition. Let R be a rectangle in $\mathbb{R}^n$, and f and g bounded functions on R. If $f \le g$ on R, then $\overline{\int_R} f\, dV \le \overline{\int_R} g\, dV$ and $\underline{\int_R} f\, dV \le \underline{\int_R} g\, dV$.

IX.3.1.22. Corollary. Let R be a rectangle in $\mathbb{R}^n$, and f a bounded function on R. If $m \le f(\boldsymbol{x}) \le M$ for all $\boldsymbol{x} \in R$, then

$$m \cdot V(R) \le \underline{\int_R} f\, dV \le \overline{\int_R} f\, dV \le M \cdot V(R) \ .$$

In particular, if $f \ge 0$ on R, then $\underline{\int_R} f\, dV \ge 0$.

Integrability of Products

Although the result is a special case of the general characterization of integrable functions in (), we can give a simple proof that a product of integrable functions is integrable.

IX.3.1.23. Lemma. Let R be a rectangle in $\mathbb{R}^n$, and f a bounded function on R. If $|f(\boldsymbol{x})| \le B$ for all $\boldsymbol{x} \in R$, then, for any partition $\mathcal{P} = \{R_1, \ldots, R_m\}$ of R,

$$\overline{\mathcal{S}}(f^2, \mathcal{P}) - \underline{\mathcal{S}}(f^2, \mathcal{P}) \le 2B[\overline{\mathcal{S}}(f, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P})] \ .$$

Proof: For $1 \le k \le m$, we have, for any $\boldsymbol{x}, \boldsymbol{y} \in R_k$,

$$f(\boldsymbol{x})^2 - f(\boldsymbol{y})^2 = (f(\boldsymbol{x}) + f(\boldsymbol{y}))(f(\boldsymbol{x}) - f(\boldsymbol{y}))$$

$$|f(\boldsymbol{x})^2 - f(\boldsymbol{y})^2| = |f(\boldsymbol{x}) + f(\boldsymbol{y})||f(\boldsymbol{x}) - f(\boldsymbol{y})| \le 2B|f(\boldsymbol{x}) - f(\boldsymbol{y})|$$

and therefore $M_k(f^2) - m_k(f^2) \le 2B(M_k(f) - m_k(f))$, and the result follows by summing over k.

IX.3.1.24. Corollary. Let R be a rectangle in $\mathbb{R}^n$, and f a bounded function on R. If $|f(\boldsymbol{x})| \le B$ for all $\boldsymbol{x} \in R$, then

$$\overline{\int_R} f^2\,dV - \underline{\int_R} f^2\,dV \le 2B\left[\overline{\int_R} f\,dV - \underline{\int_R} f\,dV\right] .$$

In particular, if f is integrable over $\mathbb{R}$, then so is f^2.

IX.3.1.25. Proposition. Let R be a rectangle in $\mathbb{R}^n$, and f and g bounded functions on R. If f and g are integrable over R, then so is fg.

Proof: We have $f+g$ integrable over R by IX.3.1.19., and thus f^2, g^2, and $(f+g)^2$ are integrable over R by IX.3.1.24.. Since

$$fg = \frac{1}{2}\left[(f+g)^2 - f^2 - g^2\right]$$

we have that fg is integrable over R by IX.3.1.20.. 👍

Expanding the Rectangle

We now obtain a technical result which will be important when extending the notion of Riemann integral from rectangles to more general regions. If R is a rectangle, S is a subrectangle, and f is integrable on S, extend f to $\mathbb{R}$ by setting $f(\boldsymbol{x}) = 0$ for $\boldsymbol{x} \in R \setminus S$. Then the integral of the extended function over R should be the same as the integral of f over S. It is:

IX.3.1.26. Theorem. Let R be a rectangle in $\mathbb{R}^n$, and S a subrectangle of R. Let $f : S \to \mathbb{R}$ be a bounded function. Define $g : R \to \mathbb{R}$ by

$$g(\boldsymbol{x}) = \begin{cases} f(\boldsymbol{x}) & \text{if} \quad \boldsymbol{x} \in S \\ 0 & \text{if} \quad \boldsymbol{x} \in R \setminus S \end{cases} .$$

Then

$$\overline{\int_R} g\,dV = \overline{\int_S} f\,dV \text{ and } \underline{\int_R} g\,dV = \underline{\int_S} f\,dV .$$

In particular, g is integrable over R if and only if f is integrable over S, and in this case

$$\int_R g\,dV = \int_S f\,dV .$$

There would seem to be a simple proof: consider partitions of R consisting of a partition of S and some additional rectangles on which f is zero. But the problem is that the rectangles in a partition are only nonoverlapping, not disjoint, so some of the additional rectangles will contain points of ∂S at which f may well be nonzero. Thus we must work harder to prove the theorem, taking partitions for which all the rectangles covering ∂S but not in S have a small total content.

IX.3.1.27. The following construction will be used in the proof. Let $S = [a_1, b_1] \times \cdots \times [a_n, b_n]$ be a rectangle in $\mathbb{R}^n$. If $\delta > 0$, set

$$S_\delta = [a_1 - \delta, b_1 + \delta] \times \cdots \times [a_n - \delta, b_n + \delta] \ .$$

Then S_δ is a rectangle in $\mathbb{R}^n$ containing S in its interior. $V(S_\delta)$ is a polynomial in δ, so by continuity, for any $\epsilon > 0$ there is a $\delta > 0$ such that $V(S) < V(S_\delta) < V(S) + \epsilon$.

We now give the proof of IX.3.1.26..

PROOF: We may assume R contains S in its interior, since if not two applications of the theorem for a larger rectangle containing both R and S in its interior give the result. Then $S_\delta \subseteq R$ for all sufficiently small $\delta > 0$. Note that if $S_\delta \subseteq R$, any partition of S can be extended to a partition of R in which S_δ as well as S is a union of rectangles in the partition.

Fix $\epsilon > 0$. Let B be a bound for $|f|$ on S. Choose $\delta > 0$ so that $S_\delta \subseteq R$ and $V(S_\delta) < V(S) + \frac{\epsilon}{3B}$. If $\mathcal{P}$ is any partition of S, extend $\mathcal{P}$ to a partition $\mathcal{Q}$ of R for which S_δ is a union of rectangles in $\mathcal{Q}$. Let $\mathcal{Q}_1$ be the set of rectangles in $\mathcal{Q}$ contained in S_δ but not in S, and $\mathcal{Q}_2$ the set of rectangles in $\mathcal{Q}$ not contained in S_δ. Then

$$\overline{\mathcal{S}}(g, \mathcal{Q}) = \sum_{k=1}^{m} M_k \cdot V(R_k) = \sum_{R_k \in \mathcal{P}} M_k \cdot V(R_k) + \sum_{R_k \in \mathcal{Q}_1} M_k \cdot V(R_k) + \sum_{R_k \in \mathcal{Q}_2} M_k \cdot V(R_k) \ .$$

The first sum is exactly $\overline{\mathcal{S}}(f, \mathcal{P})$, and the last sum is 0 since g is identically 0 on the rectangles in $\mathcal{Q}_2$. If $R_k \in \mathcal{Q}_2$, $|M_k| \leq B$, so the second sum in absolute value is dominated by

$$\sum_{R_k \in \mathcal{Q}_2} B \cdot V(R_k) = B(V(S_\delta) - V(S)) < \frac{\epsilon}{3}$$

and therefore

$$|\overline{\mathcal{S}}(f, \mathcal{P}) - \overline{\mathcal{S}}(g, \mathcal{Q})| < \frac{\epsilon}{3}$$

i.e. for every partition $\mathcal{P}$ of S there is a partition $\mathcal{Q}$ of R for which this holds. On the other hand, if $\tilde{\mathcal{Q}}$ is any refinement of $\mathcal{Q}$, then $\tilde{\mathcal{Q}}$ is of this form for some refinement $\tilde{\mathcal{P}}$ of $\mathcal{P}$. We can thus choose $\mathcal{P}$ and $\mathcal{Q}$ so that

$$\overline{\mathcal{S}}(f, \mathcal{P}) - \overline{\int_S} f \, dV < \frac{\epsilon}{3}$$

$$\overline{\mathcal{S}}(g, \mathcal{Q}) - \overline{\int_R} g \, dV < \frac{\epsilon}{3}$$

from which it follows that

$$\left| \overline{\int_S} f \, dV - \overline{\int_S} g \, dV \right| < \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, the upper integrals are equal. The argument for the lower integrals is almost identical. 👍

See IX.3.12.2. for an alternate version of the proof.

IX.3.2. Content and Jordan Regions

Using the integral over rectangles, we can say what the "volume" is of more general subsets of Euclidean space.

IX.3.2.1. DEFINITION. Let E be a bounded subset of $\mathbb{R}^n$. The *upper n-dimensional (Jordan) content* of E is

$$\overline{V_n}(E) = \overline{\int_R \chi_E \, dV}$$

where R is a rectangle in $\mathbb{R}^n$ containing E.
The *lower n-dimensional (Jordan) content* of E is

$$\underline{V_n}(E) = \underline{\int_R} \chi_E \, dV$$

where R is a rectangle in $\mathbb{R}^n$ containing E.
E is a *Jordan region* if $\overline{V_n}(E) = \underline{V_n}(E)$; the *(Jordan) content* $V_n(E)$ is the common value.

IX.3.2.2. Note that the upper and lower content are well defined and independent of the containing rectangle R by IX.3.1.26.. We usually suppress the words "n-dimensional" and the subscript n, but the dimension must be carefully kept in mind. Some authors use the term "volume" instead of (Jordan) content. See IX.3.1.2..

IX.3.2.3. A bounded subset E of $\mathbb{R}^n$ is a Jordan region if and only if χ_E is integrable over some (hence every by IX.3.1.26.) rectangle R containing E, and $V(E) = \int_R \chi_E \, dV$.

IX.3.2.4. PROPOSITION. If R is a rectangle in $\mathbb{R}^n$, then R is a Jordan region and its Jordan content is $V(R)$, as defined in IX.3.1.1..

PROOF: We can take the containing rectangle to be R itself. Then χ_R is the constant function 1 on R. By IX.3.1.22. (or by simple direct calculation), χ_R is integrable on R and $\int_R \chi_R \, dV = \int_R 1 \, dV = V(R)$. 👍

Thus our notation and terminology is consistent.

IX.3.2.5. A subset of $\mathbb{R}^n$ is a Jordan region if and only if it boundary has zero content (IX.3.2.24.). "Geometrically reasonable" subsets of $\mathbb{R}^n$ are thus Jordan regions. But a set like the intersection of the set A of IX.3.1.15. with a rectangle is not a Jordan region. Note that Jordan regions are by definition bounded.

IX.3.2.6. If A and B are bounded subsets of $\mathbb{R}^n$ with $A \subseteq B$, then $\overline{V}(A) \leq \overline{V}(B)$ and $\underline{V}(A) \leq \underline{V}(B)$ (cf. IX.3.1.22.).

The next observation will be considerably improved in IX.3.2.25., but this form is needed to logically develop the theory and characterization of Jordan regions:

IX.3.2.7. LEMMA. Let A and B be Jordan regions in $\mathbb{R}^n$. Then $A \cup B$ is a Jordan region if and only if $A \cap B$ is a Jordan region. In this case, we have

$$V(A \cup B) = V(A) + V(B) - V(A \cap B) \ .$$

PROOF: We have $\chi_{A\cup B} = \chi(A) + \chi(B) - \chi(A \cap B)$. Let R be a rectangle containing both A and B. By assumption, $\chi(A)$ and $\chi(B)$ are integrable over R, so it follows from IX.3.1.20. that $\chi_{A\cup B}$ is integrable over R if and only if $\chi_{A\cap B}$ is. The volume formula also follows from IX.3.1.20.. 👍

IX.3.2.8. COROLLARY. If $\{R_1, \ldots, R_m\}$ is a finite set of rectangles in $\mathbb{R}^n$, not necessarily nonoverlapping, then $\cup_{k=1}^m R_k$ is a Jordan region and

$$V\left(\bigcup_{k=1}^{m} R_k\right) \leq \sum_{k=1}^{m} V(R_k)$$

with equality if and only if the R_k are nonoverlapping.

PROOF: For $m = 2$ the result follows immediately from IX.3.2.4. and IX.3.2.7. since the intersection of two rectangles is a rectangle. The result for general m follows by induction. 👍

Along the same lines, the next observation is needed for the logical development although it will be improved in IX.3.2.25.:

IX.3.2.9. PROPOSITION. Let E be a Jordan region, and R a rectangle containing E. Then $R \setminus E$ is also a Jordan region, and $V(R \setminus E) = V(R) - V(E)$.

PROOF: We have that $\chi_{R\setminus E} = \chi_R - \chi_E$; χ_E is integrable over R by assumption, and χ_R is integrable over R by IX.3.2.4., so $\chi_{R\setminus E}$ is integrable over R and the content formula holds by IX.3.1.20.. 👍

An Alternate Description of Content

We can give an illuminating direct description of content by explicitly describing upper and lower sums for the integral of an indicator function.

IX.3.2.10. Let E be a bounded subset of $\mathbb{R}^n$. If R is a rectangle in $\mathbb{R}^n$ containing E and $\mathcal{P} = \{R_1, \ldots, R_m\}$ is a partition of R, we have

$$\overline{\mathcal{S}}(\chi_E, \mathcal{P}) = \sum_{R_k \cap E \neq \emptyset} V(R_k)$$

$$\underline{\mathcal{S}}(\chi_E, \mathcal{P}) = \sum_{R_k \subseteq E} V(R_k)$$

i.e. $\overline{V}(E)$ is estimated as the content of the union of the rectangles in $\mathcal{P}$ containing points of E, and $\underline{V}(E)$ is estimated as the content of the union of the rectangles in $\mathcal{P}$ entirely contained in E; in fact, they are the infimum and supremum of such contents over all partitions of R.

Combining with IX.3.2.8., we obtain:

IX.3.2.11. PROPOSITION. If E is a bounded subset of $\mathbb{R}^n$, then

$$\underline{V}(E) = \sup\left(\sum_{k=1}^{m} V(R_k)\right)$$

where the supremum is over all finite sets $\{R_1, \ldots, R_m\}$ of pairwise nonoverlapping rectangles contained in E.

For upper sums, since any finite set of rectangles has a subdivision into nonoverlapping rectangles, we can relax the requirement that the rectangles be nonoverlapping:

IX.3.2.12. PROPOSITION. If E is a bounded subset of $\mathbb{R}^n$, then

$$\overline{V}(E) = \inf\left(\sum_{k=1}^{m} V(R_k)\right)$$

where the infimum is over all finite sets $\{R_1, \ldots, R_m\}$ of rectangles covering E.

Sets of Zero Content

IX.3.2.13. DEFINITION. A subset E of $\mathbb{R}^n$ has *zero content* if $\overline{V}(E) = 0$.
Two subsets A and B of $\mathbb{R}^n$ are *nonoverlapping* if $A \cap B$ has zero content.

IX.3.2.14. If E has zero content, it is a Jordan region since $0 \leq \underline{V}(E) \leq \overline{V}(E) = 0$. Any subset of a set of zero content also has zero content. A rectangle has zero content if and only if it is degenerate. Thus two rectangles are nonoverlapping in the sense of IX.3.2.13. if and only if they are nonoverlapping in the sense of IX.3.1.4..

The next result is then an immediate consequence of IX.3.2.7.:

IX.3.2.15. PROPOSITION. Let $E_1, \ldots, E_m$ be pairwise nonoverlapping Jordan regions. Then $\cup_{k=1}^{m} E_k$ is a Jordan region and

$$V\left(\bigcup_{k=1}^{m} E_k\right) = \sum_{k=1}^{m} V(E_k) \ .$$

IX.3.2.16. Corollary. A finite union of sets of zero content has zero content.

The next result gives a large supply of sets of zero content:

IX.3.2.17. Proposition. Let E be a compact Jordan region in $\mathbb{R}^{n-1}$, $\phi : E \to \mathbb{R}$ a continuous function, and G the graph of ϕ, i.e.

$$G = \{(x_1, \ldots, x_n) : (x_1, \ldots, x_{n-1}) \in E, x_n = \phi(x_1, \ldots, x_{n-1})\} \subseteq \mathbb{R}^n \ .$$

Then G is a set of zero content in $\mathbb{R}^n$.

Proof: Let R be a rectangle in $\mathbb{R}^n$ containing E. Let $\epsilon > 0$. Since E is compact, ϕ is uniformly continuous on E, so there is a $\delta > 0$ such that $|\phi(\boldsymbol{x}) - \phi(\boldsymbol{y})| < \frac{\epsilon}{V(R)}$ whenever $\boldsymbol{x}, \boldsymbol{y} \in E$ and $|\boldsymbol{x} - \boldsymbol{y}| < \delta$. There is a partition $\mathcal{P} = \{R_1, \ldots, R_m\}$ of R such that the diameter of each R_k is less than δ; thus if M_k and m_k are the supremum and infimum of ϕ over $R_k \cap E$ for each R_k containing points of E, we have $M_k - m_k \leq \frac{\epsilon}{V(R)}$ for all such k. Then if

$$\tilde{R}_k = R_k \times [m_k, M_k]$$

for each such k, then the $\tilde{R}_k$ are nonoverlapping rectangles covering G, and

$$\sum_k V(\tilde{R}_k) \leq \sum_k V(R_k) \cdot \frac{\epsilon}{V(R)} \leq \epsilon$$

(the sum is over all k for which $R_k \cap E \neq \emptyset$). Thus $\overline{V_n}(G) \leq \epsilon$. Since $\epsilon > 0$ is arbitrary, $\overline{V_n}(G) = 0$. 👍

IX.3.2.18. If E is a compact set in $\mathbb{R}^n$ and every point of E has a neighborhood in E which is a set of zero content in $\mathbb{R}^n$, then a simple compactness argument and IX.3.2.16. shows that E is a set of zero content. In particular, if E is compact and locally the graph of a continuous function of some $n-1$ of the coordinates, then E is a set of zero content. Many sets can be shown to be of this form by the Implicit Function Theorem.

IX.3.2.19. It is crucial to specify the n when saying that a set has zero content in $\mathbb{R}^n$. If we regard $\mathbb{R}^n$ as a subset of $\mathbb{R}^{n+1}$ by identifying it with an affine subspace, every bounded subset of $\mathbb{R}^n$ has zero content in $\mathbb{R}^{n+1}$. In fact, the notion of Jordan region in $\mathbb{R}^n$ depends on n: any bounded subset of $\mathbb{R}^n$ is thus a Jordan region in $\mathbb{R}^{n+1}$. So the property of E being a Jordan region is not intrinsic to E, but depends on the choice of Euclidean space containing E (and also how E is embedded in that space). ✋

IX.3.2.20. Proposition. Let A and B be bounded regions in $\mathbb{R}^p$ and $\mathbb{R}^q$ respectively. If A has zero content in $\mathbb{R}^p$, then $A \times B$ has zero content in $\mathbb{R}^{p+q}$.

Proof: Let S be a bounded rectangle in $\mathbb{R}^q$ containing B. Let $\epsilon > 0$. There is a finite set $\{R_1, \ldots, R_n\}$ in $\mathbb{R}^p$ covering A with

$$\sum_{k=1}^{n} V(R_k) < \frac{\epsilon}{V(S) + 1} \ .$$

Then $\{R_1 \times S, \ldots, R_n \times S\}$ is a finite set of rectangles covering $A \times B$, and $V(R_k \times S) = V(R_k)V(S)$, so

$$\overline{V}(A \times B) \leq \sum_{k=1}^{n} V(R_k \times S) = V(S) \sum_{k=1}^{n} V(R_k) < \epsilon \ .$$

The next theorem is a key result about integrability, generalizing IX.3.1.14.. This is, however, not the ultimate characterization of integrability, which will be given in ().

IX.3.2.21. THEOREM. Let R be a rectangle in $\mathbb{R}^n$, and $f : R \to \mathbb{R}$ a bounded function. If f is continuous except on a set of zero content, then f is integrable over R.

PROOF: Suppose f is continuous except on a set A with $V(A) = 0$. We will use the following notation. If $\mathcal{P} = \{R_1, \ldots, R_m\}$ is a partition of R, set $J = \{j : R_j \cap A \neq \emptyset\}$ and $K = \{k : R_k \cap A = \emptyset\}$.

Let M be a bound for $|f|$ on R. Let $\epsilon > 0$. Then, since A has volume 0, there is a partition $\mathcal{P}$ of R such that

$$\sum_{j \in J} V(R_j) < \frac{\epsilon}{4M} \ .$$

Let $B = \cup_{k \in K} R_k$. Then B is compact and f is continuous on B, hence uniformly continuous, so there is a $\delta > 0$ such that $|f(\boldsymbol{x}) - f(\boldsymbol{y})| < \frac{\epsilon}{2V(R)}$ whenever $\boldsymbol{x}, \boldsymbol{y} \in B$ and $|\boldsymbol{x} - \boldsymbol{y}| < \delta$. By subdividing the R_k for $k \in K$ if necessary, we may assume that the diameter of each R_k is less than δ. Thus if M_k and m_k are the supremum and infimum of f over R_k, we have $M_k - m_k \leq \frac{\epsilon}{2V(R)}$. Furthermore, for each $j \in J$ we have $M_j - m_j \leq 2M$. Thus

$$\overline{\mathcal{S}}(f, \mathcal{P}) - \underline{\mathcal{S}}(f, \mathcal{P}) = \sum_{j \in J} (M_j - m_j)V(R_j) + \sum_{k \in K} (M_k - m_k)V(R_k)$$

$$\leq 2M \sum_{j \in J} V(R_j) + \frac{\epsilon}{2V(R)} \sum_{k \in K} V(R_k) \leq 2M \frac{\epsilon}{4M} + \frac{\epsilon}{2V(R)} V(R) = \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, f is integrable over R. 

Characterization of Jordan Regions

The first result is a corollary of IX.3.2.21.

IX.3.2.22. COROLLARY. Let E be a bounded set in $\mathbb{R}^n$. If ∂E has zero content, then E is a Jordan region.

PROOF: The indicator function χ_E is discontinuous exactly on ∂E. 

IX.3.2.23. PROPOSITION. If E is a Jordan region in $\mathbb{R}^n$, then $\bar{E}$ and E^o are also Jordan regions, and

$$V(\bar{E}) = V(E^o) = V(E) \ .$$

PROOF: Let R be a rectangle containing E. Let $\epsilon > 0$, and let $\mathcal{P} = \{R_1, \ldots, R_m\}$ be a partition of R such that

$$\sum_{j \in J} V(R_j) < V(E) + \epsilon$$

where J is the set of j for which $R_j \cap E \neq \emptyset$. Let $B = \cup_{j \in J} R_j$. Then B is a closed set and $E \subseteq B$, so $\bar{E} \subseteq B$, and B is a Jordan region by IX.3.2.8.. We have

$$V(E) = \underline{V}(E) \leq \underline{V}(\bar{E}) \leq \overline{V}(\bar{E}) \leq \overline{V}(B) = V(B) = \sum_{j \in J} V(R_j) < V(E) + \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, we have

$$V(E) = \underline{V}(E) = \underline{V}(\bar{E}) = \overline{V}(\bar{E})$$

so $\bar{E}$ is a Jordan region and $V(\bar{E}) = V(E)$.

By IX.3.2.9., $R \setminus E$ is a Jordan region, so $\overline{R \setminus E} = R \setminus E^o$ is a Jordan region, and hence E^o is a Jordan region; and we have

$$V(R) - V(E^o) = V(R \setminus E^o) = V(\overline{R \setminus E}) = V(R \setminus E) = V(R) - V(E)$$

and it follows that $V(E^o) = V(E)$. 👍

We now come to the main theorem characterizing Jordan regions.

IX.3.2.24. THEOREM. Let E be a bounded subset of $\mathbb{R}^n$. Then E is a Jordan region in $\mathbb{R}^n$ if and only if ∂E has zero content.

PROOF: If ∂E has zero content, then E is a Jordan region by IX.3.2.22.. Conversely, suppose E is a Jordan region. Then $\bar{E}$ and E^o are also Jordan regions, and $V(\bar{E}) = V(E^o) = V(E)$ by IX.3.2.23.. Let R be a rectangle containing E. If $\mathcal{P} = \{R_1, \ldots, R_m\}$ is a partition of R, we can partition $\{1, \ldots, m\}$ into three sets I, J, K, where I is the set of i such that $R_i \subseteq E^o$, J is the set of j such that $R_j \subseteq R \setminus \bar{E}$ (i.e. such that $R_j \cap \bar{E} = \emptyset$), and K is the set of k such that $R_k \cap \partial E \neq \emptyset$.

Let $\epsilon > 0$. If $\mathcal{P}$ is sufficiently fine, then by IX.3.2.11. and IX.3.2.9. we have

$$\sum_{i \in I} V(R_i) > \underline{V}(E^o) - \frac{\epsilon}{2} = V(E) - \frac{\epsilon}{2}$$

$$\sum_{j \in J} V(R_j) > \underline{V}(R \setminus \bar{E}) - \frac{\epsilon}{2} = V(R) - V(E) - \frac{\epsilon}{2} \ .$$

$$\sum_{i \in I} V(R_i) + \sum_{j \in J} V(R_j) > \left[V(E) - \frac{\epsilon}{2}\right] + \left[V(R) - V(E) - \frac{\epsilon}{2}\right] = V(R) - \epsilon \ .$$

By IX.3.1.6., we have

$$V(R) = \sum_{i\in I} V(R_i) + \sum_{j\in J} V(R_j) + \sum_{k\in K} V(R_k)$$

so we conclude

$$\sum_{k\in K} V(R_k) < \epsilon \ .$$

If we let $B = \cup_{k\in K} R_k$, then $\partial E \subseteq B$, so by IX.3.2.8.

$$\overline{V}(\partial E) \leq \overline{V}(B) = V(B) = \sum_{k\in K} V(R_k) < \epsilon$$

and since $\epsilon > 0$ is arbitrary, $\overline{V}(\partial E) = 0$. 👍

IX.3.2.25. Corollary. Let A and B be Jordan regions in $\mathbb{R}^n$. Then $A \cup B$, $A \cap B$, and $A \setminus B$ are Jordan regions, and

$$V(A \cup B) = V(A) + V(B) - V(A \cap B)$$
$$V(A \setminus B) = V(A) - V(A \cap B) \ .$$

Proof: By IX.3.2.24., ∂A and ∂B have zero content. We have $\partial(A \cup B) \subseteq \partial A \cup \partial B$, and $\partial A \cup \partial B$ has zero content by IX.3.2.16.; thus $\partial(A \cup B)$ has zero content and $A \cup B$ is a Jordan region by IX.3.2.24.. It then follows from IX.3.2.7. that $A \cap B$ is a Jordan region and the first content formula holds. If R is a rectangle containing A and B, then $R \setminus B$ is a Jordan region by IX.3.2.9., so $A \setminus B = A \cap (R \setminus B)$ is a Jordan region. We have

$$V(A) = V(A \cap B) + V(A \setminus B)$$

since $A \cap B$ and $A \setminus B$ are disjoint. 👍

IX.3.2.26. Corollary. Let A and B be Jordan regions in $\mathbb{R}^p$ and $\mathbb{R}^q$ respectively. Then $A \times B$ is a Jordan region in $\mathbb{R}^{p+q}$.

Proof: We have $\partial(A \times B) = (\partial A \times B) \cup (A \times \partial B)$, which is a set of zero content by IX.3.2.20.. 👍

IX.3.3. Integration over Jordan Regions

It is now a simple matter to extend the integral to general Jordan regions.

IX.3.3.1. Definition. Let E be a Jordan region in $\mathbb{R}^n$, and $f : E \to \mathbb{R}$. Denote by $f\chi_E$ the function from $\mathbb{R}^n$ to $\mathbb{R}$ defined by

$$f\chi_E(\boldsymbol{x}) = \begin{cases} f(\boldsymbol{x}) & \text{if} \quad \boldsymbol{x} \in E \\ 0 & \text{if} \quad \boldsymbol{x} \notin E \end{cases} \ .$$

This definition is a slight abuse of notation since f is only defined on E, so $f\chi_E$ is technically not a product; but this ambiguity will cause no trouble.

IX.3.3.2. DEFINITION. Let E be a Jordan region in $\mathbb{R}^n$, and $f : E \to \mathbb{R}$ a function. Define

$$\underline{\int_E} f\,dV = \underline{\int_R} f\chi_E\,dV \quad \text{and} \quad \overline{\int_E} f\,dV = \overline{\int_R} f\chi_E\,dV$$

where R is any rectangle containing E (cf. IX.3.1.26.). The function f is *(Riemann) integrable over* E if $f\chi_E$ is integrable over some (hence every) rectangle containing E, i.e. if

$$\underline{\int_E} f\,dV = \overline{\int_E} f\,dV\ .$$

If f is integrable over E, define

$$\int_E f\,dV = \underline{\int_E} f\,dV = \overline{\int_E} f\,dV\ .$$

Note that an integrable function is necessarily bounded.

IX.3.3.3. Comparing definitions, the constant function 1 is integrable over E, and $\int_E 1\,dV = V(E)$. (This example indicates that it is not reasonable to try to similarly define the integral of a function over a set which is not a Jordan region, since even constant functions will not then be integrable).

IX.3.3.4. PROPOSITION. Let A and B be Jordan regions in $\mathbb{R}^n$, with $B \subseteq A$. If $f : A \to \mathbb{R}$ is integrable on A, then $f|_B$ is integrable on B.

PROOF: We have $f\chi_B = (f\chi_A)\chi_B$ (this is an honest product). If R is a rectangle containing A, then $f\chi_A$ and χ_B are integrable over R by assumption, so $(f\chi_A)\chi_B$ is integrable over R by IX.3.1.25.. 👍

The next extension of IX.3.2.21. gives a large supply of integrable functions including almost all functions of interest in applications:

IX.3.3.5. THEOREM. Let E be a Jordan region in $\mathbb{R}^n$, and $f : E \to \mathbb{R}$ a bounded function. If f is continuous except on a set of zero content, then f is integrable over E.

PROOF: Suppose f is continuous on E except on a subset A of zero content. If R is a rectangle containing E, then $f\chi_E$ is continuous on R except (possibly) on $A \cup \partial E$, which is a set of zero content (IX.3.2.16.). Thus $f\chi_E$ is integrable over R by IX.3.2.21.. 👍

Note that even if f is continuous on E, IX.3.2.21. is needed to show that f is integrable on E; IX.3.1.14. is not enough.

Properties of the Integral

The standard properties of the integral over Jordan regions then follow immediately from the properties of integrals over rectangles (note e.g. that $(f+g)\chi_E = f\chi_E + g\chi_E$, etc.)

IX.3.3.6. PROPOSITION. The integral over a fixed Jordan region is linear: if f and g are integrable over a Jordan region E, and $\alpha, \beta \in \mathbb{R}$, then $\alpha f + \beta g$ is integrable over E and

$$\int_E (\alpha f + \beta g)\, dV = \alpha \int_E f\, dV + \beta \int_E g\, dV \ .$$

IX.3.3.7. PROPOSITION. Let E be a Jordan region in $\mathbb{R}^n$, and f and g bounded functions on E. If $f \leq g$ on E, then

$$\int_E f\, dV \leq \int_E g\, dV \ .$$

IX.3.3.8. COROLLARY. Let E be a Jordan region in $\mathbb{R}^n$, and f a bounded function on E. If $m \leq f(\boldsymbol{x}) \leq M$ for all $\boldsymbol{x} \in E$, then

$$m \cdot V(E) \leq \int_E f\, dV \leq M \cdot V(E) \ .$$

In particular, if $f \geq 0$ on E, then $\int_E f\, dV \geq 0$.

IX.3.3.9. PROPOSITION. Let E be a set of zero content, and $f : E \to \mathbb{R}$ a bounded function. Then f is integrable over E, and $\int_E f\, dV = 0$.

PROOF: Suppose $m \leq f(\boldsymbol{x}) \leq M$ for all $\boldsymbol{x} \in E$. If R is a rectangle containing E, then $m\chi_E \leq f\chi_E \leq M\chi_E$ on R, so

$$0 = mV(E) = \int_R m\chi_E\, dV \leq \underline{\int_R} f\chi_E\, dV \leq \overline{\int_R} f\chi_E\, dV \leq \int_R M\chi_E\, dV = 0 \ .$$

👍

IX.3.3.10. PROPOSITION. Let A and B be Jordan regions in $\mathbb{R}^n$, and $f : A \cup B \to \mathbb{R}$ an integrable function. Then f is integrable over A, B, and $A \cap B$, and

$$\int_{A \cup B} f\, dV = \int_A f\, dV + \int_B f\, dV - \int_{A \cap B} f\, dV \ .$$

PROOF: We have f integrable over A, B, $A \cap B$ by IX.3.3.4., and the formula then follows by linearity. 👍

IX.3.3.11. Corollary. Let $E_1, \dots, E_m$ be pairwise nonoverlapping Jordan regions in $\mathbb{R}^n$, and $E = E_1 \cup \cdots \cup E_n$. If $f : E \to \mathbb{R}$ is a function, then f is integrable over E if and only if $f|_{E_k}$ is integrable over E_k for each k. If this is the case, then

$$\int_E f\,dV = \sum_{k=1}^{m} \int_{E_k} f\,dV\ .$$

IX.3.4. Fubini's Theorem

IX.3.4.1. The definition of the integral works more or less the same for $\mathbb{R}^n$, $n > 1$, as it does for $\mathbb{R}$. But there is one dramatic difference: so far we have no effective way of calculating integrals in the multivariable case, i.e. there is no Fundamental Theorem of Calculus in the vector case (actually there is, Stokes' Theorem (), but this is usually not useful for computing the integral).

IX.3.4.2. Many authors use different notation for multivariable integrals, e.g. writing

$$\iint_R f\,dA \quad (n = 2)$$

$$\iiint_R f\,dV \quad (n = 3)$$

$$\int \cdots \int_R f\,dV \quad (n \text{ integral signs})$$

in general for $\int_R f\,dV$. I prefer the single integral sign notation, since the integral is a single integral over a multidimensional set; to emphasize the dimension, we can write $\int_R f\,dV_n$. But the multiple integral notation is suggestive of a possible way to compute the integral: as an n-fold repeated one-dimensional integral, each of which can (potentially) be calculated using the Fundamental Theorem of Calculus. Fubini's Theorem (the Riemann integral form) says that this can be done under reasonable hypotheses.

Iterated Integrals

IX.3.4.3. If $A \subseteq \mathbb{R}^p$ and $B \subseteq \mathbb{R}^q$, we can regard $A \times B$ as a subset of $\mathbb{R}^{p+q} \cong \mathbb{R}^p \times \mathbb{R}^q$. If f is a bounded real-valued function on $A \times B$, for each $\boldsymbol{x} \in A$ we have a function $f_{[\boldsymbol{x}]} : B \to \mathbb{R}$ defined by $f_{[\boldsymbol{x}]}(\boldsymbol{y}) = f(\boldsymbol{x}, \boldsymbol{y})$. If A and B are Jordan regions and we set

$$g(\boldsymbol{x}) = \overline{\int_B} f_{[\boldsymbol{x}]}\,dV$$

then g is a bounded function from A to $\mathbb{R}$; we symbolically write

$$\overline{\int_A} g\,dV = \overline{\int_A} \left[\overline{\int_B} f(\boldsymbol{x}, \boldsymbol{y})\,dV(\boldsymbol{y})\right] dV(\boldsymbol{x}) = \overline{\int_A \int_B} f(\boldsymbol{x}, \boldsymbol{y})\,dV(\boldsymbol{y})\,dV(\boldsymbol{x})$$

(the brackets are typically omitted), and similarly

$$h(\boldsymbol{x}) = \underline{\int_B} f_{[\boldsymbol{x}]}\, dV$$

$$\underline{\int_A} h\, dV = \underline{\int_A \int_B} f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{y})\, dV(\boldsymbol{x}) \ .$$

In the same way, for each $\boldsymbol{y} \in B$ we have a function $f^{[\boldsymbol{y}]} : A \to \mathbb{R}$ defined by $f^{[\boldsymbol{y}]}(\boldsymbol{x}) = f(\boldsymbol{x},\boldsymbol{y})$, and if

$$g(\boldsymbol{y}) = \overline{\int_A} f^{[\boldsymbol{y}]}\, dV$$

we write

$$\overline{\int_B} g\, dV = \overline{\int_B \int_A} f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{x})\, dV(\boldsymbol{y})$$

and if

$$h(\boldsymbol{y}) = \underline{\int_A} f^{[\boldsymbol{y}]}\, dV$$

$$\underline{\int_B} h\, dV = \underline{\int_B \int_A} f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{x})\, dV(\boldsymbol{y}) \ .$$

These are called *iterated upper and lower integrals* (we could in principle also define $\overline{\int_A}\underline{\int_B} f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{y})\, dV(\boldsymbol{x})$, etc., but these are rarely if ever used). If all the functions involved are integrable, we can write

$$\int_A \int_B f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{y})\, dV(\boldsymbol{x}) \text{ or } \int_B \int_A f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{x})\, dV(\boldsymbol{y}) \ .$$

These are *iterated integrals*.

Fubini's Theorem for Rectangles

IX.3.4.4. THEOREM. [FUBINI'S THEOREM, UPPER AND LOWER FORM] Let R be a rectangle in $\mathbb{R}^p$ and S a rectangle in $\mathbb{R}^q$, so that $R \times S$ is a rectangle in $\mathbb{R}^{p+q}$. Let $f : R \times S \to \mathbb{R}$ be a bounded function. Then

$$\underline{\int_{R\times S}} f\, dV \le \underline{\int_R \int_S} f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{y})\, dV(\boldsymbol{x}) \le \overline{\int_R \int_S} f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{y})\, dV(\boldsymbol{x}) \le \overline{\int_{R\times S}} f\, dV \ .$$

To emphasize the dimensions of the integrals, we can write

$$\underline{\int_{R\times S}} f\, dV_{p+q} \le \underline{\int_R \int_S} f(\boldsymbol{x},\boldsymbol{y})\, dV_q(\boldsymbol{y})\, dV_p(\boldsymbol{x}) \le \overline{\int_R \int_S} f(\boldsymbol{x},\boldsymbol{y})\, dV_q(\boldsymbol{y})\, dV_p(\boldsymbol{x}) \le \overline{\int_{R\times S}} f\, dV_{p+q} \ .$$

IX.3.4.5. Note that the order of R and S is arbitrary: we equally obtain

$$\underline{\int_{R\times S}} f\,dV \le \underline{\int_S\int_R} f(\boldsymbol{x},\boldsymbol{y})\,dV(\boldsymbol{x})\,dV(\boldsymbol{y}) \le \overline{\int_S\int_R} f(\boldsymbol{x},\boldsymbol{y})\,dV(\boldsymbol{x})\,dV(\boldsymbol{y}) \le \overline{\int_{R\times S}} f\,dV$$

by interchanging R and S.

Proof: We prove the third inequality; the proof of the first is almost identical, and the second inequality is trivial. So, for $\boldsymbol{x}\in R$, set

$$g(\boldsymbol{x}) = \overline{\int_S} f_{[\boldsymbol{x}]}\,dV = \overline{\int_S} f(\boldsymbol{x},\boldsymbol{y})\,dV(\boldsymbol{y})\ .$$

We must prove

$$\overline{\int_R} g\,dV \le \overline{\int_{R\times S}} f\,dV\ .$$

Since every grid partition of $R\times S$ is of the form $\mathcal{P}\times\mathcal{Q}$ for some partitions $\mathcal{P}$ of R and $\mathcal{Q}$ of S, it suffices to show that

$$\overline{\mathcal{S}}(g,\mathcal{P}) \le \overline{\mathcal{S}}(f,\mathcal{P}\times\mathcal{Q})$$

for any such $\mathcal{P}$ and $\mathcal{Q}$, since then the desired inequality is obtained by taking the infimum over all $\mathcal{P}$ and $\mathcal{Q}$.

So let $\mathcal{P}=\{R_1,\dots,R_m\}$ and $\mathcal{Q}=\{S_1,\dots,S_n\}$ be partitions of R and S. For $1\le j\le m$ and $1\le k\le n$, let $M_{jk}(f)$ be the supremum of f over $R_j\times S_k$, and let $M_j(g)$ be the supremum of g over R_j. We then have

$$\overline{\mathcal{S}}(f,\mathcal{P}\times\mathcal{Q}) = \sum_{j=1}^m\sum_{k=1}^n M_{jk}(f)V(R_j)V(S_k)$$

$$\overline{\mathcal{S}}(g,\mathcal{P}) = \sum_{j=1}^m M_j(g)V(R_j)$$

so it suffices to show that for each j,

$$M_j(g) \le \sum_{k=1}^n M_{jk}(f)V(S_k)\ .$$

Fix j. For $\boldsymbol{x}\in R_j$,

$$g(\boldsymbol{x}) = \overline{\int_S} f_{[\boldsymbol{x}]}\,dV \le \overline{\mathcal{S}}(f_{[\boldsymbol{x}]},\mathcal{Q}) = \sum_{k=1}^n M_k(f_{[\boldsymbol{x}]})V(S_k)$$

where

$$M_k(f_{[\boldsymbol{x}]}) = \sup_{\boldsymbol{y}\in S_k} f(\boldsymbol{x},\boldsymbol{y}) \le M_{jk}(f)$$

since $\boldsymbol{x}\in R_j$. Thus

$$g(\boldsymbol{x}) \le \sum_{k=1}^n M_{jk}(f)V(S_k)$$

and, taking the supremum $M_j(g)$ over $\boldsymbol{x}\in R_j$, the desired inequality follows. 👍

The next result, an immediate corollary of IX.3.4.4., is the case of most interest:

IX.3.4.6. Corollary. [Fubini's Theorem, Riemann Integral Version] Let R be a rectangle in $\mathbb{R}^p$ and S a rectangle in $\mathbb{R}^q$, so that $R \times S$ is a rectangle in $\mathbb{R}^{p+q}$. Let $f : R \times S \to \mathbb{R}$ be a bounded function.
(i) Suppose f is integrable over $R \times S$ and, for each $\boldsymbol{x} \in R$, $f_{[\boldsymbol{x}]}$ is integrable over S. If

$$g(\boldsymbol{x}) = \int_S f_{[\boldsymbol{x}]}\, dV$$

for $\boldsymbol{x} \in R$, then g is integrable over R, and

$$\int_{R\times S} f\, dV = \int_R g\, dV = \int_R \int_S f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{y})\, dV(\boldsymbol{x}) \ .$$

(ii) Suppose f is integrable over $R \times S$ and, for each $\boldsymbol{y} \in S$, $f^{[\boldsymbol{y}]}$ is integrable over R. If

$$h(\boldsymbol{y}) = \int_R f^{[\boldsymbol{y}]}\, dV$$

for $\boldsymbol{y} \in S$, then h is integrable over S, and

$$\int_{R\times S} f\, dV = \int_S h\, dV = \int_S \int_R f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{x})\, dV(\boldsymbol{y}) \ .$$

(iii) If both (i) and (ii) hold (i.e. if f and each $f_{[\boldsymbol{x}]}$ and $f^{[\boldsymbol{y}]}$ are integrable), then

$$\int_R \int_S f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{y})\, dV(\boldsymbol{x}) = \int_S \int_R f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{x})\, dV(\boldsymbol{y}) \ \left(= \int_{R\times S} f\, dV \right) \ .$$

Proof: (i): From the Theorem, we have

$$\int_{R\times S} f\, dV \le \underline{\int_R} \int_S f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{y})\, dV(\boldsymbol{x}) \le \overline{\int_R} \int_S f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{y})\, dV(\boldsymbol{x}) \le \int_{R\times S} f\, dV$$

so the inequalities are equalities, and the middle equality exactly says that g is integrable over R. The proof of (ii) is almost identical, and (iii) is just a combination of (i) and (ii). 👍

A clean and especially important special case (cf. IX.3.1.14., XX.10.3.5.(c)) is:

IX.3.4.7. Corollary. [Fubini's Theorem, Continuous Version] Let R be a rectangle in $\mathbb{R}^p$ and S a rectangle in $\mathbb{R}^q$, so that $R \times S$ is a rectangle in $\mathbb{R}^{p+q}$. Let $f : R \times S \to \mathbb{R}$ be a continuous function. Then

$$\int_{R\times S} f\, dV = \int_R \int_S f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{y})\, dV(\boldsymbol{x}) = \int_S \int_R f(\boldsymbol{x},\boldsymbol{y})\, dV(\boldsymbol{x})\, dV(\boldsymbol{y}) \ .$$

In particular, the two iterated integrals are equal.

IX.3.4.8. This result (IX.3.4.6.) can be interpreted, and used, in two different ways. On the one hand, it says that (under certain conditions) the integral over $R \times S$ can be computed by an iterated integral. On the other hand, (iii) says that (under certain conditions) the order of integration can be reversed in an iterated integral. Both interpretations are important in different contexts; for example, it is sometimes possible to evaluate an iterated integral in one order but not the other using the FTC (cf. IX.3.12.5.).

IX.3.4.9. Actually these versions of "Fubini's Theorem" may have been "known" before FUBINI, who proved a general version for Lebesgue integration (XVIII.3.1.). All theorems involving changing the order of iterated summation or integration are now generically called "Fubini's Theorem" since they are special cases of XVIII.3.1.14.. See IX.3.4.34. for further comments.

If $p = q = 1$, IX.3.4.7. can be rephrased, changing notation slightly:

IX.3.4.10. THEOREM. [FUBINI'S THEOREM IN $\mathbb{R}^2$, RECTANGLE CONTINUOUS VERSION] Let $R = [a, b] \times [c, d]$ be a rectangle in $\mathbb{R}^2$, and $f : R \to \mathbb{R}$ a continuous function. Then

$$\int_R f \, dV = \iint_R f \, dA = \int_a^b \int_c^d f(x, y) \, dy \, dx = \int_c^d \int_a^b f(x, y) \, dx \, dy \ .$$

In particular, the two iterated integrals are equal.

IX.3.4.11. In calculating the inner integral (e.g. by the FTC), the outer variable is treated as a constant. Thus the inner integral can be regarded as a "partial antiderivative."

IX.3.4.12. If p or q is greater than 1, the iterated integrals can be further broken into iterated integrals of smaller dimension by repeatedly applying the various versions of Fubini's Theorem. It is cumbersome to explicitly state the appropriate hypotheses for the higher iterated version of IX.3.4.6., but IX.3.4.7. can be cleanly stated. We only state the ultimate reduced version as in IX.3.4.10.:

IX.3.4.13. THEOREM. [FUBINI'S THEOREM IN $\mathbb{R}^n$, RECTANGLE CONTINUOUS VERSION] Let $R = [a_1, b_1] \times \cdots \times [a_n, b_n]$ be a rectangle in $\mathbb{R}^n$, and $f : R \to \mathbb{R}$ a continuous function. Then

$$\int_R f \, dV = \int_{a_1}^{b_1} \int_{a_2}^{b_2} \cdots \int_{a_n}^{b_n} f(x_1, \ldots, x_n) \, dx_n \cdots dx_2 \, dx_1 \ .$$

The iterated integrals can be done in any order.

Iterated Integrals over Other Regions

In applications we frequently want to integrate over regions more general than rectangles. In good cases such integrals can also be calculated as iterated integrals. Note that even to do this when integrating a continuous function requires the version of Fubini's Theorem in IX.3.4.6., i.e. IX.3.4.7. is not enough.

We will not try to do this in the utmost generality, which requires cumbersome notation and hypotheses; instead, we will restrict to clean forms which are adequate for almost all applications. The first version is straightforward:

IX.3.4.14. THEOREM. Let A and B be Jordan regions in $\mathbb{R}^p$ and $\mathbb{R}^q$ respectively (so $A \times B$ is a Jordan region in $\mathbb{R}^{p+q}$). If $f : A \times B \to \mathbb{R}$ is bounded and continuous, then

$$\int_{A\times B} f\,dV = \int_A \int_B f(\boldsymbol{x},\boldsymbol{y})\,dV(\boldsymbol{y})\,dV(\boldsymbol{x}) = \int_B \int_A f(\boldsymbol{x},\boldsymbol{y})\,dV(\boldsymbol{x})\,dV(\boldsymbol{y})$$

(in particular, the iterated integrals exist and are equal).

PROOF: $A \times B$ is a Jordan region (IX.3.2.26.). Let R and S be rectangles containing A and B respectively, and apply IX.3.4.6. to $f\chi_{A\times B}$ on $R \times S$ (it is easily checked that the hypotheses apply). ☝

IX.3.4.15. COROLLARY. Let A and B be Jordan regions in $\mathbb{R}^p$ and $\mathbb{R}^q$ respectively (so $A \times B$ is a Jordan region in $\mathbb{R}^{p+q}$). Then $V(A \times B) = V(A)V(B)$.

To handle regions more general than products, we begin with subsets of $\mathbb{R}^2$:

IX.3.4.16. DEFINITION. A subset E of $\mathbb{R}^2$ is *projectable* (with respect to the order x, y) if there are intervals $[a, b]$ and continuous functions $\phi, \psi : [a, b] \to \mathbb{R}$ with $\phi \le \psi$ and

$$E = \{(x, y) : a \le x \le b,\ \phi(x) \le y \le \psi(x)\}\ .$$

IX.3.4.17. See Figure IX.21 (adapted from http://tutorial.math.lamar.edu/Classes/CalcIII/DIGeneralRegion.aspx). We can also define projectability in the order y, x: E is projectable in the order y, x if there is an interval $[c, d]$ and functions $\phi, \psi : [c, d] \to \mathbb{R}$ such that

$$E = \{(x, y) : c \le y \le d,\ \phi(y) \le x \le \psi(y)\}\ .$$

A set E is *projectable* if it is projectable in at least one order; some simple regions are projectable in either order, and others projectable in one order but not the other. Most regions in $\mathbb{R}^2$ one would want to integrate over are projectable, or at least a finite union of nonoverlapping projectable regions. Note that a projectable region is compact.

IX.3.4.18. The boundary of a projectable region

$$E = \{(x, y) : a \le x \le b,\ \phi(x) \le y \le \psi(x)\}$$

consists of the graphs of ϕ and ψ, and the vertical line segments

$$\{(a, y) : \phi(a) \le y \le \psi(a)\} \text{ and } \{(b, y) : \phi(b) \le y \le \psi(b)\}$$

(one or both vertical segments can be degenerate), all of which have volume 0 in $\mathbb{R}^2$ by IX.3.2.17.. Thus E is a Jordan region in $\mathbb{R}^2$.

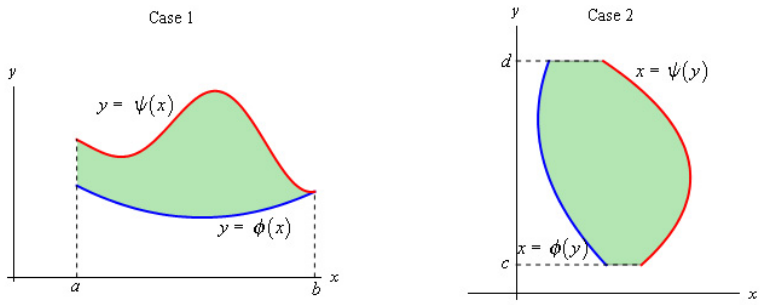

Figure IX.21: Projectable Regions.

IX.3.4.19. If E is the projectable region above, fix c and d with $c \le \phi(x) \le \psi(x) \le d$ for all $x \in [a,b]$. If $f : E \to \mathbb{R}$ is a function, then f can be considered a function on $R = [a,b] \times [c,d]$ in the usual way by setting it 0 on $R \setminus E$. If f is continuous on E, then for each $x \in [a,b]$ we have that $f_{[x]}$ is piecewise-continuous on $[c,d]$, supported on $[\phi(x), \psi(x)]$, hence integrable on $[c,d]$. Fubini's Theorem (IX.3.4.6.(i) form) applies to give

$$\int_E f\,dV = \int_R f\,dV = \int_a^b \int_c^d f(x,y)\,dy\,dx = \int_a^b \int_{\phi(x)}^{\psi(x)} f(x,y)\,dy\,dx\ .$$

Thus we obtain:

IX.3.4.20. Theorem. [Fubini's Theorem for Projectable Sets in $\mathbb{R}^2$] Let

$$E = \{(x,y) : a \le x \le b,\ \phi(x) \le y \le \psi(x)\}$$

be a projectable region (with respect to the order x, y) in $\mathbb{R}^2$, and $f : E \to \mathbb{R}$ a continuous function. Then

$$\int_E f\,dV = \int_a^b \int_{\phi(x)}^{\psi(x)} f(x,y)\,dy\,dx$$

(in particular, the iterated integral exists).

IX.3.4.21. Of course, the same result holds with x and y interchanged: if

$$E = \{(x,y) : c \le y \le d,\ \phi(y) \le x \le \psi(y)\}$$

and f is continuous on E, then

$$\int_E f\,dV = \int_c^d \int_{\phi(y)}^{\psi(y)} f(x,y)\,dx\,dy\ .$$

If E is projectable in either order, we thus get a result about interchanging order of integration:

IX.3.4.22. Corollary. [Fubini's Theorem for Iterated Integrals on Projectable Regions] Let

$$E = \{(x,y) : a \le x \le b,\ \phi_1(x) \le y \le \psi_1(x)\} = \{(x,y) : c \le y \le d,\ \phi_2(y) \le x \le \psi_2(y)\}$$

be a region in $\mathbb{R}^2$ which is projectable in either order. If $f : E \to \mathbb{R}$ is continuous, then

$$\int_a^b \int_{\phi_1(x)}^{\psi_1(x)} f(x,y)\,dy\,dx = \int_c^d \int_{\phi_2(y)}^{\psi_2(y)} f(x,y)\,dx\,dy$$

(in particular, the iterated integrals exist).

IX.3.4.23. However, note that in general $[c,d] \neq [a,b]$, $\phi_2 \neq \phi_1$, $\psi_2 \neq \psi_1$, so the limits of integration must be carefully modified. It is frequently easy to do an iterated integral in one order and difficult or even impossible in the other order; cf. IX.3.12.5..

IX.3.4.24. We can do the same thing in higher dimensions, although the notation becomes cumbersome. Fix an ordering $x_{j_1}, \ldots, x_{j_n}$ of the coordinates of $\mathbb{R}^n$. To streamline notation, we will write things out with $j_k = k$ for all k; the masochistic reader can easily adapt to the general situation. Inductively define $E_k \subseteq \mathbb{R}^k$ as follows. Let $E_1 = [a,b]$ be an interval in $\mathbb{R}$, and $\phi_1, \psi_1 : E_1 \to \mathbb{R}$ continuous functions with $\phi_1 \le \psi_1$ on E_1. Suppose $E_1, \ldots, E_k$ have been defined, and $\phi_k, \psi_k : E_k \to \mathbb{R}$ continuous functions with $\phi_k \le \psi_k$ on E_k. Set

$$E_{k+1} = \{(x_1, \ldots, x_{k+1}) \in \mathbb{R}^{k+1} : (x_1, \ldots, x_k) \in E_k, \phi_k(x_1, \ldots, x_k) \le x_{k+1} \le \psi_k(x_1, \ldots, x_k)\}\ .$$

By inductively applying IX.3.2.17. as in IX.3.4.18., we obtain that E_k is a Jordan region in $\mathbb{R}^k$ for each k.

IX.3.4.25. Definition. A set $E \subseteq \mathbb{R}^n$ is called a *projectable region* with respect to the order $x_1, \ldots, x_n$ if $E = E_n$ for some set of continuous functions as in IX.3.4.24..

Let E be a projectable region (for the order $x_1, \ldots, x_n$), and $f : E \to \mathbb{R}$ a continuous function. Use the notation of IX.3.4.24.. By successively applying the argument of IX.3.4.19., we obtain (note that all the integrals exist as Riemann integrals):

IX.3.4.26. Theorem. [Fubini's Theorem for Projectable Sets in $\mathbb{R}^n$] Let E be a projectable region (for the order $x_1, \ldots, x_n$), and $f : E \to \mathbb{R}$ a continuous function. Then

$$\int_E f\,dV = \int_a^b \int_{\phi_1(x_1)}^{\psi_1(x_1)} \cdots \int_{\phi_{n-1}(x_1,\ldots,x_{n-1})}^{\psi_{n-1}(x_1,\ldots,x_{n-1})} f(x_1, \ldots, x_n)\,dx_n \cdots dx_2\,dx_1\ .$$

IX.3.4.27. If E is also projectable in another ordering of the coordinates, the integral $\int_E f\,dV$ can be computed by an iterated integral in that order, although the ϕ_k and ψ_k will change in general when the ordering of the coordinates is changed. Thus we obtain as a corollary that the iterated integrals in the two orders are equal. The precise statement along the lines of IX.3.4.22. is left to the reader.

The case $n = 3$ is important enough for applications that it is worth stating explicitly:

IX.3.4.28. THEOREM. [FUBINI'S THEOREM FOR PROJECTABLE SETS IN $\mathbb{R}^3$] Let $[a,b]$ be an interval in $\mathbb{R}$, ϕ_1, ψ_1 continuous functions from $[a,b]$ to $\mathbb{R}$ with $\phi_1 \le \psi_1$ on $[a,b]$, $E_2 = \{(x,y) : a \le x \le b, \phi_1(x) \le y \le \psi_1(x)\}$, ϕ_2, ψ_2 continuous functions from E_2 to $\mathbb{R}$ with $\phi_2 \le \psi_2$, and

$$E = \{(x,y,z) : a \le x \le b, \phi_1(x) \le y \le \psi_1(x), \phi_2(x,y) \le z \le \psi_2(x,y)\} \ .$$

Let $f : E \to \mathbb{R}$ be a continuous function. Then

$$\int_E f \, dV = \int_a^b \int_{\phi_1(x)}^{\psi_1(x)} \int_{\phi_2(x,y)}^{\psi_2(x,y)} f(x,y,z) \, dz \, dy \, dx \ .$$

If E can be similarly written with respect to a different ordering of x, y, z, $\int_E f \, dV$ can be also calculated as an iterated integral in that order, and in particular the iterated integrals in the two orders are equal.

Most calculus texts have extensive examples of computing areas, volumes, and multiple integrals.

Counterexamples

We now give some examples showing that the hypotheses of Fubini's Theorem are necessary.

IX.3.4.29. EXAMPLES. Existence and equality of the iterated integrals does not imply integrability of f:
(i) Let $R = [0,1]^2 \subseteq \mathbb{R}^2$. Define $f : R \to \mathbb{R}$ by

$$f(x,y) = \begin{cases} 2^n & \text{if} \quad 2^{-n} < x, y \le 2^{-n+1} \\ 0 & \text{otherwise} \end{cases} \ .$$

Then $f_{[x]}$ and $f^{[y]}$ are integrable for all x and y, and all have integral 1, so the iterated integrals exist and

$$\int_0^1 \int_0^1 f(x,y) \, dy \, dx = \int_0^1 \int_0^1 f(x,y) \, dx \, dy = 1 \ .$$

But f is not integrable over R since it is unbounded.
(ii) A bounded example is more complicated. Let $R = [0,1]^2 \subseteq \mathbb{R}^2$. Define $f : R \to \mathbb{R}$ by setting $f(x,y) = 1$ if x and y are rational numbers with the same denominator when written in lowest terms, and $f(x,y) = 0$ otherwise. Then for fixed x, $f(x,y) = 1$ for only finitely many y, hence $f_{[x]}$ is integrable and has integral 0. Similarly, any $f^{[y]}$ is integrable and has integral 0. Thus the iterated integrals both exist and are 0. However, if $\mathcal{P}$ is any partition of R, it is easily seen that $\overline{\mathcal{S}}(f,\mathcal{P}) = 1$ and $\underline{\mathcal{S}}(f,\mathcal{P}) = 0$, so f is not integrable over R. In fact, f is discontinuous everywhere on R.

IX.3.4.30. EXAMPLE. Existence of the iterated integrals does not imply they are equal if f is not integrable: let $R = [0,1]^2 \subseteq \mathbb{R}^2$. Define $f : R \to \mathbb{R}$ by

$$f(x,y) = \begin{cases} 2^{2n} & \text{if} \quad 2^{-n} < x, y \le 2^{-n+1} \\ -2^{2n+1} & \text{if} \quad 2^{-n} < x \le 2^{-n+1}, \ 2^{-n-1} < y \le 2^{-n} \\ 0 & \text{otherwise} \end{cases} \ .$$

Then $f_{[x]}$ is integrable on $[0,1]$ and $\int_0^1 f_{[x]}(y)\,dy = 0$ for all x; thus

$$\int_0^1 \int_0^1 f(x,y)\,dy\,dx \text{ exists and equals } 0\ .$$

Also, $f^{[y]}$ is integrable on $[0,1]$ for all y; $\int_0^1 f^{[y]}(x)\,dx = 0$ if $y \le \frac{1}{2}$ but $\int_0^1 f^{[y]}(x)\,dx = 2$ if $y > \frac{1}{2}$; thus

$$\int_0^1 \int_0^1 f(x,y)\,dy\,dx \text{ exists and equals } 1\ .$$

So the iterated integrals are not equal. Note that f is unbounded and hence not integrable on R.
This example is an adaptation of the double sum example IV.2.10.6..

IX.3.4.31. EXAMPLE. Integrability of f does not imply integrability of $f_{[\boldsymbol{x}]}$ or $f^{[\boldsymbol{y}]}$ for all $\boldsymbol{x}$, $\boldsymbol{y}$: let $R = [0,1]^2 \subseteq \mathbb{R}^2$, B any finite subset of $[0,1]$, and set

$$f(x,y) = \begin{cases} 1 & \text{if} \quad x \in B,\ y \in \mathbb{Q} \\ 0 & \text{otherwise} \end{cases}\ .$$

Then f is bounded, and continuous except on $B \times [0,1]$, a set of content 0, so f is integrable on R. However, for $x \in B$, $f_{[x]}$ is not integrable on $[0,1]$. The example can be easily modified to also make $f^{[y]}$ nonintegrable for finitely many y. Replacing B with the Cantor set () gives examples where $f_{[x]}$ and/or $f^{[y]}$ are nonintegrable for infinitely many x, y.

IX.3.4.32. The full measure-theoretic form of Fubini's Theorem implies that if f is Riemann integrable on $R \times S$, hence continuous except on a set E of measure 0, then the vertical cross sections $E_{\boldsymbol{x}}$ have measure 0 for almost all $\boldsymbol{x}$, and hence $f_{[\boldsymbol{x}]}$ is Riemann integrable on S for almost all $\boldsymbol{x}$, and similarly $f^{[\boldsymbol{y}]}$ is Riemann integrable on R for almost all $\boldsymbol{y}$. Thus IX.3.4.31. is nearly as bad as the situation can get. But $f_{[\boldsymbol{x}]}$ and/or $f^{[\boldsymbol{y}]}$ can fail to be Riemann integrable for a dense set of $\boldsymbol{x}$ and/or $\boldsymbol{y}$ (Exercise IX.3.12.4.).

IX.3.4.33. The example IX.3.4.30. of an f where the iterated integrals exist but are unequal has an unbounded f. In fact, a bounded example is impossible. For the full Fubini Theorem () implies that if $f : R \times S \to \mathbb{R}$ is bounded and Lebesgue measurable, a very mild restriction satisfied by any function which can be explicitly described, the iterated integrals (which automatically exist as Lebesgue integrals) are equal. Whether or not f is Lebesgue measurable (but bounded), if $f_{[\boldsymbol{x}]}$ and $f^{[\boldsymbol{y}]}$ are Riemann integrable for all $\boldsymbol{x}$ and $\boldsymbol{y}$, the iterated integrals automatically exist as Riemann integrals and are equal ([**?**], [**?**]; cf. [Bog07, 3.10.57]). Tonelli's Theorem () also rules out an example with an unbounded nonnegative (measurable) f, hence an example with (measurable) f bounded either above or below.

IX.3.4.34. Some authors have objected to the use of the name "Fubini's Theorem" for results like IX.3.4.10. or even IX.3.4.6., on the grounds that they were "known" to people like EULER, long before FUBINI. But the multidimensional Riemann integral was not even defined until the 1870s (by JORDAN), so IX.3.4.10. as stated could not have been known to EULER. The part of this result about interchanging

order of integration in an iterated integral (the "Weak Fubini Theorem" IX.3.5.2.), or its equivalent IX.3.5.1., might have been a folklore result in Euler's time, but it is highly doubtful it had been proved (for one thing, at some point in the proof compactness or uniform continuity is needed, concepts not understood until the nineteenth century). Even justifying interchanging order of summation in a double infinite sum (IV.2.10.8.) requires careful analysis not nailed down until the nineteenth century. Some results which can be viewed as special cases of Fubini's Theorem, or more accurately of Cavalieri's Principle, such as computing the volume of a solid of revolution, had been proved (by the standards of the time), but such results only occasionally involved iterated integrals. I have yet to see clear evidence that anyone proved IX.3.4.10. or any other true version of Fubini's Theorem before Fubini. Thus I see no reason not to continue to use the term "Fubini's Theorem" generically for these results.

IX.3.5. Interchanging Differentiation and Integration

From Fubini's Theorem we can obtain an important result on interchanging the order of differentiation and integration: for a function of two or more variables, differentiation with respect to one variable commutes with integration with respect to another variable. We will obtain a more general version in XVIII.2.1.1., but from IX.3.4.10. we can easily get the continuous version, which is adequate for many (perhaps most) applications.

IX.3.5.1. Theorem. Let I be an open interval in $\mathbb{R}$, $[c,d]$ a closed bounded interval in $\mathbb{R}$, and $R = I \times [c,d]$ the corresponding rectangle in $\mathbb{R}^2$. Let $f : R \to \mathbb{R}$ be a function such that f and $\frac{\partial f}{\partial x}$ are continuous on R. For $x \in I$ define

$$g(x) = \int_c^d f(x,y)\,dy \ .$$

Then g is $\mathcal{C}^1$ on I and, for $x \in I$,

$$g'(x) = \int_c^d \frac{\partial f}{\partial x}(x,y)\,dy \ .$$

Slightly informally,

$$\frac{d}{dx}\left(\int_c^d f(x,y)\,dy\right) = \int_c^d \frac{\partial f}{\partial x}(x,y)\,dy$$

(often called "differentiation under the integral sign.")

In fact, for the proof we only need the part of Fubini's Theorem asserting that iterated integrals are equal:

IX.3.5.2. Theorem. [Weak Fubini Theorem] Let $R = [a,b] \times [c,d]$ be a rectangle in $\mathbb{R}^2$, and $f : R \to \mathbb{R}$ a continuous function. Then

$$\int_a^b \int_c^d f(x,y)\,dy\,dx = \int_c^d \int_a^b f(x,y)\,dx\,dy \ .$$

In particular, the two iterated integrals exist as Riemann integrals.

IX.3.5.3. Actually, Theorem IX.3.5.1. is equivalent to the Weak Fubini Theorem in the sense that each is an easy corollary of the other.

For the proofs, we need the following uniform continuity result, which is a special case of ():

IX.3.5.4. PROPOSITION. Let I be an interval and $[c,d]$ a closed bounded interval in $\mathbb{R}$, and let $f : I \times [c,d] \to \mathbb{R}$ be a continuous function. Then for every $x_0 \in I$ and $\epsilon > 0$, there is a $\delta > 0$ such that $|f(x,y) - f(x_0,y)| < \epsilon$ for any $x \in I$, $|x - x_0| < \delta$, and every $y \in [c,d]$.

IX.3.5.5. COROLLARY. Let I be an interval and $[c,d]$ a closed bounded interval in $\mathbb{R}$, and let $f : I \times [c,d] \to \mathbb{R}$ be a continuous function. For $x \in I$, define

$$\phi(x) = \int_c^d f(x,y)\,dy \ .$$

Then ϕ is a continuous function from I to $\mathbb{R}$.

PROOF: Let $x_0 \in I$. If $\epsilon > 0$, choose $\delta > 0$ such that $|f(x,y) - f(x_0,y)| < \frac{\epsilon}{d-c}$ for any $x \in I$, $|x - x_0| < \delta$, and every $y \in [c,d]$. Then, for $x \in I$, $|x - x_0| < \delta$,

$$|\phi(x) - \phi(x_0)| = \left| \int_c^d [f(x,y) - f(x_0,y)]\,dy \right| \leq \int_c^d |f(x,y) - f(x_0,y)|\,dy < \frac{\epsilon}{d-c}(d-c) = \epsilon \ .$$

IX.3.5.6. We now give the proof of IX.3.5.1. from IX.3.5.2.:

PROOF: For $x \in I$, define

$$\phi(x) = \int_c^d \frac{\partial f}{\partial x}(x,y)\,dy \ .$$

Then ϕ is a continuous function from I to $\mathbb{R}$ (IX.3.5.5.). Fix $x_0 \in I$, and fix $a \in I$, $a < x_0$. For $x \in I$, $x > a$, define

$$h(x) = \int_a^x \phi(t)\,dt = \int_a^x \int_c^d \frac{\partial f}{\partial x}(t,y)\,dy\,dt \ .$$

Then, by the Fundamental Theorem of Calculus (FTC1), h is differentiable and $h'(x) = \phi(x)$ for $x \in I$, $x > a$, and in particular $h'(x_0) = \phi(x_0)$. On the other hand, by IX.3.5.2. and the FTC2, for $x \in I$, $x > a$ we have

$$h(x) = \int_c^d \int_a^x \frac{\partial f}{\partial x}(t,y)\,dt\,dy = \int_c^d [f(x,y) - f(a,y)]\,dy$$
$$= \int_c^d f(x,y)\,dy - \int_c^d f(a,y)\,dy = g(x) - g(a)$$

so g is differentiable and $g'(x) = h'(x) = \phi(x)$ for $x \in I$, $x > a$, and in particular g is differentiable at x_0 and $g'(x_0) = \phi(x_0)$.

IX.3.5.7. Conversely, we can easily deduce IX.3.5.2. from IX.3.5.1.:

PROOF: Let $B > b$ and extend f to a continuous function from $[a, B] \times [c, d]$ to $\mathbb{R}$ by setting $f(x, y) = f(b, y)$ for $x \in [b, B]$, $y \in [c, d]$. For $x \in [a, B]$, define

$$g(x) = \int_c^d \int_a^x f(t, y)\, dt\, dy \ .$$

Then $g(a) = 0$, and by IX.3.5.1. and the FTC1 g is differentiable on (a, B) and

$$g'(x) = \int_c^d \frac{\partial}{\partial x} \left[\int_a^x f(t, y)\, dt \right] dy = \int_c^d f(x, y)\, dy$$

for $x \in (a, B)$. Since g' is continuous, by the FTC2 we have, for $x \in (a, B)$,

$$g(x) = g(a) + \int_a^x g'(t)\, dt = \int_a^x \int_c^d f(t, y)\, dy\, dt \ .$$

Then IX.3.5.2. follows by setting $x = b$. 👍

IX.3.5.8. We can give a direct proof of Theorem IX.3.5.1., which by IX.3.5.7. gives an alternate proof of IX.3.5.2.:

PROOF: Fix $x_0 \in I$. Then, for h small enough that $x_0 + h \in I$, we have

$$\frac{g(x_0 + h) - g(x_0)}{h} - \int_c^d \frac{\partial f}{\partial x}(x_0, y)\, dy = \int_c^d \left[\frac{f(x_0 + h, y) - f(x_0, y)}{h} - \frac{\partial f}{\partial x}(x_0, y) \right] dy \ .$$

By the Mean Value Theorem, if the interval between x_0 and $x_0 + h$ is contained in I, then for each $y \in [c, d]$ there is a u_y between x_0 and $x_0 + h$ (depending on y and h) with

$$\frac{f(x_0 + h, y) - f(x_0, y)}{h} = \frac{\partial f}{\partial x}(u_y, y) \ .$$

Let $\epsilon > 0$. Since $\frac{\partial f}{\partial x}$ is continuous, by IX.3.5.4. there is a $\delta > 0$ such that

$$\left| \frac{\partial f}{\partial x}(x, y) - \frac{\partial f}{\partial x}(x_0, y) \right| < \frac{\epsilon}{d - c}$$

whenever $x \in I$, $|x - x_0| < \delta$, and $y \in [c, d]$. Thus, if h is sufficiently small,

$$\left| \frac{g(x_0 + h) - g(x_0)}{h} - \int_c^d \frac{\partial f}{\partial x}(x_0, y)\, dy \right| = \left| \int_c^d \left[\frac{\partial f}{\partial x}(u_y, y) - \frac{\partial f}{\partial x}(x_0, y) \right] dy \right|$$

$$\leq \int_c^d \left| \frac{\partial f}{\partial x}(u_y, y) - \frac{\partial f}{\partial x}(x_0, y) \right| dy < \frac{\epsilon}{d - c}(d - c) = \epsilon \ .$$

👍

Note, however, that this does not give a proof of the full Fubini Theorem, even IX.3.4.10., without additional argument. ✋

Using the Chain Rule, we can extend IX.3.5.1. to integration over more general regions:

IX.3.5.9. THEOREM. Let U be an open set in $\mathbb{R}^2$ containing the closed set

$$S = \{(x,y) \in \mathbb{R}^2 : a \le x \le b, u(x) \le y \le v(x)\}$$

where u and v are differentiable functions from $I = [a,b]$ to $\mathbb{R}$ with $u \le v$. Let $f : U \to \mathbb{R}$ be a function such that f and $\frac{\partial f}{\partial x}$ are continuous on U. For $x \in I$ define

$$g(x) = \int_{u(x)}^{v(x)} f(x,y)\,dy \ .$$

Then g is differentiable on I and, for $x \in I$,

$$g'(x) = \int_{u(x)}^{v(x)} \frac{\partial f}{\partial x}(x,y)\,dy + f(x,v(x))v'(x) - f(x,u(x))u'(x) \ .$$

If u and v are $\mathcal{C}^1$, so is g.

PROOF: Set $\phi(x,u,v) = \int_u^v f(x,y)\,dy$. Then ϕ is defined on a suitable neighborhood W of

$$\{(x,u,v) : a \le x \le b, u(x) \le u \le v \le v(x)\}$$

in $\mathbb{R}^3$, and $g(x) = \phi(x,u(x),v(x))$. By IX.3.5.1.,

$$\frac{\partial \phi}{\partial x}(x,u,v) = \int_u^v \frac{\partial f}{\partial x}(x,y)\,dy \ .$$

In particular, $\frac{\partial \phi}{\partial x}$ exists and is continuous on W. By the FTC, $\frac{\partial \phi}{\partial v}(x,u,v) = f(x,v)$ and $\frac{\partial \phi}{\partial u}(x,u,v) = -f(x,u)$ and are thus continuous on W. Therefore ϕ is differentiable ($\mathcal{C}^1$) on W. By the Chain Rule, g is diffrentiable on I and, for $x \in I$,

$$\begin{aligned} g'(x) &= \frac{\partial \phi}{\partial x}(x,u(x),v(x)) \cdot 1 + \frac{\partial \phi}{\partial u}(x,u(x),v(x))u'(x) + \frac{\partial \phi}{\partial v}(x,u(x),v(x))v'(x) \\ &= \int_{u(x)}^{v(x)} \frac{\partial f}{\partial x}(x,y)\,dy - f(x,u(x))u'(x) + f(x,v(x))v'(x) \ . \end{aligned}$$

Multidimensional versions can be obtained similarly, such as (cf. Exercise IX.3.12.7.):

IX.3.5.10. THEOREM. Let R be an open rectangle in $\mathbb{R}^p$, S a closed bounded rectangle in $\mathbb{R}^q$, and $f(x_1,\ldots,x_p,y_1,\ldots,y_q) : R \times S \to \mathbb{R}$ a function such that f and $\frac{\partial f}{\partial x_i}$ are continuous on $R \times S$ for some i, $1 \le i \le p$. For $\boldsymbol{x} = (x_1,\ldots,x_p) \in R$ define

$$g(\boldsymbol{x}) = \int_S f(\boldsymbol{x},\boldsymbol{y})\,dV(\boldsymbol{y}) \ .$$

Then $\frac{\partial g}{\partial x_i}$ exists and is continuous on R and, for $\boldsymbol{x} \in R$,

$$\frac{\partial g}{\partial x_i}(\boldsymbol{x}) = \int_S \frac{\partial f}{\partial x_i}(\boldsymbol{x},\boldsymbol{y})\,dV(\boldsymbol{y}) \ .$$

If $\frac{\partial f}{\partial x_i}$ exists and is continuous on $R \times S$ for all i, $1 \le i \le p$ (and f is continuous), then g is $\mathcal{C}^1$ on R.

IX.3.6. Change of Variable

IX.3.6.1. EXAMPLE. Here is a standard elementary example ("polar coordinates") of a change of variable for which the hypotheses of () are not satisfied. Let $U = V = \mathbb{R}^2$. Denote the coordinates in U by (r, θ) and those of V by (x, y). Let $\boldsymbol{f} : U \to V$ be

$$\boldsymbol{f}(r, \theta) = (r \cos\theta, r \sin\theta) \ .$$

Fix $b > 0$ and let $R = [0, b] \times [0, 2\pi] \subseteq U$ and S the closed disk of radius b around $\mathbf{0}$ in V. Then $\boldsymbol{f}$ maps R onto S, and R° homeomorphically into $S^{\mathbf{0}}$. But $\boldsymbol{f}$ is not a proper map from U to V (the preimage of $\{\mathbf{0}\}$ is the entire θ-axis), and is not a proper map from R° to S° (for one thing, its range is not closed in S°, cf. ()); $\boldsymbol{f}$ is not one-to-one on ∂R, and $\boldsymbol{f}(\partial R)$ is not contained in ∂S.

The function $\boldsymbol{f}$ is smooth, and

$$det(D\boldsymbol{f}(r, \theta)) = det\left(\begin{bmatrix} \cos\theta & -r\sin\theta \\ \sin\theta & r\cos\theta \end{bmatrix}\right) = r \ .$$

Thus $det(D\boldsymbol{f}) \geq 0$ on R and is strictly positive on R°. Although () does not apply as stated, it is nonetheless true that if $g : S \to \mathbb{R}$ is a continuous function, then

$$\int_S g \, dV = \int_R (g \circ \boldsymbol{f}) det(D\boldsymbol{f}) \, dV = \int_0^{2\pi} \int_0^b g(r\cos\theta, r\sin\theta) \, r \, dr \, d\theta \ .$$

We need a version of () which applies in this and similar examples to give the conclusion.

IX.3.7. Improper Integrals

IX.3.8. Step Functions

Riemann integration can be alternately described via step functions. There are some subtleties which must be addressed in this approach concerning values on boundaries of rectangles; these subtleties are "wasted" in the sense that they have no ultimate effect, but they are necessary for a logically complete development, and they can be handled cleanly if done right.

IX.3.8.1. DEFINITION. A *step function* on $\mathbb{R}^p$ is a finite linear combination of indicator functions of rectangles (degenerate rectangles are allowed).

IX.3.8.2. Any (finite) linear combination of step functions is a step function.

IX.3.8.3. If $\phi = \sum_{k=1}^{n} \alpha_k \phi_{R_k}$ is a step function, there is a rectangle R such that $R_k \subseteq R$ for all k. A partition $\mathcal{P}$ of R is *ϕ-fine* if each R_k is a union of rectangles in $\mathcal{P}$. By (), every step function ϕ has a ϕ-fine partition of any sufficiently large rectangle. Any refinement of a ϕ-fine partition is ϕ-fine.

IX.3.8.4. In the step function approach to Riemann integration, it is very convenient to allow partitions which include degenerate rectangles. In fact, it is most convenient to work with *full partitions* $\mathcal{P}$, in which any nonempty intersection of rectangles in $\mathcal{P}$ is also in $\mathcal{P}$ (all such intersections are, of course, degenerate since the rectangles in $\mathcal{P}$ are nonoverlapping). A grid in which every one-dimensional factor has all transition points included as degenerate intervals is a full partition, so any partition has a full refinement.

If ϕ is a step function and $\mathcal{P}$ is a full ϕ-fine partition, then ϕ can be written as a linear combination of indicator functions of rectangles in $\mathcal{P}$. This is an immediate consequence of the following fact, which has a straightforward but notationally complex proof by induction on n left to the reader:

IX.3.8.5. PROPOSITION. Let X be a set, and $A_1, \ldots, A_n$ subsets of X. Then

$$\chi_{A_1 \cup \cdots \cup A_n} = \sum_{k=1}^{n} \chi_{A_k} - \sum_{j<k} \chi_{A_j \cap A_k} + \sum_{i<j<k} \chi_{A_i \cap A_j \cap A_k} - \cdots + (-1)^{n+1} \chi_{A_1 \cap \cdots \cap A_n}$$

where each sum is over all strictly increasing sets of distinct indices.

IX.3.8.6. Each rectangle R has an "interior" R^o consisting of all points of R not contained in a boundary rectangle of smaller dimension. If R is a singleton, set $R^o = R$. Note that R^o is not the topological interior of R in $\mathbb{R}^p$ if R is degenerate, but is rather the topological interior relative to the affine subspace of $\mathbb{R}^p$ generated by R. R^o is a relatively open subset of R. If $\mathcal{P}$ is a full partition of a rectangle R, for each $R_k \in \mathcal{P}$ we have that R_k^o is the set of points of R_k not contained in any $R_j \in \mathcal{P}$ properly contained in R_k. Then R is the disjoint union of the R_k^o. Any linear combination ϕ of the indicator functions of the R_k^o is a step function (use IX.3.8.5.) for which $\mathcal{P}$ is ϕ-fine, and any step function ψ for which $\mathcal{P}$ is ψ-fine can be written uniquely as a linear combination of these indicator functions.

IX.3.8.7. It follows immediately that any finite maximum or minimum of step functions is a step function. [Consider a full partition which is fine for all the step functions.]

Integrals of Step Functions

IX.3.8.8. If $\phi = \sum_{k=1}^{m} \alpha_k \chi_{R_k}$ is a step function, then ϕ is Riemann integrable over any rectangle R containing all the R_k and

$$\int_R \phi \, dV = \sum_{k=1}^{m} \alpha_k V(R_k) \ .$$

It is fairly easily verified using IX.3.8.5. that the sum on the right depends only on ϕ and not on how it is written as a linear combination of indicator functions; thus it can be taken as the *definition* of the integral of ϕ over R. The integral of step functions so defined is easily verified to be linear, additive, and monotone. It also has a continuity property (IX.3.8.20.).

IX.3.8.9. The Riemann integral can be alternately defined and constructed using this integral for step functions, without using the upper and lower sum definitions previously used ().

Maximum and Minimum Step Functions

IX.3.8.10. Let R be a rectangle and f a bounded function on R. If $\mathcal{P}$ is a full partition of R, then there is a unique largest step function ϕ for which $\mathcal{P}$ is ϕ-fine and $\phi \le f$. If $\mathcal{P} = \{R_1, \ldots, R_m\}$, then ϕ is the function whose value on R_k^o is the infimum of f on R_k^o. Similarly, there is a smallest step function ψ for which $\mathcal{P}$ is ψ-fine and $f \le \psi$; on R_k^o ψ equals the supremum of f on R_k^o. We have

$$\underline{\mathcal{S}}(f, \mathcal{P}) \le \int_R \phi \, dV \le \underline{\int_R} f \, dV \le \overline{\int_R} f \, dV \le \int_R \psi \, dV \le \overline{\mathcal{S}}(f, \mathcal{P}) \ .$$

Write $\phi(f, \mathcal{P})$ and $\psi(f, \mathcal{P})$ for ϕ and ψ. If $\mathcal{Q}$ is a refinement of $\mathcal{P}$, then $\phi(f, \mathcal{P}) \le \phi(f, \mathcal{Q})$ and $\psi(f, \mathcal{Q}) \le \psi(f, \mathcal{P})$.

IX.3.8.11. PROPOSITION. Let R be a rectangle in $\mathbb{R}^p$, and $f : \mathbb{R} \to \mathbb{R}$ a bounded function. The following are equivalent:

(i) f is Riemann integrable on R.

(ii) There are sequences (ϕ_n) and (ψ_n) of step functions supported on R with

$$\phi_n \le \phi_{n+1} \le f \le \psi_{n+1} \le \psi_n$$

on R for all n and

$$\lim_{n\to\infty} \int_R \phi_n \, dV = \sup_n \int_R \phi_n \, dV = \inf_n \int_R \psi_n \, dV = \lim_{n\to\infty} \int_R \psi_n \, dV \ .$$

PROOF: (ii) $\Rightarrow$ (i) since

$$\int_R \phi_n \, dV \le \underline{\int_R} f \, dV \le \overline{\int_R} f \, dV \le \int_R \psi_n \, dV$$

for each n by monotonicity.
For (i) $\Rightarrow$ (ii), choose a sequence $\mathcal{P}_n$ of full partitions of R such that $\mathcal{P}_{n+1}$ refines $\mathcal{P}_n$ for all n and $\lim_{n\to\infty}[\overline{\mathcal{S}}(f, \mathcal{P}_n) - \underline{\mathcal{S}}(f, \mathcal{P}_n)] = 0$. Set $\phi_n = \phi(f, \mathcal{P}_n)$, $\psi_n = \psi(f, \mathcal{P}_n)$ and apply IX.3.8.10.. 👍

Two more equivalent conditions will be added in IX.3.10.6..

Sets of Measure Zero

There is a more general and flexible notion of "negligibly small" sets than content zero:

IX.3.8.12. DEFINITION. A subset A of $\mathbb{R}^p$ has *measure zero* if for any $\epsilon > 0$ there is a sequence (R_k) of rectangles in $\mathbb{R}^p$ (degenerate rectangles are allowed) such that $A \subseteq \cup_{k=1}^{\infty} R_k$ and

$$\sum_{k=1}^{\infty} V(R_k) < \epsilon \ .$$

IX.3.8.13. Since degenerate rectangles are allowed in the definition, a set of zero content is a set of measure zero. A set of measure zero is not necessarily a Jordan region; in fact, it is not even necessarily bounded. Any subset of a set of measure zero is a set of measure zero. A finite or even countable union of sets of measure zero is a set of measure zero (). In particular, since a singleton set has measure zero, any countable subset of $\mathbb{R}^p$ has measure zero. Thus the set of all points with rational coordinates has measure zero.

We do have ():

IX.3.8.14. PROPOSITION. Let $A \subseteq \mathbb{R}^p$. Then

(i) If A is bounded, then A has zero content if and only if $\bar{A}$ has measure zero.

(ii) If A is a Jordan region, then A has measure zero if and only if it has zero content.

(iii) If A is compact (closed and bounded) and has measure zero, then A has zero content (and is thus a Jordan region).

IX.3.8.15. The notion of a set of measure zero is part of the theory of Lebesgue measure, which is discussed in detail in (). A notion of size or "measure" is defined for all reasonable ("measurable") subsets of $\mathbb{R}^p$, which extends Jordan content, i.e. the measure of a Jordan region is exactly its Jordan content. But many more sets are measurable; in fact, every subset of $\mathbb{R}^p$ which can be explicitly described turns out to be measurable. There is an extended notion of integral called the Lebesgue integral: "measurable" functions can be integrated over measurable sets (with some technical size restrictions related to boundedness).

We also make the following definition:

IX.3.8.16. DEFINITION. Let $A \subseteq \mathbb{R}^p$, and $f, g : A \to \mathbb{R}$. Then $f = g$ *almost everywhere on* A if

$$\{\boldsymbol{x} \in A : f(\boldsymbol{x}) \neq g(\boldsymbol{x})\}$$

is a set of measure zero. "Almost everywhere" is abbreviated *a.e.*

Characterization of Sets of Measure Zero

Sets of measure 0 can be characterized using integrals of step functions:

IX.3.8.17. THEOREM. Let R be a rectangle in $\mathbb{R}^p$, and $A \subseteq R$. Then A has measure 0 if and only if, for every $\epsilon > 0$, there is a nondecreasing sequence (ϕ_n) of step functions such that $\sup_n \phi_n(\boldsymbol{x}) \geq 1$ for all $\boldsymbol{x} \in A$ and $\int_R \phi_n \, dV < \epsilon$ for all n.

The proof consists of the following two lemmas.

IX.3.8.18. LEMMA. Let R be a rectangle in $\mathbb{R}^p$, and $A \subseteq R$. If, for every $\epsilon > 0$, there is a nonnegative step function ϕ such that $\phi(\boldsymbol{x}) \geq 1$ for all $\boldsymbol{x} \in A$ and $\int_R \phi \, dV < \epsilon$, then A has measure 0.

PROOF: Let $\epsilon > 0$ and ϕ the corresponding step function. Let $\phi = \sum \alpha_k \chi_{R_k^o}$ be the canonical representation of ϕ (IX.3.8.6.), and let $k_1, \ldots, k_n$ be the k for which $\alpha_k \geq 1$. Then $A \subseteq \cup_{j=1}^n R_{k_j}$ and

$$\sum_{j=1}^n V(R_{k_j}) \leq \sum_{j=1}^n \alpha_{k_j} V(R_{k_j}) \leq \int_R \phi \, dV < \epsilon \; .$$

Since $\epsilon > 0$ is arbitrary, A has measure 0. 👍

IX.3.8.19. LEMMA. Let R be a rectangle in $\mathbb{R}^p$, and $A \subseteq R$. If A has measure zero, then for any $\epsilon > 0$ there is a nondecreasing sequence (ϕ_n) of step functions such that $\sup_n \phi_n(\boldsymbol{x}) = +\infty$ for all $\boldsymbol{x} \in A$ and $\int_R \phi_n \, dV < \epsilon$ for all n.

PROOF: For each n there is a finite collection $\{R_{n,1}, \ldots, R_{n,m_n}\}$ of rectangles with $A \subseteq E_n := \cup_{k=1}^{m_n} R_{n,k}$ and $\sum_{k=1}^{m_n} V(R_{n,k}) < 2^{-n}\epsilon$. Then E_n is a Jordan region, $V(E_n) \leq 2^{-n}\epsilon$, and χ_{E_n} is a step function. Set

$$\phi_n = \sum_{k=1}^n \chi_{E_n} \; .$$

Then (ϕ_n) is a nondecreasing sequence of step functions, $\phi_n(\boldsymbol{x}) = n$ for $\boldsymbol{x} \in A$, and

$$\int_R \phi_n \, dV = \sum_{k=1}^n V(E_k) < \sum_{k=1}^n 2^{-k}\epsilon < \epsilon$$

for all n. 👍

IX.3.8.20. PROPOSITION. Let (ψ_n) be a nonincreasing sequence of nonnegative step functions supported on a fixed rectangle R. If

$$\lim_{n\to\infty} \int_R \psi_n \, dV = \inf_n \int_R \psi_n \, dV = 0$$

Then $\psi_n \to 0$ pointwise a.e.

PROOF: It suffices to show that $A_m = \{\boldsymbol{x} \in \mathbb{R} : \inf_n \psi_n(\boldsymbol{x}) \geq \frac{1}{m}\}$ has measure 0 for all $m \in \mathbb{N}$, since $\psi_n \to 0$ pointwise on the complement of $\cup_m A_m$. Fix m. For any $\epsilon > 0$, there is an n such that $\int_R \psi_n \, dV < \frac{\epsilon}{m}$. Then $\phi = m\psi_n$ is a step function with $\phi(\boldsymbol{x}) \geq 1$ for all $\boldsymbol{x} \in A_m$ and $\int_R \phi \, dV < \epsilon$. Thus A_m has measure 0 by IX.3.8.18.. 👍

We will prove an important converse in IX.3.9.6..

IX.3.9. The Monotone Convergence Theorem

The Monotone Convergence Theorem is an important continuity property of integrals:

IX.3.9.1. THEOREM. [MONOTONE CONVERGENCE THEOREM FOR RIEMANN INTEGRATION] Let R be a rectangle in $\mathbb{R}^p$, and (f_n) a nondecreasing sequence of nonnegative Riemann integrable functions on R converging pointwise a.e. on R to a Riemann integrable function f. Then

$$\int_R f\,dV = \lim_{n\to\infty} \int_R f_n\,dV = \sup_n \int_R f_n\,dV\ .$$

Note that it is the sequence which is nondecreasing, i.e. $f_n(\boldsymbol{x}) \le f_{n+1}(\boldsymbol{x})$ for all n and all $\boldsymbol{x} \in R$.

IX.3.9.2. There are two difficulties with this statement. First, the hypothesis that the limit function f is Riemann integrable on R is not automatic, even if the f_n are uniformly bounded. For example, let (r_n) be an enumeration of the rational numbers in $[0,1]$, and define $f_n(x)$ to be 1 if $x = r_k$ for some k, $1 \le k \le n$, and $f_n(x) = 0$ otherwise. Then f_n is 0 except at finitely many points, hence is Riemann integrable on $[0,1]$, but $f_n \to \chi_{\mathbb{Q}}$ pointwise on $[0,1]$, and $\chi_{\mathbb{Q}}$ is not Riemann integrable on $[0,1]$. Thus the Riemann integrability of f must be included as a hypothesis. To avoid this difficulty, replacing f_n by $f - f_n$ and using linearity of the Riemann integral the theorem may be more cleanly stated:

IX.3.9.3. THEOREM. Let R be a rectangle in $\mathbb{R}^p$, and (f_n) a nonincreasing sequence of nonnegative Riemann integrable functions on R converging pointwise a.e. on R to 0. Then

$$\lim_{n\to\infty} \int_R f_n\,dV = \inf_n \int_R f_n\,dV = 0\ .$$

IX.3.9.4. There is a second difficulty: proving this theorem. Although a direct proof can be given, it is quite complicated to do so. The simplest approach is to work via the Lebesgue integral and prove a more general theorem applicable to arbitrary Lebesgue measurable functions (XVIII.1.4.1.). In fact, overcoming both the difficulties with the Riemann integration statement of the theorem was one of the principal motivations for developing Lebesgue integration theory.

IX.3.9.5. We will content ourselves here with proving only the following special case, which will be crucial in developing the Daniell integral ().

IX.3.9.6. THEOREM. [MONOTONE CONVERGENCE THEOREM FOR STEP FUNCTIONS] Let R be a rectangle in $\mathbb{R}^p$, and (ψ_n) a nonincreasing sequence of nonnegative step functions on R converging pointwise a.e. on R to 0. Then

$$\lim_{n\to\infty} \int_R \psi_n\,dV = \inf_n \int_R \psi_n\,dV = 0\ .$$

PROOF: Let A be the set of $\boldsymbol{x} \in R$ for which $(\psi_n(\boldsymbol{x}))$ fails to converge to 0, and B the set of $\boldsymbol{x}$ at which at least one ψ_n is discontinuous, and $C = A \cup B$. Then C has measure 0. Let M be a bound for ϕ_1 on R.

Let $\epsilon > 0$. There is a sequence (R_k^o) of open rectangles covering C for which

$$\sum_{k=1}^{\infty} V(R_k^o) < \frac{\epsilon}{2M} \ .$$

If $E = R \setminus \cup_k R_k^o$, then for each $\boldsymbol{x} \in E$ there is an $n_{\boldsymbol{x}}$ and an open rectangle $R_{\boldsymbol{x}}^o$ containing $\boldsymbol{x}$ such that $\psi_{n_{\boldsymbol{x}}}$ takes a constant value less than $\frac{\epsilon}{2V(R)}$ on $R_{\boldsymbol{x}}^o$. The R_k^o and $R_{\boldsymbol{x}}^o$ cover R, so by compactness finitely many R_k^o and $R_{\boldsymbol{x}}^o$ cover E, say $R_{k_1}^o, \ldots, R_{k_r}^o, R_{\boldsymbol{x}_1}^o, \ldots, R_{\boldsymbol{x}_m}^o$. Let $R_{\boldsymbol{x}_k}$ be the closure of $R_{\boldsymbol{x}_k}^o$. By subdividing and eliminating overlaps we may assume the $R_{\boldsymbol{x}_k}$ are nonoverlapping, so $\sum_{k=1}^m V(R_{\boldsymbol{x}_k}) \leq V(R)$.

Set $N = \max\{n_{\boldsymbol{x}_1}, \ldots, n_{\boldsymbol{x}_m}\}$. Then if $n \geq N$, we have

$$\int_R \psi_n \, dV \leq \sum_{j=1}^{r} \int_{R_{k_j}^o} \psi_n \, dV + \sum_{k=1}^{m} \int_{R_{\boldsymbol{x}_k}} \psi_n \, dV < \frac{\epsilon}{2M} \sum_{k=1}^{\infty} MV(R_k^o) + \sum_{k=1}^{m} \frac{\epsilon}{2V(R)} V(R_{\boldsymbol{x}_k}) \leq \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \ .$$

IX.3.9.7. What this argument really shows is a special case of Egorov's Theorem (XVII.1.8.1.): under the hypotheses, ψ_n for n sufficiently large is actually uniformly close to 0 on the complement of a set of small measure. This is also reminiscent of Dini's Theorem ().

IX.3.10. Characterization of Riemann Integrable Functions

Using the Monotone Convergence Theorem (IX.3.9.6.), we can add a third equivalent condition to the characterization of Riemann integrability:

IX.3.10.1. THEOREM. Let R be a rectangle in $\mathbb{R}^p$, and $f : \mathbb{R} \to \mathbb{R}$ a bounded function. The following are equivalent:

(i) f is Riemann integrable on R.

(ii) There are sequences (ϕ_n) and (ψ_n) of step functions supported on R with

$$\phi_n \le \phi_{n+1} \le f \le \psi_{n+1} \le \psi_n$$

on R for all n and

$$\lim_{n\to\infty} \int_R \phi_n \, dV = \sup_n \int_R \phi_n \, dV = \inf_n \int_R \psi_n \, dV = \lim_{n\to\infty} \int_R \psi_n \, dV \ .$$

(iii) There are sequences (ϕ_n) and (ψ_n) of step functions supported on R with

$$\phi_n \le \phi_{n+1} \le f \le \psi_{n+1} \le \psi_n$$

on R for all n and $\phi_n \to f$ a.e. and $\psi_n \to f$ a.e. on R.

PROOF: (i) $\iff$ (ii) by IX.3.8.11.. For (ii) $\Rightarrow$ (iii), let ϕ_n, ψ_n be as in (ii). Then $(\psi_n - \phi_n)$ is a nonincreasing sequence of nonnegative step functions with

$$\lim_{n\to\infty} \int_R (\psi_n - \phi_n) \, dV = 0$$

and hence $\psi_n - \phi_n \to 0$ pointwise a.e., i.e. $\inf_n \psi_n(\boldsymbol{x}) = \sup_n \phi_n(\boldsymbol{x})$ for almost all $\boldsymbol{x} \in R$. Since $\sup_n \phi_n(\boldsymbol{x}) \le f(\boldsymbol{x}) \le \inf_n \psi_n(\boldsymbol{x})$ for all $\boldsymbol{x} \in R$, it follows that $\phi_n \to f$ a.e. and $\psi_n \to f$ a.e. (IX.3.8.20.).
Conversely, suppose ϕ_n and ψ_n are as in (iii). Then $(\psi_n - \phi_n)$ is a nonincreasing sequence of nonnegative step functions on R and $\psi_n - \phi_n \to 0$ pointwise a.e. Then by the Monotone Convergence Theorem we have

$$\lim_{n\to\infty} \int_R (\psi_n - \phi_n) \, dV = 0$$

so (ii) is satisfied. 👍

Upper and Lower Envelopes

IX.3.10.2. There is an alternate way of describing condition (iii) of IX.3.10.1. which leads to LEBESGUE'S characterization of Riemann integrability. Let f be a bounded function on a rectangle R. For each $\boldsymbol{a} \in R$, define

$$\underline{f}(\boldsymbol{a}) = \min\left(f(\boldsymbol{a}), \liminf_{\boldsymbol{x}\to\boldsymbol{a}} f(\boldsymbol{x})\right)$$

$$\overline{f}(\boldsymbol{a}) = \max\left(f(\boldsymbol{a}), \limsup_{\boldsymbol{x}\to\boldsymbol{a}} f(\boldsymbol{x})\right)$$

(these numbers are finite for all $\boldsymbol{a}$ since f is bounded). Then $\underline{f}$ and $\overline{f}$ are bounded functions on R, and $\underline{f} \le f \le \overline{f}$ on R; $\underline{f}(\boldsymbol{a}) = f(\boldsymbol{a}) = \overline{f}(\boldsymbol{a})$ if and only if f is continuous at $\boldsymbol{a}$. The functions $\overline{f}$ and $\underline{f}$ are called the *upper and lower envelopes* of f.

IX.3.10.3. Let $\mathcal{P}$ be a partition of R, and let $\phi(f,\mathcal{P})$ and $\psi(f,\mathcal{P})$ be the step functions defined in IX.3.8.10.. Then $\phi_n(f,\mathcal{P}) \le \underline{f}$ on the interior of any nondegenerate rectangle in $\mathcal{P}$, hence $\phi_n(f,\mathcal{P}) \le \underline{f}$ a.e. on R. Thus, if ϕ is any step function with $\phi \le f$ a.e. on R, then $\phi \le \underline{f}$ a.e. on R. Similarly, if ψ is any step function with $f \le \psi$ a.e. on R, then $\overline{f} \le \psi$ a.e. on R.

IX.3.10.4. PROPOSITION. Let R be a rectangle, and f a bounded function on R. Let $(\mathcal{P}_n)$ be a sequence of full partitions of R such that $\|\mathcal{P}_n\| \to 0$ as $n \to \infty$. Then $\phi(f,\mathcal{P}_n) \to \underline{f}$ a.e. and $\psi(f,\mathcal{P}_n) \to \overline{f}$ a.e. on R.

PROOF: The union of the degenerate rectangles in $\mathcal{P}_n$ has measure 0 (zero content) for each n. Hence if A is the set of points of R which are interior points of nondegenerate rectangles of $\mathcal{P}_n$ for every n, then $R \setminus A$ has measure 0. Fix $\boldsymbol{a} \in A$, and let $\epsilon > 0$. There is a $\delta > 0$ such that $f(\boldsymbol{x}) > \underline{f}(\boldsymbol{a}) - \epsilon$ for all $\boldsymbol{x} \in R \cap B_\delta(\boldsymbol{a})$. Then there is a N with $\|\mathcal{P}_n\| < \delta$ for $n \ge N$; for such an n the nondegenerate rectangle in $\mathcal{P}_n$ containing $\boldsymbol{a}$ is contained in $B_\delta(\boldsymbol{a})$ and thus $\underline{f}(\boldsymbol{a}) - \epsilon \le \phi(f,\mathcal{P}_n)(\boldsymbol{a}) \le \underline{f}(\boldsymbol{a})$. Therefore $\phi(f,\mathcal{P}_n)(\boldsymbol{a}) \to \underline{f}(\boldsymbol{a})$. So $\phi(f,\mathcal{P}_n) \to \underline{f}$ pointwise on A. Similarly, $\psi(f,\mathcal{P}_n) \to \overline{f}$ pointwise on A.

IX.3.10.5. In fact, it is easily verified () that $\underline{f}$ is precisely the supremum of all step functions ϕ satisfying $\phi \le f$, and $\overline{f}$ the infimum of all step functions ψ satisfying $f \le \psi$.

We can then add another equivalent condition for Riemann integrability:

IX.3.10.6. THEOREM. Let R be a rectangle in $\mathbb{R}^p$, and $f : \mathbb{R} \to \mathbb{R}$ a bounded function. The following are equivalent:

(i) f is Riemann integrable on R.

(ii) There are sequences (ϕ_n) and (ψ_n) of step functions supported on R with

$$\phi_n \le \phi_{n+1} \le f \le \psi_{n+1} \le \psi_n$$

on R for all n and

$$\lim_{n\to\infty} \int_R \phi_n \, dV = \sup_n \int_R \phi_n \, dV = \inf_n \int_R \psi_n \, dV = \lim_{n\to\infty} \int_R \psi_n \, dV \ .$$

(iii) There are sequences (ϕ_n) and (ψ_n) of step functions supported on R with

$$\phi_n \le \phi_{n+1} \le f \le \psi_{n+1} \le \psi_n$$

on R for all n and $\phi_n \to f$ a.e. and $\psi_n \to f$ a.e. on R.

(iv) We have $\underline{f} = \overline{f}$ a.e. on R (and in particular $\underline{f} = f$ a.e. and $\overline{f} = f$ a.e. on R).

PROOF: (i)–(iii) are equivalent by IX.3.10.1.. If ϕ_n, ψ_n are as in (iii), we have

$$\phi_n \le \underline{f} \le f \le \overline{f} \le \psi_n \text{ a.e.}$$

for each n; since $\phi_n \to f$ a.e. and $\psi_n \to f$ a.e. we have $\underline{f} = f = \overline{f}$ a.e.
Conversely, if (iv) is satisfied, let $(\mathcal{P}_n)$ be a sequence of full partitions of R such that $\|\mathcal{P}_n\| \to 0$ as $n \to \infty$, such that $\mathcal{P}_{n+1}$ refines $\mathcal{P}_n$ for all n. Then by IX.3.10.4. $\phi(f, \mathcal{P}_n) \nearrow f$ a.e. and $\psi(f, \mathcal{P}_n) \searrow f$ a.e. on R, so (iii) is satisfied. 👍

Noting that $\underline{f} = f = \overline{f}$ precisely at the points of continuity of f, we obtain LEBESGUE'S characterization:

IX.3.10.7. COROLLARY. Let R be a rectangle in $\mathbb{R}^p$, and $f : R \to \mathbb{R}$. Then f is Riemann integrable on R if and only if f is continuous almost everywhere and bounded on R.

This can be quickly extended to Jordan regions:

IX.3.10.8. COROLLARY. Let E be a Jordan region in $\mathbb{R}^p$, and $f : E \to \mathbb{R}$. Then f is Riemann integrable on E if and only if f is continuous almost everywhere and bounded on E.

PROOF: If f is continuous on E except on a set $A \subseteq E$ of measure zero, then $f\chi_E$ is continuous on any rectangle R containing E except on $A \cup \partial E$, which is a set of measure zero. 👍

Here is another useful observation:

IX.3.10.9. PROPOSITION. Let E be a Jordan region in $\mathbb{R}^n$, and $f : \bar{E} \to \mathbb{R}$ a bounded function. Then the following are equivalent:

(i) f is Riemann integrable over E.

(ii) f is Riemann integrable over $\bar{E}$.

(iii) f is Riemann integrable over E^o.

If these are satisfied, then

$$\int_E f\,dV = \int_{\bar{E}} f\,dV = \int_{E^o} f\,dV\ .$$

PROOF: (ii) $\Rightarrow$ (i) $\Rightarrow$ (iii) follow from IX.3.3.4..
(iii) $\Rightarrow$ (ii): If f is Riemann integrable over E^o, then it is continuous on E^o except on a set $A \subseteq E^o$ of measure zero. Thus f is continuous on $\bar{E}$ except on $A \cup \partial E$, which is a set of measure zero.
The last formula follows from IX.3.3.11. and IX.3.3.9.. 👍

IX.3.11. The Extended Riemann Integral

IX.3.11.1. In this section, we will extend the Riemann integral from Jordan regions to arbitrary open sets in $\mathbb{R}^p$. This extended integral will serve several purposes:

(i) It covers most (but not all!) instances of what can be called "improper Riemann integrals."

(ii) It makes the Change of Variables Theorem simpler and more natural.

(iii) It provides a good conceptual transition from the Riemann integral to the Lebesgue integral without measure-theoretic technicalities.

IX.3.11.2. We will only define the extended Riemann integral over *open* subsets of $\mathbb{R}^p$; thus it is not technically a generalization of the ordinary Riemann integral over Jordan regions since a Jordan region is not necessarily open. However, the distinction is unimportant since integration over open Jordan regions includes all essential features of the theory due to IX.3.2.23. and IX.3.10.9.. Following [**?**] (on which our exposition is partly based), we will call this theory the "extended Riemann integral" rather than the "improper Riemann integral" since it does not include all integrals which can be called "improper Riemann integrals."

IX.3.11.3. DEFINITION. (i) Let U be an open set in $\mathbb{R}^p$, and let $f : U \to \mathbb{R}$ be a nonnegative function. Then f is *Riemann integrable over U in the extended sense*, or *extended Riemann integrable over U*, if

(a) f is Riemann integrable over every compact Jordan region contained in U and

(b) $\sup\left[\int_E f\,dV\right] < \infty$, where the supremum is over all compact Jordan regions E contained in U.

If f is extended Riemann integrable over U, write

$$\int_U f\,dV = \sup\left[\int_E f\,dV\right]$$

where the supremum is over all compact Jordan regions E contained in U.

(ii) Let U be an open set in $\mathbb{R}^p$, and let $f : U \to \mathbb{R}$ be a function. Then f is *Riemann integrable over U in the extended sense* if both $f_+ = \max(f, 0)$ and $f_- = \max(-f, 0)$ are extended Riemann integrable over U. If this is the case, set

$$\int_U f\,dV = \int_U f_+\,dV - \int_U f_-\,dV\ .$$

Generating Sequences

Here is a crucial technical tool for the study of the extended integral:

IX.3.11.4. DEFINITION. Let U be an open set in $\mathbb{R}^p$. A *generating sequence* for U is an (increasing) sequence (E_n) of compact Jordan regions in U such that $U = \cup_{n=1}^{\infty} E_n$ and $E_n \subseteq E_{n+1}^o$ for all n.

IX.3.11.5. PROPOSITION. Let U be an open set in $\mathbb{R}^p$, and (E_n) a generating sequence for U. Then

(i) If K is any compact subset of U, then there is an n such that $K \subseteq E_n^o$.

(ii) If f is a nonnegative function on U, then f is extended Riemann integrable on U if and only if it is Riemann integrable on each E_n and $\sup_n \left[\int_{E_n} f\,dV\right] < \infty$. In this case,

$$\int_U f\,dV = \sup_n \left[\int_{E_n} f\,dV\right] .$$

If f is a general extended Riemann integrable function on U, then

$$\int_U f\,dV = \lim_{n\to\infty} \left[\int_{E_n} f\,dV\right] .$$

PROOF: (i) is an immediate consequence of compactness: $\{E_n^o\}$ is an open cover of K, which has a finite subcover.

(ii) If f is nonnegative and Riemann integrable on each E_n, then for any compact Jordan region $K \subseteq U$ we have, for $K \subseteq E_n^o$, f is Riemann integrable over K by IX.3.3.4. and

$$\int_K f\,dV \le \int_{E_n} f\,dV \le \int_U f\,dV$$

so taking the supremum over all K, we obtain the first formula. We then have that

$$\left(\int_{E_n} f\,dV\right)$$

is a bounded nondecreasing sequence converging to its supremum. The second formula then follows for general f by linearity. 👍

IX.3.11.6. PROPOSITION. Let U be an open set in $\mathbb{R}^p$. Then there exists a generating sequence for U.

PROOF: Let ρ be the standard metric on $\mathbb{R}^p$ (). Then

$$U = \{\boldsymbol{x} \in \mathbb{R}^p : \rho(\boldsymbol{x}, U^c) > 0\} .$$

Set

$$A_n = \{\boldsymbol{x} \in \mathbb{R}^p : \|\boldsymbol{x}\| \le n, \rho(\boldsymbol{x}, U^c) \ge 1/n\} .$$

Then A_n is compact, $A_n \subseteq A_{n+1}^o$, and $\cup_n A_n = U$. However, A_n is not necessarily a Jordan region since its boundary does not necessarily have zero content. But for each $\boldsymbol{x} \in A_n$, there is an open ball $B_{\boldsymbol{x}}$ centered at $\boldsymbol{x}$ such that $\bar{B}_{\boldsymbol{x}} \subseteq A_{n+1}^o$. The $B_{\boldsymbol{x}}$ form an open cover of A_n, which has a finite subcover; let E_n be the union of finitely many $\bar{B}_{\boldsymbol{x}}$ whose interiors cover A_n. Then E_n is a compact Jordan region, and we have $A_n \subseteq E_n \subseteq A_{n+1}^o \subseteq E_{n+1}^o$ for each n. 👍

Compare with ().

IX.3.11.7. Thus in computing the extended Riemann integral or proving its properties, we may work with a generating sequence. There are in general many generating sequences, and they are all equally good in principle; in fact, if (E_n) and (E'_n) are two generating sequences, by IX.3.11.5.(i) there is an increasing sequence (k_n) such that $E_n \subseteq E'_{k_n}$ and $E'_n \subseteq E_{k_n}$ for each n, so any two generating sequences are "almost the same." (Note too that $(E_n \cup E'_n)$ is also a generating sequence.) But in practice, in any situation there may be certain generating sequences which are easier to work with than others, and we are free to choose any convenient one.

IX.3.11.8. EXAMPLES. (i) Let $p = 1$ and $U = \mathbb{R}$. Set $f(x) = \frac{1}{x^2+1}$. We may take $E_n = [-n, n]$. Since f is continuous, it is Riemann integrable on each E_n. We have

$$\int_{E_n} f\,dV = \int_{-n}^{n} \frac{1}{x^2+1}\,dx = 2\tan^{-1} n$$

for each n. So f is extended Riemann integrable over $\mathbb{R}$, and $\int_{\mathbb{R}} f\,dV = \pi$. This is the usual improper Riemann integral

$$\int_{-\infty}^{+\infty} \frac{1}{x^2+1}\,dx\ .$$

In fact, the extended Riemann integral of any *nonnegative* function over $\mathbb{R}$ (or $(0, +\infty)$) is exactly the improper Riemann integral as defined in ().

(ii) Let $p = 1$, $U = (0, 1)$, and $f(x) = x^{-1/2}$. We may take $E_n = \left[\frac{1}{n}, 1 - \frac{1}{n}\right]$ for each n. Since f is continuous on U, it is Riemann integrable on each E_n, and

$$\int_{E_n} f\,dV = \int_{1/n}^{1-1/n} x^{-1/2}\,dx = 2\sqrt{1 - \frac{1}{n}} - 2\sqrt{\frac{1}{n}}\ .$$

Thus f is extended Riemann integrable over $(0, 1)$ and $\int_{(0,1)} f\,dV = 2$. This is the ordinary improper Riemann integral

$$\int_0^1 x^{-1/2}\,dx\ .$$

Thus an extended Riemann integrable function need not be bounded.

(iii) Let $p = 1$, $U = (0, +\infty)$, and $f(x) = \frac{\sin x}{x}$. We have that

$$\int_0^{+\infty} \frac{\sin x}{x}\,dx$$

exists as an improper Riemann integral in the sense of (). However,

$$\int_0^{2\pi n} \left(\frac{\sin x}{x}\right)_+ dx \geq c + \sum_{k=2}^{n} \frac{2}{\pi k}$$

where c is a constant, which is unbounded in n, so f is not extended Riemann integrable on U.

(iv) Here is an example where making a good choice of generating sequence is very helpful. Let $p = 2$, $U = \mathbb{R}^2$, and $f(x, y) = e^{-(x^2+y^2)}$. If we let $E_n = [-n, n] \times [-n, n]$, then (E_n) is a generating sequence for $\mathbb{R}^2$; but we have to calculate

$$\int_{E_n} f\,dV = \int_{-n}^{n}\int_{-n}^{n} e^{-(x^2+y^2)}\,dy\,dx$$

or the iterated integral in the other order, which cannot be calculated exactly. However, suppose instead we let E'_n be the closed disk of radius n centered at $\mathbf{0}$. We can easily calculate the integral over E'_n by changing to polar coordinates ():

$$\int_{E'_n} f\,dV = \int_0^{2\pi}\int_0^n e^{-r^2}\,r\,dr\,d\theta = \int_0^{2\pi}\left[\frac{1}{2} - \frac{e^{-n^2}}{2}\right]d\theta = \left[\frac{1}{2} - \frac{e^{-n^2}}{2}\right](2\pi) = \pi(1-e^{-n^2})$$

so f is extended Riemann integrable over $\mathbb{R}^2$ and $\int_{\mathbb{R}^2} f\,dV = \pi$.

IX.3.11.9. PROPOSITION. Let U be an open set in $\mathbb{R}^p$. Then

(i) If $f : U \to \mathbb{R}$ is Riemann integrable on each Jordan region in U, then f is extended Riemann integrable on U if and only if $|f|$ is.

(ii) If f and g are extended Riemann integrable functions on U and $\alpha \in \mathbb{R}$, then $f+g$ and αf are extended Riemann integrable on U, and

$$\int_U (f+g)\,dV = \int_U f\,dV \quad \text{and} \quad \int_U \alpha f\,dV = \alpha\int_U f\,dV\ .$$

PROOF: Fix a generating sequence (E_n) in U. We first prove (ii) if f, g, and α are nonnegative. For each n,

$$\int_{E_n}(f+g)\,dV = \int_{E_n} f\,dV + \int_{E_n} g\,dV \le \int_U f\,dV + \int_U g\,dV$$

so $f+g$ is extended Riemann integrable on U by IX.3.3.6. and IX.3.11.5., and we have

$$\int_U (f+g)\,dV = \lim_{n\to\infty}\int_{E_n}(f+g)\,dV = \lim_{n\to\infty}\left[\int_{E_n} f\,dV + \int_{E_n} g\,dV\right]$$

$$= \lim_{n\to\infty}\left[\int_{E_n} f\,dV\right] + \lim_{n\to\infty}\left[\int_{E_n} g\,dV\right] = \int_U f\,dV + \int_U g\,dV\ .$$

If $\alpha \ge 0$, then αf is nonnegative, and for each n

$$\int_{E_n}\alpha f\,dV = \alpha\int_{E_n} f\,dV \le \alpha\int_U f\,dV$$

so αf is extended Riemann integrable on U, and

$$\int_U \alpha f\,dV = \lim_{n\to\infty}\left[\int_{E_n}\alpha f\,dV\right] = \lim_{n\to\infty}\left[\alpha\int_{E_n} f\,dV\right] = \alpha\lim_{n\to\infty}\left[\int_{E_n} f\,dV\right] = \alpha\int_U f\,dV\ .$$

For (i), if f is extended Riemann integrable on U, then by definition f_+ and f_- are extended Riemann integrable on U, hence so is $|f| = f_+ + f_-$. Conversely, if $|f|$ is extended Riemann integrable on U, then so are f_+ and f_- since $0 \le f_+, f_- \le |f|$ ($f_+ = \frac{|f|+f}{2}$ and $f_- = \frac{|f|-f}{2}$ are Riemann integrable over each E_n).

To finish (ii), if f and g are extended Riemann integrable on U, so is $|f|+|g|$, and hence so is $|f+g|$ since $|f+g| \le |f|+|g|$ (obviously $|f+g|$ is Riemann integrable on each E_n). We then have

$$\int_U (f+g)\,dV = \lim_{n\to\infty} \int_{E_n} (f+g)\,dV = \lim_{n\to\infty} \left[\int_{E_n} f\,dV + \int_{E_n} g\,dV \right]$$

$$= \lim_{n\to\infty} \left[\int_{E_n} f\,dV \right] + \lim_{n\to\infty} \left[\int_{E_n} g\,dV \right] = \int_U f\,dV + \int_U g\,dV$$

as before. For scalar multiples, there is a slight subtlety. If $\alpha \ge 0$, we have $(\alpha f)_+ = \alpha f_+$ and $(\alpha f)_- = \alpha f_-$ and

$$\int_U \alpha f\,dV = \int_U (\alpha f)_+\,dV - \int_U (\alpha f)_-\,dV = \int_U \alpha f_+\,dV - \int_U \alpha f_-\,dV = \alpha \left[\int_U f_+\,dV - \int_U f_-\,dV \right] = \alpha \int_U f\,dV\,.$$

But if $\alpha < 0$, we have $(\alpha f)_+ = |\alpha| f_-$ and $(\alpha f)_- = |\alpha| f_+$, so

$$\int_U \alpha f\,dV = \int_U (\alpha f)_+\,dV - \int_U (\alpha f)_-\,dV = \int_U |\alpha| f_-\,dV - \int_U |\alpha| f_+\,dV$$

$$= |\alpha| \left[\int_U f_-\,dV - \int_U f_+\,dV \right] = -|\alpha| \int_U f\,dV = \alpha \int_U f\,dV\,.$$

Some other properties of the extended Riemann integral:

IX.3.11.10. PROPOSITION. Let U and W be open sets in $\mathbb{R}^p$, with $U \subseteq W$. If $f : W \to \mathbb{R}$ is extended Riemann integrable on W, then $f|_U$ is extended Riemann integrable on U. If f is additionally nonnegative on W, then

$$0 \le \int_U f\,dV \le \int_W f\,dV\,.$$

PROOF: Suppose f is nonnegative and extended Riemann integrable on W. If K is a compact Jordan region contained in U, then $K \subseteq W$, so f is Riemann integrable over K and $0 \le \int_K f\,dV \le \int_W f\,dV$. Thus the supremum of $\int_K f\,dV$ over all such K is finite and $\le \int_W f\,dV$, so f is extended Riemann integrable over U and $0 \le \int_U f\,dV \le \int_W f\,dV$. The case of general f now follows by applying this to f_+ and f_-.

IX.3.11.11. PROPOSITION. Let U and W be open sets in $\mathbb{R}^p$, and $f : U \cup W \to \mathbb{R}$. Then f is extended Riemann integrable on $U \cup W$ if and only if f is extended Riemann integrable on both U and W. If this is the case, f is automatically extended Riemann integrable on $U \cap W$ (where we make the convention that every function is integrable over $\emptyset$, with zero integral), and

$$\int_{U\cup W} f\,dV = \int_U f\,dV + \int_W f\,dV - \int_{U\cap W} f\,dV\,.$$

PROOF: If f is extended Riemann integrable on $U \cup W$, then it is extended Riemann integrable on U and W by IX.3.11.10.. So suppose f is extended Riemann integrable on U and W. Then f is extended Riemann integrable on $U \cap W$ by IX.3.11.10..

Let (E_n) and (E'_n) be generating sequences for U and W respectively. We claim that $(E_n \cup E'_n)$ and $(E_n \cap E'_n)$ are generating sequences for $U \cup V$ and $U \cap V$ respectively. $E_n \cup E'_n$ and $E_n \cap E'_n$ are compact Jordan regions (conventionally calling $\emptyset$ a compact Jordan region) by IX.3.2.25.. We have

$$E_n \cup E'_n \subseteq E^o_{n+1} \cup {E'}^o_{n+1} \subseteq (E_{n+1} \cup E'_{n+1})^o$$

$$E_n \cap E'_n \subseteq E^o_{n+1} \cap {E'}^o_{n+1} \subseteq (E_{n+1} \cap E'_{n+1})^o \ .$$

We clearly have $\cup_{n=1}^{\infty}(E_n \cup E'_n) = U \cup W$. If $\boldsymbol{x} \in U \cap W$, then $\boldsymbol{x} \in E_{n_1}$ and $\boldsymbol{x} \in E_{n_2}$ for some n_1, n_2. If $n = \max(n_1, n_2)$, then $\boldsymbol{x} \in E_n \cap E'_n$. Thus $\cup_{n=1}^{\infty}(E_n \cap E'_n) = U \cap W$.

For each n, we have that f is Riemann integrable on E_n and on E'_n, hence also on $E_n \cup E'_n$ and $E_n \cap E'_n$ by (), and

$$\int_{E_n \cup E'_n} f\,dV = \int_{E_n} f\,dV + \int_{E'_n} f\,dV - \int_{E_n \cap E'_n} f\,dV$$

for each n. The formula now follows by taking the limit as $n \to \infty$. 👍

The next result extends IX.3.11.5.(ii) and is a version of the Monotone Convergence Theorem.

IX.3.11.12. PROPOSITION. Let (U_n) be an increasing sequence of open sets in $\mathbb{R}^p$, and $U = \cup_{n=1}^{\infty} U_n$. If $f : U \to \mathbb{R}$ is nonnegative, then f is extended Riemann integrable on U if and only if f is extended Riemann integrable on each U_n and $\sup_n \left[\int_{U_n} f\,dV\right] < \infty$. In this case,

$$\int_U f\,dV = \sup_n \int_{U_n} f\,dV \ .$$

PROOF: If f is extended Riemann integrable on U, it is extended Riemann integrable on each U_n by IX.3.11.10., and $\int_{U_n} f\,dV \leq \int_U f\,dV$ for all n.

Conversely, suppose f is extended Riemann integrable on each U_n. Let K be a compact Jordan region in U. Since the U_n give an open cover for K which has a finite subcover, and the U_n are increasing, we have $K \subseteq U_n$ for some n, and thus f is Riemann integrable over K, and

$$\int_K f\,dV \leq \int_{U_n} f\,dV \ .$$

If $M := \sup_n \left[\int_{U_n} f\,dV\right] < \infty$, we have that $\int_K f\,dV \leq M$ for every compact Jordan region $K \subseteq U$; thus by definition f is extended Riemann integrable on U and $\int_U f\,dV \leq M$. Since the other inequality was observed at the beginning of the proof, the proof is complete. 👍

IX.3.11.13. COROLLARY. Let (U_n) be an increasing sequence of open sets in $\mathbb{R}^p$, and $U = \cup_{n=1}^{\infty} U_n$. If $f : U \to \mathbb{R}$ is extended Riemann integrable on U, then f is extended Riemann integrable on each U_n, and

$$\int_U f\, dV = \lim_{n\to\infty} \int_{U_n} f\, dV \ .$$

PROOF: Apply the proposition to f_+ and f_- and replace the supremum by limit. 👍

Properties of Extended Riemann Integrable Functions

IX.3.11.14. We have so far not used (or needed to use) Theorem () characterizing Riemann integrable functions. But this result gives a better picture of extended Riemann integrable functions, although there is not such a clean characterization.

IX.3.11.15. PROPOSITION. Let U be an open set in $\mathbb{R}^p$, and let f be an extended Riemann integrable function on U. Then f is continuous almost everywhere on U.

PROOF: Let (E_n) be a generating sequence for U. Since f is Riemann integrable on E_n, by () f is continuous on E_n except on a subset A_n of measure zero. Since $E_n \subseteq E_{n+1}^o$ for all n, it follows that f is continuous on U except on the set $\cup_{n=1}^{\infty} A_n$, which is a set of measure zero (). 👍

IX.3.11.16. Simply being continuous a.e. is not enough for a function to be extended Riemann integrable on U: although it does not need to be bounded on U, it at least has to be bounded on each compact Jordan region in U (this is automatic if the function is continuous on U, but not if it is only continuous a.e.) There is a cleaner way of expressing this:

IX.3.11.17. DEFINITION. Let U be an open set in $\mathbb{R}^p$, and $f : U \to \mathbb{R}$. Then f is *locally bounded* on U if for every $\boldsymbol{x} \in U$ there is an open ball $B_{\boldsymbol{x}}$ centered at $\boldsymbol{x}$, contained in U, on which f is bounded.

IX.3.11.18. Note that if f is either bounded or continuous on U, then it is locally bounded on U.

IX.3.11.19. PROPOSITION. Let U be an open set in $\mathbb{R}^p$, and $f : U \to \mathbb{R}$. Then f is bounded on every compact subset of U if and only if it is locally bounded on U.

PROOF: This is a compactness/local compactness argument. If f is bounded on every compact subset of U, and $\boldsymbol{x} \in U$, then there is an open ball B centered at $\boldsymbol{x}$ with $\bar{B} \subseteq U$. Since $\bar{B}$ is compact, f is bounded on B. Thus f is locally bounded on U. Conversely, if f is locally bounded on U and $K \subseteq U$ is compact, for each $\boldsymbol{x} \in K$ there is an open ball $B_{\boldsymbol{x}}$ centered at $\boldsymbol{x}$, contained in U, and a constant $M_{\boldsymbol{x}}$ such that $|f| \leq M_{\boldsymbol{x}}$ on $B_{\boldsymbol{x}}$. The $B_{\boldsymbol{x}}$ form an open cover of K which has a finite subcover $\{B_{\boldsymbol{x}_1}, \ldots, B_{\boldsymbol{x}_n}\}$. If $M = \max(M_{\boldsymbol{x}_1}, \ldots, M_{\boldsymbol{x}_n})$, then $|f| \leq M$ on K. 👍

IX.3.11.20. Corollary. Let U be an open set in $\mathbb{R}^p$, and $f : U \to \mathbb{R}$. Then f is Riemann integrable over every compact Jordan region in U if and only if f is continuous a.e. and locally bounded on U.

IX.3.11.21. Thus if f is extended Riemann integrable on U, then it is continuous a.e. and locally bounded on U. The converse is not quite true: the Riemann integrals of $|f|$ over compact Jordan regions in U also have to be uniformly bounded.

The Extended Integral vs. the Ordinary Integral

IX.3.11.22. If U is an open set which is also a Jordan region, we have defined two integrals over U: the (ordinary) Riemann integral and the extended Riemann integral. They are not the same: only bounded functions are Riemann integrable, but extended Riemann integrable functions can be unbounded (IX.3.11.8.(ii); in fact, for any nonempty U there are unbounded extended Riemann integrable functions on U). And even if f is both Riemann integrable and extended Riemann integrable on U, it is not obvious the two integrals have the same value. We will (temporarily) write $(R)\int_U f\,dV$ and $(E)\int_U f\,dV$ for the two integrals when defined.

IX.3.11.23. Theorem. Let U be an open Jordan region in $\mathbb{R}^p$, and $f : U \to \mathbb{R}$. Then f is Riemann integrable on U if and only if it is bounded on U and extended Riemann integrable on U. If this is the case, the two integrals of f over U are equal.

Proof: First suppose f is nonnegative. If f is Riemann integrable on U, then it is bounded, and Riemann integrable on any compact Jordan region $K \subseteq U$, with

$$(R)\int_K f\,dV \le (R)\int_U f\,dV$$

by IX.3.3.4.; thus f is extended Riemann integrable on U, and

$$(E)\int_U f\,dV \le (R)\int_U f\,dV\ .$$

Conversely, if f is bounded and extended Riemann integrable on U, then it is continuous a.e. on U (IX.3.11.15.), and hence Riemann integrable on U by IX.3.10.8..

It only remains to show (for nonnegative f) that if f is Riemann integrable on U, then $(R)\int_U f\,dV \le (E)\int_U f\,dV$. Let R be a rectangle containing U, and $\mathcal{P}$ a partition of R. Let $R_1, \dots, R_n$ be the rectangles in $\mathcal{P}$ contained in U, and $K = R_1 \cup \cdots \cup R_n$. Then K is a compact Jordan region contained in U. If m_j is the infimum of f on R_j, then we have

$$\underline{\mathcal{S}}(f\chi_U, \mathcal{P}) = \sum_{j=1}^{n} m_j V(R_j) \le (R)\int_K f\,dV \le (E)\int_U f\,dV$$

and the inequality follows by taking the supremum over all $\mathcal{P}$.

For general f, apply the above to f_+ and f_-. 👍

IX.3.12. Exercises

IX.3.12.1. Use the continuous version of Fubini's Theorem (IX.3.4.7.; IX.3.5.2. suffices) to prove the following version of the equality of mixed partials VIII.2.2.4. (compare with VIII.2.2.8.):

THEOREM. Let U be an open set in $\mathbb{R}^2$, and $f : U \to \mathbb{R}$ a function such that $\dfrac{\partial^2 f}{\partial x\,\partial y}$ and $\dfrac{\partial^2 f}{\partial y\,\partial x}$ exist and are continuous on U. Then $\dfrac{\partial^2 f}{\partial x\,\partial y} = \dfrac{\partial^2 f}{\partial y\,\partial x}$ on U.

(a) Show using the Fundamental Theorem of Calculus that if $R = [a,b] \times [c,d] \subseteq U$, then

$$\int_a^b \int_c^d \frac{\partial^2 f}{\partial y\,\partial x}(x,y)\,dy\,dx = \int_c^d \int_a^b \frac{\partial^2 f}{\partial x\,\partial y}(x,y)\,dx\,dy \ .$$

(b) If there is an $(x_0,y_0) \in U$ with $\frac{\partial^2 f}{\partial y\,\partial x}(x_0,y_0) > \frac{\partial^2 f}{\partial x\,\partial y}(x_0,y_0)$, then there is a rectangle R around (x_0,y_0) contained in U such that $\frac{\partial^2 f}{\partial y\,\partial x} - \frac{\partial^2 f}{\partial x\,\partial y} > 0$ on R, and hence

$$\int_R \left[\frac{\partial^2 f}{\partial y\,\partial x} - \frac{\partial^2 f}{\partial x\,\partial y}\right] dV > 0 \ .$$

Draw a similar conclusion if there is an $(x_0,y_0) \in U$ with $\frac{\partial^2 f}{\partial y\,\partial x}(x_0,y_0) < \frac{\partial^2 f}{\partial x\,\partial y}(x_0,y_0)$.

(c) Use Fubini's Theorem to obtain a contradiction from (a) and (b).

(d) Extend to functions of several variables and higher-order mixed partials.

IX.3.12.2. Explain why Theorem IX.3.1.26. is not an immediate corollary of Proposition IX.3.1.16.. Identify what else in addition to IX.3.1.16. is needed, and prove it.

IX.3.12.3. Let A be a Jordan region in $\mathbb{R}^n$, and $f : A \to \mathbb{R}$ a nonnegative continuous function. Let

$$B = \{(\boldsymbol{x}, y) : \boldsymbol{x} \in A, 0 \le y \le f(\boldsymbol{x})\} \subseteq \mathbb{R}^{n+1} \ .$$

Show that B is a Jordan region in $\mathbb{R}^{n+1}$, and that

$$V_{n+1}(B) = \int_A f\,dV_n \ .$$

IX.3.12.4. Let E be the subset of $R = [0,1]^2 \subseteq \mathbb{R}^2$ consisting of the points on the x-axis and, for each rational $x = \frac{p}{q}$ in lowest terms, the points in a Cantor set of positive measure () on the vertical segment

$$\left\{(x,y) : 0 \le y \le \frac{1}{q}\right\} \ .$$

(i) Show that E is a closed set of measure 0, hence of content 0.

(ii) Show that $f = \chi_E$ is Riemann integrable over R, but that $f_{[x]}$ is not Riemann integrable on $[0,1]$ if x is rational.

(iii) Modify this example to one for which $f^{[y]}$ is also not Riemann integrable for y rational.

IX.3.12.5. Evaluate

$$\int_0^1 \int_x^1 e^{-y^2}\, dy\, dx$$

by applying Fubini's Theorem to interchange the order of integration.

IX.3.12.6. Give the details of the proof of Theorem IX.3.4.14..

IX.3.12.7. (a) Prove IX.3.5.10..
(b) Generalize to the case where S is replaced by an arbitrary Jordan region in $\mathbb{R}^q$ (cf. IX.3.4.14.).

IX.4. The Jacobian and Change of Variable

The literature is somewhat inconsistent about the definition of the Jacobian of a differentiable function, and the notation for it (cf. IX.4.2.7.). We will take a fairly general path and use a version of the definition and notation which seems to encapsulate the most information.

IX.4.1. Inner Products on Exterior Powers

In this section, we will mostly consider only finite-dimensional vector spaces over $\mathbb{R}$, although some of the theory works in greater generality.

There are at least two natural ways to define an induced inner product on exterior powers of an inner product space. They are not too different: they are just scalar multiples of each other. We begin with perhaps the most useful one, which has the best geometric interpretation.

IX.4.1.1. Let $(V, \langle\cdot,\cdot\rangle)$ be a (real) inner product space. The inner product defines an isometric linear map $\phi : V \to V^*$ by $[\phi(v)](w) = \langle v, w\rangle$ (). Then ϕ extends to an injective graded algebra-homomorphism $\bigwedge \phi$ from $\bigwedge(V)$ to $\bigwedge(V^*)$: $\bigwedge \phi = \bigoplus_k \bigwedge^k \phi$, where $\bigwedge^k \phi$ is an injective linear map from $\bigwedge^k(V)$ to $\bigwedge^k(V^*)$. Identifying $\bigwedge^k(V^*)$ with a subspace of $(\bigwedge^k(V))^*$ (), we get an induced map $\psi_k : \bigwedge^k(V) \to (\bigwedge^k(V))^*$. (If V is finite-dimensional, then all these maps are isomorphisms.)

IX.4.1.2. Now define a map $\bigwedge^k(V) \times \bigwedge^k(V) \to \mathbb{R}$ by

$$\langle x, y\rangle = [\psi_k(x)](y)$$

for $x, y \in \bigwedge^k(V)$.

IX.4.1.3. Proposition. The map $\langle\cdot,\cdot\rangle_k$ is well defined and an inner product on $\bigwedge^k(V)$.

This inner product has a much more concrete description if V is finite-dimensional. Let $\{v_1, \ldots, v_n\}$ be an ordered orthonormal basis for V. For each strictly increasing k-multiindex $I = (i_1, \ldots, i_k)$, set $v_I = v_{i_1} \wedge \cdots \wedge v_{i_k} \in \bigwedge^k(V)$.

IX.4.1.4. Proposition. The set $B = \{v_I\}$, where I runs over all strictly increasing k-multiindices, is an orthonormal basis for $\bigwedge^k(V)$ (with respect to the inner product $\langle\cdot,\cdot\rangle_k$).

Proof: B is a basis for $\bigwedge^k(V)$ (). We show that B is an orthonormal set (showing again that it is a basis by dimension counting). 👍

IX.4.1.5. Example. Suppose $k = n$ in the above situation. Then $\bigwedge^n(V)$ is one-dimensional, spanned by $v_1 \wedge \cdots \wedge v_n$, which is a unit vector. The inner product on $\bigwedge^n(V) \cong \mathbb{R}$ is the usual one from the identification of $v_1 \wedge \cdots \wedge v_n$ with 1.

Another Inner Product

Although the above inner product is a nice one, and the one we will use in the sequel, there is another inner product which comes from the subspace construction of the exterior power.

IX.4.1.6. Let V be a real inner product space. Then $\mathcal{T}^k(V)$ has a natural induced inner product (), and $\bigwedge^k(V) \cong \mathcal{A}^k(V)$ is a subspace, so the inner product on $\mathcal{T}^k(V)$ restricts to an inner product on $\mathcal{A}^k(V)$ we denote by $(\cdot,\cdot)_k$. (This definition works even if V is not finite-dimensional, but we will restrict to the finite-dimensional case.)

IX.4.1.7. PROPOSITION. Let $\{v_1,\dots,v_n\}$ be an orthonormal basis in V. Let $k \leq n$, and if $I = (i_1,\dots,i_k)$ is a strictly increasing k-multiindex, let $v_I = v_{i_1} \wedge \cdots \wedge v_{i_k}$. Then, if I and J are strictly increasing k-multiindices, we have

$$(v_I, v_J)_k = \begin{cases} \frac{1}{k!} & \text{if} \quad I = J \\ \\ 0 & \text{if} \quad I \neq J \end{cases} .$$

PROOF: We have

$$v_I = \frac{1}{k!} \sum_{\sigma \in S_k} v_{\sigma(i_1)} \otimes \cdots \otimes V_{\sigma(i_k)}$$

and similarly for v_j, so

$$(v_I, v_J)_k = \frac{1}{(k!)^2} \sum_{\sigma \in S_k} \sum_{\tau \in S_k} sign(\sigma) sign(\tau) \langle v_{i_{\sigma(1)}}, v_{i_{\tau(1)}} \rangle \cdots \langle v_{i_{\sigma(k)}}, v_{i_{\tau(k)}} \rangle \ .$$

If $I \neq J$, there is a $j \in J \setminus I$, so every term will have a factor which is the inner product of one of the v_i with v_j, so $(v_I, v_J) = 0$.
If $I = J$, any term with $\tau \neq \sigma$ will have a factor of $\langle v_{i_{\sigma(m)}}, v_{i_{\tau(m)}} \rangle$ for an m with $\sigma(m) \neq \tau(m)$, so only the terms with $\sigma = \tau$ are nonzero. Each of these is 1, and there are $k!$ of these terms. 👍

Thus, since the v_I are an orthonormal basis for $\bigwedge^k(V)$ for $\langle \cdot,\cdot \rangle_k$, we obtain:

IX.4.1.8. PROPOSITION. If V is a finite-dimensional (real) inner product space, then for each k we have $(\cdot,\cdot)_k = \frac{1}{k!}\langle \cdot,\cdot \rangle_k$ on $\bigwedge^k(V)$.

IX.4.1.9. Thus if $\| \cdot \|_\otimes$ denotes the norm on $\bigwedge^k(V)$ from $(\cdot,\cdot)_k$, and $\| \cdot \|$ the ordinary norm from $\langle \cdot,\cdot \rangle_k$, we have

$$\| \cdot \|_\otimes = \frac{1}{\sqrt{k!}} \| \cdot \| \ .$$

To see where the factor of $\sqrt{k!}$ comes from, note that if $\{v_1,\dots,v_m\}$ are orthogonal unit vectors in an inner product space, then

$$\|v_1 + \cdots + v_m\| = \sqrt{m} \ .$$

IX.4.1.10. This suggests that in the identification of $\bigwedge^k(V)$ with $\mathcal{A}^k(V)$ in (), if $\mathbb{F} = \mathbb{R}$ we should use the map $\sqrt{k!}A_k$ instead of A_k, i.e.

$$v_1 \wedge \cdot \wedge v_k \mapsto \frac{1}{\sqrt{k!}} \sum_{\sigma \in S_k} v_{\sigma(1)} \otimes \cdots \otimes v_{\sigma(k)}$$

and thus a different normalization of the wedge product than the two standard ones (one "halfway between"), cf. III.11.19.13.. This of course is special to the case $\mathbb{F} = \mathbb{R}$ and does not even make sense for a general field $\mathbb{F}$.

Adjoints

IX.4.1.11. Let V and W be finite-dimensional (real) inner product spaces. If $T \in \mathcal{L}(V, W)$, then T has an adjoint $T^* \in \mathcal{L}(W, V)$. For each k, $\bigwedge^k T$ has an adjoint $(\bigwedge^k T)^* \in \mathcal{L}(\bigwedge^k(W), \bigwedge^k(V))$. T^* also induces linear maps $\bigwedge^k(T^*) \in \mathcal{L}(\bigwedge^k(W), \bigwedge^k(V))$ for each k.

IX.4.1.12. Proposition. If $T \in \mathcal{L}(V, W)$, then $(\bigwedge^k T)^* = \bigwedge^k(T^*)$ for each k.

IX.4.1.13. As a special case (using III.11.17.44.), if T is orthogonal (an isometric bijection), so is $\bigwedge^k T$ for every k.

IX.4.2. The Jacobian(s) of a Linear Transformation

IX.4.2.1. Let V and W be finite-dimensional real inner product spaces, and $T : V \to W$ a linear transformation. Then for each k we have an induced linear transformation $\bigwedge^k T : \bigwedge^k(V) \to \bigwedge^k(W)$. If $dim(V) = n$ and $dim(W) = m$, then $\bigwedge^k T = 0$ for $k > \min(n, m)$, so this is only interesting for $k \leq \min(n, m)$. The most important case is when $k = \min(n, m)$; the case $k < \min(n, m)$ is rarely used even in geometric measure theory.

IX.4.2.2. Definition. The *k-Jacobian* of T is $J^k_T = \| \bigwedge^k T \|$ (operator norm with respect to the induced inner products).

IX.4.2.3. Actually, the inner products $(\cdot, \cdot)_k$ can be used on $\bigwedge^k(V)$ and $\bigwedge^k(W)$ to evaluate J^k_T, since they each differ from $\langle \cdot, \cdot \rangle_k$ by the same factor $k!$. But the geometric interpretation using $(\cdot, \cdot)_k$ is not as nice.

Here is a key example:

IX.4.2.4. Example. Suppose $k = m = n$. Then $\bigwedge^n(V)$ and $\bigwedge^n(W)$ are one-dimensional inner product spaces and can be identified with $\mathbb{R}$ by choosing a unit vector in each. Then $\bigwedge^n T$ is multiplication by a scalar λ. The sign of λ depends on the choices of the unit vectors, but $|\lambda| = \| \bigwedge^n T \| = J^n_T$ is well determined. To evaluate $|\lambda|$, fix ordered orthonormal bases $\{v_1, \ldots, v_n\}$ of V and $\{w_1, \ldots, w_n\}$ of W; then T has an $n \times n$ matrix $A = [T]$ with respect to these ordered bases. Then, if the unit vectors are chosen to be $v_1 \wedge \cdots \wedge v_n$

and $w_1 \wedge \cdots \wedge w_n$ respectively, $\lambda = det(A)$ (), and thus $J_T^n = |det(A)|$. (To see directly that this does not depend on the choice of the ordered orthonormal bases, choosing different ordered orthonormal bases amounts to pre- and/or postmultiplying A by orthogonal matrices, which does not change the determinant except possibly for sign since the determinant of an orthogonal matrix is ± 1.)

The Signed Jacobian

IX.4.2.5. We now specialize to the case $V = \mathbb{R}^n$ and $W = \mathbb{R}^m$ (this is not a real restriction, since it essentially just amounts to fixing ordered orthonormal bases for V and W.) Then T has a matrix $A = [T]$ (with respect to the standard bases), and if $m = n$ $J_T^n = |det(A)|$. But $det(A)$ carries more information than $|det(A)|$: the sign of $det(A)$ (if nonzero) indicates whether T is orientation-preserving or orientation-reversing.

IX.4.2.6. DEFINITION. Let $T \in \mathcal{L}(\mathbb{R}^n)$. The *(signed) Jacobian* of T is $J_T = det(T) = det(A)$.

IX.4.2.7. The notation may be slightly confusing: $J_T^n = |J_T|$, not J_T. Some authors define the Jacobian of T to be J_T and others $|J_T|$. Others call A the "Jacobian matrix" of T and J_T (or $|J_T|$) the "Jacobian determinant" of T. Various notations for the Jacobian (however defined) are also used. We have chosen definitions and notation which seem to retain the most information.

IX.4.2.8. The difference between J_T and $J_T^n = |J_T|$ (in the case $n = m$) is closely related to the difference between oriented and unoriented integration (the factor J_T or $|J_T|$ appears in change-of-variables formulas). In geometric measure theory, there are usually no natural orientations, and unoriented integration is frequently used; but integration of differential forms uses oriented integration. In the case where k, m, n are not all equal (mostly just used in geometric measure theory), there are no natural orientations, so there is no natural signed version of J_T^k.

Geometric Interpretation

IX.4.2.9. First consider the case $k = n = m$. By IX.4.2.4., J_T^n is the factor by which volumes are multiplied by under T (). Specifically, if $\{v_1, \ldots, v_n\}$ is an orthonormal basis for V, then $[\bigwedge^n T](v_1 \wedge \cdots \wedge v_n)$ is the volume of the parallelepiped in W with edges $Tv_1, \ldots, Tv_n$. [To see that all volumes are multiplied by a common factor, note that if T is invertible, i.e. $J_T^n > 0$, then T sends Lebesgue measurable sets in $V \cong \mathbb{R}^n$ to Lebesgue measurable sets in W (also identified with $\mathbb{R}^n$ via an orthonormal basis), and we may define a measure μ on $\mathbb{R}^n$ by $\mu(E) = \lambda(T(E))$. Then μ is a translation-invariant measure on $\mathbb{R}^n$ and hence a scalar multiple of Lebesgue measure.]

IX.4.2.10. Now consider the general case where $k \leq \min(n, m)$. Let X be a k-dimensional subspace of V, and Y a k-dimensional subspace of Y containing $T(X)$ ($Y = T(X)$ if T is one-to-one on X). Let S be the restriction of T to X, regarded as an element of $\mathcal{L}(X, Y)$. The embedding of X into V extends to an injective algebra-homomorphism of $\bigwedge X$ into $\bigwedge(V)$ which is isometric on each summand (), and similarly for the embedding of Y into W. Thus, if $\{v_1, \ldots, v_k\}$ is an orthonormal basis for X, then $\|[\bigwedge^k T](v_1 \wedge \cdots \wedge v_k)\|$ is the k-volume of the parallelepiped in W with edges $Tv_1, \ldots, Tv_k$, and is the factor by which k-volumes of general (measurable) sets in X are multiplied by under T. This factor may vary for different X's; we will show that J_T^k is the maximum (supremum) of these factors over all X.

IX.4.2.11. Suppose $V = W$ and T is positive (). Then all eigenvalues of T are nonnegative, and T is diagonalizable (), i.e. there is an ordered orthonormal basis $\{v_1, \ldots, v_n\}$ for V consisting of eigenvectors of T with eigenvalues $\lambda_i \geq 0$ which we may assume are in decreasing (nonincreasing) order. Then the vectors v_I for strictly increasing I form an orthonormal basis for $\bigwedge^k(V)$, and each is an eigenvector for $\bigwedge T$: if $I = (i_1, \ldots, i_k)$, then v_I is an eigenvector with eigenvalue $\lambda_{i_1} \cdots \lambda_{i_k}$. Thus $\bigwedge^k T$ is positive and diagonalized by the v_I, so $\| \bigwedge^k T\|$ is the largest eigenvalue, $\lambda_1 \cdots \lambda_k$, which is $\|[\bigwedge^k T](v_1 \wedge \cdots \wedge v_k)\|$.

IX.4.2.12. For general T, we can apply this argument to T^*T, since by IX.4.1.12. and III.11.17.44.

$$\| \bigwedge^k T\|^2 = \|(\bigwedge^k T)^*(\bigwedge^k T)\| = \|(\bigwedge^k T^*)(\bigwedge^k T)\| = \| \bigwedge^k (T^*T)\|$$

and so

$$\| \bigwedge^k T\| = \sqrt{\lambda_1 \cdots \lambda_k} = \|[\bigwedge^k T](v_1 \wedge \cdots \wedge v_k)\|$$

where $(\lambda_1, \ldots, \lambda_n)$ are the eigenvalues of T^*T in nonincreasing order and $\{v_1, \ldots, v_n\}$ a corresponding orthonormal basis of eigenvectors as above, i.e. J_T^k is the square root of the product of the k largest eigenvalues of T^*T. Geometrically, it is the largest k-volume of a parallelepiped with edges $Tw_1, \ldots, Tw_k$, for $w_1, \ldots, w_k$ an orthonormal set in V of size k.

IX.4.2.13. This argument does not work for a general linear transformation from $\bigwedge^k(V)$ to $\bigwedge^k(W)$ since there are many unit vectors in $\bigwedge^k(V)$ which are not simple. But operators of the form $\bigwedge^k T$ for $T \in \mathcal{L}(V, W)$ are special. Note that the linear map $T \mapsto \bigwedge^k T$ from $\mathcal{L}(V, W)$ to $\mathcal{L}(\bigwedge^k(V), \bigwedge^k(W))$ has small range in general since $dim(\mathcal{L}(\bigwedge^k(V), \bigwedge^k(W)))$ is typically much larger than $dim(\mathcal{L}(V, W))$, e.g. if k is near $n/2$.

Evaluating Jacobians

Now let $V = \mathbb{R}^n$ and $W = \mathbb{R}^m$ for convenience, so we have the standard ordered orthonormal bases. Then T is multiplication by an $m \times n$ matrix A.

IX.4.2.14. If $k \leq \min(n, m)$, then by the above we have that J_T^k is the square root of the product of the k largest eigenvalues of A^tA. In the case $k < \min(n, m)$, there may be no better systematic way to compute J_T^k: even if $k = 1$, where $J_T^1 = \|T\|$, there is no formula in terms of the entries of A (XX.12.6.6.).

IX.4.2.15. If $k = n \leq m$, though, J_T^n is just the square root of $det(A^tA)$, which is nothing but $|det(A)|$, giving a simpler formula.

IX.4.2.16. There is another formula in the case $k = n \leq m$. To motivate it, consider the case $k = n = 1 < m$. The matrix A is a column vector $\boldsymbol{w}$, and $J_T^1 = \|T\| = \|\boldsymbol{w}\|$, so $(J_T^1)^2$ is the sum of the squares of the entries in A.

Now suppose $k = n < m$. $\bigwedge^n(\mathbb{R}^n)$ is one-dimensional, spanned by the unit vector $\boldsymbol{e}_1^{(n)} \wedge \cdots \wedge \boldsymbol{e}_n^{(n)}$; the image is a one-dimensional subspace of $\bigwedge^n(\mathbb{R}^m)$, spanned by the vector $\boldsymbol{y} = (T\boldsymbol{e}_1^{(n)}) \wedge \cdots \wedge (T\boldsymbol{e}_n^{(n)})$, and $J_T^n = \|\boldsymbol{y}\|$. The vectors $\boldsymbol{e}_I^{(m)}$, where I ranges over strictly increasing n-multiindices for $\mathbb{R}^m$, form an orthonormal basis for $\bigwedge^n(\mathbb{R}^m)$, so $\|\boldsymbol{y}\|^2$ is the sum of the squares of the coefficients.

If $I = (i_1, \ldots, i_m)$, then the coefficient α_I of $\boldsymbol{y}$ with respect to $\boldsymbol{e}_I^{(m)}$ is the projection $Q_I\boldsymbol{y}$, where Q_I is the one-dimensional projection of $\bigwedge^n(\mathbb{R}^m)$ onto the span of $\boldsymbol{e}_I^{(m)}$, identified with $\mathbb{R}$. Then $Q_I = \bigwedge^n P_I$,

where P_I is the projection of $\mathbb{R}^m$ onto the span of $\{\boldsymbol{e}_{i_1}^{(m)}, \ldots, \boldsymbol{e}_{i_n}^{(m)}\} \cong \mathbb{R}^n$. Thus this coefficient is $J_{T_I}^n$, where $T_I = P_I T$ regarded as an element of $\mathcal{L}(\mathbb{R}^n)$. The matrix A_I of T_I consists of the columns of A corresponding to I, so the coefficient is the determinant of A_I. We thus have:

IX.4.2.17. PROPOSITION. Let $n \leq m$, and $T \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ with matrix A. Then $(J_T^n)^2$ is the sum of the squares of the determinants of the $n \times n$ minors of A.

IX.4.2.18. In the case $k = m < n$, we may apply the above arguments to T^*, since $J_T^m = J_{T^*}^m$, to obtain that J_T^m is $det(AA^t)$ and is also the square root of the sum of the squares of the determinants of the $m \times m$ minors of A.

IX.4.3. The Jacobian(s) of a Differentiable Function

In this section, we work exclusively in the case $V = \mathbb{R}^n$, $W = \mathbb{R}^m$, mainly for convenience. We will extend the various notions of Jacobian from linear functions to general differentiable functions.

IX.4.3.1. DEFINITION. Let U be an open set in $\mathbb{R}^n$, $\boldsymbol{f} : U \to \mathbb{R}^m$ a function, and $\boldsymbol{a} \in U$. If $\boldsymbol{f}$ is differentiable at $\boldsymbol{a}$, then for each k we define

$$J_{\boldsymbol{f}}^k(\boldsymbol{a}) = J_{d\boldsymbol{f}(\boldsymbol{a})}^k$$

and, if $n = m$,

$$J_{\boldsymbol{f}}(\boldsymbol{a}) = J_{d\boldsymbol{f}(\boldsymbol{a})} = det(D\boldsymbol{f}(\boldsymbol{a})) \ .$$

IX.4.3.2. If $T : \mathbb{R}^n \to \mathbb{R}^m$ is linear, then T is differentiable at each $\boldsymbol{a}$ and dT is the constant function T; thus, for each $\boldsymbol{a}$, $J_T(\boldsymbol{a}) = J_T$ and $J_T^k(\boldsymbol{a}) = J_T^k$ for each k, so the notation is consistent.

We will call $J_{\boldsymbol{f}}^k(\boldsymbol{a})$ the *k-Jacobian of $\boldsymbol{f}$ at $\boldsymbol{a}$* and, if $n = m$, $J_{\boldsymbol{f}}(\boldsymbol{a})$ the *Jacobian of $\boldsymbol{f}$ at $\boldsymbol{a}$*. Some authors call $D\boldsymbol{f}(\boldsymbol{a})$ the "Jacobian matrix of $\boldsymbol{f}$ at $\boldsymbol{a}$" and (if $n = m$) $J_{\boldsymbol{f}}(\boldsymbol{a})$ (or $|J_{\boldsymbol{f}}(\boldsymbol{a})|$) the "Jacobian determinant of $\boldsymbol{f}$ at $\boldsymbol{a}$."

Geometric Interpretation

IX.4.3.3. If U is an open set in $\mathbb{R}^n$ and $\boldsymbol{f} : U \to \mathbb{R}^n$ is a $\mathcal{C}^1$ function, and $\boldsymbol{a} \in U$, then $|J_{\boldsymbol{f}}(\boldsymbol{a})|$ is the "local factor" by which volumes of "infinitesimally small" regions around $\boldsymbol{a}$ are multiplied by under $\boldsymbol{f}$ (the sign of $J_{\boldsymbol{f}}(\boldsymbol{a})$, if nonzero, indicates whether $\boldsymbol{f}$ is locally orientation-preserving or orientation-reversing at $\boldsymbol{a}$). More precisely, note that if E is a Jordan region whose closure is contained in U, then $f(E)$ is a Jordan region (), and we have:

IX.4.3.4. PROPOSITION.

$$|J_{\boldsymbol{f}}(\boldsymbol{a})| = \lim_{\epsilon \to 0} \frac{Vol(\boldsymbol{f}(B_\epsilon(\boldsymbol{a})))}{Vol(B_\epsilon(\boldsymbol{a}))}$$

where $B_\epsilon(\boldsymbol{a})$ is the open ball of radius ϵ around $\boldsymbol{a}$ (cubes could also be used). More generally, for any $\epsilon > 0$ there is a $\delta > 0$ such that, whenever E is a Jordan region containing $\boldsymbol{a}$ whose closure is contained in U and whose diameter is less than δ,

$$\Big| Vol(\boldsymbol{f}(E)) - |J_{\boldsymbol{f}}(\boldsymbol{a})| Vol(E) \Big| \leq \epsilon \, Vol(E) \ .$$

IX.4.3.5. Replacing "Volume" by n-dimensional Lebesgue measure and "Jordan region" by "Lebesgue measurable set," the statement remains true.

IX.4.4. Change of Variable

Chapter X

Differential Forms and Vector Analysis

"The real difficulty with forms is imagining what they are."

J. & B. Hubbard[1]

The subject of differential forms can at first be regarded as a way of explaining, justifying, and using Leibniz notation. But it becomes much more than that: by combining Leibniz notation with the formalism of exterior algebra and some elementary multivariable calculus, all of vector analysis, notably Stokes' Theorem (the Fundamental Theorem of Vector Calculus) in its various forms, can be efficiently and elegantly obtained, as well as some significant algebraic topology. And the theory can be nicely extended to smooth manifolds, greatly expanding its scope and usefulness; indeed, it is one of the bases for the subject of differential geometry. The thesis of [Spi65] is that, once the results of vector calculus are obtained (some of which are admittedly not easy), almost the entire difficulty of the theory of differential forms lies in making the proper definitions, developing good notation, and properly phrasing the results; the actual proofs are mostly quite easy.

One big advantage of the differential form approach to vector analysis is that it works essentially identically in any dimension. Vector analysis in dimensions two and three can be done without forms (and is in many references), and gives important theorems like Green's Theorem, the Divergence Theorem, and the classical Stokes' Theorem which are special to those dimensions. But these theorems must each be done separately in that approach. Using forms they are naturally all applications of the general Stokes' Theorem. And they do not have analogs in higher dimensions. Such subjects as electromagnetism and relativity in physics need vector analysis in four dimensions (and string theory needs it in multiple dimensions), which can only reasonably be done with the forms approach.

We will work only in the $\mathcal{C}^\infty$ setting, and for us *smooth* will mean $\mathcal{C}^\infty$. Much of the theory can be done with relaxed differentiability hypotheses, but the definitions and results then tend to be clumsy to state carefully, and the increased generality is of dubious practical benefit. Some authors rather imprecisely take "smooth" to mean "continuously differentiable as many times as necessary" (2 is often enough, sometimes even 1).

[1] [HH99, p. 516].

X.1. Vector Fields

X.1.1. The Tangent and Cotangent Bundle on $\mathbb{R}^n$

X.1.1.1. DEFINITION. Let U be an open set in $\mathbb{R}^n$. The *tangent bundle* of U is

$$TU = U \times \mathbb{R}^n \ .$$

The *cotangent bundle* of U is

$$T^*U = U \times (\mathbb{R}^n)^*$$

where $(\mathbb{R}^n)^*$ is the dual space to $\mathbb{R}^n$ (). Give TU and T^*U the product topology and the product smooth structure; then they are smooth $2n$-manifolds.

Since $(\mathbb{R}^n)^*$ is naturally isomorphic to $\mathbb{R}^n$ (), the tangent and cotangent bundles are also naturally isomorphic and are only notationally different. But it will be very convenient, even crucial, to distinguish between them.

The case $U = \mathbb{R}^n$ is especially important; $T\mathbb{R}^n \cong \mathbb{R}^{2n}$, but we must carefully distinguish the two copies of $\mathbb{R}^n$ and think of $T\mathbb{R}^n$ as $\mathbb{R}^n \times \mathbb{R}^n$, not $\mathbb{R}^{2n}$.

X.1.1.2. It may not be obvious why either of the words in the term "tangent bundle" is used. The "bundle" is used since the tangent (and cotangent) bundles are real vector bundles over U (trivial bundles in this case) in the sense of (). And the "tangent" and "cotangent" make sense if the more general context of () is considered. Note also that these terms have nothing to do with trigonometry.

X.1.1.3. There are continuous (smooth) projections $\pi : TU \to U$ and $\rho : TU \to \mathbb{R}^n$ with $\pi(\boldsymbol{p}, \boldsymbol{v}) = \boldsymbol{p}$, $\rho(\boldsymbol{p}, \boldsymbol{v}) = \boldsymbol{v}$. For $\boldsymbol{p} \in U$, set

$$T_{\boldsymbol{p}}U = \pi^{-1}(\{\boldsymbol{p}\}) = \{(\boldsymbol{p}, \boldsymbol{v}) : \boldsymbol{v} \in \mathbb{R}^n\} \cong \mathbb{R}^n \ .$$

$T_{\boldsymbol{p}}U$ is called the *tangent space* to U at $\boldsymbol{p}$. Similarly, there are projections, also denoted π and ρ, from T^*U to U and $(\mathbb{R}^n)^*$, and $T^*_{\boldsymbol{p}}U = \pi^{-1}(\{\boldsymbol{p}\})$ is the *cotangent space* to U at $\boldsymbol{p}$. (We should write π^* and ρ^* for these projections, but this notation will be needed elsewhere.) For fixed $\boldsymbol{p} \in U$, we will regard $T_{\boldsymbol{p}}U$ and $T^*_{\boldsymbol{p}}U$ as vector spaces over $\mathbb{R}$, and we can identify $T^*_{\boldsymbol{p}}U$ with $(T_{\boldsymbol{p}}U)^*$.

X.1.1.4. We can think of the tangent bundle construction as attaching a separate copy of $\mathbb{R}^n$ at each point of U, in such a way that the copies "vary smoothly" over U. It is a way of carefully codifying the familiar informal procedure of drawing vectors "from $\boldsymbol{p}$ to $\boldsymbol{q}$" with tail at $\boldsymbol{p}$ and head at $\boldsymbol{q}$, and identifying such a vector with the vector from $\boldsymbol{0}$ to $\boldsymbol{q} - \boldsymbol{p}$. For fixed $\boldsymbol{p}$, the tangent space $T_{\boldsymbol{p}}\mathbb{R}^n$ can be thought of as consisting of the vectors with tail at $\boldsymbol{p}$, thinking of $(\boldsymbol{p}, \boldsymbol{q} - \boldsymbol{p})$ as the "vector from $\boldsymbol{p}$ to $\boldsymbol{q}$," i.e. identifying $(\boldsymbol{p}, \boldsymbol{v})$ with the vector $\boldsymbol{v}$ drawn with tail at $\boldsymbol{p}$ (the vector from $\boldsymbol{p}$ to $\boldsymbol{p} + \boldsymbol{v}$).

X.1.2. Sections and Vector Fields

X.1.2.1. Informally, a (smooth) vector field on $\mathbb{R}^n$, or an open set U in $\mathbb{R}^n$, consists of attaching a vector in $\mathbb{R}^n$ at each point of U so that the vectors "vary smoothly." A vector field on U is often defined to be a smooth function from U to $\mathbb{R}^n$, and this is not a bad way to do it, but using the tangent bundle is better:

X.1.2.2. DEFINITION. Let U be an open set in $\mathbb{R}^n$. A *(smooth) section* of TU is a smooth function $\sigma : U \to TU$ such that, for each $\boldsymbol{p} \in U$, $\sigma(\boldsymbol{p}) \in T_{\boldsymbol{p}}U$ (i.e. $\pi \circ \sigma$ is the identity on U). A smooth section of TU is called a *vector field* on U.

The definition of a vector field from X.1.2.1. is then just obtained by composing a section with ρ (the correspondence $\sigma \leftrightarrow \rho \circ \sigma$ is a bijection). It is customary to use letters like X and Y to denote vector fields. If X is a vector field on U, for $\boldsymbol{p} \in U$ we denote by $X_{\boldsymbol{p}}$ the vector $\rho \circ X(\boldsymbol{p})$ in $\mathbb{R}^n$, i.e. $X(\boldsymbol{p}) = (\boldsymbol{p}, X_{\boldsymbol{p}})$.

X.1.2.3. Let $\Sigma(TU)$ be the set of vector fields on U (smooth sections of TU). There are some natural algebraic operations on $\Sigma(TU)$, using the vector space structure on each $T_{\boldsymbol{p}}U$:

If $X, Y \in \Sigma(TU)$, then $X + Y \in \Sigma(TU)$, where $(X+Y)_{\boldsymbol{p}} = X_{\boldsymbol{p}} + Y_{\boldsymbol{p}}$ for $\boldsymbol{p} \in U$.

If $X \in \Sigma(TU)$ and $f \in \mathcal{C}^\infty(U)$, then $fX \in \Sigma(TU)$, where $(fX)_{\boldsymbol{p}} = f(\boldsymbol{p})X_{\boldsymbol{p}}$ for $\boldsymbol{p} \in U$. In particular, if $\alpha \in \mathbb{R}$, then $\alpha X \in \Sigma(TU)$, where $(\alpha X)_{\boldsymbol{p}} = \alpha(X_{\boldsymbol{p}})$.

It is easily checked that these operations make $\Sigma(TU)$ into a $\mathcal{C}^\infty(U)$-module, and in particular a real vector space (infinite-dimensional!).

X.1.2.4. Since TU is a product bundle, there are constant sections: if $\boldsymbol{v} \in \mathbb{R}^n$, define $X^{\boldsymbol{v}}$ by $X^{\boldsymbol{v}}(\boldsymbol{p}) = (\boldsymbol{p}, \boldsymbol{v})$ (i.e. $X^{\boldsymbol{v}}_{\boldsymbol{p}} = \boldsymbol{v}$ for all $\boldsymbol{p} \in U$). In particular, for each standard basis vector $\boldsymbol{e}_j$ in $\mathbb{R}^n$, there is a constant vector field $X^{\boldsymbol{e}_j}$. We write

$$\frac{\partial}{\partial x_j} = X^{\boldsymbol{e}_j}$$

for $1 \le j \le n$, i.e. $\frac{\partial}{\partial x_j}$ is a vector field with $\left(\frac{\partial}{\partial x_j}\right)_{\boldsymbol{p}} = \boldsymbol{e}_j$ for each $\boldsymbol{p} \in U$. The reason for this seemingly off-the-wall notation will become apparent in X.1.4.2..

X.1.2.5. If $X \in \Sigma(TU)$, then for each $\boldsymbol{p} \in U$ the vectors $\{(\boldsymbol{p}, \boldsymbol{e}_1), \ldots, (\boldsymbol{p}, \boldsymbol{e}_n)\}$ form a basis for $T_{\boldsymbol{p}}U$, so there are unique scalars $g_1(\boldsymbol{p}), \ldots, g_n(\boldsymbol{p})$ such that

$$X_{\boldsymbol{p}} = \sum_{j=1}^{n} g_j(\boldsymbol{p})\boldsymbol{e}_j$$

for each $\boldsymbol{p} \in U$, and the g_j give functions from U to $\mathcal{R}$, which are obviously smooth ($g_j = \phi_j \circ \rho \circ X$, where ϕ_j is the projection of $\mathbb{R}^n$ onto the span of $\boldsymbol{e}_j$). Thus

$$X = \sum_{j=1}^{n} g_j \frac{\partial}{\partial x_j}$$

and so the $\frac{\partial}{\partial x_j}$ form a basis for $\Sigma(TU)$ as a $\mathcal{C}^\infty(U)$-module (i.e. $\Sigma(TU)$ is a free $\mathcal{C}^\infty(U)$-module of dimension n).

X.1.3. Change of Basis

X.1.4. Lie Differentiation

X.1.4.1. If X is a vector field on $U \subseteq \mathbb{R}^n$, one can differentiate smooth functions "in the direction of X." If $f \in \mathcal{C}^\infty(U)$, define $\frac{\partial f}{\partial X} : U \to \mathbb{R}$ by

$$\frac{\partial f}{\partial X}(\boldsymbol{p}) = \frac{\partial f}{\partial X_{\boldsymbol{p}}}(\boldsymbol{p})$$

where $\frac{\partial f}{\partial X_{\boldsymbol{p}}}(\boldsymbol{p})$ is the directional derivative of f at $\boldsymbol{p}$ with respect to $X_{\boldsymbol{p}}$ (VIII.2.3.2.; note that $X_{\boldsymbol{p}}$ is not a unit vector in general). The function $\frac{\partial f}{\partial X}$ is called the *Lie derivative* of f in the direction of X. The function $\frac{\partial f}{\partial X}$ is often written $L_X f$ or, even more commonly, Xf (do not confuse Xf with fX which is just the product (X.1.2.3.)).

X.1.4.2. If $X^{\boldsymbol{e}_j} = \frac{\partial}{\partial x_j}$, then

$$X^{\boldsymbol{e}_j} f(\boldsymbol{p}) = \frac{\partial f}{\partial X^{\boldsymbol{e}_j}}(\boldsymbol{p}) = \frac{\partial f}{\partial x_j}(\boldsymbol{p})$$

so $X^{\boldsymbol{e}_j} f = \frac{\partial}{\partial x_j} f = \frac{\partial f}{\partial X^{\boldsymbol{e}_j}} = \frac{\partial f}{\partial x_j}$, explaining the notation for the basic vector fields. More generally, if

$$X = \sum_{j=1}^{n} g_j \frac{\partial}{\partial x_j}$$

with the $g_j \in \mathcal{C}^\infty(U)$, i.e. $X_{\boldsymbol{p}} = (g_1(\boldsymbol{p}), \ldots, g_n(\boldsymbol{p}))$ for $\boldsymbol{p} \in U$, we have, by VIII.3.5.4.,

$$(Xf)(\boldsymbol{p}) = \left[\left(\sum_{j=1}^{n} g_j \frac{\partial}{\partial x_j} \right) f \right] (\boldsymbol{p}) = \nabla f(\boldsymbol{p}) \cdot X_{\boldsymbol{p}} = \sum_{j=1}^{n} g_j(\boldsymbol{p}) \frac{\partial f}{\partial x_j}(\boldsymbol{p})$$

so the notation is consistent; $X \mapsto \frac{\partial}{\partial X}$ is $\mathcal{C}^\infty$-linear, and $Xf = \frac{\partial f}{\partial X} \in \mathcal{C}^\infty(U)$.

X.1.4.3. If $X \in \Sigma(TU)$, then the operator $\frac{\partial}{\partial X} : \mathcal{C}^\infty(U) \to \mathcal{C}^\infty(U)$ is a derivation (), i.e. is $\mathbb{R}$-linear and satisfies the product rule

$$\frac{\partial}{\partial X}(fg) = f \frac{\partial g}{\partial X} + g \frac{\partial f}{\partial X}$$

or

$$X(fg) = f(Xg) + g(Xf)$$

for $f, g \in \mathcal{C}^\infty(U)$.

X.1.4.4. If $1 \leq j, k \leq n$, then $\frac{\partial}{\partial x_j}$ and $\frac{\partial}{\partial x_k}$ commute as operators on $\mathcal{C}^\infty(U)$ by Clairaut's Theorem. But if $X, Y \in \Sigma(TU)$, then $\frac{\partial}{\partial X}$ and $\frac{\partial}{\partial Y}$ do not commute in general. If

$$X = \sum_{j=1}^{n} g_j \frac{\partial}{\partial x_j}, \quad Y = \sum_{j=1}^{n} h_j \frac{\partial}{\partial x_j}$$

we have, for $f \in \mathcal{C}^\infty(U)$,

$$(XY)f = X(Yf) = X\left(\sum_{k=1}^{\infty} h_k \frac{\partial f}{\partial x_k}\right) = \sum_{j=1}^{n}\sum_{k=1}^{n} g_j \frac{\partial}{\partial x_j}\left(h_k \frac{\partial f}{\partial x_k}\right)$$

$$= \sum_{j=1}^{n}\sum_{k=1}^{n} g_j \left(\frac{\partial h_k}{\partial x_j}\frac{\partial f}{\partial x_k} + h_k \frac{\partial^2 f}{\partial x_j \partial x_k}\right) = \sum_{j=1}^{n}\sum_{k=1}^{n} g_j \frac{\partial h_k}{\partial x_j}\frac{\partial f}{\partial x_k} + \sum_{j=1}^{n}\sum_{k=1}^{n} g_j h_k \frac{\partial^2 f}{\partial x_j \partial x_k}$$

$$(YX)f = Y(Xf) = Y\left(\sum_{j=1}^{\infty} g_j \frac{\partial f}{\partial x_j}\right) = \sum_{k=1}^{n}\sum_{j=1}^{n} h_k \frac{\partial}{\partial x_k}\left(g_j \frac{\partial f}{\partial x_j}\right)$$

$$= \sum_{k=1}^{n}\sum_{j=1}^{n} h_k \left(\frac{\partial g_j}{\partial x_k}\frac{\partial f}{\partial x_j} + g_j \frac{\partial^2 f}{\partial x_k \partial x_j}\right) = \sum_{k=1}^{n}\sum_{j=1}^{n} h_k \frac{\partial g_j}{\partial x_k}\frac{\partial f}{\partial x_j} + \sum_{k=1}^{n}\sum_{j=1}^{n} g_j h_k \frac{\partial^2 f}{\partial x_k \partial x_j}$$

$$(XY - YX)f = \sum_{j=1}^{n}\sum_{k=1}^{n} g_j \frac{\partial h_k}{\partial x_j}\frac{\partial f}{\partial x_k} - \sum_{k=1}^{n}\sum_{j=1}^{n} h_k \frac{\partial g_j}{\partial x_k}\frac{\partial f}{\partial x_j}$$

since the second-order terms cancel by Clairaut's Theorem. Interchanging indices j and k in the first double sum, we have

$$(XY - YX)f = \sum_{k=1}^{n}\sum_{j=1}^{n} g_k \frac{\partial h_j}{\partial x_k}\frac{\partial f}{\partial x_j} - \sum_{k=1}^{n}\sum_{j=1}^{n} h_k \frac{\partial g_j}{\partial x_k}\frac{\partial f}{\partial x_j}$$

$$= \sum_{j=1}^{n}\left[\sum_{k=1}^{n}\left(g_k \frac{\partial h_j}{\partial x_k} - h_k \frac{\partial g_j}{\partial x_k}\right)\right]\frac{\partial f}{\partial x_j}$$

and thus

$$[X,Y] := (XY - YX) = \sum_{j=1}^{n}\left[\sum_{k=1}^{n}\left(g_k \frac{\partial h_j}{\partial x_k} - h_k \frac{\partial g_j}{\partial x_k}\right)\right]\frac{\partial}{\partial x_j} \in \Sigma(TU)\ .$$

$[X,Y]$ is called the *Lie bracket* of X and Y.

X.1.4.5. Note that XY and YX are second-order (not vector fields or derivations), but $[X,Y]$ is a vector field (derivation), since the second-order derivative terms cancel. There is a nice geometric interpretation of the Lie bracket (). See also Exercise X.1.7.1..

X.1.4.6. If X and Y are constant vector fields, then $[X,Y] = 0$, i.e. X and Y commute. Thus if we choose a different basis $\{\boldsymbol{y}_1, \ldots, \boldsymbol{y}_n\}$ for $\mathbb{R}^n$ and take $\frac{\partial}{\partial y_1}, \ldots, \frac{\partial}{\partial y_n}$ as the corresponding vector fields, then these vector fields commute. Thus Clairaut's Theorem is "coordinate-free" (and in particular does not rely on the fact that $\{\boldsymbol{e}_1, \ldots, \boldsymbol{e}_n\}$ is orthonormal). See X.1.7.1.(d) for a generalization.

X.1.5. Integral Curves

X.1.5.1. If X is a vector field on $U \subseteq \mathbb{R}^n$, and $\boldsymbol{p} \in U$, we would like to find a parametrized curve $\gamma(t)$ through $\boldsymbol{p}$ such that $\gamma'(t) = X_{\gamma(t)}$ for all t, i.e. the vector $X_{\boldsymbol{q}}$ is the tangent vector to the curve at the point $\boldsymbol{q}$, for every $\boldsymbol{q}$ on the curve. This is possible, at least locally:

X.1.5.2. THEOREM. Let X be a vector field on $U \subseteq \mathbb{R}^n$, $\boldsymbol{p} \in U$, and $t_0 \in \mathbb{R}$. Then there is an open neighborhood V of $\boldsymbol{p}$, contained in U, and an $\epsilon > 0$ such that, for every $\boldsymbol{q} \in V$ there is a unique parametrized curve $\gamma_{\boldsymbol{q}} : (t_0 - \epsilon, t_0 + \epsilon) \to U$ such that $\gamma_{\boldsymbol{q}}(t_0) = \boldsymbol{q}$ and $\gamma'_{\boldsymbol{q}}(t) = X_{\gamma_{\boldsymbol{q}}(t)}$ for all $t \in (t_0 - \epsilon, t_0 + \epsilon)$. Furthermore, each such $\gamma_{\boldsymbol{q}}$ is $\mathcal{C}^\infty$.

PROOF: This is a straightforward application of XI.1.3.4.. The differential equation

$$\boldsymbol{y}' = X_{\boldsymbol{y}}$$

is an autonomous first-order vector differential equation. To put it in standard form, set

$$X_{\boldsymbol{q}} = \boldsymbol{g}(\boldsymbol{q}) = (g_1(\boldsymbol{q}), \ldots, g_n(\boldsymbol{q}))$$

for $\boldsymbol{q} \in U$; then the differential equation becomes

$$\boldsymbol{y}' = \boldsymbol{g}(\boldsymbol{y})$$

or, in coordinates, the system

$$\begin{aligned} y'_1 &= g_1(y_1, \ldots, y_n) \\ &\vdots \\ y'_n &= g_n(y_1, \ldots, y_n) \end{aligned}$$

and $\boldsymbol{g}$ is $\mathcal{C}^\infty$, hence locally Lipschitz, so the IVP $\boldsymbol{y}' = \boldsymbol{g}(\boldsymbol{y})$, $\boldsymbol{y}(t_0) = \boldsymbol{q}$ has a unique solution, which is $\mathcal{C}^\infty$, in a neighborhood of t_0, for $\boldsymbol{q}$ in a neighborhood of $\boldsymbol{p}$. 👍

X.1.5.3. Since the differential equation is autonomous, the solution does not depend on t_0, in the sense that if $\gamma^0_{\boldsymbol{q}}$ is the solution to the IVP for $t_0 = 0$, then for any t_0 the function $\gamma^{t_0}_{\boldsymbol{q}}$ given by $\gamma^{t_0}_{\boldsymbol{q}}(t) = \gamma^0_{\boldsymbol{q}}(t - t_0)$ is the solution for that t_0. This makes sense, since the image curves (for fixed $\boldsymbol{q}$) are all the same, traversed at the same "speed."

Note that the integral "curve" is degenerate if $X_{\boldsymbol{p}} = \boldsymbol{0}$: $\gamma^{t_0}_{\boldsymbol{p}}$ is the constant function with value $\boldsymbol{p}$.

X.1.5.4. Much less than $\mathcal{C}^\infty$ is needed for the function X (or $\boldsymbol{g}$) to get unique integral curves: $\boldsymbol{g}$ needs only to be locally Lipschitz, not necessarily even $\mathcal{C}^1$. In fact, the subject of integral curves is essentially the same thing as the theory of autonomous systems of first-order differential equations.

X.1.5.5. The integral curve through a point $\boldsymbol{p}$ is only defined locally. Local solutions can be cobbled together into a maximal interval of definition, which is an open interval. The maximal interval of definition of the curve will have a (finite) endpoint in one direction if the curve approaches the boundary of U in that direction, and only then (X.1.6.4., X.1.7.2.). But if the maximal interval goes to $\pm\infty$, the curve does not necessarily approach the boundary of U (X.1.6.4.).

X.1.6. The Local Flow

X.1.6.1. Thus each point $\boldsymbol{p}$ of U has an open neighborhood V which partitions into pairwise disjoint integral curves. These curves "vary continuously," i.e. if we define

$$\phi_t(\boldsymbol{x}) = \gamma^0_{\boldsymbol{x}}(t)$$

for $|t| < \epsilon$ and $\boldsymbol{x} \in V$, then $\phi : (-\epsilon, \epsilon) \times V \to U$ is continuous by XI.1.5.5.. In fact, much more is true:

X.1.6.2. THEOREM. Let X be a vector field on $U \subseteq \mathbb{R}^n$, and $\boldsymbol{p} \in U$. Then there is an open neighborhood V of $\boldsymbol{p}$, an $\epsilon > 0$, and a $\mathcal{C}^\infty$ function $\psi : (-\epsilon, \epsilon) \times V \to U$ such that

(i) For each $t \in (-\epsilon, \epsilon)$, ϕ_t defined by $\phi_t(\boldsymbol{x}) = \psi(t, \boldsymbol{x})$ is a diffeomorphism from V to an open set $V_t \subseteq U$.

(ii) $\phi_0(\boldsymbol{x}) = \boldsymbol{x}$ for all $\boldsymbol{x} \in V$.

(iii) If $s, t, s + t \in (-\epsilon, \epsilon)$, then $\phi_{s+t} = \phi_s \circ \phi_t$.

(iv) If $\boldsymbol{q} \in V$, then $\gamma(t) = \phi(t, \boldsymbol{q})$ is the unique integral curve $\gamma^0_{\boldsymbol{q}}(t)$ of X.1.5.2..

X.1.6.3. In other words, "flowing" each point along its integral curve gives a *local flow* on small open subsets of U. This flow is not globally defined in general, even if $U = \mathbb{R}^n$ (X.1.6.4.). Piecing the local flows together into a "maximal" flow is much more problematic than with integral curves (since the ϵ can go to 0 toward the edge of U), and cannot be done satisfactorily in general (but see () for the case of compact manifolds).

X.1.6.4. EXAMPLE. Define a vector field X on $\mathbb{R}^2$ by $X_{(x,y)} = (0, y^2)$. If $\boldsymbol{p} = (x_0, y_0)$ with $y_0 \neq 0$, the integral curve $\gamma^0_{\boldsymbol{p}}$ is given by

$$\gamma^0_{\boldsymbol{p}}(t) = \left(x_0, \frac{1}{c - t}\right)$$

where $c = \frac{1}{y_0}$. If $y_0 > 0$, the trajectory is the (open) vertical ray in the upper half plane with x-coordinate x_0. As $t \to -\infty$, $\gamma^0_{\boldsymbol{p}}(t) \to (x_0, 0)$. But $\gamma^0_{\boldsymbol{p}}(t)$ goes to infinity as $t \to c-$, so the maximal interval on which the integral curve is defined is $(-\infty, c)$. If $y_0 < 0$, so $c = \frac{1}{y_0} < 0$, the trajectory is the ray in the lower half plane with x-coordinate x_0; $\gamma^0_{\boldsymbol{p}}(t) \to (x_0, 0)$ as $t \to +\infty$, and $\gamma^0_{\boldsymbol{p}}(t)$ goes to infinity as $t \to c+$, so the maximal interval on which the integral curve is defined is $(c, +\infty)$. There is no global flow defined on any open interval around 0 since the larger $|y_0|$ is, the faster the integral curve goes to infinity (i.e. $c \to 0$ as $|y_0| \to \infty$).
The integral curve $\gamma^0_{\boldsymbol{p}}$ is the constant function $\boldsymbol{p}$ if $\boldsymbol{p} = (x_0, 0)$.

X.1.7. Exercises

X.1.7.1. Prove that the Lie Bracket of vector fields () has the following properties for vector fields X, Y, Z:
(a) $[X + Y, Z] = [X, Z] + [Y, Z]$ and $[\lambda X, Y] = \lambda[X, Y]$ for $\lambda \in \mathbb{R}$.
(b) $[Y, X] = -[X, Y]$. In particular, $[X, X] = 0$. So from (a), $[X, Y + Z] = [X, Y] + [X, Z]$ and $[X, \lambda Y] = \lambda[X, Y]$ for $\lambda \in \mathbb{R}$.
(c) $[X, [Y, Z]] + [Y, [Z, X]] + [Z, [X, Y]] = 0$ (Jacobi Identity).

Thus the set of smooth vector fields on U has the structure of a Lie algebra from $[\cdot, \cdot]$.

(d) If j is fixed, then

$$\left[\frac{\partial}{\partial x_j}, \sum_{k=1}^{\infty} g_k \frac{\partial}{\partial x_k}\right] = \sum_{k=1}^{\infty} \frac{\partial g_k}{\partial x_j} \frac{\partial}{\partial x_k} \ .$$

X.1.7.2. Let X be a vector field on $U \subseteq \mathbb{R}^n$, and $\boldsymbol{p} \in U$. Suppose the integral curve $\gamma^0_{\boldsymbol{p}}$ is defined on $[0, t_0)$ for some $t_0 > 0$, and suppose the curve $\gamma^0_{\boldsymbol{p}}([0, t_0))$ has a cluster point $\boldsymbol{q} \in U$ as $t \to t_0-$. Show that $\gamma^0_{\boldsymbol{p}}$ can be extended to $[0, t_0 + \epsilon)$ for some $\epsilon > 0$ with $\gamma^0_{\boldsymbol{p}}(t_0) = \boldsymbol{q}$. [Reindex the integral curve so that $t_0 = 0$, and consider the local flow at $\boldsymbol{q}$. Note that $\|X\|$ is bounded near $\boldsymbol{q}$.] Obtain a similar result if $t_0 < 0$.

X.2. Differential Forms

In the original conception of Leibniz notation, an expression like dx was regarded as an "infinitesimal" or "differential." From an equation $y = f(x)$ was obtained the relation $dy = f'(x)\,dx$ (although LEIBNIZ himself did not use functional or prime notation, which was not yet invented), interpreted to mean that at the point x, the infinitesimal (differential) dy was related to the infinitesimal dx by a factor of $f'(x)$, i.e. $\frac{dy}{dx} = f'(x)$ (LEIBNIZ would just say $dy = \frac{dy}{dx}\,dx$), and that

$$y = \int dy = \int f'(x)\,dx\ .$$

These ideas, while a useful heuristic, were too vague to be careful mathematics.

We want to make careful mathematical sense out of expressions like dx, especially in higher dimensions, and what it means to integrate them. Our interpretation may seem unrecognizably different from that of LEIBNIZ, but will give the same formulas and results (rigorously!)

> "The notation df/dx, always a little too tempting, has inspired many (usually meaningless) definitions of dx and df separately, the sole purpose of which is to make the equation
>
> $$df = \frac{df}{dx} \cdot dx$$
>
> work out. If $f : \mathbb{R}^2 \to \mathbb{R}$ then df is *defined*, classically, as
>
> $$df = \frac{\partial f}{\partial x}\,dx + \frac{\partial f}{\partial y}\,dy$$
>
> (whatever dx and dy mean).
>
> [We will make] rigorous definitions which enable us to prove the above equations as theorems. It is a touchy question whether or not these modern definitions represent a real improvement over classical formalism; this the reader must decide for himself [sic]."
>
> *M. Spivak*[2]

(In my opinion, they do.)

X.2.1. Differential Forms on $\mathbb{R}^1$

X.2.1.1. So what should dx, or $f'(x)\,dx$, mean? It should be an *(oriented!) integrand* (whatever that means), i.e. if it is applied to an interval I from a to b (oriented, i.e. we could have $a < b$ or $a > b$),

$$dx(I) = \int_a^b dx = b - a$$

or, more generally,

$$[f'(x)\,dx](I) = \int_a^b f'(x)\,dx = f(b) - f(a)$$

[2] [Spi65, p. 45].

so it should be some kind of object which can be "integrated" over oriented intervals. (Actually, whether the "integrand" is itself oriented is a little obscure; the orientation can be regarded as confined to the interval it is applied to. In our approach, both will be oriented. Orientation leads to what I find is one of the biggest technical difficulties of working with forms: keeping careful track of signs. But it is ultimately very pretty to see how everything works out so neatly.)

X.2.1.2. To follow and motivate the approach we take, we must distinguish between the scalars $\mathbb{R}$ and the one-dimensional vector space $\mathbb{R}^1$, which consists of the 1-tuples (α) or the column 1-vectors $[\alpha]$. The usual identification $\alpha \leftrightarrow (\alpha) \leftrightarrow [\alpha]$ of $\mathbb{R}$ with $\mathbb{R}^1$ uses the standard basis $\{(1)\} = \{[1]\}$ for $\mathbb{R}^1$. This distinction may seem artificial, but turns out to be conceptually crucial, especially when we extend to higher dimensions. Under this distinction, we will regard a closed bounded interval in $\mathbb{R}$ as a compact oriented submanifold with boundary in $\mathbb{R}^1$, i.e. we will integrate forms over such submanifolds.

X.2.1.3. We must also distinguish between $\mathbb{R}^1$ and $(\mathbb{R}^1)^*$: $(\mathbb{R}^1)^*$ is the set of linear functionals on $\mathbb{R}^1$, which assign to each vector in $\mathbb{R}^1$ a scalar. $(\mathbb{R}^1)^*$ is usually also identified with $\mathbb{R}$, identifying the scalar α with the linear functional given by multiplication by α (or more precisely the linear functional $[x] \mapsto \alpha x$). In this connection, if f is a (smooth) function from $U \subseteq \mathbb{R}$ to $\mathbb{R}$, we have two standard points of view for the derivative at a point $p \in U$:

(i) If f is regarded as a function from U to $\mathbb{R}$, then $f'(p)$ is a real number (point of view of elementary one-variable calculus).

(ii) If f is regarded as a function from $U \subseteq \mathbb{R}^1$ to $\mathbb{R}^1$, then the (total) differential $df(p)$ is a linear transformation from $\mathbb{R}^1$ to $\mathbb{R}^1$ (point of view of vector calculus).

We will take a third, somewhat intermediate point of view:

(iii) If f is regarded as a function from $U \subseteq \mathbb{R}^1$ to $\mathbb{R}$, then $df(p) = f'(p)$ is a linear functional on $\mathbb{R}^1$ (element of $(\mathbb{R}^1)^*$), namely the linear functional of multiplication by the scalar $f'(p)$.

Thus we may think of df as a (smooth) function from U to $(\mathbb{R}^1)^*$, whose value at a point $p \in U$ is the linear functional corresponding to multiplication by the scalar $f'(p)$; thus df is a (smooth) section of the cotangent bundle of U. So we are led to the following definition:

X.2.1.4. Definition. Let U be an open subset of $\mathbb{R}^1$. A smooth section of the cotangent bundle T^*U is called a *differential 1-form* on U. Write $\Omega^1(U)$ for the set of differential 1-forms on U.

X.2.1.5. We write df for the differential 1-form on U described above. In particular, we may regard dx as the differential 1-form corresponding to the function $f(x) = x$, i.e. as the constant section of T^*U corresponding to the number 1.

X.2.1.6. Just as for vector bundles, we may add differential 1-forms pointwise and multiply them pointwise by smooth functions; thus $\Omega^1(U)$ becomes a $\mathcal{C}^\infty(U)$-module. It is a free $\mathcal{C}^\infty(U)$-module of rank 1 with basis $\{dx\}$, i.e. every differential 1-form ω on U can be written uniquely as $\omega = g\,dx$ for a $\mathcal{C}^\infty$ function $g : U \to \mathbb{R}$, where $\omega(p)$ is the linear functional corresponding to multiplication by $g(p)$, for each $p \in U$. If G is an antiderivative for g on U, then $\omega = dG$, so every differential 1-form on U is of the form df for some (not quite unique) $f \in \mathcal{C}^\infty(U)$.

X.2.1.7. The word "differential" in the term *differential 1-form* really has no meaning in this context, and is used for historical reasons because of the way the concept and notation arose, and because we use the term *differential* to mean an important construction in the theory (partially described above). We often omit the "differential," i.e. we will just write *1-form* to mean *differential 1-form* (one could more generally define 1-forms $g\,dx$ for functions g with less, even no, differentiability, but we will not consider such forms). Differential 1-forms are also often called *exterior 1-forms* for reasons described below.

Integrating 1-Forms

X.2.1.8. Let U be an open set in $\mathbb{R}^1$, ω a 1-form on U, and I an oriented closed bounded interval in U from a to b (we could have $a < b$ or $a > b$). We want to define the integral of ω over I. We have $\omega = g\,dx$ for some smooth function $g : U \to \mathbb{R}$. Let f be an antiderivative for g on U.

There are (at least) three approaches to defining $\int_I \omega$:

(i) Declare by fiat that

$$\int_I \omega = f(b) - f(a)$$

(this is independent of the choice of f). This approach requires no knowledge about Riemann integration.

(ii) Pretend we haven't yet developed Riemann integration. Develop (or redevelop) the entire theory allowing for oriented intervals: if $a > b$, a partition of the interval from a to b runs from right to left, with the increments Δx_k negative. The entire theory, including the FTC (properly phrased), works in this slight generality. We then define

$$\int_I \omega = \int_a^b g(x)\,dx = f(b) - f(a)$$

where the integral is the Riemann integral extended to this oriented situation.

(iii) First develop the usual theory of Riemann integration as in (). Now parametrize the interval from a to b by taking a smooth function $\phi : [c, d] \to U$ $(c < d)$ with $\phi(c) = a$ and $\phi(d) = b$, and define

$$\int_I \omega = \int_c^d g(\phi(t))\phi'(t)\,dt$$

where the integral is the usual Riemann integral. The change-of-variables formula gives that this number is well defined independent of the choice of the parametrization ϕ, and the FTC gives that $\int_I \omega = f(b) - f(a)$.

X.2.1.9. All three approaches give the same value, $f(b) - f(a)$, for $\int_I \omega$. The first approach is not very satisfactory, though, since it does not extend in any obvious way to the higher-dimensional case and leads to few if any applications. Approaches (ii) and (iii) are much better. They extend nicely to higher dimensions, are somewhat complementary, and lead to many important applications.

0-Forms on $\mathbb{R}^1$

X.2.1.10. If $U \subseteq \mathbb{R}^1$, we also define a *(differential) 0-form* on U to be just an element of $\mathcal{C}^\infty(U)$, i.e. $\Omega^0(U) = \mathcal{C}^\infty(U)$ (this is technically not quite the correct definition, cf. (), but will do for now). Thus if $f \in \Omega^0(U)$, then f has a differential $df \in \Omega^1(U)$, and every 1-form is the differential of a 0-form.

Integrating 0-Forms

X.2.1.11. "Integrating" a 0-form over an oriented 0-submanifold of $\mathbb{R}^1$ is straightforward and simple-minded. A compact 0-submanifold of $U \subseteq \mathbb{R}^1$ is just a finite set $X = \{p_1, \ldots, p_n\}$ in U. An orientation of a point p is a choice σ_p of $+$ or $-$ (or, if you will, ± 1); thus an orientation of X is a choice of sign for each p_k. If f is a smooth function on U, define

$$\int_X f = \sum_{k=1}^{n} \sigma_{p_k} f(p_k) \ .$$

Stokes' Theorem in $\mathbb{R}^1$

X.2.1.12. Now let I be an oriented interval in $U \subseteq \mathbb{R}^1$ from a to b. Set $\partial I = \{a, b\}$ (the boundary of I). Give ∂I the orientation with $\sigma_b = +$ and $\sigma_a = -$ (the *induced orientation* from the orientation of I). If $\omega = f$ is a 0-form on U, so that $d\omega = f'\,dx$, the FTC says that

$$\int_I d\omega = f(b) - f(a)$$

but this is exactly the integral of ω over ∂I; so the FTC can be rephrased

$$\int_I d\omega = \int_{\partial I} \omega$$

for any 0-form ω on U. The general Stokes' Theorem () asserts that this formula holds if U is an open set in $\mathbb{R}^n$, ω is a $(k-1)$-form on U, and I a smooth k-submanifold of U.

X.2.2. Differential 1-Forms and Line Integrals on $\mathbb{R}^n$

X.2.3. Higher Differential Forms on $\mathbb{R}^n$

X.2.3.1. If U is an open set in $\mathbb{R}^n$, for $k \geq 0$ we denote by $\Omega^k(U)$ the set of k-forms on U. $\Omega^k(U)$ is naturally a real vector space, and $\Omega^k(U) = 0$ if $k > n$.

Multi-index Notation

X.2.3.2. If $1 \leq k \leq n$, a *k-multiindex* for $\mathbb{R}^n$ is a k-tuple of natural numbers between 1 and n, e.g. $I = (i_1, \ldots, i_k)$. We normally only consider k-multiindices where the terms are strictly increasing (and in particular distinct), but we do not make this a blanket assumption.

X.2.3.3. If $I = (i_1, \ldots, i_k)$ is a k-multiindex, write dx_I for the k-form $dx_{i_1} \cdots dx_{i_k}$. Then $dx_I = 0$ if the i_m are not all distinct, and $dx_I = (-1)^\sigma dx_J$, where J is the set $\{i_1, \ldots, i_k\}$ in increasing order and σ is the sign of the reordering permutation.

With this notation, a general k-form ω is uniquely of the form

$$\omega = \sum_I f_I \, dx_I$$

where the sum is over k-multiindices in strictly increasing order.

Wedge Product

Although we are generally omitting the wedges in writing differential forms, we should think of them as being there. This allows the operations of exterior algebra to be applied to forms, although the application is not quite immediate. We can take the wedge product of a k-form and an ℓ-form on $\mathbb{R}^n$ to yield a $(k+\ell)$-form.

X.2.3.4. The simplest definition uses the standard basis. Every k-form on $\mathbb{R}^n$ is a sum of terms of the form

$$f\,dx_{i_1}\,dx_{i_2}\cdots dx_{i_k}$$

with the i_m strictly increasing and similarly for ℓ-forms. So we take

$$(f\,dx_{i_1}\,dx_{i_2}\cdots dx_{i_k})\wedge(g\,dx_{j_1}\,dx_{j_2}\cdots dx_{j_\ell}) = fg\,dx_{i_1}\,dx_{i_2}\cdots dx_{i_k}\,dx_{j_1}\,dx_{j_2}\cdots dx_{j_\ell}$$

reordered to strictly increasing order using

$$dx_i\,dx_i = 0 \text{ for all } i \text{ and } dx_i\,dx_j = -dx_j\,dx_i \text{ for all } i \neq j$$

(so the wedge is zero unless the i's and j's are all distinct) and extend to sums by linearity (applying this definition term-by-term). This is consistent with regarding the k-form $f\,dx_{i_1}\cdots dx_{i_k}$ as the wedge of the 0-form f and the k-form $dx_{i_1}\cdots dx_{i_k}$.

X.2.4. Integration of Differential Forms on $\mathbb{R}^n$

X.2.4.1. It is a delicate issue what subsets of $\mathbb{R}^n$ we should (or even reasonably can) define the integral of a k-form over. We should at least be able to integrate over

smooth (oriented) compact k-submanifolds with boundary

k-rectangles

and, more generally, "smooth oriented k-submanifolds with corners." We will at least need all such sets to be compact Jordan regions, and would like the collection of admissible subsets to be closed under diffeomorphisms (in a general sense).

X.2.5. The Differential of a Form

The main feature of differential forms which sets them apart from mere exterior algebra is the differential, the fundamental analysis component.

The Differential of a Function

X.2.5.1. A smooth real-valued function f on a region U in $\mathbb{R}^n$ has a "(total) differential" df defined as in (): if $\boldsymbol{x}_0 \in U$, $df(\boldsymbol{x}_0)$ is the linear transformation from $\mathbb{R}^n$ to $\mathbb{R}^1$ with matrix

$$Df(\boldsymbol{x}_0) = \left[\begin{array}{cccc} \frac{\partial f}{\partial x_1}(\boldsymbol{x}_0) & \frac{\partial f}{\partial x_2}(\boldsymbol{x}_0) & \cdots & \frac{\partial f}{\partial x_n}(\boldsymbol{x}_0) \end{array} \right]$$

which is a linear functional on $\mathbb{R}^n$ (an element of $(\mathbb{R}^n)^*$). Thus df can be regarded as a smooth function from U to $(\mathbb{R}^n)^*$, i.e. a smooth section of the cotangent bundle of U, which is a 1-form. Thus we have three standard pictures of the derivative of a smooth function $f : U \to \mathbb{R}$:

The (total) derivative Df, a function from U to the $1 \times n$ matrices.

The gradient ∇f, a vector field on U.

The differential df, a 1-form on U.

Each of these pictures is useful in various contexts.

X.2.5.2. The 1-form df can of course be written in terms of the standard basis; it is easily checked that

$$df = \frac{\partial f}{\partial x_1}\, dx_1 + \frac{\partial f}{\partial x_2}\, dx_2 + \cdots + \frac{\partial f}{\partial x_n}\, dx_n$$

(Exercise X.2.12.1.) which is certainly the expected formula.

Using this notation, we can state a general version of the Fundamental Theorem of Calculus:

X.2.5.3. THEOREM. Let f be a smooth function on a region $U \subseteq \mathbb{R}^n$, and C be an oriented smooth curve in U from $\boldsymbol{x}_0$ to $\boldsymbol{x}_1$, with $\partial C = \{\boldsymbol{x}_0, \boldsymbol{x}_1\}$ oriented with $\sigma_{\boldsymbol{x}_1} = 1$ and $\sigma_{\boldsymbol{x}_0} = -1$ (the induced orientation). Then

$$\int_C df = \int_{\partial C} f \ .$$

This is a special case of Stokes' Theorem (). It can be immediately proved by taking a smooth parametrization of C and applying the usual FTC and the Chain Rule of vector calculus.

X.2.5.4. We also have the product rule

$$d(fg) = f\, dg + g\, df$$

($f, g \in \mathcal{C}^\infty(U)$) which is easily verified by a simple calculation left to the reader.

Differential of a General Form

X.2.5.5. We will now define the differential (often called the *exterior differential*) of a general form. It is enough to define the differential of the k-form

$$f\,dx_{j_1}\,dx_{j_2}\cdots dx_{j_k} \in \Omega^k(U)$$

to be

$$(df)\wedge(dx_{j_1}\,dx_{j_2}\cdots dx_{j_k})$$

which is a $(k+1)$-form. The differential of a general k-form is then defined by linearity. This defines a map $d:\Omega^k(U)\to\Omega^{k+1}(U)$. (We should technically call this d_k since it is a different map for each k, but the k is customarily omitted.) In multiindex notation, we have

$$d\left(\sum_I f_I\,dx_I\right)=\sum_I (df_I)\wedge dx_I$$

where the sum is over all k-multiindices with strictly increasing terms. In fact, using the observations of X.2.3.3., it is easily seen that this formula holds for general sums over k-multiindices which are not necessarily strictly increasing.

X.2.5.6. We could just make this definition by fiat, and later see that it is the useful one; but it is better to give at least a little motivation. Consider the case $U=\mathbb{R}^2$ and $k=1$. The general 1-form is $\omega=f\,dx+g\,dy$, and the general 2-form is $h\,dx\,dy$. If we want $d\omega$ to be a 2-form with the property that if R is a (solid) rectangle in $\mathbb{R}^2$ with boundary ∂R parametrized once around counterclockwise, then

$$\int_{\partial R}\omega=\int_R d\omega$$

we calculate that h must be $\frac{\partial g}{\partial x}-\frac{\partial f}{\partial y}$ (Exercise X.2.12.3.). Then note that by the above definition

$$d\omega=(df)\wedge dx+(dg)\wedge dy=\left(\frac{\partial f}{\partial x}\,dx+\frac{\partial f}{\partial y}\,dy\right)dx+\left(\frac{\partial g}{\partial x}\,dx+\frac{\partial g}{\partial y}\,dy\right)dy$$

$$=\frac{\partial f}{\partial x}\,dx\,dx+\frac{\partial f}{\partial y}\,dy\,dx+\frac{\partial g}{\partial x}\,dx\,dy+\frac{\partial g}{\partial y}\,dy\,dy=-\frac{\partial f}{\partial y}\,dx\,dy+\frac{\partial g}{\partial x}\,dx\,dy=\left(\frac{\partial g}{\partial x}-\frac{\partial f}{\partial y}\right)dx\,dy\ .$$

See Theorem X.2.5.9. for further motivation.

X.2.5.7. The general coordinate formula for the differential is very complicated and is of doubtful usefulness to even write down. A few more special cases are simple and illuminating:

1-form:

$$d(f\,dx_j)=\left(\frac{\partial f}{\partial x_1}\,dx_1+\cdots+\frac{\partial f}{\partial x_n}\right)\wedge dx_j$$

$$=\frac{\partial f}{\partial x_1}\,dx_1\,dx_j+\cdots+\frac{\partial f}{\partial x_{j-1}}\,dx_{j-1}\,dx_j-\frac{\partial f}{\partial x_{j+1}}\,dx_j\,dx_{j+1}-\cdots-\frac{\partial f}{\partial x_n}\,dx_j\,dx_n\ .$$

A general 1-form is canonically a sum of these.

$(n-1)$-form:

$$d(f\,dx_1\,dx_2\cdots dx_{j-1}\,dx_{j+1}\cdots dx_n) = \left(\frac{\partial f}{\partial x_1}\,dx_1 + \cdots + \frac{\partial f}{\partial x_n}\,dx_n\right) \wedge (dx_1\,dx_2\cdots dx_{j-1}\,dx_{j+1}\cdots dx_n)$$

$$= \frac{\partial f}{\partial x_j}\,dx_j\,dx_1\cdots dx_{j-1}\,dx_{j+1}\cdots dx_n = (-1)^{j-1}\frac{\partial f}{\partial x_j}\,dx_1\cdots dx_n\ .$$

A general $(n-1)$-form is canonically a sum of these.

"constant" form:

$$d(dx_I) = d(1\,dx_{i_1}\cdots dx_{i_k}) = (d1)\wedge(dx_{i_1}\cdots dx_{i_k}) = 0$$

where $I = (i_1,\dots,i_k)$ is an arbitrary k-multiindex and 1 is the constant function 1 (note that $d1 = 0$).

Of course, if ω is an n-form, then $d\omega = 0$.

Properties

X.2.5.8. PROPOSITION. Let U be an open set in $\mathbb{R}^n$.
(i) Let $\omega_1,\omega_2\in\Omega^k(U)$ $(0\le k\le n)$. Then

$$d(\omega_1+\omega_2) = d\omega_1 + d\omega_2\ .$$

(ii) Let $\omega_1\in\Omega^k(U)$ and $\omega_2\in\Omega^\ell(U)$. Then

$$d(\omega_1\wedge\omega_2) = (d\omega_1)\wedge\omega_2 + (-1)^k\omega_1\wedge(d\omega_2)\ .$$

(iii) Let $\omega\in\Omega^k(U)$. Then $d(d\omega) = 0$.

PROOF: (i) is obvious; in fact it is obvious that d is linear (respects both addition and scalar multiplication).
(ii): By linearity, it suffices to prove this for $\omega_1 = f\,dx_I$ and $\omega_2 = g\,dx_J$, where I is a k-multiindex and J an ℓ-multiindex. Then

$$\omega_1\wedge\omega_2 = fg\,(dx_I\wedge dx_J) = fg\,dx_K$$

where for $I = (i_1,\dots,i_k)$ and $J = (j_1,\dots,j_\ell)$ we take K to be the $(k+\ell)$-multiindex $(i_1,\dots,i_k,j_1,\dots,j_\ell)$; K is not necessarily strictly increasing, but by X.2.5.4. and the last observation of X.2.5.5.

$$d(\omega_1\wedge\omega_2) = d(fg)\wedge dx_K = (f\,dg + g\,df)\wedge dx_K = (f\,dg + g\,df)\wedge dx_I\wedge dx_J$$

$$= g\,[df\wedge dx_I]\wedge dx_J + f\,[dg\wedge dx_I\wedge dx_J]$$

$$= g\,[df\wedge dx_I]\wedge dx_J + (-1)^k f\,[dx_I\wedge dg\wedge dx_J]$$

$$= [df\wedge dx_I]\wedge[g\,dx_J] + (-1)^k\,[f\,dx_I]\wedge[dg\wedge dx_J] = (d\omega_1)\wedge\omega_2 + (-1)^k\omega_1\wedge(d\omega_2)\ .$$

(iii) By (ii), we have, for any k-multiindex I,

$$d(d(f\,dx_I)) = d((df)\wedge(dx_I)) = d(df)\wedge dx_I - (df)\wedge d(dx_I)\ .$$

The second term is 0 (cf. X.2.5.7.), so it suffices to show that $d(df) = 0$ for any f.

$$d(df) = d\left(\sum_{j=1}^{n} \frac{\partial f}{\partial x_j}\, dx_j\right) = \sum_{j=1}^{n} \left[\sum_{i<j} \frac{\partial^2 f}{\partial x_i\, \partial x_j}\, dx_i\, dx_j - \sum_{i>j} \frac{\partial^2 f}{\partial x_i\, \partial x_j}\, dx_j\, dx_i\right] .$$

Using Clairaut's Theorem, the terms cancel in pairs, so the sum is 0. 👍

A Characterization

The properties in X.2.5.8., along with the basic formula for 0-forms, uniquely characterize the differential:

X.2.5.9. THEOREM. Let U be an open set in $\mathbb{R}^n$. Then the differential as defined in X.2.5.5. is the unique set of functions from $\Omega^k(U)$ to $\Omega^{k+1}(U)$ $(0 \le k \le n)$ satisfying the properties of X.2.5.8. and for which df $(f \in \mathcal{C}^\infty(U) = \Omega^0(U))$ is as defined in X.2.5.1..

X.2.6. Stokes' Theorem for Rectangles in $\mathbb{R}^n$

X.2.6.1. Our general setup in this section is as follows. Let U be an open set in $\mathbb{R}^n$, and

$$R = \prod_{j=1}^{n} [a_j, b_j]$$

an n-rectangle in U. The boundary ∂R is a union of $2n$ $(n-1)$-faces which we denote 0_j and 1_j $(1 \le j \le n)$, where

$$0_j = \{(x_1, \ldots, x_{j-1}, a_j, x_{j+1}, \ldots, x_n) \in R\}$$
$$1_j = \{(x_1, \ldots, x_{j-1}, b_j, x_{j+1}, \ldots, x_n) \in R\}$$

(the faces for different j overlap in faces of dimension $n-2$). Denote by R_j the product $\prod_{i \ne j} [a_i, b_i] \subseteq \mathbb{R}^{n-1}$.

Induced Orientation

X.2.6.2. The rectangle R inherits a natural orientation from $\mathbb{R}^n$ using the standard basis. The induced orientation on ∂R () is easy to describe: on each $(n-1)$-face it is the one with "outward-pointing normal." On the faces 1_j it is $(-1)^{j-1}$ times the one from the map

$$\pi_{j1} : (x_1, \ldots, x_{j-1}, x_{j+1}, \ldots, x_n) \mapsto (x_1, \ldots, x_{j-1}, b_j, x_{j+1}, \ldots, x_n) : R_j \to 1_j$$

and for 0_j it is the negative of $(-1)^{j-1}$ times the one from the corresponding map

$$\pi_{j0} : (x_1, \ldots, x_{j-1}, x_{j+1}, \ldots, x_n) \mapsto (x_1, \ldots, x_{j-1}, a_j, x_{j+1}, \ldots, x_n) : R_j \to 0_j$$

so if $f \in \mathcal{C}^\infty(U)$ we have

$$\int_{1_j} f\, dx_1 \cdots dx_{j-1}\, dx_{j+1} \cdots dx_n = (-1)^{j-1} \int_{R_j} f \circ \pi_{j1}\, dV$$

$$\int_{0_j} f\,dx_1\cdots dx_{j-1}\,dx_{j+1}\cdots dx_n = -(-1)^{j-1}\int_{R_j} f\circ\pi_{j0}\,dV$$

where $\int_{R_j}\cdot dV$ is the usual Riemann integral.

Note also that

$$\int_{1_i} f\,dx_1\cdots dx_{j-1}\,dx_{j+1}\cdots dx_n = \int_{0_i} f\,dx_1\cdots dx_{j-1}\,dx_{j+1}\cdots dx_n = 0$$

if $i \neq j$.

Statement and Proof of the Theorem

X.2.6.3. THEOREM. [STOKES' THEOREM FOR RECTANGLES] Let U be an open set in $\mathbb{R}^n$, R an n-rectangle in U, and $\omega \in \Omega^{n-1}(U)$. Give R the natural orientation and ∂R the induced orientation. Then

$$\int_R d\omega = \int_{\partial R}\omega\ .$$

PROOF: By linearity it suffices to prove the theorem for $\omega = f\,dx_1\cdots dx_{j-1}\,dx_{j+1}\cdots dx_n$ for some j, $1 \leq j \leq n$. We then have

$$d\omega = (-1)^{j-1}\frac{\partial f}{\partial x_j}\,dx_1\cdots dx_n$$

(X.2.5.7.). So we have

$$\int_R d\omega = (-1)^{j-1}\int_R \frac{\partial f}{\partial x_j}\,dV\ .$$

Using the above notation, by Fubini's Theorem (IX.3.4.13.) this equals

$$(-1)^{j-1}\int_{R_j}\left[\int_{a_j}^{b_j}\frac{\partial f}{\partial x_j}(x_1,\ldots,x_{j-1},t,x_{j+1},\ldots,x_n)\,dt\right]dV$$

$$= (-1)^{j-1}\int_{R_j}\left[f(x_1,\ldots,x_{j-1},b,x_{j+1},\ldots,x_n) - f(x_1,\ldots,x_{j-1},a,x_{j+1},\ldots,x_n)\right]dV$$

by the Fundamental Theorem of Calculus (IX.2.9.5.). As above, this equals

$$(-1)^{j-1}\int_{R_j} f\circ\pi_{j1}\,dV - (-1)^{j-1}\int_{R_j} f\circ\pi_{j0}\,dV = \int_{1_j}\omega + \int_{0_j}\omega = \int_{\partial R}\omega$$

since $\int_{1_i}\omega = \int_{0_i}\omega = 0$ for $i \neq j$. 👍

X.2.6.4. It is claimed in [Spi65] that Stokes' Theorem is "trivial." While there is some justifiable truth to this statement, it is overblown because (among other reasons) the proof depends on

The Fundamental Theorem of Calculus (IX.2.9.5.)

Fubini's Theorem (IX.3.4.13.)

neither of which is trivial (granted, the proof of Stokes' Theorem is pretty easy modulo these results); and the general Stokes' Theorem, even in $\mathbb{R}^n$ (), also depends on

The Change of Variables Theorem () (unless the integral on chains is defined by fiat)

The Partition of Unity Theorem (XIII.11.10.15.)

which are definitely nontrivial.

X.2.7. Pullbacks of Forms

If U and V are open sets in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, and $\boldsymbol{f}$ is a smooth map from U to V, there is a systematic way to "pull back" a form ω on V to a form $\boldsymbol{f}^*\omega$ on U respecting wedge products, differentials and, to the greatest extent possible, integrals. Pullbacks are closely related to the Change of Variable Theorem (). There is an elegant coordinate-free definition of the pullback (), but we will take a lower-tech approach using coordinates which will result in more useful explicit formulas.

Pullback of a Function

X.2.7.1. There is an obvious way to pull back an element g of $\Omega^0(V) = \mathcal{C}^\infty(V)$ to an element $\boldsymbol{f}^*(g)$ of $\Omega^0(U) = \mathcal{C}^\infty(U)$: set $\boldsymbol{f}^*(g) = g \circ \boldsymbol{f}$. In fact, this is forced by the requirement that $\boldsymbol{f}^*$ preserve "integration": if $\boldsymbol{x} \in U$ and $\boldsymbol{y} = \boldsymbol{f}(\boldsymbol{x})$, and σ is $+1$ or -1, the integral of $g \in \mathcal{C}^\infty(V)$ over the oriented 0-submanifold $Y = \{\boldsymbol{y}; \sigma\}$ is $\sigma g(\boldsymbol{y})$. So to preserve integration we need to have the integral $\sigma[\boldsymbol{f}^*(g)](\boldsymbol{x})$ of $\boldsymbol{f}^*(g)$ over the oriented 0-submanifold $\{\boldsymbol{x}; \sigma\}$ of U to be $\sigma g(\boldsymbol{y}) = \sigma g(\boldsymbol{f}(\boldsymbol{x}))$. This must be true for all $\boldsymbol{x} \in U$.

Pullback of a 1-Form

X.2.7.2. Now suppose $\omega \in \Omega^1(V)$. We want to define $\boldsymbol{f}^*\omega \in \Omega^1(U)$ so that $\boldsymbol{f}^*$ is linear and preserves wedge products and differentials. By linearity, it suffices to assume $\omega = g\,dy_j$ for $g \in \Omega^0(V)$ and $1 \le j \le m$. We need

$$\boldsymbol{f}^*(g\,dy_j) = \boldsymbol{f}^*(g \wedge dy_j) = \boldsymbol{f}^*(g) \wedge \boldsymbol{f}^*(dy_j) = \boldsymbol{f}^*(g) \wedge d(\boldsymbol{f}^*(y_j)) \ .$$

But y_j is just the j-th coordinate map of V, $y_j(\alpha_1, \ldots, \alpha_m) = \alpha_j$, so $\boldsymbol{f}^*(y_j) = y_j \circ \boldsymbol{f} = f_j$, where f_j is the j'th coordinate function of $\boldsymbol{f}$. So $\boldsymbol{f}^*\omega$ must be $(g \circ \boldsymbol{f})\,df_j$. In other words, we must define

$$\boldsymbol{f}^*\left(\sum_{j=1}^m g_j\,dy_j\right) = \sum_{j=1}^m (g_j \circ \boldsymbol{f})\,df_j \ .$$

X.2.7.3. Let us check that this definition respects integration in the following sense. Suppose I is an oriented 1-manifold in U, i.e. a simple smooth curve from $\boldsymbol{x}_0$ to $\boldsymbol{x}_1$, and that $J = \boldsymbol{f}(I)$ is an oriented 1-manifold in V, i.e. a simple smooth curve from $\boldsymbol{y}_0 = \boldsymbol{f}(\boldsymbol{x}_0)$ to $\boldsymbol{y}_1 = \boldsymbol{f}(\boldsymbol{x}_1)$ ($\boldsymbol{f}$ does not have to be one-to-one on I). Then, if ω is a 1-form on V,

X.2.7.4. In fact, the definition of the integral of a 1-form is based on a pullback. Suppose U is an open set in $\mathbb{R}^n$ and C a simple oriented smooth curve from $\boldsymbol{x}_0$ to $\boldsymbol{x}_1$. A smooth parametrization of C is a smooth function γ from $[a,b] \subseteq \mathbb{R}^1$ to C with $\gamma(a) = \boldsymbol{x}_0$ and $\gamma(b) = \boldsymbol{x}_1$ (technically we should extend γ to a slightly larger open interval in $\mathbb{R}^1$). If ω is a 1-form on U, then $\int_C \omega$ is *defined* to be $\int_{[a,b]} \gamma^*\omega$ (the Change of Variables Theorem in $\mathbb{R}^1$ then shows that this is well defined). If $\omega = \sum_{j=1}^n g_j\, dx_j$, we have

$$\int_C \omega = \int_{[a,b]} \gamma^*\omega = \int_{[a,b]} \left(\sum_{j=1}^n (g_j \circ \gamma)\, d\gamma_j \right) = \int_a^b \left(\sum_{j=1}^n (g_j(\gamma(t))\, \gamma_j'(t) \right) dt \ .$$

This is exactly the line integral along C of the vector field $\boldsymbol{g} = (g_1, \ldots, g_n)$ associated with ω ().

Pullback of a k-Form

X.2.7.5. The way to extend to a general k-form is then obvious (and forced):

$$\boldsymbol{f}^*(g\, dy_{j_1} \cdots dy_{j_k}) = (g \circ \boldsymbol{f})\, df_{j_1} \wedge \cdots \wedge df_{j_k}$$

(the wedges are often omitted from this formula) and the pullback of a general k-form defined by linearity.

Pullback of an n-Form

X.2.7.6. The coordinate formula for a general pullback has a nice form if $k = n$. First consider the case $k = m = n$. The general n-form on V is $\omega = g\, dy_1 \cdots dy_n$, and

$$f^*\omega = (g \circ \boldsymbol{f})\, df_1 \wedge \cdots \wedge df_n$$

$$= (g \circ \boldsymbol{f}) \left[\left(\frac{\partial f_1}{\partial x_1}\, dx_1 + \cdots \frac{\partial f_1}{\partial x_n}\, dx_n \right) \wedge \cdots \wedge \left(\frac{\partial f_n}{\partial x_1}\, dx_1 + \cdots \frac{\partial f_n}{\partial x_n}\, dx_n \right) \right]$$

When the expression in brackets is expanded by linearity and reordering coordinates to

$$(g \circ \boldsymbol{f})\, h\, dx_1 \cdots dx_n$$

the function h is exactly $det(D\boldsymbol{f})$ (Exercise ()). [In fact, using the coordinate-free approach of (), this is an elegant way to define and characterize the determinant, cf. ().]

X.2.7.7. Now consider the general case where $k = n$ (it will only be interesting if $n \leq m$). If $I = (i_1, \ldots, i_n)$ is an n-multiindex in $\mathbb{R}^m$, let $\pi_I : \mathbb{R}^m \to \mathbb{R}^n$ be

$$\pi_I(x_1, \ldots, x_m) = (x_{i_1}, \ldots, x_{i_n})$$

and $\boldsymbol{f}_I = \pi_I \circ \boldsymbol{f}$. One can think of $\boldsymbol{f}_I$ as the "I'th coordinate function of $\boldsymbol{f}$." Then $\boldsymbol{f}_I : U \to \mathbb{R}^n$, and a calculation () shows that

$$\boldsymbol{f}^* \left(\sum_I g_I\, dy_I \right) = \left[\sum_I (g_I \circ \boldsymbol{f})\, det(D\boldsymbol{f}_I) \right] dx_1 \cdots dx_n \ .$$

(This formula also works if the I's in the sum are not strictly increasing.)

This formula agrees with the previous one if $k = n = m$, and with the line integral if $k = n = 1$.

X.2.12.1. Verify the formula in X.2.5.2..

X.2.12.2. Give the details of the proof of Theorem X.2.5.3.. (Note that $\int_{\partial C} f = f(\boldsymbol{x}_1) - f(\boldsymbol{x}_0)$.)

X.2.12.3. Carry out the calculation of $\int_{\partial R} \omega$ in X.2.5.6. and verify the formula for h, as follows. Let $R = [a,b] \times [c,d]$.

(a) Calculate

$$\int_{\partial R} (f\,dx + g\,dy) = \int_a^b f(x,c)\,dx + \int_c^d g(b,y)\,dy + \int_b^a f(x,d)\,dx + \int_d^c g(a,y)\,dy$$

$$= \int_c^d [g(b,y) - g(a,y)]\,dy - \int_a^b [f(x,d) - f(x,c)]\,dx = \int_c^d \left[\int_a^b \frac{\partial g}{\partial x}(x,y)\,dx\right] dy - \int_a^b \left[\int_c^d \frac{\partial f}{\partial y}(x,y)\,dy\right] dx\ .$$

(b) Note that dx and dy each stand for two different things in (a) and explain the notation.

(c) Apply Fubini's Theorem (IX.3.4.10.).

Chapter XI

Differential Equations

> "The most widely and successfully used concept in mathematical descriptions of scientific problems has been the differential equation, even though success has often been impeded by the fact that differential equations can be extremely difficult to analyze. These difficulties, rather than thwarting progress, have instead stimulated more research and better understanding. As a result, the subject of differential equations contains a wealth of deep theories and subtle methods of analysis."
>
> *E. A. Herman*[1]

The subject of Differential Equations consists of the study of differential equations, how to solve them (exactly or approximately), and the properties the solutions must have. A *differential equation* is an equation involving an unknown function and its derivatives. A *solution* to a differential equation is a sufficiently differentiable function satisfying the equation, usually also satisfying some specified initial or boundary conditions. The unknown function may be a function of one independent variable or more than one. A differential equation involving a function of one independent variable is an *ordinary differential equation* or *ODE*; a differential equation involving a function of more than one independent variable is a *partial differential equation* or *PDE*. One can also consider systems of ODEs or PDEs involving several unknown functions. In general, as might be easily predicted, the theory of PDEs is much more difficult than the theory of ODEs, and most active research in Differential Equations today involves PDEs.

Differential equations are of fundamental importance in both pure and applied mathematics. For example, the basic laws of physics, beginning with $F = ma$, are really differential equations [if $y(t)$ is position at time t, and $F(y)$ is the force at position y, then the equation is

$$my''(t) = F(y(t)) \ .$$

The force could also be a function of both y and t. There are variations possible such as taking both y and F to be vector-valued.]

The subject of Differential Equations is one of the largest areas of mathematics, bridging pure and applied mathematics. Entire books are written on the solutions to important specific differential equations. A considerable part of Numerical Analysis involves computing numerical approximations to solutions of

[1] [**?**, p. 161].

differential equations. We will only treat the most basic aspects of the theory, with an emphasis on the analysis tools needed to obtain them, and we will concentrate on establishing general theorems about existence, uniqueness, and properties of solutions rather than the elaborate techniques used to actually find them explicitly.

> "Newton's *Principia* was impressive, with its revelation of deep mathematical laws underlying natural phenomena. But what happened next was even more impressive. Mathematicians tackled the entire panoply of physics – sound, light, heat, fluid flow, gravitation, electricity, magnetism. In every case, they came up with differential equations that described the physics, often very accurately.
>
> The long-term implications have been remarkable. Many of the most important technological advances, such as radio, television, and commercial jet aircraft depend, in numerous ways, on the mathematics of differential equations. The topic is still the subject of intense research activity, with new applications emerging almost daily. It is fair to say that Newton's invention of differential equations, fleshed out by his successors in the 18th and 19th centuries, is in many ways responsible for the society in which we now live. This only goes to show what is lurking just behind the scenes, if you care to look."
>
> *Ian Stewart*[2]

The following warning from [**?**, p. vii] should be well heeded:

> "In elementary courses one frequently gets the impression that [differential] equations can usually be 'solved,' i.e., that explicit formulas for solutions (in terms of powers, exponentials, trigonometric functions, and the like) can usually be found. Nothing could be further from the truth. In fact, only very exceptional equations can be explicitly integrated – those that appear in the exercise sections of classical textbooks."

The situation is similar to the fact that it is rarely possible to find an explicit formula for a function implicitly defined by an equation $F(x, y) = 0$, even for nice F ((); in fact, such an equation can be thought of as a "differential equation of order zero").

[2] *The Story of Mathematics*, p. 136.

XI.1. Existence and Uniqueness of Solutions to Ordinary Differential Equations

XI.1.1. Elementary Considerations and Terminology

XI.1.1.1. It is customary (although by no means universal) in the theory of ODEs to denote the independent variable by t, since in many applications the independent variable represents time. The unknown function is typically denoted x or y; we will standardize on using y as being less confusing to those of us used to using x as an independent variable. While t is always assumed to be a real variable, usually ranging over an interval, y can be real-valued or vector-valued (we will use x's to denote elements of the range space and y's to denote functions from $\mathbb{R}$ to the range space).

XI.1.1.2. An ODE is thus an equation involving $t, y, y', \ldots, y^{(n)}$, which can be put in the form

$$F(t, y, y', \ldots, y^{(n)}) = 0$$

by putting everything on one side of the equation. Such an equation is called an *ordinary differential equation of order n* (most differential equations arising in physics and other applications have order 1 or 2). For the most part, we consider only differential equations of the *standard form* (or *Cauchy form*)

$$y^{(n)} = f(t, y, y', \ldots, y^{(n-1)})$$

which is an abbreviation for

$$y^{(n)}(t) = f(t, y(t), y'(t), \ldots, y^{(n-1)}(t))$$

where f is a specified real-valued (or, more generally, vector-valued) function with reasonable properties (usually at least continuous) and the equation is to hold for all t in a suitable subset of $\mathbb{R}$. Most reasonable ODEs can in principle be put into this form using the Implicit Function Theorem (Exercise XI.1.10.2.), and most ODE's arising in applications are already of this form or can easily be put into it explicitly (with the exception of certain linear ODEs; cf. ()).

If f is a function of only $y, y', \ldots, y^{(n-1)}$ (i.e. not explicitly of t), the differential equation is called *autonomous*; when t is interpreted as time, an autonomous differential equation is "time-independent." Many, but by no means all, differential equations in applications are autonomous.

A solution y to an n'th order ODE is necessarily a function which is n-times differentiable; for an equation in standard form, if f is continuous, y must be $\mathcal{C}^n$ since the right side will be a continuous function of t. If f is $\mathcal{C}^r$, then $y^{(n)}$ is $\mathcal{C}^r$ by the Chain Rule, so y is $\mathcal{C}^{n+r}$.

XI.1.1.3. We almost always want to consider only solutions to differential equations on intervals, generally open intervals; sometimes solutions given by formulas have domains consisting of a disjoint union of open intervals, in which case the restriction to each of the subintervals is considered a separate solution. Most commonly we want a solution $y(t)$ on an interval I taking a specified value x_0 at a specified number $t_0 \in I$ (our use of x_0 for the initial value instead of y_0 is nonstandard, but the reasons for using this notation will be apparent later, and it is consistent with our convention described in XI.1.1.1.). A differential equation with a specified value at an "initial" point t_0 is called an *initial-value problem* or *IVP* (for a higher-order differential equation, initial values for lower-order derivatives are also needed, or values at more than one point, called a *boundary-value problem* or *BVP*). While differential equations typically have many solutions, with various intervals of definition, in reasonable cases initial-value problems have unique solutions.

XI.1.1.4. In fact, the general principle of the theory of differential equations is that, subject to some mild technical restrictions, the general solution to an n'th order differential equation is a family of functions determined by n more or less independent constants (parameters), which can be expressed in various ways. (Conversely, a family of smooth functions determined by n independent parameters is the general solution set to an n'th order differential equation, again subject to mild technical restrictions, cf. Exercise XI.1.10.5..)

However, it is usually impossible to find an explicit or closed formula for the general solution to even simple differential equations (cf. XI.1.1.5.(i), XII.12.3.13., XII.12.3.18.). Implicit relations can be found in somewhat greater generality, but even these can be difficult or impossible to come by in many cases. Power-series solutions can often be found if the differential equation is sufficiently regular. But in many cases the best one can do is generate approximate numerical solutions, and there are now powerful and efficient techniques for doing this.

XI.1.1.5. Examples. Here are some simple examples of first- and second-order differential equations that illustrate the general nature of the subject.

(i) Let f be a real-valued continuous function on an interval I. A solution to the first-order differential equation

$$y' = f(t)$$

is simply an antiderivative for f on I. There is thus a solution by V.8.5.9., in fact infinitely many, all differing by constants. If $t_0 \in I$ is fixed and x_0 is a fixed real number, then there is a unique solution y on I satisfying the differential equation (i.e. an antiderivative for f on I) and also the initial condition $y(t_0) = x_0$.

(ii) Consider the autonomous first-order differential equation

$$y' = ky$$

on $\mathbb{R}$, where $k \in \mathbb{R}$ is a constant. A solution is $y(t) = Ae^{kt}$, where A is an arbitrary real constant. To see that these are all the solutions, suppose y is a solution which is not identically 0, and fix t_0 with $y(t_0) \neq 0$. Then y is nonzero in an interval around t_0, and we have, for t in this interval,

$$\frac{d}{dt}\left(\log|y(t)|\right) = \frac{y'(t)}{y(t)} = k$$

so $\log|y(t)| = kt + C$ for some constant C. Thus $|y(t)| = e^C e^{kt}$ for some C, at least for t near enough to t_0. But it follows easily that $y(t) = \pm e^C e^{kt}$ for t near t_0 (with constant sign depending on the sign of $y(t_0)$), and this solution extends uniquely to a solution on all of $\mathbb{R}$. If we specify the initial condition $y(t_0) = x_0$, we have a unique solution with $A = x_0 e^{-kt_0}$, valid on all of $\mathbb{R}$. The "time-independence" of the equation is that if $y = f(t)$ is a solution, then so is $y = f(t + b)$ for any constant b.

(iii) Let $k > 0$ be a constant, and consider the autonomous second-order differential equation

$$y'' = k^2 y\ .$$

The function

$$y(t) = Ae^{kt} + Be^{-kt}$$

is a solution on all of $\mathbb{R}$ for arbitrary real constants A and B. The differential equation

$$y'' = -k^2 y$$

has as solution

$$y(t) = A\cos kt + B\sin kt$$

for constants A, B. It can be shown that in both cases, every solution is of this form (). Simple calculations show that if we fix $t_0 \in \mathbb{R}$ and real constants x_0 and x_0', then in either case there is a unique solution (i.e. unique choice of A and B) with $y(t_0) = x_0$ and $y'(t_0) = x_0'$.

Here are some more examples which illustrate other characteristics of solutions to differential equations:

XI.1.1.6. EXAMPLES. (i) Consider the autonomous first-order differential equation

$$y' = |y| \ .$$

The constant function $f_0(t) = 0$ is a solution, as is $f_A(t) = Ae^t$ for $A > 0$ and $f_A(t) = Ae^{-t}$ for $A < 0$. It can be shown (Exercise ()) that every solution on an interval I is the restriction of one of these solutions to I. These solutions are $\mathcal{C}^\infty$ on all of $\mathbb{R}$ despite the fact that $|y|$ is not a differentiable function of y. It is easily checked that for every t_0 and x_0 there is a unique choice of $A \in \mathbb{R}$ for which f_A is a solution to the IVP

$$y' = |y|, \quad y(t_0) = x_0 \ .$$

The function $f(t, y) = |y|$ is continuous on $\mathbb{R}^2$; although it is not differentiable in y for $y = 0$, it satisfies a uniform Lipschitz condition in y: $|f(t, y_2) - f(t, y_1)| \leq |y_2 - y_1|$ for all $t, y_1, y_2 \in \mathbb{R}$.

(ii) Consider the autonomous first-order differential equation

$$y' = y^2 \ .$$

The constant function 0 is a solution, as is

$$f_c(t) = \frac{1}{c - t}$$

for $c \in \mathbb{R}$. It can be shown (Exercise ()) that every solution on an interval I is the restriction of one of these solutions to I. For any t_0 and x_0, the initial-value problem

$$y' = y^2, \quad y(t_0) = x_0$$

has a unique solution in an interval around t_0: if $x_0 = 0$, the solution is the constant function 0, and if $x_0 \neq 0$, the solution is the restriction of f_c, where $c = t_0 + \frac{1}{x_0}$. This solution is only defined on the interval $(-\infty, c)$ or $(c, +\infty)$ around t_0, not on all of $\mathbb{R}$. The (maximum) domain of the solution depends on t_0 and x_0.

(iii) Consider the autonomous first-order differential equation

$$y' = \frac{3}{2} y^{1/3}$$

(the constant $\frac{3}{2}$ just makes subsequent calculations easy). The constant function 0 is a solution, as are

$$\phi_c^+(t) = \begin{cases} 0 & \text{if} \quad t < c \\ (t - c)^{3/2} & \text{if} \quad t \geq c \end{cases}$$

$$\phi_c^-(t) = \begin{cases} 0 & \text{if} \quad t < c \\ -(t-c)^{3/2} & \text{if} \quad t \geq c \end{cases}$$

for any $c \in \mathbb{R}$. Note that these solutions are defined and $\mathcal{C}^1$ (but not $\mathcal{C}^2$) on all of $\mathbb{R}$. It can be shown (Exercise ()) that every solution on an interval I is the restriction of one of these solutions to I. Note that $f(t,y) = \frac{3}{2}y^{1/3}$ is continuous on $\mathbb{R}^2$, but does not satisfy a Lipschitz condition in y around $y = 0$.

If $t_0, x_0 \in \mathbb{R}$, the initial-value problem

$$y' = \frac{3}{2}y^{1/3}, \quad y(t_0) = x_0$$

always has a solution. If $x_0 \neq 0$, the unique solution is $\phi_c^{\pm}$, where $c = t_0 - x_0^{2/3}$ and the sign is the sign of x_0. If $x_0 = 0$, there are many solutions: the constant function 0 is a solution, as are ϕ_c^+ and ϕ_c^- for any $c \geq t_0$. The solutions 0, $\phi_{t_0}^+$, and $\phi_{t_0}^-$ do not agree on any interval around t_0, so the solutions are not locally unique.

(iv) Consider the autonomous first-order differential equation

$$y' = 3y^{2/3} \ .$$

The constant function 0 is a solution, as are

$$\phi_c(t) = (t-c)^3$$

$$\psi_c^+(t) = \begin{cases} 0 & \text{if} \quad t < c \\ (t-c)^3 & \text{if} \quad t \geq c \end{cases}$$

$$\psi_c^-(t) = \begin{cases} (t-c)^3 & \text{if} \quad t < c \\ 0 & \text{if} \quad t \geq c \end{cases}$$

for any $c \in \mathbb{R}$, and

$$\psi_{c,d}(t) = \begin{cases} (t-c)^3 & \text{if} \quad t < c \\ 0 & \text{if} \quad c \leq t \leq d \\ (t-d)^3 & \text{if} \quad t > d \end{cases}$$

for any $c, d \in \mathbb{R}$, $c < d$ (we could write $\psi_{c,c} = \phi_c$). Note that these solutions are defined on all of $\mathbb{R}$; ϕ_c is $\mathcal{C}^\infty$ (even analytic) on $\mathbb{R}$, and $\psi_c^{\pm}$ and $\psi_{c,d}$ ($c < d$) are $\mathcal{C}^2$ but not $\mathcal{C}^3$ on $\mathbb{R}$. It can be shown (Exercise ()) that every solution on an interval I is the restriction of one of these solutions to I. Note that $f(t,y) = 3y^{2/3}$ is continuous on $\mathbb{R}^2$, but does not satisfy a Lipschitz condition in y around $y = 0$.

If $t_0, x_0 \in \mathbb{R}$, the initial-value problem

$$y' = 3y^{2/3}, \quad y(t_0) = x_0$$

always has a solution. If $x_0 \neq 0$, there is locally a unique solution ϕ_c, where $c = t_0 - x_0^{1/3}$. However, this solution is not globally unique: $\psi_c^{\pm}$ (where the sign is the sign of x_0) is also a solution, as is $\psi_{c,d}$ for any $d > c$ if $x_0 < 0$ and $\psi_{d,c}$ for any $d < c$ if $x_0 > 0$. If $x_0 = 0$, there are many solutions: the constant function 0 is a solution, as are ϕ_{t_0}, ψ_c^+ for any $c \geq t_0$, ψ_c^- for any $c \leq t_0$, and $\psi_{c,d}$ for $c \leq t_0 \leq d$. The solutions 0, ϕ_{t_0}, $\psi_{t_0}^+$, and $\psi_{t_0}^-$ do not agree on any interval around t_0, so the solutions are not locally unique.

XI.1.2. Existence and Uniqueness Theorem for First-Order ODEs

In this subsection, we prove a general theorem about existence and uniqueness of local solutions to a first-order initial-value problem

$$y' = f(t, y), \quad y(t_0) = x_0$$

where y is an unknown function from an interval I in $\mathbb{R}$ to a (real) Banach space $\mathcal{X}$. In most elementary applications $\mathcal{X}$ will be $\mathbb{R}$, or $\mathbb{R}^n$ for some n; we use a general Banach space since the result is then cleaner to state as well as more general, and the proof is the same. This fundamental theorem is closely related to the Implicit and Inverse Function Theorems, at least in spirit (cf. XI.1.10.12.). In particular, it is a local result, but we have control over the size of the interval on which the solution is valid, which in some key special cases gives global solutions. This result was first obtained by E. PICARD in 1890; our exposition is adapted from [**?**]. The result is called the *Picard Existence Theorem*, *Picard-Lindelöf Theorem*, or *Cauchy-Lipschitz Theorem* in various references (the Cauchy-Lipschitz Theorem is properly the crucial special case XI.1.2.7., obtained before PICARD'S general result).

XI.1.2.1. The setup of this theorem is as follows. Let $\mathcal{X}$ be a Banach space and $x_0 \in \mathcal{X}$. Let $\bar{B}_r(x_0)$ be the closed ball in $\mathcal{X}$ centered at x_0 with radius $r > 0$. Let $t_0 \in \mathbb{R}$, and I an interval in $\mathbb{R}$ with $t_0 \in I$. Let f be a continuous function from $I \times \bar{B}_r(x_0)$ to $\mathcal{X}$. We suppose in addition there is a constant M such that $\|f(t,x)\| \leq M$ for all $(t,x) \in I \times \bar{B}_r(x_0)$, and that f satisfies a uniform Lipschitz condition in x (or, as we usually write, in y) on $I \times \bar{B}_r(x_0)$, i.e. there is a constant K such that for every $t \in I$ and $x_1, x_2 \in \bar{B}_r(x_0)$ we have

$$\|f(t,x_2) - f(t,x_1)\| \leq K\|x_2 - x_1\| \ .$$

We seek an interval $I_0 \subseteq I$, $t_0 \in I_0$, and a differentiable function $y : I_0 \to \mathcal{X}$ such that $y'(t) = f(t, y(t))$ for $t \in I_0$ and $y(t_0) = x_0$, and to show that any two such functions agree on I_0.

XI.1.2.2. THEOREM. [EXISTENCE AND UNIQUENESS THEOREM FOR FIRST-ORDER ODES] Using the above notation, set

$$I_0 = I \cap \left[t_0 - \frac{r}{M}, t_0 + \frac{r}{M}\right] \ .$$

Then there is a unique differentiable function $y : I_0 \to \mathcal{X}$ such that $y'(t) = f(t, y(t))$ for $t \in I_0$ and $y(t_0) = x_0$. Additionally, y is $\mathcal{C}^1$ on I_0. If $\tilde{I}$ is any subinterval of I_0 containing t_0, the restriction of y to $\tilde{I}$ is the unique solution to the IVP on $\tilde{I}$.

PROOF: It suffices to show there is a unique solution on any closed subinterval J of I_0 containing t_0. The strategy of the proof is to use the (Extended) Banach Fixed-Point Theorem (VI.2.10.10.) to obtain the solution on J as the unique fixed point of a suitable strict power contraction on a complete metric space. To this end, set $\epsilon = \frac{r}{M}$ and let Y be the set of continuous functions from J to the closed ball $\bar{B}_r(x_0)$ in $\mathcal{X}$ of radius r centered at x_0. Define a metric ρ on Y by

$$\rho(\phi, \psi) = \max_{t \in J} \|\phi(t) - \psi(t)\| \ .$$

Then Y is a complete metric space under ρ (it is a closed subset of $C(J, \mathcal{X})$ ()). Define a map $T : Y \to Y$ by

$$[T(\phi)](t) = x_0 + \int_{t_0}^{t} f(u, \phi(u))\, du \ .$$

It is obvious from () that $T(\phi)$ is a continuous function from J to $\mathcal{X}$. We must show that $T(\phi) \in Y$ if $\phi \in Y$, and that there is an n and a constant $\alpha < 1$ such that $\rho(T^n(\phi), T^n(\psi)) \le \alpha\rho(\phi, \psi)$ for all $\phi, \psi \in Y$.

We have, for $t \in J$ and $\phi \in Y$,

$$\|[T(\phi)](t) - x_0\| = \left\| \int_{t_0}^{t} f(u, \phi(u))\, du \right\| \le \int_{t_0}^{t} \|f(u, \phi(u)\|\, du \le M|t - t_0| \le M\epsilon = r$$

so $T(\phi) \in Y$. And we have, for $\phi, \psi \in Y$ and $t \in J$,

$$\|T(\phi)(t) - T(\psi)(t)\| = \left\| \int_{t_0}^{t} [f(u, \phi(u)) - f(u, \psi(u))]\, du \right\|$$

$$\le \int_{t_0}^{t} \|f(u, \phi(u)) - f(u, \psi(u))\|\, du \le K \int_{t_0}^{t} \|\phi(u) - \psi(u)\|\, du$$

$$\le K\epsilon \max_{u \in J} \|\phi(u) - \psi(u)\| = K\epsilon\rho(\phi, \psi)\ .$$

Similarly, for each n we have

$$\|T^n(\phi) - T^n(\psi)\| \le K \left| \int_{t_0}^{t} \|T^{n-1}(\phi)(u_1) - T^{n-1}(\psi)(u_1)\|\, du_1 \right|$$

$$\le K^2 \left| \int_{t_0}^{t} \int_{t_0}^{u_1} \|T^{n-2}(\phi)(u_2) - T^{n-2}(\psi)(u_2)\|\, du_2\, du_1 \right|$$

$$\le \cdots \le K^n \left| \int_{t_0}^{t} \int_{t_0}^{u_1} \cdots \int_{t_0}^{u_{n-1}} \|\phi(u_n) - \psi(u_n)\|\, du_n \cdots du_1 \right|$$

$$\le K^n \rho(\phi, \psi) \left| \int_{t_0}^{t} \int_{t_0}^{u_1} \cdots \int_{t_0}^{u_{n-1}} du_n \cdots du_1 \right| = \frac{K^n |t - t_0|^n}{n!} \rho(\phi, \psi) \le \frac{(K\epsilon)^n}{n!} \rho(\phi, \psi)\ .$$

Since t is arbitrary, we have

$$\rho(T^n(\phi), T^n(\psi)) \le \frac{(K\epsilon)^n}{n!} \rho(\phi, \psi)\ .$$

If n is sufficiently large, then

$$\frac{(K\epsilon)^n}{n!} < 1$$

and thus T^n is a strict contraction from Y to Y.

Thus, by VI.2.10.10., T has a unique fixed point y. We thus have

$$y(t) = t_0 + \int_{t_0}^{t} f(u, y(u))\, du$$

for $t \in J$, and since $g(u) = f(u, y(u))$ is continuous, by () we have that $y'(t) = f(t, y(t))$ for $t \in J$. Also obviously $y(t_0) = x_0$. Conversely, any solution on J must be a fixed point of T, and thus y is the unique solution on J.

If J' is a closed subinterval of I_0 containing t_0 different from J, say $J \subseteq J'$, the unique solution on J' restricted to J must be the unique solution on J.

Since $g(t) = f(t, y(t))$ is continuous, y' is continuous, i.e. y is $\mathcal{C}^1$. 👍

XI.1.2.3. The restriction of the domain of the solution to $[t_0 - \frac{r}{M}, t_0 + \frac{r}{M}]$ simply insures that the unique solution near t_0, when continued to the endpoints of the interval, does not leave the range of y-values for which f is defined (the restriction is a real one even if r can be chosen arbitrarily large; cf. Example XI.1.1.6.(ii)); the constant $\frac{r}{M}$ is conservative in general (cf. Exercise XI.1.10.6.). Note that the size of the Lipschitz constant K does not affect the length of the interval on which the existence of a unique solution is guaranteed by the theorem. Note also that if t_0 is in the interior of I (the usual situation in which the theorem is applied), it is also in the interior of I_0.

XI.1.2.4. The proof of Theorem XI.1.2.2. is constructive: it not only shows the existence of a unique solution, but actually gives an iterative algorithm for finding it. In fact, if ϕ is any continuous function from I_0 to $\mathcal{X}$ with $\phi(t_0) = x_0$ (e.g. the constant function x_0), then the sequence $(T^n(\phi))$ converges uniformly on I_0 to the solution. This "method of successive approximations," called *Picard iteration*, is a practical computational method for finding approximations to the solution in many cases, although there are usually better numerical techniques.

XI.1.2.5. In fact, we have the following error estimate for the successive approximation: if ϕ_0 is the constant function x_0 and $\phi_n = T^n(\phi_0)$ for $n \in \mathbb{N}$, then, for $t \in I_0$,

$$\|\phi_0(t) - \phi_1(t)\| = \left\| \int_{t_0}^{t} f(u, y_0)\, du \right\| \leq \left| \int_{t_0}^{t} \|f(t, y_0)\|\, du \right| \leq M|t - t_0|$$

and by induction

$$\|\phi_n(t) - \phi_{n+1}(t)\| \leq \frac{MK^n}{(n+1)!}|t - t_0|^{n+1} \leq \frac{M}{K}\frac{(Kr/M)^{n+1}}{(n+1)!}$$

$$\|\phi_n(t) - y(t)\| \leq \frac{M}{K}\sum_{k=n+1}^{\infty}\frac{(Kr/M)^k}{k!}$$

The sum is the error in the n'th Taylor approximation to $e^{Kr/M}$, hence by ()

$$\rho(\phi_n, y) \leq \frac{Me^{Kr/M}}{K(n+1)!}\ .$$

Thus the ϕ_n converge uniformly quite rapidly to y.

We then get a local version with a cleaner statement but less precise conclusion:

XI.1.2.6. Corollary. [Existence and Uniqueness Theorem for First-Order ODEs, Local Version] Let $\mathcal{X}$ be a Banach space, $x_0 \in \mathcal{X}$, $t_0 \in \mathbb{R}$, and $f(t, y)$ a continuous function from a neighborhood U of (t_0, x_0) in $\mathbb{R} \times \mathcal{X}$ to $\mathcal{X}$. Suppose f satisfies a uniform Lipschitz condition in y on U. Then there is a $\delta > 0$ such that the first-order initial value problem

$$y' = f(t, y), \quad y(t_0) = x_0$$

has a unique solution on $[t_0 - \delta, t_0 + \delta]$. Additionally, y is $\mathcal{C}^1$ on $[t_0 - \delta, t_0 + \delta]$.

PROOF: An r and a closed bounded interval I containing t_0 in its interior can be chosen such that $I \times \bar{B}_r(x_0)$ is contained in U. By compactness, $f(t, x_0)$ is bounded, say by N, on I. If K is the Lipschitz constant, then for $y \in \bar{B}_r(x_0)$ we have

$$\|f(t,y)\| \leq \|f(t,x_0)\| + \|f(t,y) - f(t,x_0)\| \leq N + Kr$$

so f is bounded on $I \times \bar{B}_r(y_0)$. Apply the theorem with this I and r. 👍

As a special case, we get the following version which covers most standard applications. This is the version commonly stated and (sometimes) proved in Differential Equations texts.

XI.1.2.7. COROLLARY. [EXISTENCE AND UNIQUENESS THEOREM FOR FIRST-ORDER ODES, STANDARD VERSION] Let R be a rectangle in $\mathbb{R}^2$, and (t_0, x_0) an interior point of R. Let $f(t, y)$ be a function from R to $\mathbb{R}$ with f and $\frac{\partial f}{\partial y}$ continuous on R. Then there is a $\delta > 0$ such that the initial-value problem

$$y' = f(t,y), \quad y(t_0) = x_0$$

has a unique solution on $(t_0 - \delta, t_0 + \delta)$. Additionally, y is $\mathcal{C}^1$ on $(t_0 - \delta, t_0 + \delta)$.

PROOF: Since $\frac{\partial f}{\partial y}$ is continuous, it is bounded in a neighborhood of (t_0, x_0), and thus by the MVT (V.8.2.11.) f satisfies a uniform Lipschitz condition in y on this neighborhood. 👍

Using the theorem, one can get an explicit estimate for the size δ can be. Actually R can be any neighborhood of (t_0, x_0).

Global Solutions

XI.1.2.8. The above results only give a solution in a (usually small) interval around t_0. Even if f is defined on all of $I \times \mathcal{X}$, i.e. the hypotheses of XI.1.2.2. are satisfied for all r (with the Lipschitz constant K depending on r), Example XI.1.1.6.(ii) shows that the solution may not be defined on all of I. The maximum interval on which the solution is defined can even depend on the choice of x_0 (this might be predicted since the constant M can depend on x_0 as well as on r).

But if f satisfies a uniform Lipschitz condition in y on all of $I \times \mathcal{X}$ (or even somewhat more generally), the control on the domain in XI.1.2.2. allows us to cobble together local solutions into a solution defined on all of I:

XI.1.2.9. THEOREM. [EXISTENCE AND UNIQUENESS THEOREM FOR FIRST-ORDER ODES, GLOBAL VERSION] Let $\mathcal{X}$ be a Banach space, I an interval in $\mathbb{R}$, and $t_0 \in I$. Let $f(t, y)$ be a continuous function from $I \times \mathcal{X}$ to $\mathcal{X}$ satisfying a uniform Lipschitz condition in y on every closed bounded subinterval of I. Then, for any $x_0 \in \mathcal{X}$, the initial-value problem

$$y' = f(t,y), \quad y(t_0) = x_0$$

has a unique solution defined on all of I. Additionally, the solution is $\mathcal{C}^1$ on I.

PROOF: It suffices to show that if $J = [a, b]$ is any closed bounded subinterval of I containing t_0 in its interior, then there is a unique solution to the IVP $y' = f(t, y)$, $y(t_0) = x_0$ on J. Fix such a J. If K is the Lipschitz constant on J, also fix L with $0 < L < \frac{1}{K}$.

First let $t_1 \in J$ and $x_1 \in \mathcal{X}$, and consider the IVP $y' = f(t, y)$, $y(t_1) = x_1$. The function $g(t) = f(t, x_1)$ is bounded on J by compactness, say by N. Then for any r, f is bounded on $J \times \bar{B}_r(x_1)$ by $N + Kr$ (cf. the proof of XI.1.2.6.). Thus one bound on the length of the interval on which a unique solution is guaranteed by Theorem XI.1.2.2. is $\frac{r}{N+Kr}$. If r is taken large enough, this is greater than L. Thus Theorem XI.1.2.2. gives a unique solution to this IVP on $J \cap [t_1 - L, t_1 + L]$.

Now return to the original IVP $y' = f(t, y)$, $y(t_0) = x_0$. Theorem XI.1.2.2. gives a unique solution $y = \phi_0(t)$ on $J_0 = J \cap [t_0 - L, t_0 + L]$. We now successively extend this unique solution to the right until it extends to b. If $t_0 + L \geq b$, we are done. Otherwise, fix t_1 with $t_0 + \frac{L}{2} < t_1 < t_0 + L$. Set $x_1 = \phi_0(t_1)$. Theorem XI.1.2.2. gives a unique solution $y = \phi_1(t)$ to the IVP $y' = f(t, y)$, $y(t_1) = x_1$ on $J_1 = J \cap [t_1 - L, t_1 + L]$. We must have $\phi_1 = \phi_0$ on $J_0 \cap J_1$ since both are solutions to the IVP $y' = f(t, y)$, $y(t_1) = x_1$ on $J_0 \cap J_1$, and thus we have extended ϕ_0 to a solution on $J_0 \cup J_1$.

If $t_1 + L \geq b$, we are done extending to the right. If not, we have $t_1 + L \geq (t_0 + L) + \frac{L}{2}$, i.e. we have extended to the right by at least $\frac{L}{2}$. Repeat the process, choosing t_2 with $t_1 + \frac{L}{2} < t_2 < t_1 + L$, x_2, J_2, ϕ_2, etc. Since at each stage we extend to the right by at least $\frac{L}{2}$, we reach b in a finite number of steps.

Extend ϕ_0 to the left of t_0 to a in the same manner. We obtain a solution ϕ on J in this manner. Any solution to the original IVP must agree with ϕ on a subset of J which is both relatively open and closed, hence must agree with ϕ everywhere on J. 👍

XI.1.3. Systems of First-Order Differential Equations

The result XI.1.2.2. is general enough to immediately give solutions not only to a single differential equation, but also to systems of differential equations: we want differentiable functions $y_1, \ldots, y_n$ on an interval I satisfying the n equations

$$y_k' = f_k(t, y_1, \ldots, y_n) \quad (1 \leq k \leq n) \ .$$

We also want the y_k to have specified values at some $t_0 \in I$.

XI.1.3.1. The setup is similar to the one for single equations, but we change notation slightly. We have a Banach space $\mathcal{X}$, an interval $I \subseteq \mathbb{R}$, a point $t_0 \in I$, n points $x_1^{(0)}, \ldots, x_n^{(0)}$ in $\mathcal{X}$, $r > 0$, $M > 0$, $K > 0$, and n continuous functions

$$f_1, \ldots, f_n : I \times \bar{B}_r(x_1^{(0)}) \times \cdots \times \bar{B}_r(x_n^{(0)}) \to \mathcal{X}$$

with the property that $\|f_k(t, x_1, \ldots, x_n)\| \leq M$ for $t \in I$ and $\|x_j - x_j^{(0)}\| \leq r$ $(1 \leq j, k \leq n)$, and

$$\|f_k(t, x_1^{(2)}, \ldots, x_n^{(2)}) - f_k(t, x_1^{(1)}, \ldots, x_n^{(1)})\| \leq K \max_{1 \leq j \leq n} (\|x_j^{(2)} - x_j^{(1)}\|)$$

for $1 \leq k \leq n$ whenever $t \in I$ and $x_j^{(1)}, x_j^{(2)} \in \bar{B}_r(x_j^{(0)})$ for all j (the f_k satisfy a uniform Lipschitz condition in $x_1, \ldots, x_n$ on I).

XI.1.3.2. Theorem. [Existence and Uniqueness Theorem for Systems of First-Order ODEs] Using the above notation, set

$$I_0 = I \cap \left[t_0 - \frac{r}{M}, t_0 + \frac{r}{M}\right] .$$

Then there are unique differentiable functions $y_1, \ldots, y_n : I_0 \to \mathcal{X}$ such that

$$y_k'(t) = f_k(t, y_1(t), \ldots, y_n(t))$$

$(1 \leq k \leq n)$ for $t \in I_0$ and $y_k(t_0) = x_k^{(0)}$. Additionally, the y_k are $\mathcal{C}^1$ on I_0. If $\tilde{I}$ is any subinterval of I_0 containing t_0, the restriction of the y_k to $\tilde{I}$ is the unique solution to the IVP on $\tilde{I}$.

Proof: This is an almost immediate corollary of XI.1.2.2.. Set $\tilde{\mathcal{X}} = \mathcal{X}^n$ with the ∞-norm (), and $x_0 = (x_1^{(0)}, \ldots, x_n^{(0)})$. Define $f : I \times \bar{B}_r(x_0) \to \tilde{\mathcal{X}}$ by

$$f(t, (x_1, \ldots, x_n)) = (f_1(t, x_1, \ldots, x_n), \ldots, f_n(t, x_1, \ldots, x_n)) .$$

Then the hypotheses of XI.1.2.2. are satisfied, and the coordinate functions of the solution y give the y_k. 👍

The interval on which the existence of a unique solution is guaranteed can sometimes be shown to be larger than I_0; see Exercise XI.1.10.7..

As in the single equation case, we get a local version with a cleaner statement but less precise conclusion:

XI.1.3.3. Corollary. [Existence and Uniqueness Theorem for Systems of First-Order ODEs, Local Version] Let $\mathcal{X}$ be a Banach space, $x_1^{(0)}, \ldots, x_n^{(0)} \in \mathcal{X}$, $t_0 \in \mathbb{R}$, and $f_1, \ldots, f_n$ continuous functions from a neighborhood U of $(t_0, x_1^{(0)}, \ldots, x_n^{(0)})$ in $\mathbb{R} \times \mathcal{X}^n$ to $\mathcal{X}$. Suppose each f_k satisfies a uniform Lipschitz condition in $x_1, \ldots, x_n$ on U. Then there is a $\delta > 0$ such that the first-order initial-value problem

$$y_k' = f_k(t, y_1, \ldots, y_n), \quad y_k(t_0) = x_k^{(0)} \quad (1 \leq k \leq n)$$

has a unique solution on $(t_0 - \delta, t_0 + \delta)$. Additionally, the y_k are $\mathcal{C}^1$ on $(t_0 - \delta, t_0 + \delta)$.

We also get a global version from XI.1.2.9.:

XI.1.3.4. Theorem. [Existence and Uniqueness Theorem for Systems of First-Order ODEs, Global Version] Let $\mathcal{X}$ be a Banach space, I an interval in $\mathbb{R}$, and $t_0 \in I$. Let $f_1, \ldots, f_n$ be continuous functions from $I \times \mathcal{X}^n$ to $\mathcal{X}$ satisfying a uniform Lipschitz condition in $x_1, \ldots, x_n$ on every closed bounded subinterval of I. Then, for any $x_1^{(0)}, \ldots, x_n^{(0)} \in \mathcal{X}$, the initial-value problem

$$y_k' = f_k(t, y_1, \ldots, y_n), \quad y_k(t_0) = x_k^{(0)} \quad (1 \leq k \leq n)$$

has a unique solution defined on all of I. Additionally, the solutions are $\mathcal{C}^1$ on I.

XI.1.4. Higher-Order Differential Equations and Systems

We can use the results for systems of first-order equations to obtain similar existence and uniqueness theorems for higher-order differential equations, by a simple but clever trick. We want to solve the initial-value problem

$$y^{(n)} = f(t, y, y', \ldots, y^{(n-1)}), \quad y(t_0) = x_0, y'(t_0) = x_0', \ldots, y^{(n-1)}(t_0) = x_0^{(n-1)}$$

where y is an n-times differentiable function from an interval in $\mathbb{R}$ to a Banach space $\mathcal{X}$ and f is a suitably nice function from a neighborhood of $(t_0, x_0, x_0', \ldots, x_0^{(n-1)})$ in $\mathbb{R} \times \mathcal{X}^n$ to $\mathcal{X}$.

The trick is to define new unknown functions $y_1, \ldots, y_{n-1}$ which satisfy the system of equations

$$y' = y_1, y_1' = y_2, \ldots, y_{n-2}' = y_{n-1}, y_{n-1}' = f(t, y, y_1, \ldots, y_{n-1})$$

so $y_k = y^{(k)}$. Then we have a system of n first-order equations in n unknown functions $y, y_1, \ldots, y_{n-1}$, and we can apply the various existence and uniqueness theorems for such systems. The statements are:

XI.1.4.1. Theorem. [Existence and Uniqueness Theorem for Higher-Order ODE's] Let $\mathcal{X}$ be a Banach space, I an interval in $\mathbb{R}$, $t_0 \in I$, $x_0, x_0', \ldots, x_0^{(n-1)} \in \mathcal{X}$, $r > 0$, and

$$f : I \times \bar{B}_r(x_0) \times \bar{B}_r(x_0') \times \cdots \times \bar{B}_r(x_0^{(n-1)}) \to \mathcal{X} \ .$$

Suppose f is continuous and bounded by N on $I \times \bar{B}_r(x_0) \times \bar{B}_r(x_0') \times \cdots \times \bar{B}_r(x_0^{(n-1)})$ and satisfies a uniform Lipschitz condition in the y-variables. Set

$$M = \max\{N, \|y_0'\| + r, \ldots, \|y_0^{(n-1)}\| + r\}$$

$$I_0 = I \cap \left[t_0 - \frac{r}{M}, t_0 + \frac{r}{M}\right] \ .$$

Then there is a unique n-times differentiable function $y : I_0 \to \mathcal{X}$ with $y(t_0) = x_0$, $y'(t_0) = x_0'$, $\ldots$, $y^{(n-1)}(t_0) = x_0^{(n-1)}$, and $y^{(n)}(t) = f(t, y(t), y'(t), \ldots, y^{(n-1)}(t))$ for all $t \in I_0$. Additionally, y is $\mathcal{C}^n$ on I_0.

Proof: Define $f_k(t, x_0, x_1, \ldots, x_{n-1}) = x_{k+1}$ for $0 \le k < n-1$ and $f_{n-1} = f$, and apply XI.1.3.2.. ☝

The interval on which the existence of a unique solution is guaranteed can sometimes be shown to be larger than I_0; see Exercise XI.1.10.8..

XI.1.4.2. Corollary. [Existence and Uniqueness Theorem for Higher-Order ODEs, Local Version] Let $\mathcal{X}$ be a Banach space, $x_0, x_0', \ldots, x_0^{(n-1)} \in \mathcal{X}$, $t_0 \in \mathbb{R}$, and f a continuous function from a neighborhood U of $(t_0, x_0, x_0', \ldots, x_0^{(n-1)})$ in $\mathbb{R} \times \mathcal{X}^n$ to $\mathcal{X}$. Suppose f satisfies a uniform Lipschitz condition in the y-variables on U. Then there is a $\delta > 0$ such that the first-order initial-value problem

$$y^{(n)} = f(t, y, y', \ldots, y^{(n-1)}), \quad y(t_0) = x_0, y'(t_0) = x_0', \ldots, y^{(n-1)}(t_0) = x_0^{(n-1)}$$

has a unique solution on $(t_0 - \delta, t_0 + \delta)$. Additionally, y is $\mathcal{C}^n$ on $(t_0 - \delta, t_0 + \delta)$.

XI.1.4.3. THEOREM. [EXISTENCE AND UNIQUENESS THEOREM FOR HIGHER-ORDER ODES, GLOBAL VERSION] Let $\mathcal{X}$ be a Banach space, I an interval in $\mathbb{R}$, and $t_0 \in I$. Let f be a continuous function from $I \times \mathcal{X}^n$ to $\mathcal{X}$ satisfying a uniform Lipschitz condition in the y-variables on every closed bounded subinterval of I. Then, for any $x_0, x_0', \ldots, x_0^{(n-1)} \in \mathcal{X}$, the initial-value problem

$$y^{(n)} = f(t, y, y', \ldots, y^{(n-1)}), \quad y(t_0) = x_0, y'(t_0) = x_0', \ldots, y^{(n-1)}(t_0) = x_0^{(n-1)}$$

has a unique solution defined on all of I. Additionally, the solution is $\mathcal{C}^n$ on I.

XI.1.4.4. There are similar extensions to systems of higher-order differential equations. The equations in the system do not all need to be of the same order. The extensions are straightforward, but the notation is oppressive, and it is left to the reader to formulate and prove the results.

XI.1.5. Continuous Dependence on Initial Conditions

XI.1.5.1. We now examine what happens when the initial conditions are varied. To do this we will treat the initial value as a parameter. Thus, if $f(t, y)$ is a suitably nice function (e.g. continuous and satisfying a uniform Lipschitz condition in y) defined near (t_0, x_0), the IVP

$$y' = f(t, y), \quad y(t_0) = x_0$$

has a unique solution, and the IVP

$$y' = f(t, y), \quad y(t_0) = x_1$$

even has a unique solution for any x_1 sufficiently close to x_0.

XI.1.5.2. What we would hope is that if x_1 is close to x_0, the solution with initial value x_1 should be uniformly close to the solution for initial value x_0 for t close to t_0, i.e. that the solution for initial value x should "vary continuously" (or even "smoothly") in x.

To be precise, what we might hope for is that there is a continuous (or even smooth) function $u(t, x)$ of two variables, defined near (t_0, x_0), such that if x_1 is close to x_0, the function $y(t) = u(t, x_1)$ is the unique solution to the IVP with initial value x_1. We get continuity:

XI.1.5.3. THEOREM. Let $\mathcal{X}, f, r, K, M$ be as in XI.1.2.2.. Fix ϵ, $0 < \epsilon < \min\left(\frac{r}{2M}, \frac{1}{K}\right)$. Let y_0 be the unique solution to the IVP

$$y' = f(t, y), \quad y(t_0) = x_0$$

in the interval $J = [t_0 - \epsilon, t_0 + \epsilon]$. Fix x_1, $\|x_1 - x_0\| \leq \frac{r}{2}$, and let y_1 be the unique solution to the IVP

$$y' = f(t, y), \quad y(t_0) = x_1$$

on J. Then, for any $t \in J$, we have

$$\|y_1(t) - y_0(t)\| \leq \frac{\|x_1 - x_0\|}{1 - K\epsilon} .$$

XI.1.5.4. Some initial observations:

(i) The ϵ is not the same as the one in the proof of XI.1.2.2. (it is smaller).

(ii) The interval J is shorter than the maximum length interval on which y_0 is guaranteed to exist by XI.1.2.2. and is not the same as the J in that proof, but t_0 is still in the interior of J.

(iii) It is easily checked that XI.1.2.2. guarantees the existence of the solution y_1 as well as y_0 on J.

The reason J is taken shorter in this theorem than in XI.1.2.2. is that we need the T defined in the proof to be an actual strict contraction, not just a strict power contraction, in order to apply VI.2.10.7..

XI.1.5.5. COROLLARY. Under the hypotheses and notation of XI.1.5.3., if $u(t,x)$ is the function from $I \times \bar{B}_{r/2}(x_0)$ to $\mathcal{Y}$ such that, for fixed x, $u(t,x)$ is the unique solution to the initial-value problem

$$y' = f(t,y), \quad y(t_0) = x$$

then u is uniformly continuous on $I \times \bar{B}_{r/2}(x_0)$.

We now give the proof of XI.1.5.3..

PROOF: We proceed exactly as in the proof of XI.1.2.2.. Let Y be the set of continuous functions from J to the closed ball $\bar{B}_r(x_0)$ in $\mathcal{X}$ of radius r centered at x_0. Define a metric ρ on Y by

$$\rho(\phi,\psi) = \max_{t\in J} \|\phi(t) - \psi(t)\| \ .$$

Then Y is a complete metric space under ρ (it is a closed subset of $C(J,\mathcal{X})$ ()). Define maps $T, S : Y \to Y$ by

$$[T(\phi)](t) = x_0 + \int_{t_0}^{t} f(u,\phi(u))\,du$$

$$[S(\phi)](t) = x_1 + \int_{t_0}^{t} f(u,\phi(u))\,du \ .$$

It is obvious from () that $T(\phi)$ and $S(\phi)$ are continuous functions from J to $\mathcal{X}$. We have, for $t \in J$ and $\phi \in Y$,

$$\|[T(\phi)](t) - x_0\| = \left\| \int_{t_0}^{t} f(u,\phi(u))\,du \right\| \le \int_{t_0}^{t} \|f(u,\phi(u)\|\,du \le M|t-t_0| \le M\epsilon = \frac{r}{2}$$

so $T(\phi) \in Y$. Also,

$$\|[S(\phi)](t) - x_0\| \le \|[S(\phi)](t) - x_1\| + \|x_1 - x_0\| = \left\| \int_{t_0}^{t} f(u,\phi(u))\,du \right\| + \|x_1 - x_0\|$$

$$\le \int_{t_0}^{t} \|f(u,\phi(u)\|\,du + \|x_1 - x_0\| \le M|t-t_0| + \|x_1 - x_0\| \le M\epsilon + \frac{r}{2} = \frac{r}{2} + \frac{r}{2} = r$$

so $S(\phi) \in Y$. And we have, for $\phi, \psi \in Y$ and $t \in J$,

$$\|T(\phi)(t) - T(\psi)(t)\| = \left\| \int_{t_0}^{t} [f(u,\phi(u)) - f(u,\psi(u))]\,du \right\|$$

$$\leq \int_{t_0}^{t} \|f(u,\phi(u)) - f(u,\psi(u))\|\, du \leq K \int_{t_0}^{t} \|\phi(u) - \psi(u)\|\, du$$
$$\leq K\epsilon \max_{u\in J} \|\phi(u) - \psi(u)\| = K\epsilon\rho(\phi,\psi)$$

and similarly $\|S(\phi)(t) - S(\psi)(t)\| \leq K\epsilon\rho(\phi,\psi)$. Thus T and S are strict contractions on Y with constant $K\epsilon < 1$. Since $T(\phi) - S(\phi) = x_0 - x_1$ for all ϕ, we have $\|T(\phi) - S(\phi)\| = \|x_1 - x_0\|$ for all ϕ. The fixed points for T and S are y_0 and y_1 respectively. The result now follows from an application of VI.2.10.7.. 👍

XI.1.5.6. The technicalities of the proof only yield that uniform continuity holds on a small neighborhood of each point, but it follows that continuity holds throughout the region in which unique local solutions exist. Uniform continuity can be cobbled together to hold on somewhat larger regions; details are left to the interested reader.

XI.1.5.7. The problem in XI.1.5.2. can be converted to a first-order quasilinear PDE problem (Cauchy problem): we seek a smooth function $u(t,x)$ in a neighborhood of (t_0,x_0) satisfying (writing u_t for $\frac{\partial u}{\partial t}$)

$$u_t = f(t,u)$$

with boundary condition $u(t_0,x) = x$. () then shows the solution $u(t,x)$ of XI.1.5.5. is not only continuous, but even smooth.

XI.1.5.8. We might even want to allow the function f to depend on the x, i.e. to allow the differential equation itself to vary as the initial condition is varied, or in other words to consider the PDE

$$u_t = f(t,x,u)$$

with boundary condition $u(t_0,x) = x$, where f is a suitable function defined in a neighborhood of (t_0,x_0,x_0). Under reasonable hypotheses () shows that there is also a smooth solution in this case.

XI.1.6. Peano's Existence Theorem for First-Order ODEs

If f does not satisfy a uniform Lipschitz condition in y, we cannot expect a locally unique solution to the IVP $y' = f(t,y)$, $y(t_0) = x_0$ in general (Examples XI.1.1.6.(iii)–(iv)). But we can still show existence of a local solution. The first step is to uniformly approximate f by functions which do satisfy a uniform Lipschitz condition in y; this can only done in general if the target Banach space is finite-dimensional. An application of the Arzela-Ascoli Theorem (which also needs finite-dimensionality of the target space) then gives a solution. In fact, the conclusion can fail if the Banach space $\mathcal{X}$ is infinite-dimensional, even if $\mathcal{X}$ is a separable Hilbert space [Yor70]. See [**?**] for other proofs of the theorem and some generalizations.

XI.1.6.1. Theorem. [Peano's Existence Theorem for First-Order ODEs] Let $\mathcal{X}$ be a finite-dimensional Banach space, I a closed bounded interval in $\mathbb{R}$, $t_0 \in I$, $x_0 \in \mathcal{X}$. Let $f : I \times \bar{B}_r(x_0) \to \mathcal{X}$ be a continuous function, and

$$M = \max\{\|f(t,y)\| : (t,y) \in I \times \bar{B}_r(x_0)\}\ .$$

Set

$$I_0 = I \cap \left[t_0 - \frac{r}{M}, t_0 + \frac{r}{M}\right] \ .$$

Then there is a $\mathcal{C}^1$ function $y : I_0 \to \bar{B}_r(y_0) \subseteq \mathcal{X}$ satisfying $y(t_0) = x_0$ and $y'(t) = f(t, y(t))$ for all $t \in I_0$.

PROOF: We may assume $\mathcal{X} = \mathbb{R}^n$ with a norm equivalent to the Euclidean norm. By the Weierstrass Approximation Theorem, we may approximate f uniformly on $I \times \bar{B}_r(y_0)$ by functions f_n whose coordinate functions are polynomials. Thus each f_n satisfies a uniform Lipschitz condition in y on $I \times \bar{B}_r(x_0)$. By scaling f_n slightly, we may also assume $\|f_n(t, y)\| \leq M$ for all n and all $(t, y) \in I \times \bar{B}_r(x_0)$.

Thus by Theorem XI.1.2.2. there is a (unique) solution ϕ_n to the IVP $y' = f_n(t, y)$, $y(t_0) = x_0$ on the closed bounded interval I_0. We have, for all n and all $t \in I_0$,

$$\phi_n(t) = x_0 + \int_{t_0}^{t} f_n(u, \phi_n(u))\, du$$

and thus

$$\|\phi_n(t)\| \leq \|x_0\| + \left| \int_{t_0}^{t} \|f_n(u, \phi_n(u))\|\, du \right| \leq \|x_0\| + M|t - t_0| \leq \|x_0\| + r$$

so the ϕ_n are uniformly bounded on I_0. Also, $\|\phi_n'(t)\| = \|f_n(t, \phi_n(t))\| \leq M$ for all $t \in I_0$, so the set $\{\phi_n : n \in \mathbb{N}\}$ is equicontinuous on I_0 (). Thus there is a uniformly convergent subsequence by the Arzela-Ascoli Theorem (). Passing to a subsequence, we may assume (ϕ_n) converges uniformly on I_0 to a (necessarily continuous) function ϕ. Then, for each $t \in \mathbb{R}$,

$$x_0 + \int_{t_0}^{t} f_n(u, \phi_n(u))\, du \to x_0 + \int_{t_0}^{t} f(u, \phi(u))\, du$$

by (). Since the left side is $\phi_n(t)$, we obtain

$$\phi(t) = x_0 + \int_{t_0}^{t} f(u, \phi(u))\, du$$

for all $t \in I_0$, and thus ϕ is a solution to the original IVP on I_0. The equation $\phi'(t) = f(t, \phi(t))$ shows that ϕ is $\mathcal{C}^1$, since the right side is a continuous function of t. 👍

XI.1.7. Power Series and Analytic Solutions

XI.1.8. Linear ODEs

XI.1.9. Boundary-Value Problems

XI.1.9.1. So far, we have only considered initial-value problems, ones where the value of the solution and its lower-order derivatives at a single point are specified. But an important and much more difficult type of problem, especially for second-order differential equations, is a *boundary-value problem*, where the values of the solution at two points are specified.

XI.1.9.2. Suppose we have a second-order differential equation

$$y'' = f(t, y, y')$$

in standard form. The general solution generically has two arbitrary constants, so is uniquely determined by specifying $y(t_0)$ and $y'(t_0)$ for some t_0. But it is often more important to specify the values $y(t_0)$ and $y(t_1)$ for two distinct values t_0 and t_1 of t. In principle, the two constants should be uniquely determined by these values, at least in good cases. But there are some potential difficulties, which turn out to be real difficulties:

(i) In an initial-value problem, the existence and uniqueness theorems only guarantee a solution in *some* interval around t_0, although in some cases a careful analysis can give the approximate or even exact length of the interval. But (if we take $t_0 < t_1$ without loss of generality) in a boundary-value problem we must have a solution on the entire closed interval $[t_0, t_1]$.

(ii) There may be no values of the constants which give the desired boundary values, so the problem may not have a solution even if the differential equation does on the whole interval $[t_0, t_1]$.

(iii) There may be more than one choice of the constants giving the desired boundary values, so even if there is a solution it may not be unique.

All these difficulties can occur. And there are no really general existence and uniqueness theorems in the boundary-value case.

XI.1.9.3. For a dramatic example of (iii), leading to an example of (ii), consider one of the simplest second-order differential equations:

$$y'' = -y \ .$$

The general solution () is

$$y(t) = A\cos t + B\sin t$$

where A, B are constants. If we consider the boundary-value problem $y(0) = 0$, $y(2\pi) = 0$, then

$$y(t) = B\sin t$$

is a solution for any constant B. More generally, every solution to the differential equation is periodic with period 2π, i.e. $y(0) = y(2\pi)$, so if $x_1 \neq x_0$ the boundary-value problem

$$y'' = -y \ , \quad y(0) = x_0 \ , \quad y(2\pi) = x_1$$

has no solution. And one could not directly predict the periodicity from the form of the equation and anticipate these difficulties without some analysis or experience.

XI.1.10. Exercises

XI.1.10.1. Let I be an interval, $t_0 \in I$, and $f : I \times \mathbb{R} \to \mathbb{R}$ a continuous function. Consider the differential equation

$$y' = f(t, y)$$

and the integral equation

$$y(t) = y(t_0) + \int_{t_0}^{t} f(u, y(u))\, du \ .$$

The aim of this problem is to show that a function on I satisfies the differential equation if and only if it satisfies the integral equation.

(a) Suppose y is a differentiable function on I satisfying the differential equation. Show that y is necessarily $\mathcal{C}^1$ on I. [Use continuity of f.]

(b) Suppose y is a differentiable function on I satisfying the differential equation. Integrate both sides of the differential equation to show that y also satisfies the integral equation. [Use the Fundamental Theorem of Calculus II.]

(c) Conversely, suppose y is a function on I such that the integral in the integral equation exists as a Riemann, Lebesgue, or H-K integral for each $t \in I$, and that y satisfies the integral equation. Show that y is necessarily continuous on I, and hence the integral in the integral equation exists as a Riemann integral for each $t \in I$. [Use ().]

(d) Under the assumptions of (c), show that y is differentiable on I and satisfies the differential equation. [Use the Fundamental Theorem of Calculus I.]

(e) Extend the results to the case where the range space $\mathbb{R}$ is replaced by a Banach space.

XI.1.10.2. Implicit Differential Equations. (a) Prove the following theorem about existence and uniqueness of solutions to a differential equation of the form $F(t, y, y') = 0$.

THEOREM. Let U be an open set in $\mathbb{R}^3$, and $(t_0, x_0, z_0) \in U$. Let $F : U \to \mathbb{R}$ be a continuous function with $F(t_0, x_0, z_0) = 0$. Suppose $\frac{\partial F}{\partial z}$ exists and is continuous on U and that $\frac{\partial F}{\partial z}(t_0, x_0, z_0) \neq 0$. Then

(i) There is an open interval I around t_0 and a $\mathcal{C}^1$ function $y : I \to \mathbb{R}$ such that $y(t_0) = x_0$, $y'(t_0) = z_0$, and $F(t, y(t), y'(t)) = 0$ for all $t \in I$.

(ii) If $\frac{\partial F}{\partial y}$ also exists and is continuous on U, then there is an open interval I around t_0 and a unique differentiable function $y : I \to \mathbb{R}$ such that $y(t_0) = x_0$, $y'(t_0) = z_0$, and $F(t, y(t), y'(t)) = 0$ for all $t \in I$, and additionally y is $\mathcal{C}^1$ on I.

(iii) If F is analytic on U, then there is an open interval I around t_0 and a unique differentiable function $y : I \to \mathbb{R}$ such that $y(t_0) = x_0$, $y'(t_0) = z_0$, and $F(t, y(t), y'(t)) = 0$ for all $t \in I$, and additionally y is analytic on I.

[First use the Implicit Function Theorem to rewrite the equation $F(t, y, z) = 0$ as $z = f(t, y)$. Apply VIII.5.3.4. and XI.1.6.1. in case (i), VIII.5.3.12. and XI.1.2.7. in case (ii), and () and () in case (iii).]

However, such an implicit differential equation need not have any solutions, i.e. there may be no (t_0, x_0, z_0) satisfying the hypotheses: see Exercise XI.1.10.3..

(b) Generalize to systems and to higher-order implicit equations.

XI.1.10.3. Show that the (autonomous) implicit differential equation

$$(y' - 1)^2 + y^2 = 0$$

has no (real) solutions.

XI.1.10.4. Implicit Solutions. (a) Carefully define what it means for a relation $G(t,y)=0$ to be a "solution" to the differential equation $F(t,y,y')=0$ (or a higher-order equation).

(b) [**?**, p. 3] Show that

$$t^2 = 2y^2 \log y$$

is an implicit solution to the differential equation

$$y' = \frac{ty}{t^2+y^2} \ .$$

Implicit solutions are particularly easily obtained for exact differential equations (ones which can be put in the form $g(t,y)y' + h(t,y) = 0$ with $\frac{\partial g}{\partial t} = \frac{\partial h}{\partial y}$), cf. VIII.2.2.8., and in particular for separable differential equations (ones which can be put in the form $g(y)y' = h(t)$).

XI.1.10.5. This is a sort of converse to XI.1.10.4.. Let

$$G(t, y, c_1, \dots, c_n)$$

be a $\mathcal{C}^n$ function with $\frac{\partial G}{\partial y} \neq 0$. Regard t as the independent variable, y the dependent variable, and $c_1, \dots, c_n$ as "constants" (parameters). By the Implicit Function Theorem, the equation

$$G(t, y, c_1, \dots, c_n) = 0$$

implicitly defines y as a function of t and the parameters $c_1, \dots, c_n$, i.e. $y = g(t, c_1, \dots, c_n)$.

(a) Successively differentiate y with respect to t to obtain n additional equations

$$\frac{\partial G}{\partial t} + \frac{\partial G}{\partial y} y' = 0$$

$$\frac{\partial^2 G}{\partial t^2} + 2\frac{\partial^2 G}{\partial t\, \partial y} y' + \frac{\partial^2 G}{\partial y^2}(y')^2 + \frac{\partial G}{\partial y} y'' = 0$$

$$\cdots$$

$$\frac{\partial^n G}{\partial t^n} + \cdots + \frac{\partial G}{\partial y} y^{(n)} = 0$$

(where we really mean $y^{(k)} = \frac{\partial^k g}{\partial t^k}$, but we symbolically regard the $y^{(k)}$ as new variables).

(b) Show that if $\boldsymbol{c} = (c_1, \dots, c_n)$ is independent in G in a suitable sense, then by the Implicit Function Theorem the first n equations can (in principle) be solved for $c_1, \dots, c_n$ as functions of $t, y, y', \dots, y^{(n-1)}$ and substituted into the last equation to obtain a differential equation

$$F(t, y, y', \dots, y^{(n-1)}, y^{(n)}) = 0$$

for which $G(t, y, c_1, \dots, c_n) = 0$ is a solution (in the sense of XI.1.10.4.) for any suitable $\boldsymbol{c}$ (references such as [Gou59, V. 2 Part 2] and [Inc44] state that $c_1, \dots, c_n$ "can be eliminated" from the $n+1$ equations without elaboration; in [**?**] it is at least acknowledged there is a nontrivial issue, but that "a precise statement of the conditions under which this is true is too complicated to be stated here.") Use the existence and uniqueness theorem to show that, under appropriate conditions, every solution is of this form.

(c) Generalize to the case where there is more than one G, y, and/or t (the same number of G's and y's) to obtain a system of ordinary or partial differential equations from an equation or set of equations with an arbitrary (finite) set of constants.

XI.1.10.6. Consider the IVP $y' = y^2$, $y(t_0) = x_0$ (XI.1.1.6.(ii)). Theorem XI.1.2.2. guarantees a unique solution on

$$\left[t_0 - \frac{r}{(|x_0| + r)^2}, t_0 + \frac{r}{(|x_0| + r)^2}\right]$$

for any $r > 0$. If $x_0 = 0$, the supremum of the lengths of these intervals for all r is $+\infty$, and the solution to the IVP $(y = 0)$ is defined on all of $\mathbb{R}$. If $x_0 \neq 0$, show that the maximum of $\frac{r}{(|x_0|+r)^2}$ is $\frac{1}{4|x_0|}$. In this case, the unique solution $y = \frac{1}{c-t}$, $c = t_0 + \frac{1}{x_0}$, has domain $(-\infty, c)$ if $x_0 > 0$ and $(c, +\infty)$ if $x_0 < 0$, so the maximum symmetric interval around t_0 on which the solution exists is $\left(t_0 - \frac{1}{|x_0|}, t_0 + \frac{1}{|x_0|}\right)$.

XI.1.10.7. Show that Theorem XI.1.3.2. can be generalized as follows to give a unique solution on a generally larger interval. Suppose we have a Banach space $\mathcal{X}$, an interval $I \subseteq \mathbb{R}$, a point $t_0 \in I$, n points $x_1^{(0)}, \ldots, x_n^{(0)}$ in $\mathcal{X}$, $r_1, \ldots, r_n > 0$, $M > 0$, $K > 0$, and n continuous functions

$$f_1, \ldots, f_n : I \times \bar{B}_{r_1}(x_1^{(0)}) \times \cdots \times \bar{B}_{r_n}(x_n^{(0)}) \to \mathcal{X}$$

with the property that $\|f_k(t, x_1, \ldots, x_n)\| \leq M_k$ for $t \in I$ and $\|x_j - x_j^{(0)}\| \leq r_j$ $(1 \leq j, k \leq n)$, and

$$\|f_k(t, x_1^{(2)}, \ldots, x_n^{(2)}) - f_k(t, x_1^{(1)}, \ldots, x_n^{(1)})\| \leq K \max_{1 \leq j \leq n} (\|x_j^{(2)} - x_j^{(1)}\|)$$

for $1 \leq k \leq n$ whenever $t \in I$ and $x_j^{(1)}, x_j^{(2)} \in \bar{B}_{r_j}(x_j^{(0)})$ for all j (the f_k satisfy a uniform Lipschitz condition in $x_1, \ldots, x_n$ on I). Slightly adapt the proof of Theorem XI.1.2.2. to show the following:

THEOREM. [EXISTENCE AND UNIQUENESS THEOREM FOR SYSTEMS OF FIRST-ORDER ODES] Using the above notation, set

$$L = \min\left\{\frac{r_1}{M_1}, \ldots, \frac{r_n}{M_n}\right\}$$
$$I_0 = I \cap [t_0 - L, t_0 + L] \ .$$

Then there are unique differentiable functions $y_1, \ldots, y_n : I_0 \to \mathcal{X}$ such that

$$y_k'(t) = f_k(t, y_1(t), \ldots, y_n(t))$$

$(1 \leq k \leq n)$ for $t \in I_0$ and $y_k(t_0) = x_k^{(0)}$. Additionally, the y_k are $\mathcal{C}^1$ on I_0. If $\tilde{I}$ is any subinterval of I_0 containing t_0, the restriction of the y_k to $\tilde{I}$ is the unique solution to the IVP on $\tilde{I}$.

XI.1.10.8. Use the theorem in XI.1.10.7. to obtain the following generalization of Theorem XI.1.4.1. which guarantees a unique solution on a larger interval in general:

THEOREM. [EXISTENCE AND UNIQUENESS THEOREM FOR HIGHER-ORDER ODE'S] Let $\mathcal{X}$ be a Banach space, I an interval in $\mathbb{R}$, $t_0 \in I$, $x_0, x_0', \ldots, x_0^{(n-1)} \in \mathcal{X}$, $r_0, \ldots, r_{n-1} > 0$, and

$$f : I \times \bar{B}_{r_0}(x_0) \times \bar{B}_{r_1}(x_0') \times \cdots \times \bar{B}_{r_{n-1}}(x_0^{(n-1)}) \to \mathcal{X} \ .$$

Suppose f is continuous and bounded by N on $I \times \bar{B}_r(x_0) \times \bar{B}_r(x_0') \times \cdots \times \bar{B}_r(x_0^{(n-1)})$ and satisfies a uniform Lipschitz condition in the y-variables. Set

$$L = \max\left\{ \frac{r_0}{\|x_0'\| + r_1}, \ldots, \frac{r_{n-2}}{\|x_0^{(n-1)}\| + r_{n-1}}, \frac{r_{n-1}}{N} \right\}$$

$$I_0 = I \cap [t_0 - L, t_0 + L] \ .$$

Then there is a unique n-times differentiable function $y : I_0 \to \mathcal{Y}$ with $y(t_0) = x_0$, $y'(t_0) = x_0'$, $\ldots$, $y^{(n-1)}(t_0) = x_0^{(n-1)}$, and $y^{(n)}(t) = f(t, y(t), y'(t), \ldots, y^{(n-1)}(t))$ for all $t \in I_0$. Additionally, y is $\mathcal{C}^n$ on I_0.

XI.1.10.9. Let I be an interval in $\mathbb{R}$, $\mathcal{X}$ a Banach space, and $f : I \to \mathcal{X}$ a continuous function. Then f may be regarded as a continuous function from $I \times \mathcal{X}$ to $\mathcal{X}$ satisfying a uniform Lipschitz condition in $\mathcal{X}$ with Lipschitz constant 0. Show that one step of Picard iteration gives the exact (unique) solution to the IVP $y' = f(t)$, $y(t_0) = x_0$ for any $t_0 \in I$, $x_0 \in \mathcal{X}$.

XI.1.10.10. Let $I = (0, +\infty)$. Define $f : I \times \mathbb{R} \to \mathbb{R}$ by

$$f(t, y) = \frac{y \cos(\log t)}{t} \ .$$

(a) If $(t_0, x_0) \in I \times \mathbb{R}$, show that the hypotheses of XI.1.2.9., (), and () are satisfied for the IVP

$$y' = f(t, y), \quad y(t_0) = x_0$$

(with $\mathcal{X} = \mathbb{R}$), and thus there is a unique solution, which is defined on the entire interval I.

(b) Show that the general solution is $y(t) = Ce^{\sin(\log t)}$ for $C \in \mathbb{R}$.

(c) Show that every solution is bounded and analytic on I, but no solution other than the identically zero one extends to be continuous at 0.

XI.1.10.11. [**?**] This exercise shows how differently even first-order differential equations not in standard form can behave. Define $F : \mathbb{R}^3 \to \mathbb{R}$ by

$$F(t, y, z) = y^2 + z^2 - 1 \ .$$

Then F is $\mathcal{C}^\infty$, even analytic, on all of $\mathbb{R}^3$. Consider the autonomous first-order differential equation

$$F(t, y, y') = 0$$

which can be rewritten

$$(y')^2 = 1 - y^2 \ .$$

(a) Show that

$$y = \sin(t - c)$$

is a solution for any $c \in \mathbb{R}$, and the constant functions $y = 1$ and $y = -1$ are also solutions. [The solutions $y = \cos(t - b)$ can be written in the form $y = \sin(t - c)$ for $c = b - \frac{\pi}{2}$.]

(b) Show that for any $t_0 \in \mathbb{R}$ and $-1 < x_0 < 1$ there are locally two solutions to the IVP

$$F(t, y, y') = 0 \ , \quad y(t_0) = x_0$$

and there are at least two local solutions if $x_0 = \pm 1$.

(c) The solutions in (a) are not the only solutions, however. For example, there is the solution

$$y(t) = \begin{cases} \sin t & \text{if} \quad -\frac{\pi}{2} \leq t \leq \frac{\pi}{2} \\ -1 & \text{if} \quad t < -\frac{\pi}{2} \\ 1 & \text{if} \quad t > \frac{\pi}{2} \end{cases}$$

or, more generally, (continuous) functions whose graph consists of segments of graphs of $y = \sin(t - c)$ for various c interspersed with segments of constant functions with value ± 1. These solutions, of which there are very many, are $\mathcal{C}^1$ but not even twice differentiable everywhere; compare with XI.1.1.2.. Thus the IVP of the form

$$F(t, y, y') = 0 \ , \quad y(t_0) = x_0$$

for $x_0 = \pm 1$ has many solutions on any interval around t_0 for any $t_0 \in \mathbb{R}$.

(d) Show that the solutions in (a) and (c) are all the solutions to the differential equation.

(e) Discuss how the solutions to this differential equation are related to the solutions to the two standard form differential equations

$$y' = \sqrt{1 - y^2} \ , \quad y' = -\sqrt{1 - y^2} \ .$$

XI.1.10.12. (a) Use the Existence and Uniqueness Theorem XI.1.2.7. to give an alternate proof of the one-variable $\mathcal{C}^r$ Implicit Function Theorem VIII.5.3.14. for $r \geq 2$ by considering the IVP (with x the independent variable)

$$y' = -\frac{\frac{\partial F}{\partial x}(x, y)}{\frac{\partial F}{\partial y}(x, y)} \ , \ y(a) = b \ .$$

Use the Chain Rule to show that the unique solution $y = f(x)$ satisfies $F(x, f(x)) = 0$ for all x near a. (One does not obtain uniqueness of the implicitly defined function this way, only uniqueness of a differentiable implicitly defined function.) What can one conclude from this argument if F is only $\mathcal{C}^1$? (cf. XI.1.6.1.)

(b) Generalize to the case of VIII.5.1.7. for $p = 1$ and $r \geq 2$, for general n, by considering a system of differential equations.

(c) Give a similar proof of the general $\mathcal{C}^r$ Implicit Function Theorem VIII.5.1.7. ($r \geq 2$) by considering a system of partial differential equations

$$D\boldsymbol{y} = -D_{\boldsymbol{y}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y})^{-1} D_{\boldsymbol{x}}\boldsymbol{F}(\boldsymbol{x}, \boldsymbol{y}) \ , \ \boldsymbol{y}(\boldsymbol{a}) = \boldsymbol{b} \ .$$

(d) Use these results to give explicit descriptions of sets on which the implicitly defined functions exist.

XI.1.10.13. For positive functions f and g on $[a, +\infty)$ write $f \approx g$ if

$$0 < \inf_{y \geq a} \frac{f(y)}{g(y)} \leq \sup_{y \geq a} \frac{f(y)}{g(y)} < \infty$$

(f and g are the "same order"; this is stronger than $f(y) = O(g(y))$ as $y \to +\infty$). In this problem, fix a positive function f on $[0, +\infty)$ which is Lipschitz on $[0, n]$ for all n (it suffices that f is $\mathcal{C}^1$), and consider the autonomous IVP $y' = f(y)$, $y(0) = x_0 > 0$.

(a) Show that the IVP has a unique solution $y(t)$ on some maximal interval $[0, b)$, where $0 < b \leq +\infty$.

(b) If $f(y) \approx y^\beta$ on $[a, +\infty)$ for some (hence all) $a > 0$, for some β, $0 \leq \beta < 1$, then $b = +\infty$ and $y(t) \approx t^{1/(1-\beta)}$ as $t \to +\infty$. Thus y has polynomial growth.

(c) If $f(y) \approx y$ on $[a, +\infty)$ for some (hence all) $a > 0$, then $b = +\infty$ and $\log y(t) \approx 1$. Thus y has exponential growth.

(c) If $f(y) \approx y^\alpha$ on $[a, +\infty)$ for some (hence all) $a > 0$, for some $\alpha > 1$, then $b < +\infty$ and $\lim_{t \to b-} y(t) = +\infty$, i.e. y "blows up" at b and the solution cannot be extended beyond b.

XI.2. Partial Differential Equations

> "PDEs constitute one of the most dynamic and varied domains of the mathematical sciences, defying all attempts at unification. They are found in every phenomenon studied by the physics of continuous systems, involving all states of matter (gases, fluids, solids, plasmas) and all physical theories (classical, relativistic, quantum, and so on).
>
> But partial differential equations also lurk behind many geometric problems. Geometric PDEs, as they are called, make it possible to deform geometric objects in accordance with well-established laws. The application of methods of analysis to problems in other fields of mathematics is an example of the sort of cross-fertilization that became increasingly common in the course of the twentieth century."
>
> *C. Villani*[3]

XI.2.1. Elementary Theory

It is common to denote the unknown function in a partial differential equation by u (or v, w), and the independent variables by x, y, z, and/or t. Of course, a PDE can have any number of independent variables, but PDE's arising in physics often describe an unknown function of three (or fewer) spatial coordinates (x, y, z) and/or one time coordinate t. It is also notationally economical to use the subscript notation for partial derivatives, e.g. u_x for $\frac{\partial u}{\partial x}$ or u_{xy} for $\frac{\partial^2 u}{\partial y \partial x}$ (note the order of differentiation, which is often but not always irrelevant; cf. VIII.2.2.2.).

XI.2.1.1. Example. Consider the apparently extremely simple PDE which can be variously written

$$\frac{\partial u}{\partial x} = \frac{\partial u}{\partial t}$$

$$\frac{\partial u}{\partial x} - \frac{\partial u}{\partial t} = 0$$

$$u_x - u_t = 0$$

where u is an unknown function of x and t. It is easy to check using the Chain Rule that

$$u(x,t) = f(x+t)$$

is a solution on $\Omega = \{(x,t) : x + t \in I\}$, for any real-valued function f which is differentiable on an open interval I in $\mathbb{R}$ (it turns out that these are all the solutions ()). There are several observations to take away from this example:

(i) There is not a clean standard form for PDEs such as in XI.1.1.2. (although see ()).

(ii) Even a homogeneous linear first-order PDE with constant coefficients can have solutions which are not even $\mathcal{C}^1$, much less analytic (cf. ()).

[3] [Vil16, p. 107].

(iii) The general solution to such a PDE does not just contain an arbitrary constant, but an arbitrary (differentiable) function which must be determined by initial or boundary conditions (the fact that there is one equation and two independent variables suggests that there is an arbitrary function of $2 - 1 = 1$ variables which comes into the general solution, which is correct when properly formulated ()).

XI.2.1.2. Here are a couple of worse examples from [**?**]:

(i) The general solution to the first-order PDE

$$u_t = 0$$

where u is an unknown function of x and t is a function of the form

$$u(x,t) = f(x)$$

where f is an arbitrary function, not necessarily even continuous.

(ii) The general solution to the second-order PDE

$$u_{tx} = 0$$

where u is an unknown function of x and t is a function of the form

$$u(x,t) = f(t) + g(x)$$

where f is a differentiable function and g is an arbitrary function, not necessarily even continuous. Thus, for a solution u, the mixed partial u_{xt} is not necessarily even defined, so, according to [**?**], "we are thus led to distinctions which it is embarrassing to have to make."

> "The solving of equations satisfying given boundary conditions is seldom simple and is a task for the skilled mathematician. It cannot be learned in a day. If you want to do this sort of thing as a lifework, start at sixteen or seventeen, not later than nineteen."
>
> *E. T. Bell*[4]

Well, then, I guess some of us are out of luck. (But Bell wasn't always right!)

XI.2.2. Quasilinear Partial Differential Equations

Lectures of S. N. Kruzhkov https://www.math.ntnu.no/conservation/2009/011.pdf

XI.2.3. The Cauchy Problem

A great many (but not all) important PDE problems can be put in the following very general standard form.

[4] [Bel87, p. 334].

XI.2.3.1. DEFINITION. Let N and n_j $(1 \le j \le N)$ be natural numbers, and n a nonnegative integer. A *Cauchy system* is a system of N partial differential equations of the form

$$\frac{\partial^{n_j} u_j}{\partial t^{n_j}} = F_j\left(t, x_1, \ldots, x_n, u_1, \ldots, u_N, \ldots, \cdots \frac{\partial^k u_r}{\partial t^{k_0} \partial x_1^{k_1} \cdots \partial x_n^{k_n}} \cdots\right)$$

of unknown functions $u_1, \ldots, u_N$ of $n+1$ variables $t, x_1, \ldots, x_n$ where N and n_j $(1 \le j \le N)$ are natural numbers, n a nonnegative integer, $1 \le r \le N$, $0 \le k_0 < n_j$, $0 \le k_1, \ldots, k_n \le n_j$ (r, k, and the k_i may vary from entry to entry) with $k_0 + \cdots + k_n = k \le n_j$.

In other words, none of the partials appearing on the right are of order greater than the partial on the left, and none are even of equal order with respect to t. Note that the order n_j can vary from equation to equation, but the u_j are all functions of the same independent variables.

We can specify a set of "initial conditions":

XI.2.3.2. DEFINITION. A *set of Cauchy data* for the Cauchy system in XI.2.3.1. around $(t_0, x_1^0, \ldots, x_n^0)$ is a set of (usually continuous) functions

$$\{\phi_{j,k} : 1 \le j \le N, 0 \le k \le n_j\}$$

defined on an open neighborhood U of $(x_1^0, \ldots, x_n^0)$ in $\mathbb{R}^n$.

A *Cauchy problem* is a Cauchy system with a set of Cauchy data. An *analytic Cauchy problem* is a Cauchy problem in which the F_j and the data functions $\phi_{j,k}$ are analytic.

A *solution* to a Cauchy problem is a set $\{u_1, \ldots, u_N)$ of sufficiently differentiable functions on a set of the form $I \times V$, where I is an interval containing t_0 and V an open neighborhood of $(x_1^0, \ldots, x_n^0)$ contained in U, such that the u_j satisfy the differential equations and

$$\frac{\partial^k u_j}{\partial t^k}(t_0, x_1, \ldots, x_n) = \phi_{j,k}(x_1, \ldots, x_n)$$

for all j and k and all $(x_1, \ldots, x_n) \in V$. If the Cauchy problem is analytic, the solution is *analytic* provided the u_j are all analytic in a neighborhood of $(t_0, x_1^0, \ldots, x_n^0)$.

XI.2.3.3. EXAMPLES. (i) Any ODE in standard (Cauchy) form () is a Cauchy system with $N = 1$ and $n = 0$. A set of Cauchy data is a set of functions of no variables (i.e. constants); thus an ODE IVP is a Cauchy problem, which is analytic if the F is analytic (the $\phi_{j,k}$ are vacuously analytic). More generally, a (finite) system of ODEs with initial conditions is a Cauchy system.

(ii) Any quasilinear PDE () is a Cauchy system provided there is a pure partial of maximal order (put its term on one side and the rest of the terms on the other, and divide by the coefficient function). It is analytic if all the coefficient functions are analytic and the denominator coefficient function is nonzero at $(t_0, x_1^0, \ldots, x_n^0)$.

XI.2.4. The Cauchy-Kovalevskaya Theorem

XI.2.4.1. THEOREM. [CAUCHY-KOVALEVSKAYA THEOREM] An analytic Cauchy problem around a point $(t_0, x_1^0, \ldots, x_n^0)$ has a unique analytic solution in some open neighborhood of $(t_0, x_1^0, \ldots, x_n^0)$.

XI.2.4.2. Note that the uniqueness is only among *analytic* solutions. An analytic Cauchy problem can possibly have nonanalytic solutions too (). The theorem includes () as a special case (the case $n = 0$).

Chapter XII

Fundamentals of Complex Analysis

Complex Analysis is calculus done on the complex numbers. Although at first it bears superficial resemblance to ordinary calculus, it quickly assumes a much different character.

Complex Analysis is one of the most beautiful parts of mathematics. Many of the theorems seem almost too good to be true, especially in comparison with the situation in Real Analysis. Complex Analysis is also extraordinarily important throughout mathematics, with applications ranging from number theory to geometry to mathematical physics (and almost everything else).

It is beyond the scope of this book to give a full treatment of this vast subject. We will only describe some of the most fundamental aspects and their connections with real analysis. There is an overabundant supply of texts on Complex Analysis, which are of varying quality but mostly adequate or better. Four of the best are the classic [Ahl78], [GK06], [Gam01], and [SS03].

Throughout this chapter, we will always use the standard model of the complex numbers $\mathbb{C}$, the complex plane (III.6.2.). Thus we will freely regard $\mathbb{C}$ as $\mathbb{R}^2$ with the additional operation of complex multiplication. Thus any function from $\mathbb{C}$ (or a subset) to $\mathbb{C}$ can be equally well thought of as a function from $\mathbb{R}^2$ to $\mathbb{R}^2$. In discussing limits and continuity in $\mathbb{C}$, we always use the topology on $\mathbb{C}$ obtained by the identification with $\mathbb{R}^2$. This topology is induced by the metric $\rho(z, w) = |z - w|$.

XII.1. Elementary Theory

XII.1.1. Complex Differentiation and Holomorphic Functions

We first discuss the complex analog of ordinary differentiation. Many basic definitions and results bear a close formal resemblance to corresponding notions in usual calculus of one variable.

XII.1.1.1. We will use the following standard notation. The independent variable in complex analysis is usually denoted $z = x + iy$, where $z \in \mathbb{C}$ and x and y are the real and imaginary parts of z. Then z corresponds to the point $(x, y) \in \mathbb{R}^2$. If Ω is a (usually open) subset of $\mathbb{C}$, and $f : \Omega \to \mathbb{C}$ is a function, write

$$f(z) = f(x + iy) = u(x, y) + iv(x, y)$$

where $u, v : \Omega \to \mathbb{R}$ are the real and imaginary parts of f (the coordinate functions of f when f is regarded as a function from Ω to $\mathbb{R}^2$).

XII.1.1.2. DEFINITION. Let Ω be an open subset of $\mathbb{C}$, $f : \Omega \to \mathbb{C}$ a function, and $z_0 = x_0 + iy_0 \in \Omega$. Then f is *differentiable in the complex sense* (or just *complex differentiable*) at z_0 if

$$\lim_{z \to z_0} \frac{f(z) - f(z_0)}{z - z_0}$$

exists. If the limit exists, it is called the *complex derivative* of f at z_0, denoted $f'(z_0)$.

The function f is *complex differentiable on* Ω, or *holomorphic on* Ω, if it is complex differentiable at every $z_0 \in \Omega$.

XII.1.1.3. In Complex Analysis, the term *analytic* is often used as a synonym for *holomorphic*. We will not initially use *analytic* in this way since it has a different official definition (V.16.1.1.). One of the major fundamental theorems of Complex Analysis is that the notions of being analytic and holomorphic on an open set Ω coincide (XII.4.4.7.).

Here is the relation between complex differentiation and ordinary differentiation on $\mathbb{R}^2$:

XII.1.1.4. PROPOSITION. Let Ω be an open subset of $\mathbb{C}$, $f : \Omega \to \mathbb{C}$ a function, and $z_0 = x_0 + iy_0 \in \Omega$, $c = a + ib \in \mathbb{C}$. The following are equivalent:

(i) f is complex differentiable at z_0 with $f'(z_0) = c$.

(ii) For $z \in \Omega$, $f(z) = f(z_0) + c(z - z_0) + o(|z - z_0|)$.

(iii) f (regarded as a function from Ω to $\mathbb{R}^2$) is differentiable at $z_0 = (x_0, y_0)$ in the vector calculus sense (VIII.3.1.4.) and

$$Df(x_0, y_0) = \begin{bmatrix} a & -b \\ b & a \end{bmatrix}.$$

This result gives motivation and "explanation" for the model of $\mathbb{C}$ in Exercise III.6.3.1..

PROOF: The argument is very similar to the calculation motivating the definition of vector calculus differentiation (VIII.3.1.2.). The following statements are equivalent:

$$\lim_{z \to z_0} \frac{f(z) - f(z_0)}{z - z_0} = c$$

$$\lim_{z \to z_0} \frac{f(z) - f(z_0) - c(z - z_0)}{z - z_0} = 0$$

$$\lim_{z \to z_0} \frac{|f(z) - f(z_0) - c(z - z_0)|}{|z - z_0|} = 0$$

$$\lim_{(x,y) \to (x_0,y_0)} \frac{\|f(x, y) - f(x_0, y_0) - T(\boldsymbol{h})\|}{\|\boldsymbol{h}\|} = 0$$

where $\boldsymbol{h} = (x, y) - (x_0, y_0)$ and T is the linear transformation of $\mathbb{R}^2$ given by multiplication by c. The argument is completed by noting that the matrix of T is $\begin{bmatrix} a & -b \\ b & a \end{bmatrix}$. 👍

XII.1.1.5. Corollary. Let Ω be an open subset of $\mathbb{C}$, $f = u + iv : \Omega \to \mathbb{C}$ a function, and $z_0 = x_0 + iy_0 \in \Omega$. Then f is complex differentiable at z_0 if and only if u and v are differentiable in the vector calculus sense at (x_0, y_0) and satisfy the *Cauchy-Riemann equations*:

$$\frac{\partial u}{\partial x}(x_0, y_0) = \frac{\partial v}{\partial y}(x_0, y_0), \quad \frac{\partial u}{\partial y}(x_0, y_0) = -\frac{\partial v}{\partial x}(x_0, y_0) \ .$$

The complex derivative, when it exists, is given by

$$f'(x_0 + iy_0) = \frac{\partial u}{\partial x}(x_0, y_0) + i\frac{\partial v}{\partial x}(x_0, y_0) = \frac{\partial v}{\partial y}(x_0, y_0) - i\frac{\partial u}{\partial y}(x_0, y_0) \ .$$

So f is holomorphic on Ω if and only if f is differentiable in the vector calculus sense on Ω and the Cauchy-Riemann equations hold everywhere on Ω. In particular, if $\frac{\partial u}{\partial x}$, $\frac{\partial u}{\partial y}$, $\frac{\partial v}{\partial x}$, $\frac{\partial v}{\partial y}$ are continuous on Ω and satisfy the Cauchy-Riemann equations, then f is holomorphic on Ω.

XII.1.1.6. It turns out that in XII.1.1.5., the assumption that f be differentiable in the vector calculus sense on Ω can be relaxed. If the first-order partials of u and v exist everywhere on Ω and satisfy the Cauchy-Riemann equations, and if f is continuous on Ω (Looman-Menchoff Theorem) or just locally bounded (Montel-Tolstoff Theorem), then f is automatically holomorphic on Ω. Some additional condition on f besides the Cauchy-Riemann equations is necessary: cf. Exercise XII.9.9.1.. The question of when a function satisfying the Cauchy-Riemann equations is holomorphic is a subtle one, which is discussed thoroughly in [GM78]. (And a strong version of the converse of the last statement of XII.1.1.5. also holds (XII.3.3.6.).)

XII.1.1.7. XII.1.1.4. suggests that it is qualitatively harder for a function from $\mathbb{C}$ to $\mathbb{C}$ to be complex differentiable than it is for a function from $\mathbb{R}$ to $\mathbb{R}$ to be differentiable in the usual sense. This turns out to be correct, and complex differentiability implies all sorts of remarkable properties that do not necessarily hold for usual differentiable functions on $\mathbb{R}$.

There are nonetheless many examples of holomorphic functions, enough to make a rich theory. Here are some basic ones:

XII.1.1.8. Examples. (i) If f is a polynomial in z with complex coefficients, then by a calculation using the product formula in $\mathbb{C}$ the real and imaginary parts of f are polynomials in x and y with real coefficients. Thus f is differentiable (in fact, $\mathcal{C}^\infty$) on $\mathbb{C}$. A rather ugly calculation shows that the Cauchy-Riemann equations are satisfied, so f is holomorphic on $\mathbb{C}$. A simpler argument which shows this, and that f' is given by the usual formula, is in XII.1.2.5..

(ii) Similarly, any rational function in z is holomorphic on its domain (XII.1.2.8.).

(iii) [Complex Exponential Function] For $z = x + iy \in \mathbb{C}$, set

$$e^z = e^{x+iy} = e^x \cos y + ie^x \sin y = e^x(\cos y + i \sin y) \ .$$

Then $f(z) = e^z$ is differentiable (in fact, $\mathcal{C}^\infty$) on $\mathbb{C}$, and it is easily checked that the Cauchy-Riemann equations hold; hence f is holomorphic on $\mathbb{C}$. By XII.1.1.4.,

$$f'(x + iy) = \frac{\partial u}{\partial x}(x, y) + i\frac{\partial v}{\partial x}(x, y) = f(x + iy)$$

i.e. $f' = f$. The complex exponential function also satisfies $e^{z+w} = e^z e^w$, $e^{-z} = \frac{1}{e^z}$, and $e^{z-w} = \frac{e^z}{e^w}$ for all $z, w \in \mathbb{C}$, and agrees with the usual exponential function for z real (and is the only holomorphic function extending the real exponential function, cf. Exercises XII.9.9.6. and XII.9.9.10.).

(iv) [Complex Trigonometric Functions] For $z = x + iy \in \mathbb{C}$, set

$$\sin z = \sin x \cosh y + i \cos x \sinh y$$

$$\cos z = \cos x \cosh y - i \sin x \sinh y$$

Then $f(z) = \sin z$ and $g(z) = \cos z$ are differentiable (in fact, $\mathcal{C}^\infty$) on $\mathbb{C}$, and the Cauchy-Riemann equations hold, so f and g are holomorphic on $\mathbb{C}$. By a calculation as in (iii), $f' = g$ and $g' = -f$. These functions satisfy the usual trigonometric identities, and reduce to the usual sin and cos when z is real. The other trigonometric functions can be defined from these in the usual way, and give holomorphic functions on their domains extending the usual ones and satisfying the same identities and differentiation rules.

(v) [Complex Hyperbolic Functions] For $z = x + iy \in \mathbb{C}$, set

$$\sinh z = \sinh x \cos y + i \cosh x \sin y = \frac{e^z - e^{-z}}{2}$$

$$\cosh z = \cosh x \cos y + i \sinh x \sin y = \frac{e^z + e^{-z}}{2}$$

Then similarly $f(z) = \sinh z$ and $g(z) = \cosh z$ are holomorphic on $\mathbb{C}$, and $f' = g$, $g' = f$. These functions satisfy the usual identities, and reduce to the usual sinh and cosh when z is real. The other hyperbolic functions can be defined from these in the usual way, and give holomorphic functions on their domains extending the usual ones and satisfying the same identities and differentiation rules. We have

$$\cos z = \cosh iz = \frac{e^{iz} + e^{-iz}}{2}$$

$$\sin z = -i \sinh iz = \frac{e^{iz} - e^{-iz}}{2i}$$

for all $z \in \mathbb{C}$.

These examples show the intimate connections between the exponential, trigonometric, and hyperbolic functions which become clear only when the extensions to the complex numbers are considered.

> "... In effect, if one extends these functions by allowing complex values for the arguments, then there arises a harmony and regularity which without it would remain hidden."
>
> *B. Riemann, 1851*[1]

Defining inverse functions (log, arcsin, etc., even $\sqrt{z}$) is a trickier matter, primarily due to complications of domain.

XII.1.1.9. In this case, all these functions are $\mathcal{C}^\infty$ on their domains (as functions from $\mathbb{R}^2$ to $\mathbb{R}^2$), and their derivatives of all orders are also holomorphic. This in fact is true for any holomorphic function on an open set in $\mathbb{C}$ (XII.3.3.6.), one of the remarkable properties of holomorphic functions.

[1] [SS03, p. xv].

Local Behavior and the Conformal Property

XII.1.1.10. The geometric action on $\mathbb{C}$ of multiplying by a nonzero complex number $c = re^{i\theta}$ is scaling by r and rotating by angle θ counterclockwise around the origin. Thus any plane figure has its shape preserved and its dimensions multiplied by r. In particular, two smooth oriented curves in the plane intersecting at z_0 with angle ϕ between them (between their tangent vectors) are sent to oriented curves through cz_0 with the same angle ϕ between them.

XII.1.1.11. If f is holomorphic on a region Ω, $z_0 \in \Omega$, and $f'(z_0) = re^{i\theta} \neq 0$, then near z_0 f looks approximately like the function $g(z) = f(z_0) + f'(z_0)(z - z_0)$, which consists geometrically like rotation around z_0 by angle θ, scaling by r, and translation by $f(z_0)$. Thus two smooth oriented curves in the plane intersecting at z_0 with angle ϕ between them are sent by g to oriented curves through cz_0 with the same angle ϕ between them, and the same is true for f (this can be easily verified using the Chain Rule of vector calculus since the tangent vectors are both transformed by multiplication by $f'(z_0)$ regarded as a linear transformation of $\mathbb{R}^2$).

XII.1.1.12. Thus, if f is holomorphic on Ω and f' is never zero on Ω, then f is a *conformal* map of Ω to $f(\Omega)$: any two smooth oriented curves in Ω which intersect will be sent to smooth oriented curves intersecting at the same angle at the image of the point of intersection. The function f locally looks approximately like a scaling, rotation, and translation; the scaling factor and rotation angle vary smoothly from point to point. This is an extremely important property of holomorphic functions and leads to many applications.

XII.1.1.13. The conformal property does not hold at points of Ω where $f' = 0$. The fundamental example is $f(z) = z^n$ at 0: rays from 0 with angle ϕ between them are sent to rays with angle $n\phi$ between them.

XII.1.1.14. It turns out that these power functions describe the general behavior of holomorphic functions: if f is a nonconstant holomorphic function on a connected open set Ω, then

(i) The points of Ω where $f' = 0$ are isolated ().

(ii) At each point z_0 where $f'(z_0) = 0$ there is an $n > 1$ such that f locally looks like $g(z) = f(z_0)+c(z-z_0)^n$ for some $0 \neq c \in \mathbb{C}$, and hence angles between curves intersecting at z_0 are multiplied by n, and f is locally n-to-one around z_0 ().

(iii) f is conformal and locally one-to-one around all other points of Ω.

(iv) f is an *open mapping*: if U is any open subset of Ω, then $f(U)$ is open ().

XII.1.1.15. There is even a converse: if Ω is an open set in $\mathbb{C}$, and $f : \Omega \to \mathbb{C}$ is differentiable on Ω in the vector calculus sense, and conformal and orientation-preserving, then f is holomorphic on Ω.

XII.1.2. Rules of Differentiation

There are complex analogs of the usual rules of differentiation. These can be proved by an easy adaptation of the arguments in the real case, or by rather tediously using the real results, the formulas for complex multiplication and division, and XII.1.1.4..

XII.1.2.1. Proposition. Let f be a function from an open set $\Omega \subseteq \mathbb{C}$ to $\mathbb{C}$. If f is complex differentiable at $z_0 \in \Omega$, then f is continuous at z_0.

XII.1.2.2. Theorem. [Power Rule] Let $n \in \mathbb{N}$, and $f : \mathbb{C} \to \mathbb{C}$ be defined by $f(z) = z^n$. Then f is complex differentiable at any $z_0 \in \mathbb{C}$, and

$$f'(z_0) = nz_0^{n-1} \ .$$

XII.1.2.3. Proposition. [Sum Rule] Let f and g be functions from an open set $\Omega \subseteq \mathbb{C}$ to $\mathbb{C}$, and $h = f + g : \Omega \to \mathbb{C}$. If f and g are complex differentiable at $z_0 \in \Omega$, then h is complex differentiable at z_0 and

$$h'(z_0) = f'(z_0) + g'(z_0) \ .$$

XII.1.2.4. Proposition. [Constant Multiple Rule] Let f be a function from an open set $\Omega \subseteq \mathbb{C}$ to $\mathbb{C}$, $c \in \mathbb{C}$, and $h = cf : \Omega \to \mathbb{C}$. If f is complex differentiable at $z_0 \in \Omega$, then h is complex differentiable at z_0 and

$$h'(z_0) = cf'(z_0) \ .$$

XII.1.2.5. Corollary. Any sum or constant multiple of functions holomorphic on Ω is holomorphic on Ω. In particular, a polynomial with complex coefficients is holomorphic on $\mathbb{C}$.

XII.1.2.6. Theorem. [Product Rule] Let f and g be functions from an open set $\Omega \subseteq \mathbb{C}$ to $\mathbb{C}$, and $h = fg : \Omega \to \mathbb{C}$. If f and g are complex differentiable at $z_0 \in \Omega$, then h is complex differentiable at z_0 and

$$h'(z_0) = f'(z_0)g(z_0) + f(z_0)g'(z_0) \ .$$

XII.1.2.7. THEOREM. [QUOTIENT RULE] Let f and g be functions from an open set $\Omega \subseteq \mathbb{C}$ to $\mathbb{C}$. If f and g are complex differentiable at $z_0 \in \Omega$ and $g(z_0) \neq 0$, then $h = \frac{f}{g}$ is defined in an open neighborhood of z_0 and differentiable at z_0, and

$$h'(z_0) = \frac{g(z_0)f'(z_0) - f(z_0)g'(z_0)}{[g(z_0)]^2} \ .$$

XII.1.2.8. COROLLARY. If f and g are holomorphic on Ω, then fg is holomorphic on Ω, and if g is nonzero on Ω, then $\frac{f}{g}$ is also holomorphic on Ω. In particular, every rational function with complex coefficients is holomorphic on its domain.

XII.1.2.9. THEOREM. [CHAIN RULE] Let f be defined on a neighborhood $\mathcal{U}$ of z_0 in $\mathbb{C}$ and complex differentiable at z_0, with $f(z_0) = w_0$, and let g be defined on a neighborhood $\mathcal{V}$ of w_0 in $\mathbb{C}$ and complex differentiable at w_0, with $f(\mathcal{U}) \subseteq \mathcal{V}$. Set $h = g \circ f$ on $\mathcal{U}$. Then h is complex differentiable at z_0, and

$$h'(z_0) = (g \circ f)'(z_0) = g'(w_0)f'(z_0) = g'(f(z_0))f'(z_0) \ .$$

XII.1.2.10. THEOREM. [INVERSE FUNCTION THEOREM] Let $\Omega \subseteq \mathbb{C}$ be open, f holomorphic on Ω, and $z_0 \in \Omega$. If $f'(z_0) \neq 0$, then there is an open neighborhood V of z_0 contained in Ω for which f maps bijectively to an open neighborhood W of $f(z_0)$, and the inverse function f^{-1} is holomorphic on W. If $z \in V$, then

$$(f^{-1})'(f(z)) = \frac{1}{f'(z)} \ .$$

PROOF: There is one aspect of this theorem not yet established: it follows automatically that f' is continuous (in fact, holomorphic) on Ω (XII.3.3.6.). The result now follows from the Inverse Function Theorem, since if f is regarded as a function from Ω to $\mathbb{R}^2$, we have $J_f(z) = det(Df(z)) = |f'(z)|^2$. The inverse function is holomorphic, since if $z \in V$ and $f'(z) = a + ib$, then

$$D(f^{-1})(f(z)) = \begin{bmatrix} a & -b \\ b & a \end{bmatrix}^{-1} = \frac{1}{a^2+b^2} \begin{bmatrix} a & b \\ -b & a \end{bmatrix}$$

and thus f^{-1} satisfies the Cauchy-Riemann equations; then

$$(f^{-1})'(f(z)) = \frac{a}{a^2+b^2} - i\frac{b}{a^2+b^2} = \frac{1}{f'(z)} \ .$$

Although we have stated this result in maximum generality, we have so far only given a complete proof of the following slightly weaker version:

XII.1.2.11. Corollary. Let $\Omega \subseteq \mathbb{C}$ be open, f holomorphic on Ω, and $z_0 \in \Omega$. If f' is continuous on Ω and $f'(z_0) \neq 0$, then there is an open neighborhood V of z_0 contained in Ω which f maps bijectively to an open neighborhood W of $f(z_0)$, and the inverse function f^{-1} is holomorphic on W. If $z \in V$, then

$$(f^{-1})'(f(z)) = \frac{1}{f'(z)} \ .$$

XII.1.2.12. In particular, if f is holomorphic on Ω and f' never vanishes, then f is an open mapping. If Ω is connected, this result extends to the case where f is just assumed to be not constant (). In fact, f is locally an open mapping around any point where it is not locally constant ().

At the other extreme, we have the following, which is an immediate consequence of XII.1.1.4. and VIII.2.1.8.:

XII.1.2.13. Proposition. Let Ω be a connected open set in $\mathbb{C}$, and f a holomorphic function on Ω. If f' is identically zero on Ω, then f is constant on Ω.

XII.1.2.14. Corollary. Let Ω be a connected open set in $\mathbb{C}$, and f and g holomorphic functions on Ω. If $f' = g'$ on Ω, then $f - g$ is constant on Ω.

XII.1.3. Branch Cuts and Branches

XII.1.3.1. A holomorphic function which is locally one-to-one (i.e. whose derivative does not vanish) is not globally one-to-one in general. The fundamental example is the complex exponential function: $e^{z+2\pi i} = e^z$ for any z. If we want to define an inverse function for such a function, we must restrict to regions where the function gives a bijection.

The Complex Logarithm

XII.1.3.2. The prototype problem is how to define a complex logarithm. Since we have $e^{x+iy} = e^x e^{iy}$, we have

$$|e^{x+iy}| = e^x, \quad arg(e^{x+iy}) = y$$

so we may try to define the complex logarithm using polar coordinates by

$$\log(re^{i\theta}) = \log r + i\theta \ .$$

The real part is well defined as long as $r \neq 0$ (obviously $\log 0$ cannot make sense since e^z is never zero); but the problem is that the argument θ is only defined up to adding a multiple of 2π.

XII.1.3.3. The standard solution is to restrict the exponential function to an open horizontal strip of width 2π, say the strip

$$S_\alpha = \{x + iy : \alpha < y < \alpha + 2\pi\}$$

for a fixed real number α. The exponential function maps this open strip one-one onto the plane with a ray out from 0 at angle α (measured in the usual way from the positive real axis counterclockwise) removed. An inverse function can then be defined on this open set Ω_α taking values in the strip, which is a reasonable definition of a complex logarithm function. This function is called a *branch* of the complex logarithm function with the ray as *branch cut*. There is thus one branch of the complex logarithm for each real number α. Note that for a given branch cut, there are infinitely many branches: the branch cuts for the branches corresponding to α and β are the same if (and only if) α and β differ by a multiple of 2π.

A branch of the complex logarithm cannot be continuously extended to any point on the branch cut, since the limits as the point is approached from opposite sides of the cut differ by $2\pi i$.

XII.1.3.4. The branch corresponding to $\alpha = -\pi$ is called the *principal branch* of the complex logarithm. The branch cut for the principal branch is the negative real axis, and the values are in

$$S_{-\pi} = \{x + iy : -\pi < y < \pi\} \ .$$

The principal branch of the complex logarithm agrees with the usual (real) logarithm function on the positive real axis.

XII.1.3.5. Although branch cuts are usually taken to be straight rays, any curve beginning at 0 and going to ∞ without crossing itself can be used as a branch cut, and a branch of the complex logarithm (actually infinitely many) can be defined on the complement. (The preimage of such a curve under the exponential function gives a sequence of parallel curves in the plane a vertical distance 2π apart, and the exponential function is bijective on the region between consecutive curves.)

XII.1.3.6. If f is holomorphic on a region Ω, and $f(\Omega)$ is contained in a region on which a branch ϕ of log is defined, set $g = \phi \circ f$. Then g is holomorphic on Ω and $f = e^g$ on Ω. See XII.3.9.2. for a different situation where such a g exists.

Complex Exponentiation

XII.1.3.7. If $a, b \in \mathbb{C}$ $(a \neq 0)$, how do we define a^b? An unambiguous definition cannot be given in general. But a useful way to do it, which is universally used, is to define

$$a^b = e^{b \log a} \ .$$

This is of course not unambiguous in general since $\log a$ is not well defined – it has infinitely many values. By letting $\log a$ run through all possible values, we get (in general) infinitely many values for a^b.

XII.1.3.8. If b is an integer, all these possible values coincide, and give the usual algebraic definition of a^b. If $b = \frac{p}{q}$ (in lowest terms) is a (real) rational number, there are exactly q different values for a^b. But if b is an irrational real number, or a nonreal number, all the values for a^b are distinct.

These statements are only valid if $a \neq 0$; 0^b cannot be reasonably defined unless b is a natural number (in Complex Analysis we usually don't even define things like $0^{1/2}$).

XII.1.3.9. Because of the ambiguity in definition, care must be exercised in stating and applying rules of exponents; see XII.9.9.8..

General Exponential Functions

XII.1.3.10. To define a general exponential function $f(z) = a^z$, where a is a nonzero complex number, write

$$f(z) = e^{z \log a} .$$

This defines an entire function whenever a value of $\log a$ is chosen, but there are infinitely many choices for any a.

If a is a positive real number (even if $a = 1$ or e!) there are technically infinitely many choices for $\log a$ and thus infinitely many corresponding exponential functions. But in this case it is conventional to choose the real value (i.e. the principal branch) for $\log a$, so there is by convention a well-defined exponential function, which extends the real function $f(x) = a^x$.

General Power Functions

XII.1.3.11. If b is a complex number, we can define $f(z) = z^b$ by choosing a branch of $\log z$ and defining

$$f(z) = e^{b \log z}$$

on $\mathbb{C}$ with the corresponding branch cut removed. In general, this produces infinitely many branches of f for any branch cut, and they cannot be extended to be continuous on the cut unless b is an integer. If $b = \frac{p}{q}$ (in lowest terms) is rational, there are exactly q distinct branches for any branch cut.

XII.1.3.12. If $b = \frac{1}{2}$ (or, more generally, any rational number), this process can be viewed somewhat differently without explicit reference to logarithms. Suppose we want to define $f(z) = z^{1/2} = \sqrt{z}$. The problem is that any nonzero z has two square roots, and there is no systematic (i.e. continuous) way to choose one of them over all of $\mathbb{C}$. We can define

$$f(re^{i\theta}) = \sqrt{r}e^{i\theta/2}$$

but to do this carefully we must specify a range of values for θ of length 2π, i.e. require

$$\alpha < \theta < \alpha + 2\pi$$

for some fixed $\alpha \in \mathbb{R}$. The values of the corresponding square root function lie in the open half plane of points with argument between $\alpha/2$ and $\alpha/2 + \pi$.

If α is increased by 2π, the domain of the corresponding square root function is the same, but the range is the opposite half plane. If α is increased by 4π, the function defined is the same. Thus there are two holomorphic square root functions corresponding to any branch cut.

XII.1.3.13. A square root function (actually two such functions) can be more generally defined on any simply connected () open subset of $\mathbb{C}$ not containing 0. The same can be said for the logarithm function or any power function, although there are infinitely many possibilities for these in general.

XII.1.4. The Fundamental Theorem of Algebra

The Fundamental Theorem of Algebra, that every complex polynomial has a root in $\mathbb{C}$, has many essentially different proofs. There is a nice one due to J. Milnor [Mil97], based on the results of XII.1.1., which we describe here. See XII.9.9.3. and XII.9.9.4. for two more proofs using Complex Analysis.

XII.1.4.1. Lemma. Let p be a nonconstant polynomial with complex coefficients,

$$p(z) = a_0 + a_1 z + a_2 z^2 + \cdots + a_n z^n$$

with $n \geq 1$ and $a_n \neq 0$. Then for any $M > 0$ there is a $K > 0$ such that $|p(z)| > M$ for all z with $|z| > K$.

Proof: For all z with $|z| \geq 1$, we have

$$|p(z)| = |z^n|(|a_0 z^{-n} + \cdots + a_{n-1} z^{-1} + a_n|) \geq |z|^n \left(|a_n| - |z|^{-1} \sum_{k=0}^{n-1} |a_k| \right)$$

If $|z|$ is sufficiently large, the second factor is greater than $\frac{|a_n|}{2}$, and $|z|^n > \frac{2M}{|a_n|}$. So

$$K = \max \left(1, \frac{2\sum_{k=0}^{n-1} |a_k|}{|a_n|}, \left[\frac{2M}{|a_n|} \right]^{1/n} \right)$$

will do. 👍

XII.1.4.2. Theorem. [Fundamental Theorem of Algebra] Let p be a nonconstant polynomial with coefficients in $\mathbb{C}$. Then there is at least one $c \in \mathbb{C}$ with $p(c) = 0$.

Proof: Let $R \subseteq \mathbb{C}$ be the range of p, i.e.

$$R = \{p(z) : z \in \mathbb{C}\}$$

and set

$$F = \{p(z) : z \in \mathbb{C},\ p'(z) = 0\}$$

and $S = R \setminus F$. Then F is a finite subset of R since p' is not identically zero. We will show that R is closed and S is open in $\mathbb{C}$. This will prove the theorem since if $\mathbb{C} \setminus R$ is nonempty, then S and $\mathbb{C} \setminus R$ would be disjoint nonempty open sets whose union is the connected open set $\mathbb{C} \setminus F$, a contradiction. (Note that S is nonempty since otherwise $R = F$, and F would have to be a singleton by continuity, so p would be constant.) Thus $R = \mathbb{C}$, and in particular $0 \in R$.

To show that R is closed, it suffices to show that $R \cap \bar{B}_M(0)$ is closed for all $M > 0$. Fix M. There is a K such that $|p(z)| > M$ for all z with $|z| > K$ (Lemma XII.1.4.1.). Thus

$$R \cap \bar{B}_M(0) = p(\bar{B}_K(0)) \cap \bar{B}_M(0)$$

which is compact since p is continuous ().

We now show S is open. Let $w_0 \in S$. Fix $z_0 \in \mathbb{C}$ with $p(z_0) = w_0$, $p'(z_0) \neq 0$. So by XII.1.2.11. there is a neighborhood V of z_0 which p maps homeomorphically onto a neighborhood W of w_0; thus $W \subseteq R$. Since F is finite and $w_0 \notin F$, $W \setminus F$ is a neighborhood of w_0 contained in S. 👍

XII.2. Contour Integration

Contour integration is one of the most fundamental tools of Complex Analysis. Cauchy's Theorem, which roughly says that the contour integral of a holomorphic function around a closed contour is zero, is the key to all the deeper properties of holomorphic functions.

XII.2.1. Integration along a Contour

XII.2.1.1. DEFINITION. Let $p, q \in \mathbb{C}$. A *contour* from p to q is a continuous rectifiable curve () in $\mathbb{C} \cong \mathbb{R}^2$ from p to q.

XII.2.1.2. A contour γ from p to q by definition has a continuous parametrization $\zeta : [a, b] \to \mathbb{C}$ with $\zeta(a) = p$, $\zeta(b) = q$. However, the parametrization is not unique, and is not intrinsic to γ (only the equivalence class of the parametrization is part of the definition). But since γ is rectifiable, it has an intrinsic parametrization by arc length starting at p (). More importantly, γ has an *orientation*, or specified direction of motion, with initial point p and final point q. There is an *opposite contour* $-\gamma$, which is γ traversed from q to p. If $\zeta : [a, b] \to \mathbb{C}$ is a parametrization of γ, then $\tilde{\zeta} : [0, b - a] \to \mathbb{C}$ defined by $\tilde{\zeta}(t) = \zeta(b - t)$ is a parametrization of $-\gamma$. The interval a parametrization is defined on is not important, and can be changed to any other (closed bounded) interval by a linear change of variables.

We will often consider *closed contours*, ones whose initial and final points coincide. A closed contour still has an orientation, and if γ is a simple closed contour, i.e. the image is homeomorphic to a circle, it also makes sense to say how many (net) times γ is traversed in a counterclockwise direction ().

We will almost always concern ourselves only with the special case where γ is piecewise-smooth, i.e. has a piecewise-smooth parametrization (). If γ is piecewise-smooth, parametrization by arc length is a piecewise-smooth parametrization ().

XII.2.1.3. The goal of this section is to show that if γ is a contour in $\mathbb{C}$, and f is a continuous complex-valued function on $\mathbb{C}$, then there is a well-defined complex number called the *(contour) integral of f along γ*, denoted

$$\int_\gamma f = \int_\gamma f(\zeta)\, d\zeta$$

with the usual properties of an integral. The integral does not depend on a parametrization of γ, although it is usually calculated using a parametrization. It does, however, depend on the orientation of γ: we will have

$$\int_{-\gamma} f = -\int_\gamma f \ .$$

Although contour integrals of somewhat more general functions can be defined, we will restrict to the case of continuous functions for simplicity, and because this is the crucial case for applications. In fact, almost all applications involve only contour integrals of holomorphic functions.

Integration on an Interval

Definition of the Contour Integral

Properties of Contour Integrals

The Fundamental Inequality

The next fundamental estimate is an easy consequence of the definition:

XII.2.1.4. PROPOSITION. Let $\gamma : [a, b] \to \mathbb{C}$ be a rectifiable curve, and f a continuous function on γ. If $|f(z)| \leq M$ for all $z \in \gamma$, then

$$\left| \int_\gamma f \right| \leq M \cdot \ell(\gamma) \ .$$

PROOF: Let $\mathcal{P} = \{a = t_0, t_1, \ldots, t_n = b\}$ be a partition of $[a, b]$. Then by the triangle inequality we have

$$\left| \sum_{k=1}^{n} f(\gamma(t_k))(\gamma(t_k) - \gamma(t_{k-1})) \right| \leq \sum_{k=1}^{n} |f(\gamma(t_k))||\gamma(t_k) - \gamma(t_{k-1})| \leq M \sum_{k=1}^{n} |\gamma(t_k) - \gamma(t_{k-1})| \ .$$

As the mesh of $\mathcal{P}$ goes to zero, the left side approaches $\left| \int_\gamma f \right|$ and the right side approaches $M \cdot \ell(\gamma)$. 👍

An important consequence is:

XII.2.1.5. COROLLARY. Let $\gamma : [a, b] \to \mathbb{C}$ be a rectifiable curve, and (f_n) a sequence of continuous functions on γ converging uniformly on γ to a (continuous) function f. Then

$$\int_\gamma f_n \to \int_\gamma f \ .$$

Calculation of Contour Integrals

On piecewise-smooth curves, contour integrals can be computed by an ordinary integral:

XII.2.1.6. THEOREM. If $\gamma : [a, b] \to \mathbb{C}$ is a piecewise-smooth curve in $\mathbb{C}$ and f is a complex-valued function on γ, then

$$\int_\gamma f = \int_a^b f(\gamma(t))\gamma'(t)\, dt \ .$$

XII.2.1.7. EXAMPLE. Here is perhaps the most important example of a contour integral. Let γ be the unit circle in $\mathbb{C}$, parametrized once around counterclockwise. Let $f(z) = \frac{1}{z} = \bar{z}$ for $|z| = 1$. Then

$$\int_\gamma f = \int_0^{2\pi} \frac{1}{e^{it}} ie^{it}\, dt = 2\pi i \ .$$

This integral will appear over and over in many parts of complex analysis, and many of the fundamental theorems and formulas of the subject are based on it.

The Fundamental Theorem of Calculus

The contour integral of a function with an antiderivative is easy to compute:

XII.2.1.8. PROPOSITION. If f is a continuous function on an open set Ω in $\mathbb{C}$ with an antiderivative F on Ω, and $\gamma : [a, b] \to \Omega$ is a piecewise-smooth contour from p to q, then

$$\int_\gamma f = F(q) - F(p) \ .$$

In particular, the contour integral of f along any contour depends only on the endpoints. The contour integral of f around any closed contour is 0.

PROOF: This just looks like the Fundamental Theorem of Calculus, but it does not follow immediately from the real FTC but requires a bit of calculation using the Chain Rule of vector calculus and the Cauchy-Riemann equations. By subdividing $[a, b]$, we may assume γ is smooth. Write

$$F(x + iy) = U(x, y) + iV(x, y)$$

so that

$$f(x + iy) = \frac{\partial U}{\partial x}(x, y) + i\frac{\partial V}{\partial x}(x, y) \ .$$

Write

$$\gamma(t) = \gamma_1(t) + i\gamma_2(t)$$
$$G(t) = U(\gamma_1(t), \gamma_2(t))$$
$$H(t) = V(\gamma_1(t), \gamma_2(t))$$

so that $F(\gamma(t)) = G(t) + iH(t)$. By the vector calculus Chain Rule,

$$G'(t) = \frac{\partial U}{\partial x}(\gamma_1(t), \gamma_2(t))\gamma_1'(t) + \frac{\partial U}{\partial y}(\gamma_1(t), \gamma_2(t))\gamma_2'(t)$$

$$H'(t) = \frac{\partial V}{\partial x}(\gamma_1(t), \gamma_2(t))\gamma_1'(t) + \frac{\partial V}{\partial y}(\gamma_1(t), \gamma_2(t))\gamma_2'(t) \ .$$

Then

$$\int_\gamma f = \int_a^b f(\gamma(t))\gamma'(t)\, dt$$

$$= \int_a^b \left[\frac{\partial U}{\partial x}(\gamma_1(t),\gamma_2(t)) + i\frac{\partial V}{\partial x}(\gamma_1(t),\gamma_2(t))\right][\gamma_1'(t) + i\gamma_2'(t)]\ dt$$

$$= \int_a^b \left[\frac{\partial U}{\partial x}(\gamma_1(t),\gamma_2(t))\gamma_1'(t) - \frac{\partial V}{\partial x}(\gamma_1(t),\gamma_2(t))\gamma_2'(t)\right] dt + i\int_a^b \left[\frac{\partial V}{\partial x}(\gamma_1(t),\gamma_2(t))\gamma_1'(t) + \frac{\partial U}{\partial x}(\gamma_1(t),\gamma_2(t))\gamma_2'(t)\right] dt$$

$$= \int_a^b \left[\frac{\partial U}{\partial x}(\gamma_1(t),\gamma_2(t))\gamma_1'(t) + \frac{\partial U}{\partial y}(\gamma_1(t),\gamma_2(t))\gamma_2'(t)\right] dt + i\int_a^b \left[\frac{\partial V}{\partial x}(\gamma_1(t),\gamma_2(t))\gamma_1'(t) + \frac{\partial V}{\partial y}(\gamma_1(t),\gamma_2(t))\gamma_2'(t)\right] dt$$

$$= \int_a^b G'(t)\,dt + i\int_a^b H'(t)\,dt = (G(b) - G(a)) + i(H(b) - H(a)) = F(q) - F(p)\ .$$

The Complex Mean Value Inequality

The next result is a complex version of the Mean Value Inequality (V.8.2.10.):

XII.2.1.9. PROPOSITION. Let f be a holomorphic function on an open set Ω in $\mathbb{C}$ (with f' continuous), and A a convex subset of Ω. If $|f'(z)| \le M$ for all $z \in A$, then

$$|f(z) - f(w)| \le M|z - w|$$

for all $z, w \in A$.

The requirement that f' be continuous turns out to be automatic (XII.3.3.6.).
PROOF: Let γ be the straight line segment from w to z; then $\gamma \subseteq A$ since A is convex.

$$|f(z) - f(w)| = \left|\int_\gamma f'\right| \le M\ell(\gamma) = M|z - w|\ .$$

Relation with Line Integrals

Green's Theorem for Complex Functions

XII.3. Some Big Theorems

In this section, we use contour integration to prove some of the big theorems of elementary Complex Analysis: Cauchy's Theorem, the Cauchy Integral Formula, Morera's Theorem, Cauchy's Inequalities, and Liouville's Theorem.

These are, of course, not all the theorems of Complex Analysis which can be called "big theorems." A few more more big theorems concerning power series representation and analysis of singularities will be discussed in the next sections. Other big theorems such as the Riemann Mapping Theorem (and many others) are discussed later or are beyond the scope of this book.

XII.3.1. Goursat's Theorem

We begin by proving a special case of Cauchy's Theorem, due to E. GOURSAT in 1883. This result is a considerable technical improvement over CAUCHY'S original theorem, since it assumes nothing about the properties of the derivative of a holomorphic function, and in particular makes no continuity assumption about the derivative (in fact, it will turn out later that the derivative of a holomorphic function is not only automatically continuous, but even itself holomorphic, but we do not want to assume anything about the derivative in developing the theory).

The form of Goursat's Theorem we give (originally due to A. PRINGSHEIM in 1901) uses triangles. It can be equally well stated and proved for rectangles, or for any other polygonal region that can be subdivided into a finite number of congruent pieces of smaller diameter and perimeter (GOURSAT used squares). The use of triangles gives a more flexible result which simplifies succeeding proofs.

XII.3.1.1. THEOREM. [GOURSAT'S THEOREM] Let Ω be an open set in $\mathbb{C}$, and f a holomorphic function on Ω. If T is a (solid) triangle contained in Ω, and γ is the boundary of T parametrized once around counterclockwise, then

$$\int_\gamma f = 0 \ .$$

PROOF: Let d and p be the diameter and perimeter of T respectively. Divide T into four subtriangles $T_1^{(1)}, \ldots, T_1^{(4)}$ whose vertices are the vertices of T and the midpoints of the edges of T. Then each $T_1^{(k)}$ is similar to T. If $\gamma_1^{(k)}$ is the perimeter of $T_1^{(k)}$, parametrized once around counterclockwise, then we have

$$\int_\gamma f = \int_{\gamma_1^{(1)}} f + \int_{\gamma_1^{(2)}} f + \int_{\gamma_1^{(3)}} f + \int_{\gamma_1^{(4)}} f$$

since all interior edges are traversed once in each direction, so those contour integrals cancel. Thus there is a k such that

$$\left| \int_\gamma f \right| \leq 4 \left| \int_{\gamma_1^{(k)}} f \right| \ .$$

Set $T_1 = T_1^{(k)}$ and $\gamma_1 = \gamma_1^{(k)}$ for this k. Repeat the process inductively using T_n in place of T to obtain a decreasing sequence (T_n) of triangles with boundary γ_n, with

$$\left| \int_\gamma f \right| \leq 4^n \left| \int_{\gamma_n} f \right|$$

for all n. We have that the diameter d_n and perimeter p_n of T_n satisfy $d_n = 2^{-n} d$ and $p_n = 2^{-n} p$. We have that

$$\cap_n T_n = \{z_0\}$$

for some $z_0 \in T$.

Since f is differentiable at z_0, for $z \in \Omega \setminus \{z_0\}$ we may set

$$g(z) = \frac{f(z) - f(z_0)}{z - z_0} - f'(z_0) \ .$$

If we set $g(z_0) = 0$, then g is continuous on Ω and we may write

$$f(z) = f(z_0) + f'(z_0)(z - z_0) + g(z)(z - z_0)$$

for $z \in \Omega$. Thus we have

$$\int_{\gamma_n} f(\zeta)\, d\zeta = \int_{\gamma_n} f(z_0)\, d\zeta + \int_{\gamma_n} f'(z_0)(\zeta - z_0)\, d\zeta + \int_{\gamma_n} g(\zeta)(\zeta - z_0)\, d\zeta$$

for any n. The first two integrals on the right are always zero since the integrands have antiderivatives on Ω (they are a constant function and a linear function respectively); thus for any n we have

$$\int_{\gamma_n} f(\zeta)\, d\zeta = \int_{\gamma_n} g(\zeta)(\zeta - z_0)\, d\zeta \ .$$

Let $\epsilon > 0$. Choose $\delta > 0$ such that $|g(z)| < \epsilon$ whenever $|z - z_0| < \delta$. Then for any n large enough that $d_n < \delta$, we have

$$\left| \int_{\gamma_n} f(\zeta)\, d\zeta \right| = \left| \int_{\gamma_n} g(\zeta)(\zeta - z_0)\, d\zeta \right| \leq \epsilon d_n p_n \ .$$

Combining the inequalities, for n sufficiently large we have

$$\left| \int_{\gamma} f \right| \leq 4^n \left| \int_{\gamma_n} f \right| \leq 4^n \epsilon d_n p_n = \epsilon d p \ .$$

Since $\epsilon > 0$ is arbitrary, we obtain $\int_\gamma f = 0$. 👍

It will be convenient to have a technical strengthening of this theorem:

XII.3.1.2. COROLLARY. Let Ω be an open set in $\mathbb{C}$, $\{z_1, \ldots, z_n\}$ a finite set of points in Ω, and f a holomorphic function on $\Omega \setminus \{z_1, \ldots, z_n\}$. Suppose

$$\lim_{z \to z_k} f(z)(z - z_k) = 0$$

for $1 \leq k \leq n$. If T is a (solid) triangle contained in Ω, and the boundary γ of T (parametrized once around counterclockwise) contains no z_k, then

$$\int_\gamma f = 0 \ .$$

PROOF: T can be subdivided into smaller triangles, with some of the subtriangles $T_1, \ldots, T_m$ each containing exactly one of the z_k in its interior, and the rest of the subtriangles contained in $\Omega \setminus \{z_1, \ldots, z_n\}$. Let γ_j be the boundary of T_j $(1 \leq j \leq m)$. Then

$$\int_\gamma f = \sum_{j=1}^{n} \int_{\gamma_j} f$$

since the integrals around the other triangles are 0 and all edges not part of γ or one of the γ_j are traversed once in each direction. Thus it suffices to show that $\int_{\gamma_j} f = 0$ for each j, i.e. it suffices to show the result in the case where T contains exactly one z_k in its interior.

Changing notation, we assume z_j is the only z_k in the interior of T. By a similar subdivision argument, the integral of f around any other triangle in Ω containing only z_j in its interior is the same. Thus we may assume T has arbitrarily small diameter d and circumference p.

Let $\epsilon > 0$, and choose $\delta > 0$ such that $|f(z)(z - z_j)| < \epsilon$ whenever $0 < |z - z_j| < \delta$. Choose T with $p < \delta$ (and hence $d < \delta$ also). If $\zeta \in \gamma$, we then have $|f(\zeta)| < \frac{\epsilon}{\delta}$. We then have

$$\left| \int_\gamma f \right| \leq \frac{\epsilon}{\delta} p < \epsilon \ .$$

Since the integral is independent of which T is chosen, and $\epsilon > 0$ is arbitrary, we have $\int_\gamma f = 0$. 👍

XII.3.2. The Antiderivative Theorem and Cauchy's Theorem for Convex Sets

XII.3.2.1. THEOREM. [ANTIDERIVATIVE THEOREM FOR CONVEX SETS] Let Ω be a convex open set in $\mathbb{C}$. Let f be a complex-valued continuous function on Ω. If

$$\int_\gamma f = 0$$

for every triangular contour γ in Ω, then f has an antiderivative on Ω: there is a holomorphic function F on Ω with $F' = f$ on Ω.

PROOF: Fix $z_0 \in \Omega$. For any $z \in \Omega$, define

$$F(z) = \int_\gamma f$$

where γ is the straight line segment from z_0 to z. If z and w are in Ω, then

$$F(w) - F(z) = \int_\gamma f$$

where γ is the straight line segment from z to w, since the integral of f around the triangle with vertices z_0, z, and w is 0 by assumption.

Now fix $z \in \Omega$, and fix $\eta > 0$ such that $B_\eta(z) \subseteq \Omega$. If $h \in \mathbb{C}$, $|h| < \eta$, then

$$\frac{F(z+h) - F(z)}{h} = \frac{1}{h} \int_{\gamma_h} f$$

where γ_h is the straight line segment from z to $z + h$. We have

$$\int_{\gamma_h} f(\zeta)\, d\zeta = \int_{\gamma_h} [f(\zeta) - f(z)]\, d\zeta + \int_{\gamma_h} f(z)\, d\zeta \ .$$

The second integral is the contour integral of the constant function $f(z)$ (z is fixed), hence equals $f(z)h$. Since f is continuous at z, for any $\epsilon > 0$ there is a $\delta > 0$, $\delta \leq \eta$, such that $|f(\zeta) - f(z)| < \epsilon$ whenever $|\zeta - z| < \delta$. Thus if $|h| < \delta$, we have

$$\left| \int_{\gamma_h} [f(\zeta) - f(z)]\, d\zeta \right| < \epsilon |h| \ .$$

Thus

$$\lim_{h\to 0} \frac{F(z+h) - F(z)}{h} = \lim_{h\to 0} \frac{1}{h} \int_{\gamma_h} f = \lim_{h\to 0} \frac{1}{h} \int_{\gamma_h} [f(\zeta) - f(z)]\, d\zeta + \lim_{h\to 0} \frac{1}{h} \int_{\gamma_h} f(z)\, d\zeta = f(z)$$

since the first limit on the right is 0 and the second expression is exactly $f(z)$ for all h. Thus $F'(z)$ exists and equals $f(z)$ for any $z \in \Omega$. 👍

The proof actually shows the following slightly more general version:

XII.3.2.2. THEOREM. Let Ω be a convex open set in $\mathbb{C}$, $\{z_1, \ldots, z_n\}$ a finite set of points in Ω, and f a continuous function on $\Omega \setminus \{z_1, \ldots, z_n\}$. If

$$\int_\gamma f = 0$$

for every triangular contour γ in Ω not passing through one of the z_k, then f has an antiderivative on $\Omega \setminus \{z_1, \ldots, z_n\}$: there is a holomorphic function F on $\Omega \setminus \{z_1, \ldots, z_n\}$ with $F' = f$ on $\Omega \setminus \{z_1, \ldots, z_n\}$.

PROOF: There are only a few slight modifications needed to the proof. Take $z_0 \in \Omega \setminus \{z_1, \ldots, z_n\}$, and for $z \in \Omega \setminus \{z_1, \ldots, z_n\}$ we take

$$F(z) = \int_\gamma f$$

where γ is a path from z_0 to z consisting of at most two line segments in $\Omega \setminus \{z_1, \ldots, z_n\}$ (by hypothesis, F is well defined; such angled paths will sometimes be necessary since the straight line segment from z_0 to z may pass through a z_k). If $z \in \Omega \setminus \{z_1, \ldots, z_n\}$, choose $\eta > 0$ such that $B_\eta(z) \subseteq \Omega \setminus \{z_1, \ldots, z_n\}$. The rest of the proof is identical. 👍

There is a version for general open sets, whose proof is essentially identical:

XII.3.2.3. THEOREM. [ANTIDERIVATIVE THEOREM] Let Ω be an open set in $\mathbb{C}$. Let f be a complex-valued continuous function on Ω. If

$$\int_\gamma f = 0$$

for every closed contour γ in Ω, then f has an antiderivative on Ω: there is a holomorphic function F on Ω with $F' = f$ on Ω.

PROOF: We may assume Ω is connected since F may be defined separately on each component. Fix $z_0 \in \Omega$, and for $z \in \Omega$ define

$$F(z) = \int_\gamma f$$

where γ is any contour in Ω from z_0 to z. If γ_1 and γ_2 are two such contours, then

$$\int_{\gamma_1} f - \int_{\gamma_2} f = \int_{\gamma_1 - \gamma_2} f = 0$$

by assumption, so F is well defined. If z and w lie in a convex open subset of Ω (e.g. a small disk), then

$$F(w) - F(z) = \int_{\gamma} f$$

where γ is the straight line segment from z to w, since $F(w)$ can be calculated by taking a contour from z_0 to z and appending this line segment.

The rest of the proof is identical to the proof of XII.3.2.1.. 👍

The advantage of XII.3.2.1. on convex sets is that only triangular contours need to be checked. Putting XII.3.2.1. together with Goursat's Theorem and (), we obtain:

XII.3.2.4. Corollary. [Cauchy's Theorem for Convex Sets] Let Ω be a convex open set in $\mathbb{C}$, and f a holomorphic function on Ω. Then f has an antiderivative on Ω, and if γ is any piecewise-smooth closed curve in Ω, then

$$\int_{\gamma} f = 0 \ .$$

XII.3.2.5. Example. This result can fail if Ω is not convex. For example, let $\Omega = \mathbb{C} \setminus \{0\}$, and $f(z) = \frac{1}{z}$. Then f is holomorphic on Ω, but the integral of f around the unit circle is nonzero () and f does not have an antiderivative on Ω (i.e. $\log z$ cannot be defined as a holomorphic function on all of Ω).

Cauchy's Theorem is true if Ω is simply connected ().

We do get a slight extension by using XII.3.2.2. together with XII.3.1.2.:

XII.3.2.6. Theorem. Let Ω be a convex open set in $\mathbb{C}$, $\{z_1, \ldots, z_n\}$ a finite set of points in Ω, and f a holomorphic function on $\Omega \setminus \{z_1, \ldots, z_n\}$. Suppose

$$\lim_{z \to z_k} f(z)(z - z_k) = 0$$

for $1 \leq k \leq n$. Then f has an antiderivative on $\Omega \setminus \{z_1, \ldots, z_n\}$, and if γ is any piecewise-smooth closed curve in $\Omega \setminus \{z_1, \ldots, z_n\}$, then

$$\int_{\gamma} f = 0 \ .$$

The next result can be generalized using the general form of Cauchy's Theorem, but this form is already very useful. Circles can be replaced by convex or, more generally, starlike polygonal arcs such as triangles or rectangles with the same proof (which even simplifies in this case).

XII.3.2.7. THEOREM. Let f be holomorphic on an open set Ω, and γ_1 and γ_2 circles in Ω (not necessarily concentric), parametrized once around counterclockwise, with γ_2 contained in the interior of γ_1. If the region between γ_1 and γ_2 is contained in Ω, then

$$\int_{\gamma_1} f = \int_{\gamma_2} f \ .$$

Note that the integrals around γ_1 and γ_2 are not necessarily 0!

PROOF: The inner circle γ_2 can be subdivided into arcs with consecutive endpoints $z_1, \ldots, z_n$ such that the line segments between pairs of consecutive points, and the region between the segment and the circle, are contained in Ω (cover the circle with finitely many open disks contained in Ω). Thus, if radial line segments are drawn outward from each z_k to γ_1, each wedge is contained in a convex open subset of Ω, and hence the contour integral of f around each, once around counterclockwise, is 0:

The sum of these integrals is

$$\int_{\gamma_1} f - \int_{\gamma_2} f$$

since each radial segment is traversed once in each direction, so those contour integrals cancel. Thus

$$\int_{\gamma_1} f - \int_{\gamma_2} f = 0 \ .$$

XII.3.3. The Cauchy Integral Formula

XII.3.3.1. A remarkable consequence of the theorems obtained so far is that if a function f is holomorphic on and inside a circle (or more general simple closed curve) γ, then the values of f on γ completely determine the values of f at all points inside γ (see XII.5.1.4. for a generalization), and in fact there is a simple formula involving a contour integral.

XII.3.3.2. THEOREM. [CAUCHY INTEGRAL FORMULA] Let f be holomorphic on an open set Ω in $\mathbb{C}$. Then for each $z \in \Omega$ we have

$$f(z) = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{\zeta - z}\, d\zeta$$

where γ is any circle in Ω bounding an open disk contained in Ω and containing z, parametrized once around counterclockwise.

PROOF: Fix z inside γ. If $\delta > 0$ is small enough that the circle γ_δ of radius δ centered at z is in the interior of γ, we have

$$\int_\gamma \frac{f(\zeta)}{\zeta - z}\, d\zeta = \int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z}\, d\zeta$$

by XII.3.2.7.. Thus it suffices to prove the result for the γ_δ, in fact to show that

$$f(z) = \lim_{\delta \to 0} \frac{1}{2\pi i} \int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z}\, d\zeta \ .$$

Let $\epsilon > 0$. Since f is continuous, if δ is sufficiently small then $|f(\zeta) - f(z)| < \epsilon$ for $\zeta \in \gamma_\delta$. We then have, for γ_δ inside γ,

$$\int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z}\, d\zeta = \int_{\gamma_\delta} \frac{f(\zeta) - f(z)}{\zeta - z}\, d\zeta + \int_{\gamma_\delta} \frac{f(z)}{\zeta - z}\, d\zeta \ .$$

If δ is small enough that $|f(\zeta) - f(z)| < \epsilon$ for $\zeta \in \gamma_\delta$, the first integral satisfies

$$\left| \int_{\gamma_\delta} \frac{f(\zeta) - f(z)}{\zeta - z}\, d\zeta \right| \leq \frac{\epsilon}{\delta} \cdot 2\pi\delta = 2\pi\epsilon$$

and thus the first integral approaches 0 as $\delta \to 0$. The second integral can be computed by taking $\zeta(t) = z + \delta e^{it}$, $0 \leq t \leq 2\pi$; thus

$$\int_{\gamma_\delta} \frac{f(z)}{\zeta - z}\, d\zeta = f(z) \int_0^{2\pi} \frac{1}{\delta e^{it}} i\delta e^{it}\, dt = 2\pi i f(z) \ .$$

An interesting reformulation is that if D is a closed disk and f is holomorphic on and inside D, then the value of f at the center of the disk is the average of the values on the boundary circle:

XII.3.3.3. Corollary. Let f be holomorphic on an open set Ω, and D a closed disk in Ω of radius r, centered at z_0. Then

$$f(z_0) = \frac{1}{2\pi} \int_0^{2\pi} f(z_0 + re^{it})\, dt \ .$$

Proof: Parametrize the boundary circle by $\zeta(t) = z_0 + re^{it}$, $0 \leq t \leq 2\pi$. Then

$$f(z_0) = \frac{1}{2\pi i} \int_0^{2\pi} \frac{f(z_0 + re^{it})}{re^{it}} ire^{it}\, dt \ .$$

The Cauchy Integral Formula for Derivatives

XII.3.3.4. We now obtain another remarkable consequence of the Cauchy Integral Formula. The integrand in the formula is a function of z and ζ; since we integrate with respect to ζ, it should be possible to differentiate with respect to z under the integral sign, in analogy with IX.3.5.1., to obtain an integral formula for f'. In fact, since the integrand is infinitely differentiable in z, we could expect that the function defined by the integral, namely f, is also infinitely differentiable and all its derivatives are obtained by successive differentiation under the integral sign. This expectation is valid (XII.3.3.6.). In fact, a more general result along the same lines holds, which is also useful for other purposes:

XII.3.3.5. THEOREM. Let γ be a contour in $\mathbb{C}$ (not necessarily a closed contour), and ϕ a complex-valued continuous function on γ. For $z \in \mathbb{C} \setminus \gamma$, define

$$f(z) = \int_\gamma \frac{\phi(\zeta)}{\zeta - z}\, d\zeta \ .$$

Then f is infinitely differentiable on $\mathbb{C} \setminus \gamma$, and for each $z \in \mathbb{C} \setminus \gamma$ and each n we have

$$f^{(n)}(z) = n! \int_\gamma \frac{\phi(\zeta)}{(\zeta - z)^{n+1}}\, d\zeta \ .$$

PROOF: By induction on n. The case $n = 0$ holds by assumption. Assume the result is true for $n-1$, i.e. for any $z \in \mathbb{C} \setminus \gamma$,

$$f^{(n-1)}(z) = (n-1)! \int_\gamma \frac{\phi(\zeta)}{(\zeta - z)^n}\, d\zeta \ .$$

Fix $z \in \mathbb{C} \setminus \gamma$, and fix $\delta > 0$ such that the closed disk of radius δ around z is contained in $\mathbb{C} \setminus \gamma$. If $|h| < \delta$, then

$$\frac{f^{(n-1)}(z+h) - f^{(n-1)}(z)}{h} = (n-1)! \int_\gamma \frac{\phi(\zeta)}{h} \left[\frac{1}{(\zeta - z - h)^n} - \frac{1}{(\zeta - z)^n} \right] d\zeta \ .$$

Set

$$a = \frac{1}{\zeta - z - h} \ , \quad b = \frac{1}{\zeta - z}$$

and recall the formula

$$a^n - b^n = (a-b)(a^{n-1} + a^{n-2}b + \cdots + ab^{n-2} + b^{n-1})$$

(the second factor is 1 if $n = 1$). We have

$$a - b = \frac{1}{\zeta - z - h} - \frac{1}{\zeta - z} = \frac{h}{(\zeta - z - h)(\zeta - z)}$$

so we have

$$\frac{f^{(n-1)}(z+h) - f^{(n-1)}(z)}{h} = (n-1)! \int_\gamma \frac{\phi(\zeta)}{(\zeta - z - h)(\zeta - z)} \left[a^{n-1} + a^{n-2}b + \cdots + ab^{n-2} + b^{n-1} \right] d\zeta \ .$$

Since the disk of radius δ around z is bounded away from γ, as $h \to 0$ we have that $\frac{1}{\zeta - z - h}$ converges uniformly in ζ to $\frac{1}{\zeta - z}$ on γ (i.e. $a \to b$ uniformly on γ). Since the other factors $\phi(\zeta)$ and $\frac{1}{\zeta - z}$ are uniformly bounded on γ and do not depend on h, as $h \to 0$ we have

$$\frac{\phi(\zeta)}{(\zeta - z - h)(\zeta - z)} \left[a^{n-1} + a^{n-2}b + \cdots + ab^{n-2} + b^{n-1} \right] \to \frac{\phi(\zeta)}{(\zeta - z)^2} \cdot nb^{n-1} = n \frac{f(\zeta)}{(\zeta - z)^{n+1}}$$

uniformly in ζ on γ. Thus the integrals around γ also converge. So

$$f^{(n)}(z) = \lim_{h \to 0} \frac{f^{(n-1)}(z+h) - f^{(n-1)}(z)}{h}$$

exists and equals

$$\lim_{h\to 0}(n-1)!\int_\gamma \frac{\phi(\zeta)}{(\zeta-z-h)(\zeta-z)}\left[a^{n-1}+a^{n-2}b+\cdots+ab^{n-2}+b^{n-1}\right]\,d\zeta = n!\int_\gamma \frac{\phi(\zeta)}{(\zeta-z)^{n+1}}\,d\zeta\ .$$

XII.3.3.6. Corollary. [Cauchy Integral Formula for Derivatives] Let f be holomorphic on an open set Ω in $\mathbb{C}$. Then f is infinitely differentiable on Ω, and for each $z\in\Omega$ and each n we have

$$f^{(n)}(z) = \frac{n!}{2\pi i}\int_\gamma \frac{f(\zeta)}{(\zeta-z)^{n+1}}\,d\zeta$$

where γ is any circle in Ω bounding an open disk D contained in Ω and containing z, parametrized once around counterclockwise.

Proof: For $\zeta\in\gamma$, set $\phi(\zeta)=\frac{f(\zeta)}{2\pi i}$. Then, for z inside γ, by XII.3.3.2.

$$f(z) = \int_\gamma \frac{\phi(\zeta)}{\zeta-z}\,d\zeta\ .$$

XII.3.3.7. Note that in the special case of XII.3.3.6., for $\zeta\in\gamma$ we have that $\phi(\zeta)$ is, up to a factor of $2\pi i$, the limit of $f(z)$ as $z\to\zeta$ from inside the circle. But in the general situation of XII.3.3.5., there is no such simple relationship (for example, in the situation of XII.3.3.6., the function defined by the integral is identically 0 outside γ by ()). In fact, there is no way to recover ϕ from f in general, although there is in many cases ().

Morera's Theorem

Morera's Theorem is a converse to Cauchy's Theorem:

XII.3.3.8. Theorem. [Morera's Theorem] Let Ω be an open set in $\mathbb{C}$, and f a complex-valued continuous function on Ω. If the contour integral of f around the boundary of every solid triangle contained in Ω is zero, then f is holomorphic on Ω.

Proof: It suffices to show that f is holomorphic in every open disk contained in Ω, i.e. we may assume Ω is a disk. Then f has an antiderivative F on Ω by XII.3.2.1.. But F is infinitely differentiable on Ω, hence so is $F'=f$. 

Cauchy's Inequalities

Cauchy's Inequalities are an immediate consequence of the Cauchy Integral Formula and the usual estimate for the size of a contour integral. They say that the higher derivatives of a holomorphic function do not grow too rapidly at any point.

XII.3.3.9. THEOREM. [CAUCHY'S INEQUALITIES] Let f be holomorphic on an open set Ω in $\mathbb{C}$, and $z_0 \in \Omega$. If the closed disk of radius R centered at z_0 is contained in Ω, then for all n

$$\left|f^{(n)}(z_0)\right| \leq \frac{n!}{R^n} \max_{|\zeta - z_0| = R} |f(\zeta)| \ .$$

Note that the quantity $\max_{|\zeta - z_0| = R} |f(\zeta)|$, the maximum of $|f|$ on the boundary circle, depends on R but not on n.

Liouville's Theorem

An immediate consequence of Cauchy's Inequality for $n = 1$ is the following remarkable result:

XII.3.3.10. THEOREM. [LIOUVILLE'S THEOREM] A bounded entire function is constant.

PROOF: Let f be a bounded entire function, and fix M with $|f(z)| \leq M$ for all $z \in \mathbb{C}$. Fix $z_0 \in \mathbb{C}$. Then for any $R > 0$ we have

$$|f'(z_0)| \leq \frac{M}{R}$$

and thus $f'(z_0) = 0$. Since $z_0 \in \mathbb{C}$ is arbitrary, f' is identically 0. 👍

This can be used, among many other things, to give a proof of the Fundamental Theorem of Algebra (Exercise XII.9.9.3.).

The result can be sharpened:

XII.3.3.11. COROLLARY. Let f be a nonconstant entire function. Then the range of f is dense in $\mathbb{C}$.

PROOF: Suppose the range is not dense. Then there is a $w \in \mathbb{C}$ and an $\epsilon > 0$ such that $|f(z) - w| \geq \epsilon$ for all $z \in \mathbb{C}$. Set

$$g(z) = \frac{1}{f(z) - w} \ .$$

Then g is an entire function, and $|g(z)| \leq \frac{1}{\epsilon}$ for all z. Thus g, and hence f, is constant, a contradiction. 👍

In fact, the following stronger result holds. See e.g. [] for a proof.

XII.3.3.12. THEOREM. [LITTLE PICARD THEOREM] Let f be a nonconstant entire function. Then the range of f is all of $\mathbb{C}$ except possibly one point.

This theorem is the best possible: $f(z) = e^z$ is never 0. See XII.5.2.19. for the "Big Picard Theorem" which is an even stronger statement.

XII.3.4. The Maximum Modulus Theorem

One of the important applications of ordinary calculus is finding maxima and minima of differentiable functions. But a striking difference between the real and complex cases is that if f is a nonconstant holomorphic function, then $|f|$ cannot have any local maxima:

XII.3.4.1. THEOREM. Let f be a holomorphic function on Ω, and let $\mathbb{D}$ be an open disk centered at z_0 with $\bar{\mathbb{D}} \subseteq \Omega$. Then

$$|f(z_0)| \leq \max\{|f(z)| : z \in \partial\mathbb{D}\}$$

with equality if and only if f is constant on $\mathbb{D}$.

PROOF: Multiplying f by a constant of absolute value 1, we may assume $f(z_0) \geq 0$. Let r be the radius of $\mathbb{D}$ and set $M = \max\{|f(z)| : z \in \partial\mathbb{D}\}$. By () we have

$$f(z_0) = |f(z_0)| = \left|\frac{1}{2\pi}\int_0^{2\pi} f(z_0 + re^{it})\,dt\right| \leq \frac{1}{2\pi}\int_0^{2\pi} |f(z_0 + re^{it})|\,dt \leq \frac{1}{2\pi}\int_0^{2\pi} M\,dt = M\ .$$

Suppose $f(z_0) = M$. Since

$$f(z_0) = Re(f(z_0)) = \int_0^{2\pi} Re(f(z_0 + re^{it}))\,dt$$

we have

$$0 = \int_0^{2\pi} [f(z_0) - Re(f(z_0 + re^{it}))]\,dt \geq \int_0^{2\pi} [f(z_0) - |f(z_0 + re^{it})|]\,dt \geq 0$$

because $f(z_0) - Re(f(z_0 + re^{it})) \geq f(z_0) - |f(z_0 + re^{it})| \geq 0$ for all t. Since the integrands are continuous and nonnegative, and the integrals are 0, the integrands are identically zero, i.e. we have $|f(z)| = Re(f(z)) = f(z_0)$ for all $z \in \partial\mathbb{D}$, which implies that $f(z) = f(z_0)$ for all $z \in \partial\mathbb{D}$. 👍

XII.3.4.2. COROLLARY. Let f be a holomorphic function on Ω, and let $z_0 \in \Omega$. If $|f|$ has a local maximum at z_0, then f is constant on a neighborhood of z_0.

PROOF: Let $\mathbb{D}$ be a disk centered at z_0 contained in Ω, such that $|f(z)| \leq |f(z_0)|$ for all $z \in \mathbb{D}$. Let r be less than the radius of $\mathbb{D}$. By the theorem, f is constant and equal to $f(z_0)$ on the circle of radius r centered at z_0. Since this is true for every such r, f is constant on $\mathbb{D}$. 👍

XII.3.4.3. THEOREM. [MAXIMUM MODULUS THEOREM] Let Ω be a connected open set in $\mathbb{C}$, and f a nonconstant holomorphic function on Ω. Then $|f|$ does not attain a maximum at any point of Ω.

PROOF: Suppose $|f|$ attains a maximum at $z_0 \in \Omega$. Then f is constant in a neighborhood of z_0. Let $U = \{z \in \Omega : f(z) = f(z_0)\}$. Then by the same argument f is constant in a neighborhood of any $z \in U$, i.e. U is an open set. But U is relatively closed in Ω since f is continuous. Since Ω is connected, $U = \Omega$. 👍

XII.3.4.4. Actually, under the hypotheses a stronger conclusion holds: $f(\Omega)$ is an open set ().

The Minimum Modulus Theorem

XII.3.4.5. If f is holomorphic, $|f|$ can have a local (even global) minimum even if it is not constant, since $f(z_0)$ can be 0 for some z_0. But this is the only possibility:

XII.3.4.6. Corollary. [Minimum Modulus Theorem] Let Ω be a connected open set in $\mathbb{C}$, and f a nonconstant holomorphic function on Ω which is never zero on Ω. Then $|f|$ does not attain a minimum at any point of Ω.

Proof: Apply the Maximum Modulus Theorem to $g = \frac{1}{f}$. 👍

XII.3.5. The Homotopy Theorem for Contour Integrals

Cauchy's Theorem roughly states that the contour integral of a holomorphic function along a path γ depends only on the endpoints of γ and not on which path is chosen, or alternatively that the contour integral around a closed contour is 0. But this is not literally true in general (XII.2.1.7.).

To prove, or even state, the general version of Cauchy's Theorem, we will show that if f is a holomorphic function on a region Ω and the path γ is "continuously deformed" within Ω leaving the endpoints fixed, the contour integral along γ does not change. This will imply that the integral around any closed curve in Ω which can be "continuously shrunk" to the initial point within Ω is zero.

The careful formulation of a "continuous deformation" is a homotopy:

XII.3.5.1. Definition. Let Ω be an open set in $\mathbb{C}$, $p, q \in \Omega$. Let γ_0 and γ_1 be contours from p to q in Ω with parametrizations $\zeta_0(t)$, $\zeta_1(t)$ defined on the same interval $[a, b]$. A *homotopy* from γ_0 to γ_1 in Ω is a continuous function $h : [0, 1] \times [a, b]$ to Ω such that $h(0, t) = \zeta_0(t)$ and $h(1, t) = \zeta_1(t)$ for all $t \in [a, b]$, and $h(s, 0) = p$ and $h(s, 1) = q$ for all $s \in [0, 1]$. We say γ_0 and γ_1 are *homotopic* (relative to p and q) if there is a homotopy from γ_0 to γ_1.

Technically, what we have defined is a homotopy between the parametrizations ζ_0 and ζ_1 relative to p and q (), but by slight abuse of terminology we will call it a homotopy from γ_0 to γ_1.

XII.3.5.2. If s is fixed, then $\zeta_s(t) = h(s, t)$ defines a parametrized curve γ_s in Ω from p to q, and as s varies these curves "move continuously" from γ_0 to γ_1, and conversely if "continuous deformation" is defined reasonably, the function $h(s, t) = \zeta_s(t)$ is a homotopy from γ_0 to γ_1. Thus γ_0 and γ_1 are homotopic in Ω if and only if γ_0 can be "continuously deformed" to γ_1 within Ω.

XII.3.5.3. A closed contour γ in an open set $\Omega \subseteq \mathbb{C}$ is *contractible* in Ω if it is homotopic in Ω to a constant contour, i.e. if γ is parametrized by $\zeta : [a, b] \to \mathbb{C}$ with $\zeta(a) = \zeta(b) = p$, there is a continuous $h : [0, 1] \times [a, b] \to \Omega$ with $h(0, t) = \zeta(t)$ and $h(1, t) = h(1, 0)$ for all t and $h(s, 0) = h(s, 1)$ for all s. If γ is contractible, there is such a homotopy with $h(s, 0) = h(s, 1) = h(1, t)$ for all t, i.e. the point p is fixed as the base point of each contour γ_s.

XII.3.5.4. THEOREM. [HOMOTOPY THEOREM FOR CONTOUR INTEGRALS] Let f be holomorphic on an open set Ω, and $p, q \in \Omega$. If γ_0 and γ_1 are homotopic contours in Ω from p to q, then

$$\int_{\gamma_0} f = \int_{\gamma_1} f \ .$$

PROOF: We first give a simple argument which "almost" proves the theorem but which has a serious flaw. (This argument is represented as a proof of the theorem in some Complex Analysis texts.)

Suppose ζ_0 and ζ_1 are parametrizations of γ_0 and γ_1 on the same interval, which we may take to be $[0,1]$ to simplify notation, and $h : [0,1]^2 \to \Omega$ a homotopy from ζ_0 to ζ_1 relative to p, q. Fix partitions $\mathcal{P} = \{0 = s_0, s_1, \ldots, s_m = 1\}$ and $\mathcal{Q} = \{0 = t_0, t_1, \ldots, t_n = 1\}$ of $[0,1]$. For each j and k define the curvilinear "rectangle"

$$R_{jk} = \{h(s,t) : s_{j-1} \le s \le s_j, t_{k-1} \le t \le t_k\}$$

(this curvilinear "rectangle" is a curvilinear "triangle" if $k = 1$ or $k = n$). We have that the image of h is compact, so there is an $\epsilon > 0$ such that the ball of radius ϵ around any point of the image of h is contained in Ω (). Since h is uniformly continuous on $[0,1]^2$, there is a $\delta > 0$ such that $|h(s',t') - h(s,t)| < \epsilon$ whenever $s, s', t, t' \in [0,1]$, $|s - s'| < \delta$, and $|t - t'| < \delta$. Thus if $\mathcal{P}$ and $\mathcal{Q}$ are sufficiently fine, for each j and k the "rectangle" R_{jk} is contained within an open disk in Ω. So if we integrate f around the boundary curve γ_{jk} of R_{jk} obtained by setting $s = s_{j-1}$ and letting t vary from t_{k-1} to t_k, and similarly for the other edges, we have that

$$\int_{\gamma_{jk}} f = 0$$

by XII.3.2.4.. But

$$\sum_{j,k} \int_{\gamma_{jk}} f = \int_{\gamma_1} f - \int_{\gamma_0} f$$

since all the other edges are traversed once each direction, so those contour integrals cancel. ✋

The problem with this argument is that while the γ_{jk} are continuous curves, they are not piecewise-smooth or even rectifiable in general, so $\int_{\gamma_{jk}} f$ is not even defined in general. (In fact, this "curve" does not even have to look anything like an ordinary curve topologically; it is just a continuous image of $[0,1]$.) To make this proof work as written, the homotopy h must be "piecewise-smooth," and it must be shown that homotopic piecewise-smooth contours are actually homotopic by a piecewise-smooth homotopy. This can be shown to be true (the argument below can be developed into a proof).

We will proceed differently, avoiding the difficulty by a trick (see [**?**, p. 338] for a different way around the problem). Choose the partitions and define the R_{jk} as above. However, replace γ_{jk} by the curve $\tilde{\gamma}_{jk}$ consisting of the straight line segments from $h(s_{j-1}, t_{k-1})$ to $h(s_j, t_{k-1})$, then to $h(s_j, t_k)$, then to $h(s_{j-1}, t_k)$, then back to $h(s_{j-1}, t_{k-1})$ (some of these line segments may be degenerate). If $j = 1$ or $j = m$, one of the edge curves of R_{jk} is a piece of γ_0 or γ_1, and we use this piece in $\tilde{\gamma}_{jk}$ instead of the straight line segment. Note that since R_{jk} is contained in a disk in Ω, which is convex, these line segments are also contained in the same disk. Then for each j and k, $\tilde{\gamma}_{jk}$ is a piecewise-smooth closed contour contained in a disk inside Ω. We thus have

$$\int_{\tilde{\gamma}_{jk}} f = 0$$

by XII.3.2.4.. But

$$\sum_{j,k} \int_{\tilde{\gamma}_{jk}} f = \int_{\gamma_1} f - \int_{\gamma_0} f$$

since all the other edges are traversed once each direction, so those contour integrals cancel. 👍

The Winding Number of a Closed Curve

If γ is a closed contour and z is a point of $\mathbb{C}$ not on γ, then intuitively γ "winds around z" some net number of times in the counterclockwise sense (this number can be zero or negative as well as positive). If γ is a circle parametrized once around counterclockwise, this winding number should be 1 if z is inside γ and 0 if z is outside. We can make this notion precise:

XII.3.5.5. PROPOSITION. Let γ be a closed piecewise-smooth contour in $\mathbb{C}$, and z a point of $\mathbb{C}$ not on γ. Then

$$\int_\gamma \frac{1}{\zeta - z}\, d\zeta$$

is an integer multiple of $2\pi i$.

PROOF: [Ahl78] Let $\zeta : [a, b] \to \mathbb{C}$ be a piecewise-smooth parametrization of γ with $\zeta(a) = \zeta(b) = p$. Then

$$\int_\gamma \frac{1}{\zeta - z}\, d\zeta = \int_a^b \frac{\zeta'(t)}{\zeta(t) - z}\, dt\ .$$

For $a \le x \le b$, set

$$\phi(x) = \int_a^x \frac{\zeta'(t)}{\zeta(t) - z}\, dt\ .$$

Then ϕ is differentiable at t and

$$\phi'(t) = \frac{\zeta'(t)}{\zeta(t) - z}$$

whenever $a \le t \le b$ and ζ' is continuous at t, i.e. for all but possibly finitely many $t \in [a, b]$. The function

$$\psi(t) = e^{-\phi(t)}(\zeta(t) - z)$$

is continuous on $[a, b]$, and satisfies

$$\psi'(t) = -e^{-\phi(t)}\phi'(t)(\zeta(t) - z) + e^{-\phi(t)}\zeta'(t) = 0$$

wherever ζ' is continuous. Thus ψ is constant on $[a, b]$. We have $\psi(a) = p - z$, so

$$e^{\phi(t)} = \frac{\zeta(t) - z}{p - z}$$

for $a \le t \le b$. We have $e^{\phi(b)} = 1$, so $\phi(b) = 2\pi i n$ for some $n \in \mathbb{Z}$. 👍

XII.3.5.6. DEFINITION. Let γ be a closed piecewise-smooth contour in $\mathbb{C}$, and $z \in \mathbb{C} \setminus \gamma$. The *winding number* of γ around z is

$$w(\gamma, z) = \frac{1}{2\pi i} \int_\gamma \frac{1}{\zeta - z}\, d\zeta \ .$$

By XII.3.5.5., $w(\gamma, z)$ is an integer.

XII.3.5.7. PROPOSITION. Fix a closed piecewise-smooth contour γ. The function $\omega(z) = w(\gamma, z)$ is constant on connected components of $\mathbb{C} \setminus \gamma$ and is zero on the unbounded component.

PROOF: The function ω is clearly a continuous function of z, and

$$\lim_{z \to \infty} |\omega(z)| = 0 \ .$$

Since ω takes only integer values, the result follows. 👍

XII.3.5.8. There is another interpretation of $w(\gamma, z)$. Let $\mathbb{T}$ be the unit circle in $\mathbb{C}$. Given a parametrization ζ of γ, which we may assume is on $[0, 1]$, define

$$\tilde{\gamma}(t) = \frac{\zeta(t) - z}{|\zeta(t) - z|}$$

(this closed contour is essentially the radial projection of γ onto a circle centered at z, translated to 0). Then $\tilde{\gamma}$ is a loop in $\mathbb{T}$ as defined in (), and $w(\gamma, z)$ is precisely the index of this loop.

XII.3.5.9. If γ_0 and γ_1 are closed contours not passing through z, and γ_0 and γ_1 are homotopic in $\mathbb{C} \setminus \{z\}$ (not necessarily with endpoint fixed), then the corresponding loops $\tilde{\gamma}_0$ and $\tilde{\gamma}_1$ ar homotopic as loops in $\mathbb{T}$. Thus their indices are the same (). So we obtain:

XII.3.5.10. PROPOSITION. If γ_0 and γ_1 are closed contours not passing through z, and γ_0 and γ_1 are homotopic in $\mathbb{C} \setminus \{z\}$ (not necessarily with endpoint fixed), then

$$w(\gamma_0, z) = w(\gamma_1, z) \ .$$

We may restate the Cauchy Integral Formula:

XII.3.5.11. THEOREM. Let f be holomorphic on a convex open set Ω, γ a closed piecewise-smooth contour in Ω, and $z \in \Omega$ not on γ. Then

$$f(z) w(\gamma, z) = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{\zeta - z}\, d\zeta \ .$$

XII.3.6. Homology of Contours

There is another useful relation on closed contours called *homology*, which is closely related to homotopy (and in fact slightly more general). Although we will primarily use this notion for closed contours, it is convenient to define it more generally for cycles:

XII.3.6.1. Definition. Let Ω be an open set in $\mathbb{C}$. Two cycles γ_0 and γ_1 in Ω are *homologous in* Ω if $w(\gamma_0, z) = w(\gamma_1, z)$ for all $z \in \mathbb{C} \setminus \Omega$. A cycle γ is *homologous to zero in* Ω if $w(\gamma, z) = 0$ for all $z \in \mathbb{C} \setminus \Omega$.

XII.3.6.2. The notion of homology of cycles depends on Ω. Indeed, every cycle is homologous to zero in $\mathbb{C}$. Cycles γ_0 and γ_1 in Ω are homologous in Ω if and only if $\gamma_1 - \gamma_0$ is homologous to zero in Ω. If γ_0 is homologous to zero in Ω, so is $-\gamma_0$; and $\gamma_0 + \gamma_1$ is homologous to γ_1 in Ω for any cycle γ_1 in Ω. If γ_1, $\tilde{\gamma}_1$, γ_2, and $\tilde{\gamma}_2$ are cycles in Ω, and γ_j and $\tilde{\gamma}_j$ are homologous in Ω for $j = 1, 2$, then $\gamma_1 + \gamma_2$ and $\tilde{\gamma}_1 + \tilde{\gamma}_2$ are homologous in Ω.

XII.3.6.3. If two closed contours γ_0 and γ_1 in Ω are homotopic in Ω, then it follows immediately from XII.3.5.10. that γ_0 and γ_1 are homologous in Ω. In particular, if γ is contractible in Ω, then γ is homologous to zero in Ω. The following example shows that the converse is false in general:

XII.3.6.4. Example. Let $\Omega = \mathbb{C} \setminus \{1, -1\}$. Let C_1 be the circle of radius 1 centered at 1, and C_{-1} the circle of radius 1 centered at -1. Let γ_1 be the circle C_1 parametrized once around counterclockwise starting at 0, and γ_2 the circle C_{-1} parametrized once around counterclockwise starting at 0. Set

$$\gamma = \gamma_1 + \gamma_2 - \gamma_1 - \gamma_2 \ .$$

Then γ is a piecewise-smooth closed contour in Ω, and it is easily checked that γ is homologous to zero in Ω. However, γ is not contractible in Ω; this fact, while fairly evident intuitively, is not so easy to prove rigorously (see [GK06, p. 356-358] for a nice proof).

This example shows that addition of closed contours is not commutative up to homotopy. In fact, the closed contours $\gamma_1 + \gamma_2$ and $\gamma_2 + \gamma_1$ are not homotopic in Ω.

The underlying reason for this example is that the fundamental group $\pi_1(\Omega)$ () is not abelian. In fact, it is a free group generated by the classes $[\gamma_1]$ and $[\gamma_2]$.

XII.3.7. Cauchy's Theorem, General Versions

The first general version of Cauchy's Theorem is an immediate corollary of XII.3.5.4.:

XII.3.7.1. Corollary. [Cauchy's Theorem, Version 1] Let f be holomorphic on an open set Ω, and γ a closed contour in Ω which is contractible in Ω. Then

$$\int_\gamma f = 0 \ .$$

Using the Jordan-Schönflies Theorem (), it can be shown that if γ is a simple closed contour in Ω whose interior is also in Ω, then γ is contractible in Ω. Thus we obtain another standard version of Cauchy's Theorem:

XII.3.7.2. Corollary. [Cauchy's Theorem, Version 2] Let f be holomorphic on an open set Ω, and γ a simple closed contour in Ω whose interior is also in Ω. Then

$$\int_\gamma f = 0 \ .$$

XII.3.7.3. Definition. An open set Ω in $\mathbb{C}$ is *simply connected* if it is connected and every closed contour in Ω is contractible in Ω.

The same definition works (path-connectedness is required in general, not just connectedness), and is important, in a general topological space ().

XII.3.7.4. Informally, a connected open set is simply connected if it has no "holes." In particular, any convex or star-shaped open set is simply connected, as is $\mathbb{C}$ with a branch cut removed (this set is actually star-shaped). But a plane or open disk with a point removed, or an annulus, is not simply connected. Any set homeomorphic to a simply connected open set is simply connected (and open).

For open sets in the plane, there are many equivalent characterizations of simple connectedness, such as the following (there are many more):

XII.3.7.5. Theorem. Let Ω be a connected open set in the plane. The following are equivalent:

(i) Ω is simply connected.

(ii) Whenever γ is a simple closed contour in Ω, the interior of γ is also contained in Ω.

(iii) Whenever γ is a closed contour in Ω, the winding number () of γ around any point of $\mathbb{C} \setminus \Omega$ is 0.

If Ω is bounded, these are also equivalent to

(iv) The boundary $\partial\Omega$ is connected.

(v) The complement $\mathbb{C} \setminus \Omega$ is connected.

Condition (iii) may be rephrased:

(iii′) Every cycle in Ω is homologous to zero in Ω.

XII.3.7.6. If Ω is unbounded, (iv) and (v) are still equivalent and imply (i)–(iii), but not conversely in general: consider a horizontal strip in $\mathbb{C}$. (If we work in the Riemann Sphere, the one-point compactification of $\mathbb{C}$, (i)–(v) are equivalent even if Ω is unbounded.) Also, (ii)–(v) can hold if Ω is not connected: consider a figure 8. It is not true that if Ω is simply connected, then the interior of the complement of Ω is necessarily connected, e.g. if Ω is one of the Lakes of Wada (). This example shows that simply connected open sets in $\mathbb{C}$ can be quite complicated. However, it is a (deep) theorem that every nonempty simply connected open set in $\mathbb{C}$ is homeomorphic to a disk (or, equivalently, to $\mathbb{C}$ itself). In fact, much more is true: every nonempty simply connected open proper subset of $\mathbb{C}$ is conformally equivalent to the open unit disk by the Riemann Mapping Theorem ().

We then get the most commonly stated version of Cauchy's Theorem:

XII.3.7.7. Corollary. [Cauchy's Theorem, Simply Connected Version] Let f be holomorphic on a simply connected open set Ω. Then f has an antiderivative on Ω, and if γ is any closed contour in Ω, then

$$\int_\gamma f = 0 \ .$$

The most general version of Cauchy's Theorem which can be reasonably stated is:

XII.3.7.8. Theorem. [Cauchy's Theorem, Homology Version] Let f be holomorphic on an open set Ω. Then

$$\int_\gamma f = 0$$

for every cycle γ in Ω homologous to zero in Ω.

This version is somewhat complicated to prove rigorously. See e.g. [Ahl78] or [**?**].

We get as a special case a general version of XII.3.2.7.:

XII.3.7.9. Corollary. Let f be holomorphic on an open set Ω, and γ_1 and γ_2 simple closed contours in Ω, parametrized once around counterclockwise, with γ_2 contained in the interior of γ_1. If the region between γ_1 and γ_2 is contained in Ω, then

$$\int_{\gamma_1} f = \int_{\gamma_2} f \ .$$

Proof: It is easily checked that $\gamma_1 - \gamma_2$ is homologous to zero in Ω. 👍

Note that the integrals around γ_1 and γ_2 are not necessarily 0!

XII.3.8. The Cauchy Integral Formula, General Versions

XII.3.9. Exercises

XII.3.9.1. Let Ω be an open set in $\mathbb{C}$, and $\mathbb{D}$ a disk with $\bar{\mathbb{D}} \subseteq \Omega$.

(a) Use the Cauchy Integral Formula to show that for every $z_0 \in \mathbb{D}$, there is a constant C (possibly depending on z_0) such that, whenever f is a holomorphic function on Ω,

$$|f(z_0)| \leq C \cdot \max\{|f(z)| : z \in \partial\mathbb{D}\} \ .$$

[Consider the reciprocal of the distance from z_0 to $\partial\mathbb{D}$.]

(b) Show that the inequality holds with $C = 1$ for every z_0. [If f is holomorphic on Ω, apply the inequality to f^n and take n'th roots, and let $n \to \infty$.]

This gives an alternate proof of the first part of XII.3.4.1..

XII.3.9.2. Let Ω be a convex (or, more generally, simply connected) region. Show that if f is a holomorphic function on Ω which is never zero on Ω, then there is a holomorphic function g on Ω with $f = e^g$. [The function $\frac{f'}{f}$ is holomorphic on Ω and has an antiderivative on Ω.] This is especially interesting if $\Omega = \mathbb{C}$, i.e. f is entire.

XII.4. Sequences and Series of Holomorphic Functions; Analytic Functions

In this section, we show the remarkable fact that holomorphic functions can be expanded in power series around any point in the domain.

XII.4.1. Sequences and Series of Holomorphic Functions

We begin by establishing some general results about sequences and series of holomorphic functions.

XII.4.1.1. In complex analysis, u.c. convergence (IV.3.2.1.) of sequences of holomorphic functions on an open set in $\mathbb{C}$ is sometimes called *normal convergence*. We will usually avoid this terminology since it is not universal, and is in fact ambiguous (V.15.1.4.).

The first result is an immediate corollary of Cauchy's Theorem and Morera's Theorem:

XII.4.1.2. PROPOSITION. Let Ω be an open set in $\mathbb{C}$, and (f_n) a sequence of functions from Ω to $\mathbb{C}$ converging u.c. on Ω to a function f. If each f_n is holomorphic on Ω, then f is also holomorphic on Ω.

PROOF: It suffices to show that f is holomorphic on each open disk contained in Ω; so we may assume Ω is a disk. If γ is any closed contour in Ω, then

$$\int_\gamma f_n \to \int_\gamma f$$

by (). But $\int_\gamma f_n = 0$ for all n by Cauchy's Theorem for Convex Sets (XII.3.2.4.), so $\int_\gamma f = 0$. This is true for every γ, so f is holomorphic by Morera's Theorem. 👍

XII.4.1.3. This is one more surprising property of holomorphic functions. The real analog of this statement fails spectacularly: any continuous function on a closed bounded interval, even one not differentiable anywhere (), is a uniform limit of polynomials.

Actually, the situation is even nicer for holomorphic functions, again in stark contrast to the real case ():

XII.4.1.4. THEOREM. Let Ω be an open set in $\mathbb{C}$, and (f_n) a sequence of functions from Ω to $\mathbb{C}$ converging u.c. on Ω to a function f. If each f_n is holomorphic on Ω, then f is also holomorphic on Ω, and $f_n' \to f'$ u.c. on Ω.

In this result, u.c. convergence cannot be replaced by uniform convergence in general: even if $f_n \to f$ uniformly on Ω, f_n' does not converge uniformly on Ω to f' in general, only u.c. (Exercise XII.9.9.2.).

PROOF: This is a fairly easy, although slightly delicate, consequence of the Cauchy Integral Formula for derivatives (XII.3.3.6.); the argument also gives another proof of XII.4.1.2.. By IV.3.2.5., it suffices to show that for any $z_0 \in \Omega$, there is an open disk D centered at z_0 and contained in Ω on which f is holomorphic and such that $f_n' \to f'$ uniformly on D. In fact, let D be any open disk centered at z_0 whose closure $\bar{D}$ is

contained in Ω (there is always such a disk for any $z_0 \in \Omega$). Let R be the radius of D. For sufficiently small $\delta > 0$, the closed disk of radius $R + \delta$ around z_0 is contained in Ω. Fix such a δ, and let γ be the circle centered at z_0 of radius $R + \delta$, parametrized once around counterclockwise. For $z \in \mathbb{C} \setminus \gamma$, set

$$g(z) = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{\zeta - z}\, d\zeta$$

and note that g is holomorphic on $C \setminus \gamma$ by XII.3.3.5.. By the Cauchy Integral Formula, if z is inside γ,

$$f_n(z) = \frac{1}{2\pi i} \int_\gamma \frac{f_n(\zeta)}{\zeta - z}\, d\zeta$$

for each n. We have that $f_n \to f$ uniformly on γ. As $n \to \infty$, the sequence

$$\frac{f_n(\zeta)}{\zeta - z}$$

converges uniformly on γ (for fixed z inside γ) to

$$\frac{f(\zeta)}{\zeta - z}$$

since the numerators converge uniformly and the absolute value of the denominator is always $\geq \delta$. Thus we have

$$f_n(z) = \frac{1}{2\pi i} \int_\gamma \frac{f_n(\zeta)}{\zeta - z}\, d\zeta \;\to\; \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{\zeta - z}\, d\zeta = g(z)$$

and since $f_n \to f$ pointwise on Ω, we conclude that $f(z) = g(z)$ for all z inside γ, and f is holomorphic on D. Since z_0 and D are arbitrary, f is holomorphic on Ω.

By a similar but slightly more delicate argument, if z_0, D, and γ are as above, we have that

$$\frac{f_n(\zeta)}{(\zeta - z)^2} \to \frac{f(\zeta)}{(\zeta - z)^2}$$

uniformly for $\zeta \in \gamma$ and $z \in \bar{D}$, since the numerators converge uniformly and the absolute value of the denominator is always $\geq \delta^2$, i.e. for any $\epsilon > 0$ there is an N such that

$$\left| \frac{f_n(\zeta)}{(\zeta - z)^2} - \frac{f(\zeta)}{(\zeta - z)^2} \right| < \epsilon$$

for all $n \geq N$ and all $\zeta \in \gamma$ and $z \in \bar{D}$. Thus, for $z \in \bar{D}$,

$$f_n'(z) = \frac{1}{2\pi i} \int_\gamma \frac{f_n(\zeta)}{(\zeta - z)^2}\, d\zeta \;\to\; \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{(\zeta - z)^2}\, d\zeta = f'(z)$$

uniformly on $\bar{D}$ by the Cauchy Integral Formula for derivatives. 👍

XII.4.1.5. The proof of this theorem is a bit delicate. However, the "converse," the complex analog of V.8.5.5., is simpler:

XII.4.1.6. THEOREM. Let Ω be a connected open set in $\mathbb{C}$, and (f_n) a sequence of functions from Ω to $\mathbb{C}$. If

(1) Each f_n is holomorphic on Ω.

(2) The sequence (f_n') converges u.c. on Ω to a function g.

(3) There is a $z_0 \in \Omega$ such that the sequence $(f_n(z_0))$ converges.

Then the sequence (f_n) converges u.c. on Ω to a function f; f is holomorphic on Ω, and $f' = g$ on Ω.

PROOF: The proof of V.8.5.5. uses the Mean Value Theorem, which is unavailable in $\mathbb{C}$. However, we may mimic the simpler proof of the special case (). We first show that (f_n) converges uniformly on a neighborhood of z_0 (in fact, on any closed disk centered at z_0 contained in Ω) to an antiderivative for g. Fix a closed disk D of radius r centered at z_0 and contained in Ω. Suppose $f_n(z_0) \to c$. If $z \in D$, let γ_z be the line segment from z_0 to z. Then

$$\int_{\gamma_z} f_n' = f_n(z) - f_n(z_0)$$

for any n by (); and if we define

$$f(z) = c + \int_{\gamma_z} g$$

then $f' = g$ on the interior of D. For any $\epsilon > 0$ there is an N such that, for all $n \geq N$, $|f_n'(z) - g(z)| < \frac{\epsilon}{2r}$ for all $z \in D$ and $|f_n(z_0) - c| < \frac{\epsilon}{2}$. Then, for $n \geq N$ and $z \in D$,

$$|f_n(z) - f(z)| = \left| f_n(z_0) + \int_{\gamma_z} f_n' - c - \int_{\gamma_z} g \right| \leq |f_n(z_0) - c| + \left| \int_{\gamma_z} (f_n' - g) \right| < \frac{\epsilon}{2} + \frac{\epsilon}{2r} r = \epsilon \ .$$

Thus $f_n \to f$ uniformly on D.

Now let U be the set of all $z \in \Omega$ such that (f_n) converges uniformly to an antiderivative for g on a neighborhood of z. Then U is obviously open, and $z_0 \in U$. If $w \in U$, then (f_n) converges uniformly on any closed disk centered at w contained in U to an antiderivative for g by the first part of the proof (with w in place of z_0). If $w \in \Omega$ is in the closure of U, there is a sequence (z_n) in U with $z_n \to z$. There is an $\epsilon > 0$ such that the disk of radius ϵ around w is contained in Ω. Fix n with $|z_n - w| < \frac{\epsilon}{3}$; then the closed disk around z_n of radius $\frac{\epsilon}{2}$ is contained in Ω, and is a neighborhood of w on which (f_n) converges uniformly to an antiderivative for g. Thus $w \in U$. So U is relatively closed in Ω, and since Ω is connected, $U = \Omega$. Thus (f_n) converges uniformly to an antiderivative for g on any closed disk contained in Ω; so (f_n) converges pointwise on Ω to a function f which is an antiderivative for g. Since any compact subset of Ω is contained in a finite union of closed disks in Ω, $f_n \to f$ u.c. on Ω. 👍

As usual, the sequence results have series versions, proved by applying the sequence results to the partial sums:

XII.4.1.7. PROPOSITION. Let Ω be an open set in $\mathbb{C}$, and

$$\sum_{k=1}^{\infty} f_k$$

an infinite series of functions from Ω to $\mathbb{C}$ converging u.c. on Ω to a function f. If each f_n is holomorphic on Ω, then f is also holomorphic on Ω.

XII.4.1.8. THEOREM. Let Ω be an open set in $\mathbb{C}$, and

$$\sum_{k=1}^{\infty} f_k$$

an infinite series of functions from Ω to $\mathbb{C}$ converging u.c. on Ω to a function f. If each f_n is holomorphic on Ω, then f is also holomorphic on Ω, and

$$\sum_{k=1}^{\infty} f_k'$$

converges u.c. to f' on Ω.

XII.4.1.9. THEOREM. Let Ω be a connected open set in $\mathbb{C}$, and

$$\sum_{k=1}^{\infty} f_k$$

an infinite series of functions from Ω to $\mathbb{C}$. If

(1) Each f_k is holomorphic on Ω.

(2) The infinite series

$$\sum_{k=1}^{\infty} f_k'$$

converges u.c. on Ω to a function g.

(3) There is a $z_0 \in \Omega$ such that the series

$$\sum_{k=1}^{\infty} f_k(z_0)$$

converges.

Then the infinite series

$$\sum_{k=1}^{\infty} f_k$$

converges u.c. on Ω to a function f; f is holomorphic on Ω, and $f' = g$ on Ω.

XII.4.2. Power Series

We recall some of the important general facts about power series from V.15.3. in the complex case.

XII.4.2.1. DEFINITION. If z_0 is a complex number, a *(complex) power series centered at* z_0 is an expression of the form

$$\sum_{k=0}^{\infty} a_k (z - z_0)^k$$

where the a_k are complex numbers.

XII.4.2.2. A power series is regarded as an infinite series of functions. It is conventional when working with power series to regard $(z - z_0)^0 = 1$ no matter how $z - z_0$ is interpreted; thus the $k = 0$ term of the power series is just the constant function a_0.

XII.4.2.3. A power series is, at first, only a formal expression, but it can be regarded as defining a function f of z, whose domain is the set of all z for which the series converges. Because of our convention, z_0 is always in the domain of the defined function f, with $f(z_0) = a_0$. It can happen that the domain of f consists only of $\{z_0\}$ (such power series are not very interesting as functions).

The most important basic property of power series is XII.4.2.5., which says that the domain of the defined function is a disk, or degenerate disk, centered at z_0.

XII.4.2.4. DEFINITION. Let $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ be a power series, and define

$$L = \limsup_{k \to \infty} |a_k|^{1/k} = \limsup_{k \to \infty} \sqrt[k]{|a_k|}$$

and let $R = \frac{1}{L}$ if $0 < L < +\infty$, $R = 0$ if $L = +\infty$, and $R = +\infty$ if $L = 0$. R is called the *radius of convergence* of the power series.

Note that the radius of convergence of a power series depends only on the coefficients a_k, not on the center z_0, of the power series. The slower the coefficients grow in size, or the faster they approach zero, the larger the radius of convergence.

The term "radius of convergence" is justified by the next result:

XII.4.2.5. THEOREM. Let $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ be a power series, with radius of convergence R. Then

(i) If $z \in \mathbb{C}$ and $|z - z_0| < R$, then the series $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ converges absolutely.

(ii) If $z \in \mathbb{C}$ and $|z - z_0| > R$, then the series $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ diverges.

(iii) If $r \in \mathbb{R}$ and $0 < r < R$, then the series $\sum_{k=0}^{\infty} a_k(z-z_0)^k$ converges uniformly on the closed disk $\{z : |z-z_0| \le r\}$.
(Of course, (i) and (iii) are vacuous if $R = 0$ and (ii) is vacuous if $R = +\infty$.)

PROOF: In cases (i) and (ii), apply the Root Test () to the series $\sum_{k=0}^{\infty} |a_k(z-z_0)^k|$. We have

$$\limsup |a_k(z-z_0)^k|^{1/k} = |z-z_0| \limsup |a_k|^{1/k} = \frac{|z-z_0|}{R}$$

(it is $+\infty$ if $z \neq z_0$ and $R = 0$, and 0 if $R = +\infty$ or $z = z_0$). Thus the series converges absolutely if $|z-z_0| < R$ or $z = z_0$ and diverges since the terms do not go to zero if $|z-z_0| > R$.
For (iii), use the Weierstrass M-test (). Set $M_k = |a_k| r^k$. Then $|a_k(z-z_0)^k| \le M_k$ for all k and for all x, $|z-z_0| \le r$. We have

$$\limsup M_k^{1/k} = r \limsup |a_k|^{1/k} = \frac{r}{R} < 1$$

if $0 < R < \infty$, and $\limsup M_k^{1/k} = 0$ if $R = +\infty$. Thus $\sum_{k=0}^{\infty} M_k$ converges by the Root Test. 👍

XII.4.2.6. Thus the set on which a power series centered at z_0 converges is a disk centered at z_0, possibly of radius zero, i.e. the degenerate disk $\{z_0\}$, or of infinite radius, i.e. all of $\mathbb{C}$, possibly including some or all of the points on the boundary, called the *disk of convergence* of the power series.

XII.4.2.7. Convergence behavior of a complex power series on the boundary circle of the disk of convergence is quite subtle. The series can diverge everywhere on this circle (e.g. $\sum_{k=0}^{\infty}(z-z_0)^k$) or it can converge absolutely at all points of the circle (e.g. $\sum_{k=1}^{\infty} \frac{1}{k^2}(z-z_0)^k$), or it can converge conditionally on some subset S of the boundary circle. But S cannot be an arbitrary subset of the circle (it must be an $F_{\sigma\delta}$ (), and not even all of these occur; see [Kör83]). The study of boundary behavior of analytic functions is a big topic in complex analysis, with important applications.

For the purposes of basic complex analysis, however, we want to restrict attention to open sets, so we generally consider only the *open disk of convergence* $\{z : |z-z_0| < R\}$ (provided $R > 0$).

Combining XII.4.2.5. with XII.4.1.7., we obtain:

XII.4.2.8. COROLLARY. Let $\sum_{k=0}^{\infty} a_k(z-z_0)^k$ be a power series, with radius of convergence $R > 0$. Then the series converges u.c. on the open disk of convergence, and the sum is holomorphic on this disk.

Using XII.4.1.8., we can extend this:

XII.4.2.9. COROLLARY. Let $\sum_{k=0}^{\infty} a_k(z-z_0)^k$ be a power series, with radius of convergence $R>0$. Then the series converges u.c. on the open disk of convergence $\{z : |z-z_0|<R\}$, and the sum f is holomorphic on this disk. The power series

$$\sum_{k=1}^{\infty} k a_k (z-z_0)^{k-1}$$

of term-by-term derivatives converges u.c. on $\{z : |z-z_0|<R\}$ to f'.

This can be also be proved by noting that the derived series has the same radius of convergence as the original series (V.15.3.21.) and applying XII.4.1.9..

By iterating, we obtain, for each n, that the n'th derived power series

$$\sum_{k=n}^{\infty} k(k-1)\cdots(k-n+1)a_k(z-z_0)^{k-n} = \sum_{k=n}^{\infty} \frac{k!}{(k-n)!} a_k (z-z_0)^{k-n}$$

converges u.c. to $f^{(n)}$ on $\{z : |z-z_0|<R\}$.

The coefficients a_k are thus uniquely determined by the function f defined by the power series:

XII.4.2.10. COROLLARY. Let $\sum_{k=0}^{\infty} a_k(z-z_0)^k$ be a power series, with radius of convergence $R>0$, and let f be the holomorphic function defined by the series on the open disk of convergence. Then, for any $n \geq 0$,

$$a_n = \frac{f^{(n)}(z_0)}{n!} \ .$$

The coefficients a_k can also be computed by contour integration:

XII.4.2.11. PROPOSITION. Let

$$\sum_{k=0}^{\infty} a_k (z-z_0)^k$$

be a power series with radius of convergence $R>0$, and f the function defined by the series on $\{z : |z-z_0|<R\}$. Then, for any $k \geq 0$,

$$a_k = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{(\zeta-z_0)^{k+1}}\, d\zeta$$

where γ is any circle centered at z_0 of radius less than R.

PROOF: By (), we have

$$\int_\gamma \frac{f(\zeta)}{(\zeta-z_0)^{k+1}}\, d\zeta = \int_\gamma (\zeta-z_0)^{-k-1} \left[\sum_{j=0}^{\infty} a_j (\zeta-z_0)^j \right] d\zeta$$

$$= \sum_{j=0}^{\infty} \left[\int_\gamma a_j (\zeta - z_0)^{j-k-1} \, d\zeta \right] .$$

All the terms in this sum are 0 except the term with $j = k$, which is $2\pi i a_k$ (). 👍

This result can also be concluded from XII.4.2.10. and the Cauchy Integral Formula for Derivatives (XII.3.3.6.).

XII.4.2.12. The radius of convergence of a power series $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ can always be computed as

$$R = \frac{1}{\limsup |a_k|^{1/k}}$$

(with the usual conventions if the lim sup is 0 or $+\infty$), but it is not always easy to evaluate this expression. Sometimes the radius of convergence can be computed more simply by the following:

XII.4.2.13. PROPOSITION. Let $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ be a power series, with all a_k nonzero. If

$$\lim_{k \to \infty} \left| \frac{a_k}{a_{k+1}} \right|$$

exists (in the usual or extended sense), it equals the radius of convergence of the power series.

PROOF: Let S be this limit. Apply the Ratio Test () to show that $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ converges absolutely if $|z - z_0| < S$ and diverges if $|z - z_0| > S$. Thus S must be exactly the radius of convergence. 👍

Note that in the limit of XII.4.2.13., the a_k and a_{k+1} are reversed from the way they appear in the Ratio Test ().

Another convenient characterization of the radius of convergence is the following:

XII.4.2.14. PROPOSITION. Let $\sum_{k=0}^{\infty} a_k (z - z_0)^k$ be a power series. The power series has radius of convergence $R > 0$ if and only if, for all r, $0 < r < R$, there is a constant M such that $|a_k| \leq \frac{M}{r^k}$ for all k, and there is no such M if $r > R$.

PROOF: Suppose the series has radius of convergence $R > 0$, and $0 < r < R$. Then

$$\limsup |a_k|^{1/k} < \frac{1}{r}$$

so there is a k_0 such that $|a_k| < \frac{1}{r^k}$ for all $k \geq k_0$. There is an $M \geq 1$ such that $|a_k| \leq \frac{M}{r^k}$ for $0 \leq k < k_0$. This M works for all k.

Conversely, if the condition holds for all r with $0 < r < R$ and no $r > R$, we have, for each such r with $0 < r < R$,

$$\limsup |a_k|^{1/k} \leq \limsup \frac{M^{1/k}}{r} = \frac{1}{r}$$

for some constant M, so the radius of convergence R' is $\geq R$. If $R' > R$, choose r so that $R < r < R'$; then the condition holds for r by the first half of the proof, a contradiction. 👍

XII.4.3. Inverse Power Series

It will be convenient to extend the results about power series to closely related series we call inverse power series:

XII.4.3.1. DEFINITION. An *inverse power series* centered at $z_0 \in \mathbb{C}$ is an infinite series of the form

$$\sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

where the $b_k \in \mathbb{C}$. (We could also allow a constant term b_0.)

XII.4.3.2. An inverse power series defines a complex-valued function whose domain is the set of z for which the series converges. This set is (almost) nicely describable, as in the case of power series:

XII.4.3.3. THEOREM. Let

$$\sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

be an inverse power series, and set

$$S = \limsup_{k \to \infty} |b_k|^{1/k} \ .$$

Then

(i) If $S < \infty$ and $|z - z_0| > S$, then the series converges absolutely.

(ii) If $S > 0$ and $|z - z_0| < S$, then the series diverges.

(iii) If $S < \infty$ and $s > S$, then the series converges uniformly on

$$\{z : |z - z_0| \geq s\}$$

and in particular the series converges u.c. on

$$\{z : |z - z_0| > S\} \ .$$

PROOF: This follows almost immediately from XII.4.2.5. by considering the power series

$$\sum_{k=1}^{\infty} b_k w^k$$

which has radius of convergence $R = \frac{1}{S}$. If $w = \frac{1}{z-z_0}$, then $|w| < R$ if and only if $|z - z_0| > S$, etc. 👍

XII.4.3.4. The number S is called the *inverse radius of convergence* and the set

$$\{z : |z - z_0| > S\}$$

is called the *open disk complement of convergence* of the inverse power series. If $S = 0$, this set is the entire complex plane with z_0 removed. (The series never converges for $z = z_0$. If $S = \infty$, the series does not converge for any $z \in \mathbb{C}$. If $0 < S < \infty$, the series may converge for some or all z with $|z - z_0| = S$, but not necessarily; cf. XII.4.2.7..)

XII.4.3.5. PROPOSITION. Let

$$\sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

be an inverse power series with finite inverse radius of convergence. Then the series defines a holomorphic function f on its open disk complement of convergence Ω, and the series

$$\sum_{k=1}^{\infty} \frac{-kb_k}{(z - z_0)^{k+1}}$$

of term-by-term derivatives converges u.c. to f' on Ω.

The fact that f is holomorphic is immediate from XII.4.1.7., and that term-by-term differentiation is valid follows from XII.4.1.8.. Alternatively, both parts follow from XII.4.1.9. and the fact that the derived series has the same inverse radius of convergence (cf. V.15.3.21.) and thus converges u.c. on Ω.

The coefficients b_k can be computed by contour integration:

XII.4.3.6. PROPOSITION. Let

$$\sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

be an inverse power series with finite inverse radius of convergence S, and f the function defined by the series on $\Omega = \{z : |z - z_0| > S\}$. Then, for any $k \geq 1$,

$$b_k = \frac{1}{2\pi i} \int_{\gamma} f(\zeta)(\zeta - z_0)^{k-1}\, d\zeta$$

where γ is any circle centered at z_0 of radius greater than S.

PROOF: By (), we have

$$\int_\gamma f(\zeta)(\zeta - z_0)^{k-1}\,d\zeta = \int_\gamma (\zeta - z_0)^{k-1}\left[\sum_{j=1}^{\infty}\frac{b_j}{(\zeta - z_0)^j}\right]d\zeta$$

$$= \sum_{j=1}^{\infty}\left[\int_\gamma b_j(\zeta - z_0)^{k-1-j}\,d\zeta\right] .$$

All the terms in this sum are 0 except the term with $j = k$, which is $2\pi i b_k$ (). 

XII.4.4. Analytic Functions

XII.4.4.1. DEFINITION. Let Ω be an open set in $\mathbb{C}$, and f a complex-valued function on Ω. Then f is *analytic* on Ω if for every $z_0 \in \Omega$ there is a power series centered at z_0 which converges (pointwise, hence necessarily u.c.) to f on some open disk centered at z_0.

Note that the power series representation of f around z_0 need not converge to f on all of Ω, only on *some* open disk centered at z_0. Thus analyticity is a local property: if for each $z_0 \in \Omega$ there is some neighborhood of z_0 in Ω on which f is analytic, then f is analytic on Ω. 

The following facts are immediate from XII.4.2.9.:

XII.4.4.2. COROLLARY. Let Ω be an open set in $\mathbb{C}$, and f a complex-valued function on Ω. If f is analytic on Ω, then f is holomorphic on Ω and f' is also analytic on Ω.

XII.4.4.3. Conversely, it follows easily from XII.4.1.9. that if f is holomorphic on Ω and f' is analytic on Ω, then f is analytic on Ω. We omit details since we will presently prove a much stronger result (XII.4.4.7.).

We also obtain as a consequence of XII.4.2.10.:

XII.4.4.4. COROLLARY. Let Ω be an open set in $\mathbb{C}$, and f an analytic function on Ω. For any $z_0 \in \Omega$, the power series centered at z_0 representing f in an open disk around z_0 is unique, and is

$$\sum_{k=0}^{\infty}\frac{f^{(k)}(z_0)}{k!}(z - z_0)^k$$

which is called the *Taylor series for f around z_0*.

XII.4.4.5. For real functions on an interval I, the following classes of functions are successively considerably larger:

(i) The class of analytic functions on I ().

(ii) The class of $\mathcal{C}^\infty$ functions on I ().

(iii) The class of $\mathcal{C}^1$ functions on I ().

(iv) The class of differentiable functions on I ().

The following spectacular theorem, which is the main result of this section, implies that for complex functions on an open set Ω, the above four classes of functions coincide.

XII.4.4.6. THEOREM. Let Ω be an open set in $\mathbb{C}$ and f a holomorphic function on Ω. If $z_0 \in \Omega$ and D is an open disk centered at z_0 contained in Ω, then the Taylor series for f around z_0 converges to $f(z)$ for every $z \in D$; in fact, the Taylor series converges u.c. to f on D.

Combining this with XII.4.4.2., we obtain:

XII.4.4.7. COROLLARY. Let Ω be an open set in $\mathbb{C}$ and f a complex-valued function on Ω. Then f is analytic on Ω if and only if it is holomorphic on Ω.

PROOF: Suppose f is holomorphic on Ω. Fix $z_0 \in \Omega$ and an open disk D of radius R centered at z_0 contained in Ω. Fix $z \in D$, and let γ be a circle centered at z_0 with radius r for some r, $|z - z_0| < r < R$, parametrized once around counterclockwise. Thus

$$f(z) = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{\zeta - z}\, d\zeta$$

by the Cauchy Integral Formula ().

Since $\left|\dfrac{z - z_0}{\zeta - z_0}\right| = \dfrac{|z - z_0|}{r} < 1$ for all $\zeta \in \gamma$, the infinite series

$$\sum_{k=0}^{\infty} \left(\frac{z - z_0}{\zeta - z_0}\right)^k$$

converges uniformly on γ to

$$\frac{1}{1 - \frac{z - z_0}{\zeta - z_0}} = \frac{\zeta - z_0}{\zeta - z}$$

i.e. for $\zeta \in \gamma$ we have

$$\frac{1}{\zeta - z} = \frac{1}{\zeta - z_0} \sum_{k=0}^{\infty} \left(\frac{z - z_0}{\zeta - z_0}\right)^k = \sum_{k=0}^{\infty} \frac{(z - z_0)^k}{(\zeta - z_0)^{k+1}}$$

where the series converges uniformly on γ. Thus the series

$$\sum_{k=0}^{\infty} \left[(z - z_0)^k \int_\gamma \frac{f(\zeta)}{(\zeta - z_0)^{k+1}}\, d\zeta\right] = \int_\gamma f(\zeta) \left[\sum_{k=0}^{\infty} \frac{(z - z_0)^k}{(\zeta - z_0)^{k+1}}\right] d\zeta$$

converges to

$$\int_\gamma \frac{f(\zeta)}{\zeta - z}\, d\zeta = 2\pi i f(z) \ .$$

In other words, the power series

$$\sum_{k=0}^{\infty} a_k (z - z_0)^k$$

converges to $f(z)$, where

$$a_k = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{(\zeta - z_0)^{k+1}}\, d\zeta$$

for each k. So the open disk of convergence D' of the power series contains D; since the power series converges u.c. on D' and pointwise to f on D, it converges u.c. to f on D. 👍

XII.4.4.8. The proof of the theorem as stated is then completed by either identifying a_k with $\frac{f^{(k)}(z_0)}{k!}$ by the Cauchy Integral Formula for Derivatives (XII.3.3.6.) or by using XII.4.2.10.. In fact, by combining the above proof with XII.4.2.10., we can obtain an alternate proof of the Cauchy Integral Formula for Derivatives. Note that the proof of XII.4.4.6. makes crucial use of the ordinary Cauchy Integral Formula.

XII.4.4.9. Note that XII.4.4.6. says more than just that f is analytic on Ω: if $z_0 \in \Omega$, then the Taylor series for f around z_0 does not merely converge u.c. to f on *some* open disk centered at z_0, but actually converges u.c. to f on the *largest* open disk centered at z_0 contained in Ω (if $\Omega \neq \mathbb{C}$). If $\Omega = \mathbb{C}$, i.e. if f is an entire function, this Taylor series converges u.c. to f on all of $\mathbb{C}$.

This result is again in stark contrast to the real case (cf. ()).

XII.4.4.10. As a result, from now on we will consider *analytic* and *holomorphic* as synonyms for complex functions, and will use the terms interchangeably.

Holomorphic Functions on an Annulus

We can also obtain a similar series representation for a holomorphic function on an annulus, involving both a power series and an inverse power series in general.

XII.4.4.11. Definition. Let $z_0 \in \mathbb{C}$, and fix r and R with $0 \leq r < R \leq +\infty$. The *(open) annulus* centered at z_0 with inner radius r and outer radius R is the set

$$\{z \in \mathbb{C} : r < |z - z_0| < R\} \ .$$

If $0 < r < R < +\infty$, this annulus is the open region between the circles of radius r and R centered at z_0. If $r = 0$ and $R < +\infty$, the annulus is the punctured open disk of radius R centered at z_0 with z_0 removed. If $r = 0$ and $R = +\infty$, it is the punctured plane with z_0 removed; if $r > 0$ and $R = +\infty$, it is the plane with the closed disk of radius r centered at z_0 removed. (It is convenient to include these degenerate cases.)

XII.4.4.12. THEOREM. Let Ω be an open annulus centered at z_0 with inner radius r and outer radius R, and f a holomorphic function on Ω. Then there are a unique power series

$$\sum_{k=0}^{\infty} a_k (z - z_0)^k$$

and a unique inverse power series

$$\sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

which both converge u.c. on Ω, and for which

$$f(z) = \sum_{k=0}^{\infty} a_k (z - z_0)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

for all $z \in \Omega$. For each $k \geq 0$ we have

$$a_k = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{(\zeta - z_0)^{k+1}} \, d\zeta$$

and for each $k \geq 1$ we have

$$b_k = \frac{1}{2\pi i} \int_\gamma f(\zeta)(\zeta - z_0)^{k-1} \, d\zeta$$

where γ is any circle centered at z_0 whose radius ρ satisfies $r < \rho < R$.

PROOF: The argument is similar to the previous ones. Fix $z \in \Omega$, and let γ_1 and γ_0 be circles centered at z_0 of radius S and s respectively, where $0 < s < |z - z_0| < S < R$, parametrized once around counterclockwise. Then

$$f(z) = \frac{1}{2\pi i} \int_{\gamma_1 - \gamma_0} \frac{f(\zeta)}{\zeta - z} \, d\zeta = \frac{1}{2\pi i} \int_{\gamma_1} \frac{f(\zeta)}{\zeta - z} \, d\zeta - \frac{1}{2\pi i} \int_{\gamma_0} \frac{f(\zeta)}{\zeta - z} \, d\zeta$$

by (). We analyze the two integrals on the right separately.

Since $\left| \dfrac{z - z_0}{\zeta - z_0} \right| = \dfrac{|z - z_0|}{S} < 1$ for all $\zeta \in \gamma_1$, the infinite series

$$\sum_{k=0}^{\infty} \left(\frac{z - z_0}{\zeta - z_0} \right)^k$$

converges uniformly on γ_1 to

$$\frac{1}{1 - \frac{z - z_0}{\zeta - z_0}} = \frac{\zeta - z_0}{\zeta - z}$$

i.e. for $\zeta \in \gamma_1$ we have

$$\frac{1}{\zeta - z} = \frac{1}{\zeta - z_0} \sum_{k=0}^{\infty} \left(\frac{z - z_0}{\zeta - z_0} \right)^k = \sum_{k=0}^{\infty} \frac{(z - z_0)^k}{(\zeta - z_0)^{k+1}}$$

where the series converges uniformly on γ_1. Thus the series

$$\sum_{k=0}^{\infty}\left[(z-z_0)^k\int_{\gamma_1}\frac{f(\zeta)}{(\zeta-z_0)^{k+1}}\,d\zeta\right]=\int_{\gamma_1}f(\zeta)\left[\sum_{k=0}^{\infty}\frac{(z-z_0)^k}{(\zeta-z_0)^{k+1}}\right]d\zeta$$

converges to

$$\int_{\gamma_1}\frac{f(\zeta)}{\zeta-z}\,d\zeta\ .$$

Similarly, since $\left|\dfrac{\zeta-z_0}{z-z_0}\right|=\dfrac{s}{|z-z_0|}<1$ for all $\zeta\in\gamma_0$, the infinite series

$$\sum_{j=0}^{\infty}\left(\frac{\zeta-z_0}{z-z_0}\right)^j$$

converges uniformly on γ_0 to

$$\frac{1}{1-\frac{\zeta-z_0}{z-z_0}}=-\frac{z-z_0}{\zeta-z}$$

i.e. for $\zeta\in\gamma_0$ we have

$$\frac{1}{\zeta-z}=-\frac{1}{z-z_0}\sum_{j=0}^{\infty}\left(\frac{\zeta-z_0}{z-z_0}\right)^j=-\sum_{j=0}^{\infty}\frac{(\zeta-z_0)^j}{(z-z_0)^{j+1}}$$

where the series converges uniformly on γ_0. Thus the series

$$\sum_{k=1}^{\infty}\left[\frac{1}{(z-z_0)^k}\int_{\gamma_0}f(\zeta)(\zeta-z_0)^{k-1}\,d\zeta\right]$$

$$=\sum_{j=0}^{\infty}\left[\frac{1}{(z-z_0)^{j+1}}\int_{\gamma_0}f(\zeta)(\zeta-z_0)^j\,d\zeta\right]=\int_{\gamma_0}f(\zeta)\left[\sum_{j=0}^{\infty}\frac{(\zeta-z_0)^j}{(z-z_0)^{j+1}}\right]d\zeta$$

converges to

$$-\int_{\gamma_0}\frac{f(\zeta)}{\zeta-z}\,d\zeta\ .$$

So we have that both series converge and that

$$f(z)=\sum_{k=0}^{\infty}a_k(z-z_0)^k+\sum_{k=1}^{\infty}\frac{b_k}{(z-z_0)^k}$$

where

$$a_k=\frac{1}{2\pi i}\int_{\gamma_1}\frac{f(\zeta)}{(\zeta-z_0)^{k+1}}\,d\zeta$$

$$b_k=\frac{1}{2\pi i}\int_{\gamma_0}f(\zeta)(\zeta-z_0)^{k-1}\,d\zeta\ .$$

The circles γ_1 and γ_0 depend on z. But note that if γ is any circle centered at z_0 contained in Ω, then, for any k,

$$\int_\gamma \frac{f(\zeta)}{(\zeta - z_0)^{k+1}}\, d\zeta = \int_{\gamma_1} \frac{f(\zeta)}{(\zeta - z_0)^{k+1}}\, d\zeta$$

$$\int_\gamma f(\zeta)(\zeta - z_0)^{k-1}\, d\zeta = \int_{\gamma_0} f(\zeta)(\zeta - z_0)^{k-1}\, d\zeta$$

so the a_k and b_k are independent of the choice of γ_1 and γ_0, i.e. the same series are obtained for all $z \in \Omega$, and these series converge pointwise on Ω.

Since the power series converges pointwise on Ω, its radius of convergence is at least R, hence it converges u.c. on Ω. Similarly, the inverse radius of convergence of the inverse power series is at most r, so it converges u.c. on Ω.

It remains to show uniqueness. If there are series with coefficients c_k and d_k, converging u.c. on Ω with

$$f(z) = \sum_{k=0}^{\infty} c_k (z - z_0)^k + \sum_{k=1}^{\infty} \frac{d_k}{(z - z_0)^k}$$

then for any $k \geq 0$ and any circle γ in Ω centered at z_0 we have

$$2\pi i a_k = \int_\gamma \frac{f(\zeta)}{(\zeta - z_0)^{k+1}}\, d\zeta = \sum_{j=0}^{\infty} \left[\int_\gamma c_j (\zeta - z_0)^{j-k-1}\, d\zeta \right] + \sum_{j=1}^{\infty} \left[\int_\gamma \frac{d_k}{((\zeta - z_0)^{j+k+1}}\, d\zeta \right]$$

where term-by-term integration is justified by u.c. convergence. But all terms in the second sum are zero, and all terms in the first are also zero except the term with $j = k$, which is $2\pi i c_k$. Thus $c_k = a_k$. Similarly, if $k \geq 1$ we have

$$2\pi i b_k = \int_\gamma f(\zeta)(\zeta - z_0)^{k-1}\, d\zeta = \sum_{j=0}^{\infty} \left[\int_\gamma c_j (\zeta - z_0)^{j+k-1}\, d\zeta \right] + \sum_{j=1}^{\infty} \left[\int_\gamma \frac{d_k}{((\zeta - z_0)^{j-k+1}}\, d\zeta \right]$$

and the term in the second sum with $j = k$ is $2\pi i d_k$ and all other terms are zero. 👍

The uniqueness statement in this theorem can be extended:

XII.4.4.13. Corollary. Let Ω be an open annulus centered at z_0 with inner radius r and outer radius R, and f a holomorphic function on Ω, with expansion

$$f(z) = \sum_{k=0}^{\infty} a_k (z - z_0)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

as in XII.4.4.12.. Suppose there are a power series

$$\sum_{k=0}^{\infty} c_k (z - z_0)^k$$

and an inverse power series

$$\sum_{k=1}^{\infty} \frac{d_k}{(z-z_0)^k}$$

converging pointwise on Ω with

$$f(z) = \sum_{k=0}^{\infty} c_k (z-z_0)^k + \sum_{k=1}^{\infty} \frac{d_k}{(z-z_0)^k}$$

for all $z \in \Omega$. Then $c_k = a_k$ and $d_k = b_k$ for all k.

PROOF: Since

$$\sum_{k=0}^{\infty} c_k (z-z_0)^k$$

converges pointwise on Ω, its radius of convergence is at least R, so the series converges u.c. on Ω. Similarly, the inverse power series

$$\sum_{k=1}^{\infty} \frac{d_k}{(z-z_0)^k}$$

converges pointwise on Ω, so its inverse radius of convergence is at most r, so this series converges u.c. on Ω. The result now follows from XII.4.4.12.. 👍

XII.4.4.14. If we set $a_{-k} = b_k$ for $k \geq 1$, we can more compactly write the expansion in XII.4.4.12. as

$$f(z) = \sum_{-\infty}^{\infty} a_k (z-z_0)^k$$

which is called the *Laurent expansion* of f around z_0 (it is technically only a Laurent series (III.5.3.3.) if only finitely many b_k are nonzero, which turns out to often be the case if $r = 0$). But the proper phrasing of convergence of such a series is somewhat tricky, so it is better to consider the positive and negative powers separately in general.

XII.4.4.15. One important difference between XII.4.4.12. and XII.4.4.6. is that there is no obvious interpretation of the coefficients a_k (or b_k) as values of derivatives of f at z_0, which of course do not make sense if f is defined only on an annulus around z_0. However, in at least some cases (e.g. if only finitely many b_k are nonzero) there is an analogous interpretation ().

XII.4.5. Normal Families and Montel's Theorem

There is an important compactness-like property for families of holomorphic functions which we discuss in this section.

Normal Families

XII.4.5.1. Definition. Let Ω be an open set in $\mathbb{C}$, and $\mathcal{F}$ a family of holomorphic functions on Ω. Then $\mathcal{F}$ is a *normal family* if every sequence in $\mathcal{F}$ has a subsequence which converges u.c. ("normally") on Ω.

XII.4.5.2. Normal families turn out to exist in abundance in Complex Analysis, and this fact is the key to many advanced results: they are used to construct holomorphic functions with an exact set of specified properties from families of functions approximately satisfying the properties.

Here is a nice technical simplification used in proving normality for families of holomorphic functions:

XII.4.5.3. Proposition. Let Ω be an open set in $\mathbb{C}$, and $\mathcal{F}$ a family of holomorphic functions on Ω. Suppose there is a sequence (D_j) of compact subsets of Ω such that

(i) Every compact subset of Ω is contained in the union of finitely many D_j.

(ii) For every j, every sequence in $\mathcal{F}$ has a subsequence converging uniformly on D_j.

Then $\mathcal{F}$ is a normal family.

Proof: If (f_n) is a sequence in $\mathcal{F}$, then there is a subsequence $(f_{n_{k,1}})$ which converges uniformly on D_1. This subsequence has a subsubsequence $(f_{n_{k,2}})$ which converges uniformly on D_2. Continue inductively to get, for each j, a sub$\cdots$sequence $f_{n_{k,j}}$ converging uniformly on D_j. The diagonal subsequence $(f_{n_{k,k}})$ then converges uniformly on D_j for each j, and hence on any finite union of the D_j; thus it converges u.c. on Ω. 👍

XII.4.5.4. Corollary. Let Ω be an open set in $\mathbb{C}$, and $\mathcal{F}$ a family of holomorphic functions on Ω. Then $\mathcal{F}$ is a normal family if and only if, for every closed disk D in Ω, any sequence in $\mathcal{F}$ has a subsequence which converges uniformly on D.

The proof of this Corollary really involves no Complex Analysis, only topology. The key is the following topological lemma:

XII.4.5.5. Lemma. Let Ω be an open set in $\mathbb{C}$. Then there is a sequence (D_j) of closed disks in Ω such that every compact subset of Ω is contained in the union of finitely many of the D_j.

Proof: First note that there is a sequence (K_n) of compact sets whose union is Ω: for example, set

$$K_n = \left\{ z \in \Omega : d(z, \mathbb{C} \setminus \Omega) \geq \frac{1}{n}, |z| \leq n \right\} .$$

For each $z \in \Omega$, there is an open disk B_z centered at z whose closure is contained in Ω. For each n, finitely many of the B_z cover K_n; thus countably many of the B_z cover Ω, say $\{B_{z_1}, B_{z_2}, \dots\}$. If K is any compact subset of Ω, finitely many of the B_{z_j} cover K. Take $D_j = \bar{B}_{z_j}$. 👍

This proof works essentially verbatim for any open set in any locally compact, σ-compact metric space ().

Montel's Theorem

XII.4.5.6. THEOREM. [MONTEL'S THEOREM] Let Ω be an open set in $\mathbb{C}$, and $\mathcal{F}$ a family of holomorphic functions on Ω. If $\mathcal{F}$ is uniformly bounded on every closed disk in Ω, then $\mathcal{F}$ is a normal family.

PROOF: We will use XII.4.5.3. for a carefully chosen sequence (D_j) of closed disks. The result will follow immediately from the Arzela-Ascoli Theorem () if $\mathcal{F}$ is equicontinuous on each D_j. We proceed similarly to the proof of XII.4.5.5.: for each $z \in \Omega$ there is an $r > 0$ (depending on z) such that the closed disk of radius $2r$ around z is contained in Ω. Let B_z be the open disk of radius r centered at z. As in the proof of XII.4.5.5., there is a sequence (B_{z_j}) such that every compact subset of Ω is covered by finitely many B_{z_j}. Set $D_j = \bar{B}_{z_j}$.

Equicontinuity of $\mathcal{F}$ on D_j follows from the first Cauchy Inequality, as follows. Fix j. If r is the radius of D_j, then the closed disk D of radius $2r$ centered at z_j is contained in Ω, and if $z \in D_j$, then the closed disk of radius r around z is contained in D. So if M is a bound for $\mathcal{F}$ on D, we have $|f'(z)| \leq \frac{M}{r}$ for all $f \in \mathcal{F}$ and $z \in D_j$. Then, since D_j is convex, for any $z, w \in D_j$ we have

$$|f(z) - f(w)| \leq \frac{M}{r}|z - w|$$

for all $f \in \mathcal{F}$ by XII.2.1.9., and equicontinuity of $\mathcal{F}$ on D_j follows. 👍

The most commonly used special case is called Montel's Theorem in many references:

XII.4.5.7. COROLLARY. Let Ω be an open set in $\mathbb{C}$, and $\mathcal{F}$ a family of holomorphic functions on Ω. If $\mathcal{F}$ is uniformly bounded on Ω, then $\mathcal{F}$ is a normal family.

XII.4.5.8. These are not the most general theorems proved by MONTEL. In [Gam01], XII.4.5.7. is called the "thesis grade" Montel Theorem since MONTEL proved it in his Ph.D. thesis. He later proved a spectacular generalization of XII.4.5.7. (not quite a generalization of XII.4.5.6.) related to the Picard Theorems, which is beyond the scope of this book; see e.g. [Gam01].

XII.5. Zeroes and Singularities

The existence of local power series representations for holomorphic functions has some surprising and pleasant rigidity consequences, and the closely related existence of Laurent expansions around isolated singularities yields more consequences which shed great light on the global properties of holomorphic functions. In fact, it was the philosophy of CAUCHY and, especially, RIEMANN that a holomorphic (analytic) function should be primarily understood through its zeroes and singularities.

XII.5.1. Zeroes of Holomorphic Functions

The first result is immediate from XII.4.4.6., and underlies the rest of the results of this section:

XII.5.1.1. COROLLARY. Let Ω be an open set in $\mathbb{C}$, f holomorphic on Ω, and $z_0 \in \Omega$ with $f(z_0) = 0$. Then either

(i) f is identically zero in a neighborhood of z_0

or

(ii) There is a unique $n \in \mathbb{N}$ and a unique function ϕ which is holomorphic on Ω, with $\phi(z_0) \neq 0$, for which

$$f(z) = (z - z_0)^n \phi(z)$$

for all $z \in \Omega$; and there is a neighborhood U of z_0 containing no other zeroes of f.

PROOF: Let

$$\sum_{k=0}^{\infty} \frac{f^{(k)}(z_0)}{k!}(z - z_0)^k$$

be the Taylor series for f around z_0 and D an open disk centered at z_0 on which this series converges to f. Either $f^{(k)}(z_0) = 0$ for all k, in which case this series is identically zero and f is identically zero on D, or else there is a unique $n \geq 1$ such that $f^{(n)}(z_0) \neq 0$ and $f^{(k)}(z_0) = 0$ for all $k < n$. In this case, the power series

$$\sum_{k=n}^{\infty} \frac{f^{(k)}(z_0)}{k!}(z - z_0)^{k-n}$$

has the same radius of convergence as the Taylor series, and thus converges to a holomorphic function ϕ on D which satisfies $\phi(z_0) = \frac{f^{(n)}(z_0)}{n!} \neq 0$ and

$$\phi(z) = \frac{f(z)}{(z - z_0)^n}$$

for all $z \in D \setminus \{z_0\}$. We may thus extend ϕ to a function holomorphic on Ω with the same properties by setting $\phi(z) = \frac{f(z)}{(z-z_0)^n}$ for $z \in \Omega \setminus D$. Uniqueness of n and ϕ is clear.

For the last statement, since ϕ is continuous and $\phi(z_0) \neq 0$, there is a neighborhood U of z_0 on which $\phi(z) \neq 0$ for all $z \in U$. Then

$$f(z) = (z - z_0)^n \phi(z) \neq 0$$

for all $z \in U \setminus \{z_0\}$ since both factors are nonzero. 👍

A crucial property of holomorphic functions follows, that the zeroes of a nonconstant holomorphic function are *isolated*:

XII.5.1.2. COROLLARY. Let Ω be a connected open set in $\mathbb{C}$, and f a holomorphic function on Ω. Suppose there is a sequence $(z_n) \in \Omega$ of distinct points such that $f(z_n) = 0$ for all n, and that $z_n \to z_0$ for some $z_0 \in \Omega$. Then f is identically zero on Ω.

PROOF: We have that $f(z_0) = 0$ by continuity, and thus f is identically zero in a neighborhood of z_0 by XII.5.1.1.. Let U be the set of all $z \in \Omega$ such that f is identically zero in a neighborhood of z. Then U is open and contains z_0. If $w \in \bar{U} \cap \Omega$, then there is a sequence $(w_n) \in U$ with $w_n \to w$, and thus $w \in U$ as in the first statement of the proof. So U is relatively closed in Ω. Since Ω is connected, $U = \Omega$. 👍

XII.5.1.3. This result says that the zeroes of a nonconstant holomorphic function on a connected Ω cannot have an accumulation point in Ω. Note that they can have an accumulation point outside Ω: set $\Omega = \mathbb{C} \setminus \{0\}$ and $f(z) = \sin \frac{1}{z}$. Then f is holomorphic and nonconstant on Ω and f has a sequence of zeroes (at $\frac{1}{\pi n}$) converging to 0.

Connectedness of Ω is essential: a holomorphic function on a nonconnected Ω could be identically zero on a component of Ω and not on another component.

The statement of XII.5.1.2. becomes seemingly much more powerful by the simple trick of considering $f - g$:

XII.5.1.4. THEOREM. [RIGIDITY THEOREM] Let Ω be a connected open set in $\mathbb{C}$, and f and g holomorphic functions on Ω. Suppose there is a sequence $(z_n) \in \Omega$ of distinct points such that $f(z_n) = g(z_n)$ for all n, and that $z_n \to z_0$ for some $z_0 \in \Omega$. Then f and g are identically equal on Ω.

XII.5.1.5. This result is called the Rigidity Theorem because it means that if f is holomorphic on Ω, the values of f on any small subregion of Ω (or even subset of Ω large enough to have an accumulation point in Ω) completely determine the values of f throughout all of Ω (if Ω is connected).

XII.5.1.6. If a holomorphic function f has an isolated zero at z_0, the number n in XII.5.1.1. is called the *order* of the zero at z_0. This language extends the usual notion of order of a zero of a polynomial. Part of the content of XII.5.1.1. is that an isolated zero of a holomorphic function has finite order.

Limits of Sequences of Holomorphic Functions

Using Montel's Theorem (), we can obtain a considerable extension of the Rigidity Theorem:

XII.5.1.7. THEOREM. Let Ω be a connected open set in $\mathbb{C}$, (f_k) a sequence of holomorphic functions on Ω, and (z_n) a sequence of distinct points in Ω converging to $z_0 \in \Omega$. Suppose the f_k are uniformly bounded on compact subsets of Ω, and that $w_n := \lim_{k\to\infty} f_k(z_n)$ exists for all n. Then there is a unique holomorphic function f on Ω such that $f(z_n) = w_n$ for all n, and $f_n \to f$ u.c. on Ω.

PROOF: By Montel's Theorem, there is a subsequence of (f_k) converging u.c. to a holomorphic function f on Ω, and we must have $f(z_n) = w_n$ for all n. Similarly, if (f_{m_k}) is any subsequence of (f_k), then (f_{m_k}) has a subsequence converging u.c. on Ω to a holomorphic function g with $g(z_n) = w_n$ for all n. By the Rigidity

Theorem, $g = f$ on all of Ω. Thus, if K is a compact subset of Ω containing all the z_n, every subsequence of (f_n) has a subsubsequence converging uniformly to f on K; so $f_n \to f$ uniformly on K (). 👍

This is a powerful result since it shows that to prove that a sequence of holomorphic functions converges u.c. on Ω, it suffices to show the sequence is uniformly bounded on compact subsets of Ω (a necessary condition for u.c. convergence) and converges pointwise on a subset of Ω with a limit point in Ω (e.g. a small subregion of Ω). Note that the Rigidity Theorem is the uniqueness part applied to a constant sequence. But the Rigidity Theorem cannot be considered a corollary of this result since it is used in the proof.

XII.5.2. Singularities

XII.5.2.1. DEFINITION. Let f be holomorphic on an open set Ω. Then f has an *isolated singularity* at $z_0 \in \mathbb{C} \setminus \Omega$ if there is a deleted neighborhood of z_0 contained in Ω.

In other words, f has an isolated singularity at z_0 if it is holomorphic in a neighborhood of z_0 except at z_0.

XII.5.2.2. EXAMPLES. (i) The function

$$f(z) = \frac{z-1}{z^2-1}$$

has isolated singularities at 1 and -1.

(ii) The function $f(z) = e^{1/z}$ has an isolated singularity at 0.

(iii) The function $f(z) = \tan \frac{1}{z}$ has isolated singularities at $\frac{2}{n\pi}$ for all odd n, and a "singularity" at 0 which is not an isolated singularity.

(iv) The functions $\log z$ and z^c, c not an integer, have a "singularity" at 0. But these functions cannot be defined as holomorphic functions on any deleted neighborhood of 0, so no version of them has an isolated singularity at 0. (If c is a negative integer, z^c is a well-defined holomorphic function on $\mathbb{C} \setminus \{0\}$ which has an isolated singularity at 0.)

XII.5.2.3. We will not consider "singularities" such as the ones at 0 in (iii) or (iv) which are not isolated singularities: we will use the term *singularity* to mean "isolated singularity."

The three singularities in (i) and (ii) are examples of the three types of singularity discussed below.

XII.5.2.4. If f has a singularity at z_0, then by XII.4.4.12. there is a unique Laurent expansion

$$f(z) = \sum_{k=0}^{\infty} a_k (z-z_0)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z-z_0)^k}$$

which converges u.c. in a deleted neighborhood of z_0.

Removable Singularities

A singularity such as the one at 1 in XII.5.2.2.(i) is "artificial" since the function can be defined there in such a way that the extended function is holomorphic in a whole neighborhood of 1.

XII.5.2.5. DEFINITION. If f has a singularity (isolated singularity) at z_0, the singularity is a *removable singularity* if there is a function g, holomorphic in a neighborhood of z_0, such that $f = g$ on a deleted neighborhood of z_0.

XII.5.2.6. EXAMPLES. (i) The function $f(z) = \frac{z-1}{z^2-1}$ has singularities at 1 and -1. The singularity at 1 is removable, since $f(z) = g(z) = \frac{1}{z+1}$ in a deleted neighborhood of 1, and g is holomorphic in a neighborhood of 1. The singularity of f at -1 is not removable.

(ii) The function

$$f(z) = \frac{\sin z}{z}$$

has a singularity at 0. It is not so easy to prove directly that

$$\lim_{z\to 0} \frac{\sin z}{z}$$

exists (it does, and equals 1). But on $\mathbb{C} \setminus \{0\}$ f agrees with the entire function g defined by the power series

$$g(z) = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)!} z^{2k}$$

and thus the singularity is removable.

If f has a removable singularity at z_0, it is obvious that

$$\lim_{z\to z_0} f(z)$$

exists. It is remarkable that this condition is also sufficient for the singularity to be removable; in fact, apparently much weaker conditions are also sufficient:

XII.5.2.7. THEOREM. If f has a singularity at z_0, the following are equivalent:

(i) The singularity at z_0 is removable.

(ii) $\lim_{z\to z_0} f(z)$ exists.

(iii) f is bounded in a deleted neighborhood of z_0.

(iv) $\lim_{z\to z_0} f(z)(z - z_0) = 0$.

(v) In the Laurent expansion of f around z_0, all b_k are zero.

PROOF: (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii) $\Rightarrow$ (iv) are obvious.

(iv) $\Rightarrow$ (i): Let D be an open disk centered at z_0 such that f is holomorphic on $D \setminus \{z_0\}$, and let γ be a circle of radius r centered at z_0 contained in $D \setminus \{z_0\}$. Then, for each z inside γ, $z \neq z_0$,

$$f(z) = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{\zeta - z}\, d\zeta - \frac{1}{2\pi i} \int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z}\, d\zeta$$

where γ_δ is any circle centered at z_0 of radius $\delta < |z - z_0|$ (). Note that, for fixed z, the second integral is independent of δ, as long as $0 < \delta < |z - z_0|$.

Fix z inside γ, and let $\epsilon > 0$. If $\delta > 0$ is sufficiently small, then $|f(\zeta)(\zeta - z_0)| < \epsilon$ whenever $0 < |\zeta - z_0| \leq \delta$. We may assume $\delta \leq \frac{|z-z_0|}{2}$. Then

$$|f(\zeta)| < \frac{\epsilon}{\delta}$$

$$\left|\frac{1}{\zeta - z}\right| \leq \frac{1}{|z - z_0| - \delta} \leq \frac{2}{|z - z_0|}$$

for $\zeta \in \gamma_\delta$, so

$$\left|\int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z}\, d\zeta\right| < \frac{2\epsilon}{\delta|z - z_0|} \cdot 2\pi\delta = \frac{4\pi\epsilon}{|z - z_0|} \ .$$

Since the integral is independent of δ, and $\epsilon > 0$ is arbitrary, we have

$$\int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z}\, d\zeta = 0$$

$$f(z) = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{\zeta - z}\, d\zeta \ .$$

This is true for each z inside γ, $z \neq z_0$. But the function

$$g(z) = \frac{1}{2\pi i} \int_\gamma \frac{f(\zeta)}{\zeta - z}\, d\zeta$$

is holomorphic on the entire disk inside γ by ().

(v) $\iff$ (i): Let D be an open disk centered at z_0 such that f is holomorphic on $D \setminus \{z_0\}$, of radius r. If all $b_k = 0$, the Laurent series for f around z_0 is a power series which converges to f on $D \setminus \{z_0\}$; thus its radius of convergence is at least r and it defines a function g which is holomorphic on D and agrees with f on $D \setminus \{z_0\}$. Conversely, if g is a holomorphic function on an open disk D centered at z_0 such that $f = g$ on $D \setminus \{z_0\}$, the Taylor series for g around z_0 converges to f on $D \setminus \{z_0\}$, so must be the Laurent series for f around z_0 by uniqueness of Laurent expansions. 👍

There is a simpler proof that (iii) $\Rightarrow$ (i) (Exercise XII.9.9.12.), and an even simpler proof that (ii) $\Rightarrow$ (i) (Exercise XII.9.9.13.).

XII.5.2.8. The implication (ii) $\Rightarrow$ (i) means that a continuous function from $\mathbb{C}$ (or an open subset) to $\mathbb{C}$ cannot have an isolated point where it is not differentiable (cf. Exercise XII.9.9.13.). This is in contrast to the real case, e.g. for the function $f(x) = |x|$. The theorem also rules out complex analogs of $g(x) = \sin\frac{1}{x}$ ((iii) $\Rightarrow$ (i)) and $h(x) = \frac{1}{\sqrt{|x|}}$ ((iv) $\Rightarrow$ (i)). (The function $g(z) = \sin\frac{1}{z}$ is holomorphic with an isolated singularity at 0, but g is not bounded near 0; in fact the singularity is an essential singularity.)

Poles

XII.5.2.9. Definition. If f has a singularity (isolated singularity) at z_0, the singularity is a *pole of order n* if $\frac{1}{f}$ has a removable singularity at z_0 which is a zero of order n. A pole of order 1 is called a *simple pole*.

Poles can be simply characterized:

XII.5.2.10. PROPOSITION. Suppose f has a singularity at z_0. Then f has a pole at z_0 if and only if

$$\lim_{z\to z_0} |f(z)| = +\infty$$

i.e. for any $M > 0$ there is a $\delta > 0$ such that $|f(z)| > M$ whenever $0 < |z - z_0| < \delta$.

PROOF: If f has a pole at z_0 of order n, and $\frac{1}{f} = g$ in a deleted neighborhood of z_0 and g has a zero of order n at z_0, then there is a deleted neighborhood U of z_0 such that g has no zeroes in U, and we have

$$\lim_{z\to z_0} g(z) = 0$$

and it follows that

$$\lim_{z\to z_0} |f(z)| = +\infty \ .$$

Conversely, if

$$\lim_{z\to z_0} |f(z)| = +\infty$$

there is a deleted neighborhood of z_0 on which f is nonzero, so $h = \frac{1}{f}$ is defined in a deleted neighborhood of z_0. We have

$$\lim_{z\to z_0} h(z) = 0$$

so h has a removable singularity at z_0 and the extended function g has an isolated zero at z_0. 👍

XII.5.2.11. THEOREM. If f has a singularity at z_0, the following are equivalent:

(i) f has a pole of order n at z_0.

(ii) There is a function ϕ which is holomorphic in a neighborhood of z_0 with $\phi(z_0) \neq 0$, such that

$$f(z) = \frac{\phi(z)}{(z - z_0)^n}$$

for all z in a deleted neighborhood of z_0.

(iii) In the Laurent expansion for f around z_0 (XII.5.2.4.), $b_n \neq 0$ but $b_k = 0$ for all $k > n$.

PROOF: (i) ⇒ (ii): There is a function g, holomorphic in a neighborhood of z_0, such that $\frac{1}{f(z)} = g(z)$ for z in a deleted neighborhood of z_0, and there is a function ψ, holomorphic in a neighborhood of z_0 with $\psi(z_0) \neq 0$, such that $g(z) = (z - z_0)^n \psi(z)$ in a neighborhood of z_0. Then $\psi(z) \neq 0$ in a neighborhood U of z_0, and for all $z \in U \setminus \{z_0\}$,

$$f(z) = \frac{1}{(z - z_0)^n} \cdot \frac{1}{\psi(z)} \ .$$

(ii) ⇒ (i): There is a neighborhood U of z_0 such that $\phi(z) \neq 0$ for all $z \in U$ and $f(z) = \frac{\phi(z)}{(z-z_0)^n}$ for all $z \in U \setminus \{z_0\}$. Then

$$g(z) = (z - z_0)^n \frac{1}{\phi(z)}$$

is holomorphic on U, has a zero of order n at z_0, and agrees with $\frac{1}{f}$ on $U \setminus \{z_0\}$.
(ii) $\Rightarrow$ (iii): Suppose the equation holds on $D \setminus \{z_0\}$, where D is an open disk centered at z_0. Let

$$\sum_{k=0}^{\infty} c_k (z - z_0)^k$$

be the Taylor expansion of ϕ around z_0, which converges to ϕ on D. Then $c_0 = \phi(z_0) \neq 0$. Then, for $z \in D \setminus \{z_0\}$,

$$f(z) = \frac{c_0}{(z - z_0)^n} + \cdots + \frac{c_{n-1}}{z - z_0} + \sum_{k=n}^{\infty} c_k (z - z_0)^{k-n}$$

where the power series converges u.c. on D. This must be the Laurent expansion for f around z_0 by uniqueness of Laurent expansions.
(iii) $\Rightarrow$ (ii): Suppose

$$f(z) = \frac{b_n}{(z - z_0)^n} + \cdots + \frac{b_1}{z - z_0} + \sum_{k=0}^{\infty} a_k (z - z_0)^k$$

is the Laurent expansion of f around z_0, with $b_n \neq 0$, converging u.c. on $D \setminus \{z_0\}$, for an open disk D centered at z_0. Set $c_k = b_{n-k}$ for $0 \leq k \leq n-1$ and $c_k = a_{k-n}$ for $k \geq n$. Then the power series

$$\sum_{k=0}^{\infty} c_k (z - z_0)^k$$

converges u.c. on D to a holomorphic function ϕ, with the required properties. 👍

XII.5.2.12. There is thus a symmetry between poles and zeroes: a pole of order n can be thought of as a zero of order $-n$, or a zero of order n can be considered a pole of order $-n$. Indeed, if f is holomorphic and not identically zero in a deleted neighborhood of z_0 and has a pole or removable singularity at z_0, or is already defined and differentiable also at z_0, then the Laurent expansion of f around z_0 is of the form

$$f(z) = \sum_{k=n}^{\infty} a_k (z - z_0)^k$$

where $n \in \mathbb{Z}$ may be positive, negative, or 0 and $a_n \neq 0$. If $n > 0$, f has a zero of order n at z_0 (perhaps after a singularity at z_0 has been removed). If $n < 0$, f has a pole of order $-n$ at z_0. If $n = 0$, then f is holomorphic around z_0 and $f(z_0) \neq 0$, and we may regard f as having a zero or pole at z_0 of order 0.

XII.5.2.13. EXAMPLES. The function $f(z) = \frac{1}{(z-z_0)^n}$ has a pole of order n at z_0, as does the function

$$g(z) = \frac{e^z}{(z - z_0)^n} \ .$$

Since the Taylor series for e^z around z_0 is

$$e^z = \sum_{k=0}^{\infty} \frac{e^{z_0}}{k!} (z - z_0)^k$$

we have that the Laurent series of g around z_0 is

$$\frac{e^{z_0}}{(z-z_0)^n} + \cdots + \frac{e^{z_0}}{(n-1)!(z-z_0)} + \sum_{k=n}^{\infty} \frac{e^{z_0}}{k!}(z-z_0)^{k-n} \ .$$

Essential Singularities

XII.5.2.14. DEFINITION. If f has a singularity (isolated singularity) at z_0, the singularity is an *essential singularity* if it is not a removable singularity or a pole.

XII.5.2.15. We should emphasize that the term *essential singularity* is used only for isolated singularities. Thus the "singularities" at 0 in XII.5.2.2.(iii)–(iv) are not essential singularities (these "singularities" are even more "essential" than essential singularities!)

Essential singularities can be characterized from the Laurent expansion by a process of elimination:

XII.5.2.16. PROPOSITION. If f has a singularity at z_0, and

$$f(z) = \sum_{k=0}^{\infty} a_k(z-z_0)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z-z_0)^k}$$

is its Laurent expansion around z_0, then the singularity at z_0 is an essential singularity if and only if infinitely many b_k are nonzero.

PROOF: The singularity is removable if and only if all b_k are zero, and a pole if and only if at least one b_k, but only finitely many, is/are nonzero.

XII.5.2.17. EXAMPLES. (i) Let $f(z) = e^{1/z}$. Then f has a singularity at 0. As $z \to 0$ along the positive real axis, $|f(z)| \to +\infty$, so the singularity at 0 is not removable. And as $z \to 0$ along the negative real axis, $f(z) \to 0$, so the singularity is not a pole. Thus it is an essential singularity.

This can be seen another way. If $z \neq 0$, the inverse power series

$$1 + \sum_{k=1}^{\infty} \frac{1}{k!}\frac{1}{z^k}$$

converges to $e^{1/z}$. Thus this is the Laurent expansion of f around 0. Since infinitely many negative power coefficients are nonzero, the singularity is essential.

(ii) A closely related example is Cauchy's example (V.17.2.2.) of a $\mathcal{C}^\infty$ function from $\mathbb{R}$ to $\mathbb{R}$ which is not (real) analytic. Let $f(z) = e^{-1/z^2}$. This function is holomorphic on $\mathbb{C} \setminus \{0\}$. As $z \to 0$ along the real axis, $f(z) \to 0$, and if we define $f(0) = 0$, it becomes $\mathcal{C}^\infty$ as a function from $\mathbb{R}$ to $\mathbb{R}$. But if $z \to 0$ along the imaginary axis, $|f(z)| \to +\infty$. Thus f, as a function from $\mathbb{C} \setminus \{0\}$ to $\mathbb{C}$, has an essential singularity at 0.

The next result shows that the behavior of a holomorphic function near an essential singularity is very complicated.

XII.5.2.18. THEOREM. [CASORATI-WEIERSTRASS] Let f have an essential singularity at z_0, and U a deleted neighborhood of z_0 contained in the domain of f. Then the image of U under f is dense in $\mathbb{C}$. If $w \in \mathbb{C}$, then there is a sequence (z_n) in U with $z_n \to z_0$ and $f(z_n) \to w$.

PROOF: The two statements are obviously equivalent (the second follows from the first by taking a decreasing sequence of such neighborhoods), so we prove the first. The proof is very similar to the proof of XII.3.3.11.. Suppose $f(U)$ is not dense in $\mathbb{C}$. Then there is a $w \in \mathbb{C}$ and an $\epsilon > 0$ such that $|f(z) - w| \geq \epsilon$ for all $z \in U$. Set

$$g(z) = \frac{1}{f(z) - w}$$

for $z \in U$; then g is holomorphic on U and has a singularity at z_0. We have $|g(z)| \leq \frac{1}{\epsilon}$ for all $z \in U$, so by XII.5.2.7. this singularity is removable, i.e.

$$c = \lim_{z \to z_0} g(z)$$

exists. Then, if $c \neq 0$, we have

$$\lim_{z \to z_0} f(z) = w + \frac{1}{c}$$

so the singularity of f at z_0 is removable, a contradiction. And if $c = 0$, we have

$$\lim_{z \to z_0} |f(z)| = +\infty$$

so the singularity of f at z_0 is a pole, another contradiction. 👍

Actually, a much stronger result is true:

XII.5.2.19. THEOREM. [BIG PICARD THEOREM] Let f have an essential singularity at z_0, and U a deleted neighborhood of z_0 contained in the domain of f. Then, with at most one exception, f takes every complex value infinitely many times in U.

This result is the best possible: $e^{1/z}$ never takes the value 0. The proof is beyond the scope of this book; see e.g. []. The Big Picard Theorem implies the Little Picard Theorem XII.3.3.12.; cf. Exercise XII.9.9.14..

XII.5.3. Behavior at Infinity

It also makes sense to say that certain functions have singularities at infinity:

XII.5.3.1. DEFINITION. Let f be holomorphic on a set $\{z : |z| > R\}$ for some R. Then f has a *singularity at infinity*. We say f has a *removable singularity* [resp. *pole, essential singularity*] at infinity if the function $g(z) = f\left(\frac{1}{z}\right)$ has a removable singularity [resp. pole, essential singularity] at 0.

We can characterize the types of singularities at infinity:

XII.5.3.2. PROPOSITION. Let f have a singularity at infinity. Then

(i) The singularity at infinity is removable if and only if $\lim_{z\to\infty} f(z)$ exists, i.e. there is a number $c \in \mathbb{C}$ such that, for every $\epsilon > 0$, there is an M such that $|f(z) - c| < \epsilon$ whenever $|z| > M$.

(ii) The singularity at infinity is a pole if and only if $\lim_{z\to\infty} |f(z)| = +\infty$, i.e. for every N there is an M such that $|f(z)| > N$ whenever $|z| > M$.

(iii) Otherwise, the singularity at infinity is an essential singularity.

XII.5.3.3. If f has a singularity at infinity, i.e. it is holomorphic on an annulus $\Omega = \{z : |z| > R\}$, then it has a Laurent expansion

$$f(z) = \sum_{k=0}^{\infty} a_k z^k + \sum_{k=1}^{\infty} \frac{b_k}{z^k}$$

around 0 which converges on Ω. If $g(z) = f\left(\frac{1}{z}\right)$, then the Laurent expansion of g around 0 converging on $\{z : 0 < |z| < 1/R\}$ is obtained by replacing z by z^{-1} in this expansion, effectively interchanging the a_k and b_k. Thus we obtain a classification of singularities at infinity from the Laurent expansion:

XII.5.3.4. PROPOSITION. If f is holomorphic on the annulus $\Omega = \{z : |z| > R\}$, with Laurent expansion

$$f(z) = \sum_{k=0}^{\infty} a_k z^k + \sum_{k=1}^{\infty} \frac{b_k}{z^k}$$

around 0 which converges on Ω, then the singularity at infinity is

(i) Removable if (and only if) all a_k $(k \geq 1)$ are 0.

(ii) A pole if (and only if) some a_k $(k \geq 1)$, but only finitely many, are nonzero.

(iii) Essential if (and only if) infinitely many a_k are nonzero.

As a corollary, we get an important property of entire functions:

XII.5.3.5. COROLLARY. Let f be an entire function. Then the singularity at infinity is

(i) Removable if f is constant.

(ii) A pole if f is a nonconstant polynomial.

(iii) Essential otherwise.

PROOF: The Laurent expansion of f on any annulus centered at 0 is just the Taylor series of f around 0. 👍

The fact that a nonconstant polynomial has a pole at infinity is the essential content of Lemma XII.1.4.1..

XII.5.3.6. We can also define the order of a pole of f at infinity to be the order of the pole of $g(z) = f\left(\frac{1}{z}\right)$ at 0. And we can consider a zero at infinity: f has a zero at infinity if g has a removable singularity at 0 which, when removed, is a zero. The order of the zero of f at infinity is the order of this zero of g. These orders can be read from the Laurent expansion of f in an unbounded annulus in the obvious way, as the largest n for which $a_n \neq 0$ for a pole, and similarly for the b_n for a zero.

XII.5.3.7. We have used expansions around 0 converging in an unbounded annulus centered at 0 merely for convenience. The same results hold if we use unbounded annuli centered at any z_0 by using $g(z) = f\left(\frac{1}{z-z_0} + z_0\right)$, i.e. $g(z - z_0) = f\left(\frac{1}{z-z_0}\right)$. This is occasionally useful when f is naturally expanded around some $z_0 \neq 0$.

XII.5.4. Meromorphic Functions

XII.5.4.1. Definition. Let Ω be a region in $\mathbb{C}$. A *meromorphic function* on Ω is a complex-valued function which is holomorphic on Ω except for (isolated) singularities, none of which is an essential singularity.

We do not exclude the case where the set of singularities is empty. Thus a holomorphic function on Ω is meromorphic on Ω.

XII.5.4.2. By our definition a meromorphic function can have removable singularities (some authors do not allow this). But any meromorphic function can be canonically extended to a meromorphic function with no removable singularities.

XII.5.4.3. Proposition. Let f and g be meromorphic functions on a region Ω. Then

(i) $f + g$, fg, and cf for any $c \in \mathbb{C}$ are meromorphic on Ω.

(ii) If g (extended) is not identically 0 on any component of Ω, then $\frac{f}{g}$ is meromorphic on Ω.

XII.5.4.4. In particular, a quotient of two holomorphic functions (e.g. polynomials) is meromorphic. (Such a quotient can have removable singularities, so this statement would be false if we did not allow removable singularities in meromorphic functions. Even XII.5.4.3.(i) would be false.)

XII.5.4.5. Say two meromorphic functions are equivalent if they are equal except where one has a removable singularity. It is easily checked that this is an equivalence relation. On the set of equivalence classes there are well-defined addition, multiplication, scalar multiplication, and division (by classes not identically 0 on a component). If Ω is connected, these operations make the set of equivalence classes into a field () which is an extension of $\mathbb{C}$ (identified with constant functions).

XII.5.4.6. A meromorphic function (by our definition) on a region Ω can have infinitely many singularities in Ω, but they can cluster only on the boundary of Ω. Some authors allow a meromorphic function to have only finitely many poles in Ω. Equivalence classes of such functions form a subring of the field described in XII.5.4.5., but it is not a subfield (e.g. a nonzero holomorphic function can have infinitely many zeroes in Ω, so its reciprocal has infinitely many poles).

XII.5.5. Exercises

XII.5.5.1. Schwarz Reflection Principle. If Ω is a region in $\mathbb{C}$, set $\bar{\Omega} = \{\bar{z} : z \in \Omega\}$. Then $\bar{\Omega}$ is also a region in $\mathbb{C}$.

(a) If f is holomorphic on Ω, for $z \in \bar{\Omega}$ set $f^*(z) = \overline{f(\bar{z})}$. Show that f^* is holomorphic on $\bar{\Omega}$. [Use the Cauchy-Riemann Equations.]

(b) Let Ω be a connected region containing an interval I on the real axis. Let f be holomorphic on Ω, with $f(z) \in \mathbb{R}$ for $z \in I$. Show that $f = f^*$ on $\Omega \cap \bar{\Omega}$ (which contains $\Omega \cap \mathbb{R}$.) [Use the Rigidity Theorem.]

(c) Let Ω be a region, and f be a function from Ω to $\mathbb{C}$ which is continuous on Ω and holomorphic on $\Omega \setminus \mathbb{R}$. Show that f is holomorphic on Ω. [Use Morera's Theorem.]

(d) Let Ω be a region in the upper half plane whose boundary contains an interval $I \subseteq \mathbb{R}$. Suppose f extends to be continuous on $\Omega \cup I$ and real-valued on I. Let Λ be the interior of $\Omega \cup I \cup \bar{\Omega}$ and define $g : \Lambda \to \mathbb{C}$ by

$$g(z) = \begin{cases} f(z) & \text{if} \quad z \in \Omega \cup I \\ f^*(z) & \text{if} \quad z \in \bar{\Omega} \end{cases} .$$

Show that g is holomorphic on Λ. We say f has been *reflected across* I.

(e) Use fractional linear transformations to extend to the case where I is replaced by an arc A of a circle (or interval on a line) and f takes values on A in another circle arc or line interval B.

XII.6. Mapping Properties of Analytic Functions

XII.6.1. The Complex Morse Lemma

There are complex analogs of V.10.5.2. and V.10.5.6..

XII.6.1.1. If f is analytic on an open disk D around z_0, then for any $n \in \mathbb{N}$

$$f(z) = f(z_0) + f'(z_0)(z - z_0) + \cdots + \frac{f^{(n-1)}(z_0)}{(n-1)!}(z - z_0)^{n-1} + \sum_{k=n}^{\infty} \frac{f^{(k)}(z_0)}{k!}(z - z_0)^k$$

for $z \in D$, so if we set

$$g_n(z) = \sum_{k=n}^{\infty} \frac{f^{(k)}(z_0)}{k!}(z - z_0)^{k-n}$$

for $z \in D$ (the power series converges u.c. to an analytic function on D), then

$$f(z) = f(z_0) + f'(z_0)(z - z_0) + \cdots + \frac{f^{(n-1)}(z_0)}{(n-1)!}(z - z_0)^{n-1} + (z - z_0)^n g_n(z)$$

for $z \in D$, and g_n is analytic on D.

XII.6.1.2. THEOREM. [COMPLEX GENERALIZED ONE-DIMENSIONAL MORSE LEMMA] Let $m \in \mathbb{N}$ and let f be analytic on an open disk D around z_0, with $f(z_0) = c$ and $f'(z_0) = \cdots = f^{(m-1)}(z_0) = 0$ but $f^{(m)}(z_0) \neq 0$. Then there is a conformal bijection ϕ from an open set Ω around 0 onto an open disk $\tilde{D} \subseteq D$ around z_0, with $\phi(0) = z_0$, such that

$$[f \circ \phi](w) = c + w^m$$

for all $w \in \Omega$.

PROOF: By V.10.5.2., for $z \in D$ f can be written $f(z) = c + (z - z_0)^m g_m(z)$ with g_m analytic on D and $g_m(z_0) \neq 0$. Thus there is an open disk $D_0 \subseteq D$ around z_0 in which $g_m(z)$ lies in an open disk U around $g_m(z_0)$ not containing 0. On U there is an analytic branch ρ of $z^{1/m}$. For $z \in D_0$ set

$$\psi(z) = (z - z_0)h(z)$$

where $h = \rho \circ g_m$. Then ψ is an analytic function on D_0, $\psi(z_0) = 0$, and

$$\psi'(z) = h(z) + (z - z_0)h'(z) \ .$$

Since $h(z_0) \neq 0$, $\psi'(z_0) \neq 0$. So ψ is a conformal bijection of a smaller disk $\tilde{D}$ around z_0 onto an open set Ω containing 0. Let $\phi : \Omega \to \tilde{D}$ be the inverse function. Then ϕ is also analytic by the Inverse Function Theorem (XII.1.2.10.). If $w = \psi(z) \in \Omega$, then

$$[f \circ \phi](w) = f(z) = c + (z - z_0)^m g_m(z) = c + [(z - z_0)h(z)]^m = c + \psi(z)^m = c + w^m \ .$$

XII.6.2. Local Mapping of an Analytic Function

Here is an important consequence of the Complex Morse Lemma:

XII.6.2.1. THEOREM. Let f be analytic on a region Ω, $z_0 \in \Omega$, $f(z_0) = c$. Suppose $f(z) - c$ has a zero of order n at z_0, i.e. $f'(z_0) = \cdots = f^{(n-1)}(z_0) = 0$, $f^{(n)}(z_0) \neq 0$. Then for every neighborhood U of z_0 there is a deleted neighborhood V of z_0 and a deleted neighborhood W of c, such that for each $w \in W$, there are exactly n solutions to the equation $f(z) = w$ in V, each of which is a simple zero of the function $f(z) - w$.

PROOF: By the Complex Morse Lemma, we may assume $z_0 = 0$ and f is of the form $f(z) = c + z^n$ on a neighborhood of 0, where it is obvious since every nonzero complex number w has exactly n n'th roots, each of which is a simple zero of $g(z) = z^n - w$. 

XII.6.2.2. In XII.6.2.1., we do not exclude the case $n = 1$, although this has already been proved ().

XII.6.2.3. COROLLARY. Let Ω be a connected region, and f a nonconstant analytic function on Ω. Then f is an open mapping: if U is an open subset of Ω, then $f(U)$ is open.

PROOF: Since Ω is connected, f is not constant in a neighborhood of any point. Thus if c is in the range of f, say $f(z_0) = c$, then f, z_0, and c satisfy the hypotheses of XII.6.2.1. for some n, and thus if U is any neighborhood of z_0 contained in Ω, then every w sufficiently close to c is the image of an element of U.

XII.6.2.4. COROLLARY. Let f be analytic and one-to-one on a region Ω. Then f' is never zero on Ω.

XII.6.2.5. XII.6.2.3. gives a quick alternate proof of the Maximum Modulus Theorem ().

XII.6.2.6. See XII.7.5.1. for another proof (the standard proof in texts) of XII.6.2.1..

XII.7. Residues and the Principle of the Argument

XII.7.1. The Residue Theorem

XII.7.1.1. DEFINITION. Let f be an analytic function with an isolated singularity at z_0. Write

$$f(z) = \sum_{k=0}^{\infty} a_k (z - z_0)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z - z_0)^k}$$

converging u.c. on a deleted neighborhood of z_0. The number b_1 is the *residue* of f at z_0, denoted $Res(f, z_0)$.

XII.7.1.2. Because the series representing f near z_0 is unique, the residue is well defined. Note that the residue exists at any type of singularity, not just a pole, although the residue at a removable singularity is always 0. The residue at a simple pole is always nonzero, and the residue at a higher-order pole or essential singularity may or may not be zero.

XII.7.1.3. Why single out b_1? The underlying reason is that the $\frac{b_1}{z-z_0}$ is the only term in the series which does not have an antiderivative on a deleted neighborhood of z_0 (if $b_1 \neq 0$).

XII.7.1.4. If f and g have singularities at z_0, so does $f+g$, and $Res(f+g, z_0) = Res(f, z_0) + Res(g, z_0)$ since the series can be added term-by-term. In particular, if f has a singularity at z_0 and g is analytic in a neighborhood of z_0 (or has a removable singularity at z_0), then $Res(f + g, z_0) = Res(f, z_0)$.

The main theorem of this section, one of the important theorems of Complex Analysis, is:

XII.7.1.5. THEOREM. [RESIDUE THEOREM] Let f be analytic on a region Ω except for isolated singularities. Let γ be a simple closed curve in Ω not passing through any of the singularities of f, such that the interior of γ is contained in Ω. Let $z_1, \ldots, z_n$ be the singularities of f inside γ. Then

$$\int_\gamma f = 2\pi i \sum_{k=1}^{n} Res(f, z_k) \ .$$

(There can be only finitely many singularities inside γ by compactness since the singularities are isolated.)

We give two versions of the proof (they are not really different).

XII.7.1.6. The first step is to note that if $\gamma_1, \ldots, \gamma_n$ are boundary circles of disjoint disks around the z_k contained in the interior of γ, then

$$\int_{\gamma-\gamma_1-\cdots-\gamma_n} f = 0$$

by (), and thus

$$\int_\gamma f = \sum_{k=1}^{n} \int_{\gamma_k} f \ .$$

Thus we may assume that γ is a circle in Ω centered at some z_j whose interior contains no other singularities of f (and not passing through any singularities). Thus the series representation

$$\sum_{k=0}^{\infty} a_k (z - z_j)^k + \sum_{k=1}^{\infty} \frac{b_k}{(z - z_j)^k}$$

for f around z_j converges u.c. to f on the deleted disk bounded by γ, and in particular converges uniformly to f on γ.

XII.7.1.7. The first way to finish the proof is to note that since the series converges uniformly on γ, the series

$$\sum_{k=0}^{\infty} \left[\int_\gamma a_k (\zeta - z_j)^k \, d\zeta \right] + \sum_{k=1}^{\infty} \left[\int_\gamma \frac{b_k}{(\zeta - z_j)^k} \, d\zeta \right]$$

converges to $\int_\gamma f$. Each of the terms has an antiderivative on $\mathbb{C} \setminus \{z_j\}$, thus the integral around γ is 0, except the $\frac{b_1}{\zeta - z_j}$ term. By (),

$$\int_\gamma \frac{b_1}{\zeta - z_j} \, d\zeta = 2\pi i b_1 \ .$$

XII.7.1.8. Alternatively, $\sum_{k=0}^{\infty} a_k (z - z_j)^k$ converges uniformly on and inside γ to an analytic function g, whose integral around γ is 0. And the series $\sum_{k=2}^{\infty} \frac{b_k}{(z-z_j)^k}$ converges u.c. on $\mathbb{C} \setminus \{z_j\}$ to an analytic function h. The function h has an antiderivative on $\mathbb{C} \setminus \{z_j\}$ by (), so its integral around γ is 0. We have $f(z) = g(z) + h(z) + \frac{b_1}{z - z_j}$ for z on and inside γ ($z \neq z_j$). So

$$\int_\gamma f = \int_\gamma g + \int_\gamma h + \int_\gamma \frac{b_1}{\zeta - z_j} \, d\zeta = 0 + 0 + 2\pi i b_1 \ .$$

This completes the proof of the Residue Theorem. 

XII.7.1.9. Note that from the second proof (or just from XII.3.2.3.), if f has a singularity at z_0, then $Res(f, z_0) = 0$ if and only if f has an antiderivative on a deleted neighborhood of z_0.

XII.7.1.10. It has been suggested that CAUCHY got the idea for this theorem from his dog, which left a residue at every pole. [Actually CAUCHY did not use the term *pole*, although he did introduce and use *résidue*.]

XII.7.2. Principle of the Argument

A clever application of the Residue Theorem has far-reaching implications.

XII.7.2.1. Let f be meromorphic on a region Ω, and γ a simple closed curve in Ω (this can be relaxed, cf. ()) not passing through any zero or pole of f (so f is not identically zero inside γ). Then f has only finitely many zeroes inside γ, say at $a_1, \ldots, a_r$ (some may be multiple zeroes), and finitely many poles inside γ, say at $b_1, \ldots, b_s$, since zeroes and poles are isolated in Ω. We will apply the Residue Theorem to the function $\frac{f'}{f}$ to count the number (including multiplicity) of zeroes and poles of f inside γ.

One technicality often overlooked: a meromorphic function (by our definition) can have removable singularities, some of which may become zeroes when filled in. We will assume all removable singularities of f, or at least all which become zeroes (the others do not cause problems), have been removed.

XII.7.2.2. LEMMA. If f is meromorphic on Ω, and not identically zero on any connected component, then

(i) The function $\frac{f'}{f}$ is also meromorphic on Ω, with poles precisely at the zeroes and poles of f, all of which are simple poles.

(ii) If f has a zero at $a \in \Omega$ of order n, then $Res\left(\frac{f'}{f}, a\right) = n$.

(iii) If f has a pole at $b \in \Omega$ of order m, then $Res\left(\frac{f'}{f}, b\right) = -m$.

((ii) and (iii) can be combined into one statement if a pole of order m is considered to be a zero of order $-m$.)

PROOF: The function $\frac{f'}{f}$ is analytic except at the zeroes and poles of f. If f has a zero of order n at a, then $f(z) = (z-a)^n\phi(z)$ on a neighborhood U of a for some analytic function ϕ with $\phi(z) \neq 0$ for $z \in U$. Then $f'(z) = n(z-a)^{n-1}\phi(z) + (z-a)^n\phi'(z)$ on U, so

$$\frac{f'(z)}{f(z)} = \frac{n(z-a)^{n-1}\phi(z)}{(z-a)^n\phi(z)} + \frac{(z-a)^n\phi'(z)}{(z-a)^n\phi(z)} = \frac{n}{z-a} + \frac{\phi'(z)}{\phi(z)}$$

for $z \in U \setminus a$. Since $\frac{\phi'}{\phi}$ is analytic on U, $\frac{f'}{f}$ has a simple pole at a, with $Res\left(\frac{f'}{f}, a\right) = n$.

Similarly, if f has a pole at b of order m, then $f(z) = (z-b)^{-m}\psi(z)$ on a deleted neighborhood V of b for some analytic function ψ on $W := V \cup \{b\}$ with $\psi(z) \neq 0$ for $z \in W$. Then $f'(z) = -m(z-b)^{-m-1}\psi(z) + (z-b)^{-m}\psi'(z)$ on V, so

$$\frac{f'(z)}{f(z)} = \frac{-m(z-b)^{-m-1}\psi(z)}{(z-b)^{-m}\psi(z)} + \frac{(z-b)^{-m}\psi'(z)}{(z-b)^{-m}\psi(z)} = \frac{-m}{z-b} + \frac{\psi'(z)}{\psi(z)}$$

for $z \in V$. Since $\frac{\psi'}{\psi}$ is analytic on W, $\frac{f'}{f}$ has a simple pole at b, with $Res\left(\frac{f'}{f}, b\right) = -m$.

XII.7.2.3. THEOREM. Let f be meromorphic of a region Ω, and γ a simple closed curve in Ω not passing through any zero or pole of f, and such that the interior of γ is contained in Ω. Let Z_f be the number of zeroes of f inside γ and P_f the number of poles of f inside γ, both counted with multiplicities. Then

$$\int_\gamma \frac{f'}{f} = 2\pi i(Z_f - P_f) \ .$$

In particular, if f is analytic on and inside γ, so $P_f = 0$, then

$$Z_f = \frac{1}{2\pi i}\int_\gamma \frac{f'}{f} \ .$$

PROOF: Apply the Residue Theorem to $\frac{f'}{f}$ and use Lemma XII.7.2.2.. 👍

XII.7.2.4. Note that the Residue Theorem also holds if f has some essential singularities inside γ, but in XII.7.2.3. f cannot have essential singularities inside γ. (But see XII.7.5.2..) ✋

XII.7.2.5. The contour integral in the theorem is sometimes called the *logarithmic integral* of f around γ, since the integrand $\frac{f'}{f}$ is the derivative of $\log f$ (although $\log f$ is not well defined on a large enough region in general; indeed, if it were, the contour integral would be 0).

XII.7.2.6. This leads to a very nice geometric interpretation of the logarithmic integral. The curve $\gamma_f(t) = f(\gamma(t))$ is a closed curve in $\mathbb{C}$ (not a simple closed curve in general) not passing through 0. It thus has a well-defined winding number $\omega(f \circ \gamma, 0)$ () around 0. The quantity $2\pi\omega(f \circ \gamma, 0)$ is often denoted $\Delta Arg(f \circ \gamma)$, the *change in argument* as $f \circ \gamma$ is traversed.

XII.7.2.7. PROPOSITION. Under the hypotheses of XII.7.2.3.,

$$2\pi i\omega(f \circ \gamma, 0) = i\Delta Arg(f \circ \gamma) = \int_\gamma \frac{f'}{f} \ .$$

Thus XII.7.2.3. can be rephrased:

XII.7.2.8. THEOREM. [PRINCIPLE OF THE ARGUMENT] Let f be meromorphic of a region Ω, and γ a simple closed curve in Ω not passing through any zero or pole of f, and such that the interior of γ is contained in Ω. Let Z_f be the number of zeroes of f inside γ and P_f the number of poles of f inside γ, both counted with multiplicities. Then

$$\Delta Arg(f \circ \gamma) = 2\pi(Z_f - P_f) \ .$$

In particular, if f is analytic on and inside γ, so $P_f = 0$, then

$$Z_f = \omega(f \circ \gamma, 0) \ .$$

XII.7.2.9. This can be considered a surprising result, since the winding number of $f \circ \gamma$ around 0 has no obvious *a priori* connection with the number of zeroes and poles of f.

XII.7.2.10. The best way to visualize and interpret this is to consider $f \circ \gamma$ as a contour on the Riemann surface () of $\log z$. It is not a closed contour in general: its endpoints lie on different sheets, and the value of the logarithm differs by an integer multiple of $2\pi i$ which is exactly the change of argument. The derivative of $\log f$ is $\frac{f'}{f}$, so if γ is parametrized on $[0,1]$, by XII.2.1.8. we have

$$\int_\gamma \frac{f'}{f} = \log(f(\gamma(1)) - \log(f(\gamma(0)) = i\Delta Arg(f \circ \gamma) \ .$$

(This argument is slightly informal but can be carefully justified, e.g. by analytic continuation, breaking up the path $f \circ \gamma$ into segments, each of which lie in a branch of $\log z$ agreeing at the cut points.)

XII.7.3. Rouché's Theorem

Informally, the number of zeroes of an analytic function inside a simple closed curve is "invariant under small perturbations of the function." Rouché's Theorem is a precise version:

XII.7.3.1. Theorem. [Rouché's Theorem] Let f and h be meromorphic on Ω, and γ a simple closed curve in Ω not passing through any zero or pole of f, and such that the interior of γ is contained in Ω. Suppose $|h(z)| < |f(z)|$ for all $z \in \gamma$ (so γ does not pass through any poles of h). Then $Z_{f+h} - P_{f+h} = Z_f - P_f$. If f and h are analytic on the interior of γ, then f and $f+h$ have the same number of zeroes inside γ.

Proof: By XII.7.2.8. the statement is equivalent to the statement that $\omega((f+h) \circ \gamma) = \omega(f \circ \gamma)$. For $0 \le t \le 1$ set

$$\tilde{\gamma}_t = (f + th) \circ \gamma \ .$$

Then $(\tilde{\gamma}_t)$ is a homotopy of closed paths in $\mathbb{C}$, and $\tilde{\gamma}_0 = f \circ \gamma$, $\tilde{\gamma}_1 = (f+h) \circ \gamma$. For each t and each $z \in \gamma$ we have

$$f(z) + th(z) = f(z)\left(1 + \frac{th(z)}{f(z)}\right)$$

and the second factor lies in the open ball of radius 1 around 1, hence is never zero. Since the first factor is also never zero, the homotopy $(\tilde{\gamma}_t)$ lies in $\mathbb{C} \setminus \{0\}$. Thus $\omega(\tilde{\gamma}_t, 0)$ is constant by (). 👍

XII.7.3.2. Rouché's Theorem is sometimes called the "dog-walking theorem." If a person walks a dog around $\mathbb{C}$ on a leash of variable length, and $f(\gamma(t))$ denotes the person's position at time t, and $f(\gamma(t)) + h(\gamma(t))$ the position of the dog at time t, if there is a pole at the origin and the path $f(\gamma(t))$ of the person winds around the pole some number of times, the path of the dog will wind around the same number of times and the leash will not get tangled around the pole, as long as the length $|h(\gamma(t))|$ of the leash is always kept less than the distance $|f(\gamma(t))|$ of the person from the pole. (It appears that dogs have played a significant role in the history of Complex Analysis; cf. XII.7.1.10..)

XII.7.4. Hurwitz's Theorem

The following theorem has several interesting and useful corollaries, any of which can be called "Hurwitz's Theorem" (and are in various references).

XII.7.4.1. THEOREM. [HURWITZ'S THEOREM] Let Ω be an open set in $\mathbb{C}$, and (f_n) a sequence of holomorphic functions on Ω converging u.c. on Ω to a (holomorphic) function f. Suppose f has a zero of order m at $z_0 \in \Omega$, and let γ be a circle centered at z_0 bounding a closed disk contained in Ω and containing no other zeroes of f. Then, for all sufficiently large n, f_n has exactly m zeroes inside γ, counted with multiplicity.

PROOF: Since $f_n \to f$ uniformly on γ, f_n has no zeroes on γ for sufficiently large n. Thus, passing to a tail of the sequence (f_n), we may assume no f_n has zeroes on γ. Then $\frac{f_n'}{f_n} \to \frac{f'}{f}$ uniformly on γ, so if Z_{f_n} is the number of zeroes of f_n inside γ, we have

$$Z_{f_n} = \frac{1}{2\pi i}\int_\gamma \frac{f_n'}{f_n} \to \frac{1}{2\pi i}\int_\gamma \frac{f'}{f} = m \ .$$

XII.7.4.2. COROLLARY. Let Ω be a connected open set in $\mathbb{C}$, and (f_n) a sequence of holomorphic functions on Ω converging u.c. on Ω to a (holomorphic) function f which is not identically 0. If $f(z_0) = 0$, then there is a sequence (k_n) in $\mathbb{N}$ and a sequence (z_n) in Ω with $z_n \to z_0$ and $f_{k_n}(z_n) = 0$ (informally, every zero of f is a limit of zeroes of the f_n).

PROOF: Let (γ_n) be a sequence of circles centered at z_0 of radius decreasing to 0, within a closed disk contained in Ω containing no other zeroes of f.

XII.7.4.3. The restriction that f be not identically 0 is necessary: consider the sequence $f_n(z) = \frac{e^z}{n}$.

XII.7.4.4. COROLLARY. Let Ω be a connected open set in $\mathbb{C}$, and (f_n) a sequence of holomorphic functions on Ω converging u.c. on Ω to a (holomorphic) function f which is not identically 0. If each f_n has at most m zeroes in Ω (counted with multiplicity), then f also has at most m zeroes in Ω (counted with multiplicity).

PROOF: Suppose f has zeroes at $z_1, \ldots, z_r$ of multiplicity $m_1, \ldots, m_r$ respectively, with $m_1 + \cdots + m_r > m$. For each k, let γ_k be a small circle centered at z_k so that the circles do not overlap and the bounded closed disks are contained in Ω and contain no other zeroes of f. Then, for sufficiently large n, f_n has m_k zeroes inside γ_k for each k, and hence more than m zeroes in all, a contradiction.

XII.7.4.5. Under the hypotheses, even if all f_n have exactly m zeroes in Ω, the limit function can have fewer than m if the zeroes of the f_n cluster on the boundary of Ω. As a very simple case, let Ω be the open right half plane and $f_n(z) = z - \frac{1}{n}$ for each n.

The special case $m = 0$ is often stated as Hurwitz's Theorem:

XII.7.4.6. Corollary. Let Ω be a connected open set in $\mathbb{C}$, and (f_n) a sequence of holomorphic functions on Ω converging u.c. on Ω to a (holomorphic) function f which is not identically 0. If each f_n is never zero in Ω, then f is also never zero in Ω.

Again, the example $f_n(z) = \frac{e^z}{n}$ shows that the assumption that f is not identically 0 is necessary.

The following consequence of a special case of XII.7.4.4. is especially important:

XII.7.4.7. Corollary. Let Ω be a connected open set in $\mathbb{C}$, and (f_n) a sequence of holomorphic functions on Ω converging u.c. on Ω to a (holomorphic) function f which is not constant. If each f_n is one-to-one, then f is also one-to-one.

Proof: For any $w \in \mathbb{C}$, the function $g_n = f_n - w$ has at most one zero in Ω, and hence the limit function $f - w$ also has at most one zero in Ω. 👍

XII.7.4.8. This result can be generalized: if each f_n is at most m-to-one, and f is not constant, then it is at most m-to-one too.

XII.7.5. Exercises

XII.7.5.1. Use Rouché's Theorem to give an alternate proof of XII.6.2.1. (the proof found in most Complex Analysis texts). Suppose f is analytic on Ω, $z_0 \in \Omega$, $f(z_0) = c$, and $g(z) = f(z) - c$ has a zero of order n at z_0.

(a) There is a neighborhood Λ of z_0 such that neither g nor f' has a zero in $\Lambda \setminus \{z_0\}$. Let γ be the boundary circle of a closed disk centered at z_0 contained in Λ.

(b) Let ϵ be less than the minimum of g on γ. If $|w - c| \leq \epsilon$, then the constant function $h(z) = c - w$ satisfies $|h(z)| < |g(z)|$ on γ.

(c) Apply Rouché's Theorem to conclude that $f(z) - w = g(z) + h(z)$ has the same number of zeroes inside γ as $g(z)$.

(d) Give an alternate argument for (c) using XII.7.2.3. but not Rouché's Theorem: for $|w - c| \leq \epsilon$ set

$$\phi(w) = \frac{1}{2\pi i} \int_\gamma \frac{f'(\zeta)}{f(\zeta) - w}\, d\zeta \ .$$

Show that ϕ is continuous, and use XII.7.2.3. to show that ϕ is integer-valued; thus ϕ is constant. By XII.7.2.3., $\phi(c) = n$.

XII.7.5.2. (a) If f has an essential singularity at z_0, then by the Big Picard Theorem () $\frac{f'}{f}$ almost always has a singularity at z_0 which is not isolated. The only exception is when 0 is the excluded value of f near z_0.

(b) The standard example of the exception in (a) is when $f = e^g$, where g has a pole or essential singularity at z_0. Show that in this case $Res\left(\frac{f'}{f}, z_0\right) = 0$. [$\frac{f'}{f} = g'$ near z_0.]

(c) Is it true that whenever f has an essential singularity at z_0, and is nonzero in a deleted neighborhood of z_0, then $Res\left(\frac{f'}{f}, z_0\right) = 0$ (i.e. $\frac{f'}{f}$ has an antiderivative on a deleted neighborhood of z_0, cf. XII.7.1.9.)? This seems unlikely, but if true XII.7.2.3. could be extended to allow essential singularities, as long as f has only finitely many zeroes in any compact subset of Ω.

XII.8. Conformal Equivalence and the Riemann Mapping Theorem

Throughout this section, we will let $\mathbb{D}$ denote the open unit disk in $\mathbb{C}$.

XII.8.1. The Schwarz Lemma

The Schwarz Lemma concerns analytic functions from $\mathbb{D}$ to $\mathbb{D}$. It is a simple consequence of XII.5.1.1. and the Maximum Modulus Theorem XII.3.4.3., but has remarkable consequences.

XII.8.1.1. Theorem. [Schwarz Lemma] Let f be an analytic function from $\mathbb{D}$ to $\mathbb{D}$ with $f(0) = 0$. Then

(i) $|f(z)| \leq |z|$ for all $z \in \mathbb{D}$, and $|f'(0)| \leq 1$.

(ii) If $|f(z)| = |z|$ for some $z \in \mathbb{D}$, $z \neq 0$, or if $|f'(0)| = 1$, then there is a $c \in \mathbb{C}$, $|c| = 1$, with $f(z) = cz$ for all $z \in \mathbb{D}$ (i.e. f is geometrically just a rotation around 0). In fact, in either case $c = f'(0)$.

Proof: There is an analytic function g on $\mathbb{D}$ with $f(z) = zg(z)$ by XII.5.1.1. (or XII.5.2.7.), and

$$g(0) = \lim_{z \to 0} \frac{f(z)}{z} = f'(0) \ .$$

If $0 < r < 1$, for $|z| = r$ we have

$$|g(z)| = \frac{|f(z)|}{r} < \frac{1}{r}$$

and thus by XII.3.4.2. we have $|g(z)| < \frac{1}{r}$ for all z, $|z| \leq r$. Letting $r \to 1$, we obtain $|g(z)| \leq 1$ for all $z \in \mathbb{D}$, and thus $|f(z)| \leq |z|$ for $z \in \mathbb{D}$. If $|g(z)| = 1$ for some $z \in \mathbb{D}$, then g is constant by XII.3.4.2., of absolute value 1, and equal to $g(0) = f'(0)$. 👍

XII.8.1.2. If f is an analytic bijection from $\mathbb{D}$ to $\mathbb{D}$ (so f^{-1} is too, cf. XII.8.2.1.), with $f(0) = 0$, applying the Schwarz Lemma to f and f^{-1} we obtain that $|f(z)| = |z|$ for all $z \in \mathbb{D}$, and hence $f(z) = cz$ for some $c \in \mathbb{C}$, $|c| = 1$. Thus analytic bijections from $\mathbb{D}$ to $\mathbb{D}$ are quite rigid.

XII.8.2. Conformal Equivalence

The following result is a combination of XII.1.2.10., XII.1.1.12., and XII.6.2.4.:

XII.8.2.1. Proposition. Let Ω and Λ be open sets in $\mathbb{C}$, and f an analytic bijection from Ω to Λ. Then

(i) f' is never zero on Ω.

(ii) f is a conformal mapping.

(iii) f^{-1} is an analytic, hence conformal, bijection from Λ to Ω.

XII.8.2.2. DEFINITION. Let Ω and Λ be open sets in $\mathbb{C}$. An analytic bijection from Ω to Λ is called a *conformal bijection* or *conformal equivalence*. Ω and Λ are *conformally equivalent* if there is a conformal bijection between them.

XII.8.2.3. A composition of conformal equivalences is a conformal equivalence, and conformal equivalence is an equivalence relation on open subsets of $\mathbb{C}$. Conformally equivalent open sets are obviously homeomorphic, even diffeomorphic, but diffeomorphic open sets are not necessarily conformally equivalent (XII.8.2.4.). It is a remarkable fact that any two simply connected open sets in $\mathbb{C}$ are not only homeomorphic, but even conformally equivalent (if not all of $\mathbb{C}$) by the Riemann Mapping Theorem.

XII.8.2.4. EXAMPLE. Let C be the punctured plane $\mathbb{C} \setminus \{0\}$, D the punctured disk $\mathbb{D} \setminus \{0\}$, and A a proper annulus $\{z : r < |z| < R\}$, where $0 < r < R < \infty$. Then C, D, and A are all homeomorphic, even diffeomorphic. But no two are conformally equivalent. For any analytic function from C or D to a bounded set has a removable singularity at 0 by XII.5.2.7., so extends to an analytic function on $\mathbb{C}$ or $\mathbb{D}$ respectively. If f is an analytic function from C to a bounded set, then f extends to a bounded entire function, which must be constant by Liouville's Theorem. Thus C cannot be conformally equivalent to A or D (or indeed any bounded set).

It is a little harder to show that A and D are not conformally equivalent. Suppose f is a conformal equivalence from D to A. Then f extends to an analytic function g from $\mathbb{D}$ to $\bar{A}$. The function g cannot send 0 to a point of A: if $g(0) = f(z_0)$ for some $z_0 \in D$, then a small neighborhood of z_0 and small deleted neighborhood of 0 could not have disjoint images under f. Thus $g(0)$ lies on one of the boundary circles of A. But this is impossible since $g(\mathbb{D})$ is an open set in $\mathbb{C}$.

By a more delicate argument (see e.g. [Rud87]), if A_1 and A_2 are two proper annuli, $A_1 = \{z : r_1 < |z - z_1| < R_1\}$ and $A_2 = \{z : r_2 < |z - z_2| < R_2\}$ for $z_1, z_2 \in \mathbb{C}$, $0 < r_1 < R_1 < \infty$, $0 < r_2 < R_2 < \infty$, then A_1 and A_2 are always homeomorphic (diffeomorphic), but are conformally equivalent if and only if $\frac{R_2}{r_2} = \frac{R_1}{r_1}$ (i.e. A_1 and A_2 are similar). Thus conformal equivalence of annuli is quite rigid.

XII.8.3. Simply Connected Sets in $\mathbb{C}$

It is a remarkable fact, partly topological and partly analytic, that the open sets in $\mathbb{C}$ which are conformally equivalent to $\mathbb{C}$ or $\mathbb{D}$ can be cleanly characterized in a number of ways. We first recall a special case of a definition from topology ():

XII.8.3.1. DEFINITION. Let Ω be a nonempty open set in $\mathbb{C}$. Then Ω is *simply connected* if it is connected and every closed contour in Ω is homotopic in Ω to a constant.

Some authors do not require a simply connected space to be connected; but this seems a little silly, especially for open subsets of the plane. In fact, a simply connected space should be path-connected.

XII.8.3.2. THEOREM. Let Ω be a nonempty connected open set in $\mathbb{C}$ ($\mathbb{R}^2$). The following are equivalent:

Topological conditions:

(i) Ω is simply connected.

(ii) For any $p, q \in \Omega$, any two paths from p to q are homotopic in Ω.

(iii) Ω is contractible.

(iv) Ω is homeomorphic to $\mathbb{C}$ and $\mathbb{D}$.

Intermediate condition:

(v) For every closed contour γ in Ω and $z \in \mathbb{C} \setminus \Omega$, the winding number $w(\gamma, z)$ () of γ around z is 0.

Analytic conditions:

(vi) The contour integral of any holomorphic function on Ω around any closed curve in Ω is 0.

(vii) The contour integral of any holomorphic function on Ω along any contour γ in Ω depends only on the endpoints of γ.

(viii) Every holomorphic function on Ω has an antiderivative on Ω.

(ix) Ω is conformally equivalent to $\mathbb{C}$ or $\mathbb{D}$.

If Ω is bounded, these are also equivalent to

(x) $\partial\Omega$ is connected.

(xi) $\mathbb{C} \setminus \Omega$ is connected.

XII.8.3.3. The implications (iii) $\Rightarrow$ (i) $\Longleftrightarrow$ (ii) hold in any topological space (), and (ix) $\Rightarrow$ (iv) $\Rightarrow$ (iii) $\Rightarrow$ (i) are trivial. The implication (x) $\Rightarrow$ (xi) is true in great generality (XIII.13.1.11.), but (xi) $\Rightarrow$ (x) is much more special (cf. XII.8.3.10.). Conditions (i)–(iv) and (x) make sense for open sets in $\mathbb{R}^n$ for any n (and indeed much more generally; (iv) means Ω is homeomorphic to $\mathbb{R}^n$), but are not equivalent for $n \neq 2$: the interior of a solid torus in $\mathbb{R}^3$ satisfies (x) but not (i), and the open region between two concentric spheres in $\mathbb{R}^3$ satisfies (i) but not (iii) or (x). And a contractible open set in $\mathbb{R}^3$ is not homeomorphic to $\mathbb{R}^3$ in general (). (Note also that (i) $\Rightarrow$ (x) fails for bounded open sets in $\mathbb{R}$; (i)–(iv) are equivalent in $\mathbb{R}$ since a simply connected open set in $\mathbb{R}$ is just an open interval.) The implications (xi) $\Rightarrow$ (i) and (iv) $\Rightarrow$ (xi) do not hold for unbounded open sets in $\mathbb{R}^2$, e.g. $\mathbb{C} \setminus \{0\}$ and an infinite open strip. (If we work in the Riemann sphere, (i), (x), and (xi) are equivalent.)

XII.8.3.4. Condition (v) is called an "intermediate condition" since it is essentially topological, but only makes sense in $\mathbb{R}^2$ and is closely connected with contour integration. We have (v) $\Longleftrightarrow$ (vi) $\Longleftrightarrow$ (vii) $\Longleftrightarrow$ (viii) by () and (). If Ω is bounded, (xi) $\Rightarrow$ (v) since winding number is constant on connected subsets of $\mathbb{C} \setminus \Omega$ () and is 0 on the unbounded component. Also, (i) $\Rightarrow$ (vi) is ().

XII.8.3.5. Thus, we have the following implications:

$$\text{(ix)} \Rightarrow \text{(iv)} \Rightarrow \text{(iii)} \Rightarrow \text{(i)} \Longleftrightarrow \text{(ii)} \Rightarrow \text{(v)} \Longleftrightarrow \text{(vi)} \Longleftrightarrow \text{(vii)} \Longleftrightarrow \text{(viii)}$$

and, if Ω is bounded, (x) $\Rightarrow$ (xi) $\Rightarrow$ (v).

XII.8.3.6. To finish the proof of the theorem, we will show (viii) $\Rightarrow$ (ix) and, if Ω is bounded, (v) $\Rightarrow$ (x). The implication (viii) $\Rightarrow$ (ix) is the most spectacular result, called the Riemann Mapping Theorem; the proof is complicated and is given in XII.8.4.. In [GK06], an open set satisfying (viii) is called *holomorphically simply connected*, which seems like good terminology.

XII.8.3.7. Even the implication (i) $\Rightarrow$ (iv), a purely topological result, is highly nontrivial. The simplest proof of this implication seems to be via (ix) using the Riemann Mapping Theorem, a much stronger result! As noted above, in Euclidean spaces this result is special to $\mathbb{R}^2$.

The Bounded Case

To prove that (v) $\iff$ (x) $\iff$ (xi) it is convenient to prove a more general result:

XII.8.3.8. Theorem. Let Ω be a connected open set in S^1. Then (v) $\iff$ (x) $\iff$ (xi).

We first show (v) and (xi) are equivalent in a more general setting.

XII.8.3.9. Lemma. Let U be a proper open subset of S^1, not necessarily connected. Then the following are equivalent:

(v) Whenever γ is a simple piecewise-smooth closed curve in U and $p \in S^1 \setminus U$, and $S^1 \setminus \{p\}$ is smoothly identified with $\mathbb{C}$, the winding number $w(\gamma, z)$ () of γ around z is 0 for every $z \in \mathbb{C} \setminus U$.

(xi) $S^1 \setminus U$ is connected.

(In this case (v) means that every connected component of U is simply connected.)

Proof: (xi) $\Rightarrow$ (v): Take $p \in S^1 \setminus U$, and identify $S^1 \setminus \{p\}$ with $\mathbb{C}$. Then $\mathbb{C} \setminus U$ has no bounded component. If γ is a simple piecewise-smooth curve in U, then $f(z) = w(\gamma, z)$ is constant on connected components of $\mathbb{C} \setminus U$ and zero on any unbounded component, thus is 0 everywhere on $\mathbb{C} \setminus U$.

(v) $\Rightarrow$ (xi): Suppose $S^1 \setminus U$ is not connected. Then there are nonempty disjoint closed sets E and F with $E \cup F = S^1 \setminus U$. Fix $p \in F$ and identify $S^1 \setminus \{p\}$ with $\mathbb{C}$. Then E is a compact subset of $\mathbb{C}$ and $W := \mathbb{C} \setminus F = U \cup E$ is open. By XIII.25.1.36. there is a simple closed polygonal curve γ in W with E in the inside of γ. If γ is parametrized once around counterclockwise, then $w(\gamma, z) = 1$, and thus (v) does not hold. 👍

We now give the proof of Theorem XII.8.3.8..

Proof: We already have (x) $\Rightarrow$ (xi) $\iff$ (v). Suppose U is connected and $S^1 \setminus U$ is connected. Then U satisfies (v). Let $V = S^1 \setminus \bar{U}$. Then $S^1 \setminus V = \bar{U}$ is connected since U is connected (XIII.13.1.9.). Thus V also satisfies (v). Since U and V are disjoint and satisfy (v), so does $W = U \cup V$. Therefore W satisfies (xi), i.e. $S^1 \setminus W = \partial U$ is connected. 👍

XII.8.3.10. The implication (xi) $\Rightarrow$ (x) is false in general if S^1 is replaced by another closed surface. Let X be a torus in $\mathbb{R}^3$ which is a surface of rotation of a circle in the xz-plane around the z-axis. Then the xz-plane intersects the torus in two circles C_1 and C_2. These two circles divide X into two open cylinders U and V. Then $X \setminus U$ and $X \setminus V$ are connected, but $\partial U = \partial V = C_1 \cup C_2$ is not connected.

XII.8.4. The Riemann Mapping Theorem

The Riemann Mapping Theorem is one of the major theorems of Complex Analysis:

XII.8.4.1. Theorem. [Riemann Mapping Theorem] Let Ω be a holomorphically simply connected open set in $\mathbb{C}$, i.e. a nonempty open set satisfying (viii) of XII.8.3.2., with $\Omega \neq \mathbb{C}$. Then Ω is conformally equivalent to $\mathbb{D}$. More precisely, if $z_0 \in \Omega$, then there is a unique conformal equivalence $f : \Omega \to \mathbb{D}$ with $f(z_0) = 0$ and $f'(z_0)$ a positive real number.

XII.8.4.2. Note that the restriction $\Omega \neq \mathbb{C}$ is necessary: a conformal bijection from $\mathbb{C}$ to $\mathbb{D}$ would be a bounded nonconstant entire function, contradicting Liouville's Theorem ().

XII.8.4.3. We first show uniqueness of f, assuming existence; we will first relax the last condition and show near uniqueness in that setting. Suppose f and g are conformal equivalences from Ω to $\mathbb{D}$ with $f(z_0) = g(z_0) = 0$. Set $h = f \circ g^{-1}$; then h is a conformal bijection from $\mathbb{D}$ to $\mathbb{D}$, and $h(0) = 0$. Thus there is an $\alpha \in \mathbb{C}$, $|\alpha| = 1$, with $h(z) = \alpha z$ (). As a consequence, $f(z) = \alpha g(z)$, i.e. f is just g followed by a rotation (and vice versa). By the Chain Rule we have

$$\alpha = h'(0) = f'(g^{-1}(0))(g^{-1})'(0) = f'(z_0)\frac{1}{g'(z_0)}$$

(note that $g'(z_0) \neq 0$ by ()). If $f'(z_0)$ and $g'(z_0)$ are positive real numbers, then α is a positive real number of absolute value 1, i.e. $\alpha = 1$, $f = g$.

XII.8.4.4. To show existence, we roughly follow the exposition of [GK06]. Let $\mathcal{F}$ be the set of all one-to-one holomorphic functions $f : \Omega \to \mathbb{D}$ with $f(z_0) = 0$. We will show:

1. $\mathcal{F} \neq \emptyset$.
2. There is an $f \in \mathcal{F}$ for which $|f'(z_0)|$ is maximum for all functions in $\mathcal{F}$.
3. A function $f \in \mathcal{F}$ for which $|f'(z_0)|$ is maximum is a conformal bijection.
4. Such an f can be adjusted to make $f'(z_0)$ a positive real number.

As pointed out in [GK06], this outline can be motivated by the case where $\Omega = \mathbb{D}$ and $z_0 = 0$: a holomorphic map f from $\mathbb{D}$ to $\mathbb{D}$ with $f(0) = 0$ is a conformal bijection if and only if $|f'(0)| = 1$, which is the largest possible value of $|f'(0)|$ for holomorphic functions from $\mathbb{D}$ to $\mathbb{D}$ sending 0 to 0 by the Schwarz Lemma.

For both 1 and 3, we need the following lemma:

XII.8.4.5. LEMMA. Let Ω be a holomorphically simply connected open set in $\mathbb{C}$, and f holomorphic on Ω. Suppose f is never 0 on Ω. Then

(i) There is a holomorphic function g on Ω with $e^g = f$ (i.e. g is a "logarithm" for f).

(ii) There is a holomorphic function h on Ω with $h^2 = f$ (i.e. h is a "square root" for f).

PROOF: (i): Since f is never 0 on Ω, $\frac{f'}{f}$ is holomorphic on Ω. Let ϕ be an antiderivative for $\frac{f'}{f}$ on Ω. Fix a $z_0 \in \Omega$ and α a value for $\log(f(z_0))$, i.e. so that $e^\alpha = f(z_0)$. Let $g(z) = \phi(z) + (\alpha - \phi(z_0))$. Then g is an antiderivative for $\frac{f'}{f}$, and $g(z_0) = \alpha$, so $e^{g(z_0)} = f(z_0)$. Then, if $\psi = \frac{e^g}{f}$, we have, for all $z \in \Omega$,

$$\psi'(z) = \frac{f(z)e^{g(z)}g'(z) - e^{g(z)}f'(z)}{[f(z)]^2} = \frac{f(z)e^{g(z)}\frac{f'(z)}{f(z)} - e^{g(z)}f'(z)}{[f(z)]^2} = 0$$

so ψ is constant since Ω is connected. Since $\psi(z_0) = 1$, we have $e^{g(z)} = f(z)$ for all $z \in \Omega$.
(ii): Let g be as in (i), and let $h = e^{g/2}$. 👍

XII.8.4.6. We now prove 1. If Ω is bounded, we could just scale Ω by a small positive number and translate to get an element of $\mathcal{F}$. But Ω is not necessarily bounded, so we proceed as follows. $\Omega \neq \mathbb{C}$; fix $w_0 \in \mathbb{C}\setminus\Omega$, and let ϕ be the restriction to Ω of the function $z \mapsto \frac{1}{z-w_0}$. Then ϕ is holomorphic and one-to-one on Ω, and never takes the value 0. By XII.8.4.5., there is a holomorphic function h on Ω with $h^2 = \phi$. Then not only is h one-to-one, but if it takes the value c it cannot also take the value $-c$. Suppose it takes the value c. Since h is an open mapping, there is an $\epsilon > 0$ such that it takes all values in $B_\epsilon(c)$, and thus takes no values in $B_\epsilon(-c)$. Set

$$g(z) = \frac{\epsilon}{h(z) + c}$$

and note that if $z \in \Omega$, $|h(z) + c| \geq \epsilon$ and thus $|g(z)| \leq 1$; in fact, by the Maximum Modulus Theorem $|g(z)| < 1$. Also, g is one-to-one, i.e. g is a one-to-one holomorphic function from Ω to $\mathbb{D}$. We can correct g by composing with a Möbius transformation (XII.8.6.3.) to get a one-to-one holomorphic function $f : \Omega \to \mathbb{D}$ with $f(z_0) = 0$. Thus $f \in \mathcal{F}$.

XII.8.4.7. The proof of 2 is easy (given some previous results) except for one technicality. There is an $r > 0$ such that $\bar{B}_r(z_0) \subseteq \Omega$; thus by the first Cauchy Inequality we have $|f'(z_0)| \leq \frac{1}{r}$ for all $f \in \mathcal{F}$. Thus $d := \sup\{|f'(z_0)| : f \in \mathcal{F}\}$ is finite (and positive by ()). Choose a sequence (f_n) in $\mathcal{F}$ with $|f_n'(z_0)| > d - \frac{1}{n}$. By Montel's Theorem (XII.4.5.7.), (f_n) has a subsequence (f_{k_n}) which converges u.c. on Ω to a holomorphic function f. Then (f_{k_n}') converges u.c. to f' on Ω by XII.4.1.4., and thus $|f'(z_0)| = d$. So f is not constant. We have that $f : \Omega \to \bar{\mathbb{D}}$, and by the Maximum Modulus Theorem f maps Ω into $\mathbb{D}$ (in fact we will prove later that f maps Ω onto $\mathbb{D}$).

The technicality is that it is not obvious that f is one-to-one. But this follows immediately from XII.7.4.7.. Thus $f \in \mathcal{F}$.

XII.8.4.8. To prove 3, we prove the contrapositive: if $g \in \mathcal{F}$ is not a conformal equivalence, i.e. not onto $\mathbb{D}$, we will show that $|g(z_0)| < d$. Suppose $w_0 \in \mathbb{D}$ is not in $g(\Omega)$. Let ϕ be a Möbius transformation with $\phi(w_0) = 0$. Then $\phi \circ g$ is a one-to-one holomorphic function from Ω to $\mathbb{D}$, and does not take the value 0. By Lemma XII.8.4.5., there is an h, holomorphic on Ω, with $h^2 = \phi \circ g$. Then h is one-to-one and maps Ω into $\mathbb{D}$. Set $w_1 = h(z_0)$, and let ψ be a Möbius transformation with $\psi(w_1) = 0$. Thus $\theta = \psi \circ h$ is in $\mathcal{F}$. If $s(z) = z^2$, then s maps $\mathbb{D}$ to $\mathbb{D}$ and we have

$$g = \phi^{-1} \circ s \circ \psi^{-1} \circ \theta = \omega \circ \theta$$

where $\omega = \phi^{-1} \circ s \circ \psi^{-1}$. Then ω is a holomorphic function from $\mathbb{D}$ to $\mathbb{D}$, and $\omega(0) = 0$. Since ω is not one-to-one (because s is not one-to-one) and hence is not a rotation, we have $|\omega'(0)| < 1$ by the Schwarz Lemma. By the Chain Rule,

$$|g'(z_0)| = |\omega'(\theta(z_0))||\theta'(z_0)| = |\omega'(0)||\theta'(z_0)|$$

and, since $|\omega'(0)| < 1$ and $|\theta'(z_0)| > 0$, we have $|g'(z_0)| < |\theta'(z_0)| \leq d$.

XII.8.4.9. Step 4 is easy: If f is a conformal bijection from Ω to $\mathbb{D}$ (e.g. the one constructed in 2), then $f'(z_0) \neq 0$. Set $\alpha = \frac{f'(z_0)}{|f'(z_0)|}$ and $g(z) = \bar{\alpha} f(z)$. Then g is also a conformal bijection with $g(z_0) = 0$, and $g'(z_0) = |f'(z_0)| > 0$.

This completes the proof of the Riemann Mapping Theorem. 

XII.8.5. Extension to the Boundary

It will be convenient in this section to consider a conformal bijection f from $\mathbb{D}$ to a simply connected region Ω (the inverse of a conformal bijection from Ω to $\mathbb{D}$). Note that f is defined only on the open set $\mathbb{D}$. We now examine the question whether f can be extended to a function on $\bar{\mathbb{D}}$ which is at least continuous, or better. The existence of an extension is a somewhat subtle matter.

Elementary Considerations

XII.8.5.1. The first observation is that if one conformal bijection extends, so do all. If f and g are conformal bijections from $\mathbb{D}$ to Ω, then $f^{-1} \circ g$ is a conformal bijection from $\mathbb{D}$ to $\mathbb{D}$, hence a fractional linear transformation (XII.8.6.3.), which extends to a conformal bijection h from a neighborhood of $\bar{\mathbb{D}}$ to $\mathbb{C}$, and $h(\bar{\mathbb{D}}) = \bar{\mathbb{D}}$. If f extends to $\bar{f} : \bar{\mathbb{D}} \to \mathbb{C}$, then g extends to $\bar{g} = \bar{f} \circ (h|_{\bar{\mathbb{D}}})$. If $\bar{f}$ is a bijection and/or smooth, so is $\bar{g}$.

XII.8.5.2. If f extends to a continuous function $\bar{f}$ from $\bar{\mathbb{D}}$ to $\mathbb{C}$, then $\bar{f}(\bar{\mathbb{D}})$ is compact, hence bounded, and in particular Ω is bounded. So there is only a hope of such an extension if Ω is bounded, so we will assume this from now on (until ()). Also, if f extends to $\bar{f}$, then $\bar{f}$, and hence f also, is uniformly continuous (); conversely, if f is uniformly continuous, then it extends to $\bar{\mathbb{D}}$ since $\mathbb{C}$ is complete ().

XII.8.5.3. Since $\mathbb{D}$ is dense in $\bar{\mathbb{D}}$, if f extends to $\bar{f}$ on $\bar{\mathbb{D}}$ we must have $f(\mathbb{D}) = \Omega$ dense in $\bar{f}(\bar{\mathbb{D}})$, i.e. $\bar{f}(\bar{\mathbb{D}}) \subseteq \bar{\Omega}$. Since $\bar{f}(\bar{\mathbb{D}})$ is compact and contains Ω, we must have $\bar{f}(\bar{\mathbb{D}}) = \bar{\Omega}$. Since $\bar{\mathbb{D}}$ is the disjoint union of $\mathbb{D}$ and $\partial\mathbb{D} = \mathbb{T}$ and $f(\mathbb{D}) = \Omega$, we must have $\bar{f}(\mathbb{T}) \supseteq \bar{\Omega} \setminus \Omega = \partial\Omega$.

XII.8.5.4. PROPOSITION. If f extends continuously to $\bar{f}$ on $\bar{\mathbb{D}}$, then $\bar{f}(\mathbb{T}) = \partial\Omega$.

PROOF: For $0 < r < 1$ let $\mathbb{D}_r$ be the open disk of radius r around 0, and set $\Omega_r = f(\mathbb{D}_r)$. Then Ω_r is open. We have $f(\mathbb{D} \setminus \mathbb{D}_r) = \Omega \setminus \Omega_r$ since f is a homeomorphism, so

$$\bar{f}(\mathbb{T}) \subseteq \bar{f}(\bar{\mathbb{D}} \setminus \mathbb{D}_r) \subseteq \overline{\Omega \setminus \Omega_r} = \bar{\Omega} \setminus \Omega_r$$

for any r. Since $\cup_{r<1}\Omega_r = \Omega$, the result follows. 👍

XII.8.5.5. Thus if f extends to $\bar{f}$, we must have that $\partial\Omega$ is a continuous image of $\mathbb{T}$ (so could be called a "closed curve" although this can be misleading). This is a nontrivial restriction: $\partial\Omega$ can be very bad, e.g. the Warsaw Circle (XIII.36), a pseudocircle (XIII.19.5.34.), the Land of Wada, a set as in XIII.66 closed off on the right, or worse (but recall (XII.8.3.2.(x)) that it is always at least connected). In fact, since $\mathbb{T}$ is a continuous image of $[0, 1]$ and conversely, by the Hahn-Mazurkiewicz Theorem (XIII.14.5.18.) $\partial\Omega$ is a continuous image of $\mathbb{T}$ if and only if $\partial\Omega$ is locally connected. (Of course, there are more restrictions: for example, $\partial\Omega$ must have empty interior and "surround" a bounded simply connected open set. But $\partial\Omega$ can be rather pathological even if it is locally connected (XII.8.5.10.).)

The Locally Connected Case

The locally connected property of XII.8.5.5. suffices:

XII.8.5.6. THEOREM. Let Ω be a bounded simply connected open set in $\mathbb{C}$, and f a conformal bijection from $\mathbb{D}$ to Ω. Then f extends to a continuous $\bar{f} : \bar{\mathbb{D}} \to \bar{\Omega}$ if and only if $\partial\Omega$ is locally connected.

The proof of this theorem is beyond the scope of this book. See [Pom92] or, for a good alternate exposition, [Con95].

XII.8.5.7. EXAMPLE. Let Ω be $\mathbb{D}$ with the ray $[0, 1)$ on the real axis deleted (the *slit disk*). Then Ω is simply connected and $\partial\Omega$ is $\mathbb{T} \cup [0, 1)$, which is locally connected, so a conformal bijection from $\mathbb{D}$ to Ω extends to a continuous function $\bar{f}$ from $\bar{\mathbb{D}}$ onto $\bar{\Omega} = \bar{\mathbb{D}}$. But $\bar{f}$ is not a bijection since $\partial\Omega$ is not homeomorphic to $\mathbb{T}$, and the inverse function $f^{-1} : \Omega \to \mathbb{D}$ does not extend continuously to $\bar{\Omega}$ (this type of behavior is why we consider conformal bijections from $\mathbb{D}$ to Ω, not the reverse).

XII.8.5.8. The boundary $\partial\Omega$ can be much worse, even if locally connected. It is useful to make the following distinction. If Ω is a bounded simply connected open set in $\mathbb{C}$, let Λ be the interior of $\bar{\Omega}$. Then Λ is a regular open set, $\Omega \subseteq \Lambda$, and $\bar{\Lambda} = \bar{\Omega}$, so Ω is dense in Λ and $\partial\Lambda \subseteq \partial\Omega$.

XII.8.5.9. DEFINITION. $\partial\Lambda$ is called the *regular boundary* of Ω, denoted $\partial_r\Omega$. The complement $\partial\Omega \setminus \partial_r\Omega = \Lambda \cap \partial\Omega$ is called the *inner boundary* of Ω, denoted $\partial_i\Omega$.

XII.8.5.10. EXAMPLES. (i) If Ω is a regular open set, e.g. $\mathbb{D}$ or, more generally, the interior of a Jordan curve, or even the interior of the Warsaw Circle, then $\Lambda = \Omega$ so $\partial_r\Omega = \partial\Omega$ and $\partial_i\Omega = \emptyset$.

(ii) We can have $\partial_r\Omega = \partial\Omega$ even if Ω is pathological, e.g. if Ω is one of the Lakes of Wada.

(iii) Let Ω be the slit disk $\mathbb{D} \setminus [0,1)$. Then $\Lambda = \mathbb{D}$, $\partial_r\Omega$ is $\mathbb{T}$, and $\partial_i\Omega = [0,1)$.

(iv) $\partial_r\Omega$ can be nice even if $\partial\Omega$ is bad. Let Ω be the interior of (); then $\partial_r\Omega$ is the bounding square.

(v) Let Ω be the annulus $\{z : 1 < |z| < 2\}$ with the open segment $(1,2)$ removed. Then Ω is simply connected, and $\partial\Omega$ consists of the two boundary circles and the segment $(1,2)$. Λ is the entire annulus, and thus is not simply connected; $\partial_r\Omega$ consists of the two boundary circles, and $\partial_i\Omega$ the segment $(1,2)$.

(vi) Let C be the Cantor set () as a subset of $[0,1]$. Remove from $\mathbb{D}$ the points of C, and for each open interval I in $[0,1]$ removed in the construction of C, also remove the closed disk with I as diameter. See Figure (). Let Ω be the remainder. Then Ω is a simply connected regular open set, so $\partial_r\Omega = \partial\Omega$ consists of $\mathbb{T}$ along with C and the circles bounding the removed disks. Thus $\partial\Omega$ is locally connected but looks nothing like a dendrite (). This example can be extended by removing small copies of the removed set radially from a dense set of points in $\mathbb{T}$ and densely around all boundary circles of the removed disks, so $\partial\Omega$ is not locally a dendrite around any point.

(vii) Remove from $\mathbb{D}$ the segment $[0,1)$ and the closed disk of radius $\frac{1}{2(n+1)^2}$ around $\frac{1}{n}$ for every $n \geq 2$. Then Ω is simply connected, and $\partial\Omega$ is locally connected. Λ consists of $\mathbb{D}$ with 0 and a sequence of disjoint closed disks converging to 0 removed. $\partial_r\Omega$ consists of $\mathbb{T}$ along with 0 and the boundary circles of the removed disks, and thus is not locally connected at 0. $\partial_i\Omega$ consists of the open segments on the real axis between the removed disks.

These examples show that $\partial\Omega$, even if locally connected, need not look anything like a Jordan curve. See XII.8.6.7. for more properties.

The Jordan Curve Case

XII.8.5.11. Let Ω be a bounded simply connected open set in $\mathbb{C}$, and f a conformal bijection from $\mathbb{D}$ to Ω. If f extends to an injective (hence bijective) continuous function (hence a homeomorphism) from $\bar{\mathbb{D}}$ to $\bar{\Omega}$, then $\bar{f}$ gives a homeomorphism from $\mathbb{T}$ to $\partial\Omega$, i.e. $\partial\Omega$ is a Jordan curve () in $\mathbb{C}$. Conversely:

XII.8.5.12. THEOREM. Let Ω be a bounded simply connected open set in $\mathbb{C}$, and f a conformal bijection from $\mathbb{D}$ to Ω. Then f extends to a continuous bijection $\bar{f} : \bar{\mathbb{D}} \to \bar{\Omega}$ if and only if $\partial\Omega$ is a Jordan curve.

This can be deduced from XII.8.5.6.; for more direct proofs see e.g. [Rud87] or [GK06].

Uniqueness

We can refine XII.8.5.12. to show an existence and uniqueness result once three points on the boundary are specified:

XII.8.5.13. THEOREM. Let Ω be a bounded simply connected open set in $\mathbb{C}$ with $\partial\Omega$ a Jordan curve. Let $\{a,b,c\}$ be three distinct points in $\partial\Omega$ in counterclockwise order. If $\{a',b',c'\}$ are three distinct points in $\mathbb{T}$ in counterclockwise order, then there is a unique homeomorphism $\bar{f}$ from $\bar{\mathbb{D}}$ onto $\bar{\Omega}$ such that $f = \bar{f}|_\Omega$ is a conformal bijection from $\mathbb{D}$ onto Ω and $\bar{f}(a') = a$, $\bar{f}(b') = b$, $\bar{f}(c') = c$.

PROOF: There is a conformal bijection g from $\mathbb{D}$ to Ω, which extends to a homeomorphism $\bar{g} : \bar{\mathbb{D}} \to \bar{\Omega}$. Set $a'' = \bar{g}^{-1}(a)$, $b'' = \bar{g}^{-1}(b)$, $c'' = \bar{g}^{-1}(c)$. Then $\{a'', b'', c''\}$ are in counterclockwise order on $\mathbb{T}$. There is a (unique) Möbius transformation h sending $\mathbb{D}$ to $\mathbb{D}$ and sending $\{a', b', c'\}$ to $\{a'', b'', c''\}$ (). Then $\bar{f} = \bar{g} \circ h$ is the desired map. For uniqueness, if $\bar{f}_1$ and $\bar{f}_2$ are such functions, then $f_2^{-1} \circ f_1$ is a Möbius transformation from $\mathbb{D}$ to $\mathbb{D}$ which extends to a neighborhood and leaves a', b', c' fixed, hence is the identity. 👍

The Smooth Case

XII.8.5.14. THEOREM. Let Ω be a bounded simply connected open set in $\mathbb{C}$, and f a conformal bijection from $\mathbb{D}$ to Ω. Then f extends to a $\mathcal{C}^\infty$-diffeomorphism $\bar{f} : \bar{\mathbb{D}} \to \bar{\Omega}$ if and only if $\partial\Omega$ is a $\mathcal{C}^\infty$ Jordan curve.

One direction is obvious; for the other direction only smoothness of the extension is an issue. The proof of this direction is not easy [BK87]. (One has the feeling there should be a simpler proof.)

XII.8.5.15. It is much easier to show using the Schwarz Reflection Principle that if $\partial\Omega$ is an analytic Jordan curve, then the extension is analytic. See ().

XII.8.6. Exercises

XII.8.6.1. Let (Ω_n) be an increasing sequence of open subsets of $\mathbb{C}$, and $\Omega = \cup_n \Omega_n$. Show that if each Ω_n is simply connected, so is Ω. [Any closed path in Ω is contained in some Ω_n by compactness.]

XII.8.6.2. Let f be a bounded analytic function on $\mathbb{D}$, with $|f(z)| \leq M$ for all $z \in \mathbb{D}$. Let

$$f(z) = \sum_{k=0}^{\infty} \frac{f^{(k)}(0)}{k!} z^k$$

be the Taylor expansion around 0.

(a) Let $0 < r < 1$. Integrate $|f(z)|^2$ around the circle of radius r around 0 to obtain

$$\sum_{k=0}^{\infty} \left[\left| \frac{f^{(k)}(0)}{k!} \right|^2 r^k \right] \leq M^2 \ .$$

[Justify term-by-term integration and show the cross terms integrate to 0.]

(b) Let $r \to 1$ to conclude that

$$\sum_{k=0}^{\infty} \left| \frac{f^{(k)}(0)}{k!} \right|^2 \leq M^2 \ .$$

(c) Conclude from (b) that for any k, $|f^{(k)}(0)| \leq k!M$, with equality if and only if $f(z) = cz^k$ for some c, $|c| = M$.

XII.8.6.3. Fractional Linear Transformations. Let $a, b, c, d \in \mathbb{C}$, $ad - bc \neq 0$. A function

$$T_{a,b,c,d}(z) = \frac{az + b}{cz + d}$$

is called a *fractional linear transformation* or *Möbius transformation.* If $c = 0$, $T_{a,b,c,d}$ is an affine function from $\mathbb{C}$ to $\mathbb{C}$.

(a) Show that we may assume $ad - bc = 1$ without loss of generality (it is sometimes not convenient to do this, e.g. in the second part of (i)).

(b) $T_{a,b,c,d}$ is a meromorphic function whose derivative is never zero, hence a conformal map. If $c \neq 0$, it has a simple pole at $-\frac{d}{c}$ (if $c = 0$ it is an entire function). If $c \neq 0$, then

$$\lim_{z \to \infty} T_{a,b,c,d}(z) = \frac{a}{c}$$

(c) A composition of two fractional linear transformations is a fractional linear transformation (if a possible removable singularity is filled in).

(d) If $ad - bc = 1$, then $T_{a,b,c,d} \circ T_{d,-b,-c,a}$ and $T_{d,-b,-c,a} \circ T_{a,b,c,d}$ become the identity map on $\mathbb{C}$ when a removable singularity is filled in (if $c \neq 0$). Thus $T_{a,b,c,d}$ is a conformal equivalence from $\mathbb{C} \setminus \left\{-\frac{d}{c}\right\}$ to $\mathbb{C} \setminus \left\{\frac{a}{c}\right\}$ (if $c \neq 0$; otherwise it is a conformal bijection from $\mathbb{C}$ to $\mathbb{C}$), and the set of fractional linear transformations (with removable singularities removed) forms a group under composition.

(e) The map

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \mapsto T_{a,b,c,d}$$

is a group-homomorphism from $SL_2(\mathbb{C})$ onto the group of fractional linear transformations with kernel $\{\pm I\}$, thus drops to an isomorphism from $PSL_2(\mathbb{C}) = SL_2(\mathbb{C})/\{\pm I\}$.

(f) A fractional linear transformation $T_{a,b,c,d}$ can be thought of as a conformal map from the Riemann sphere $\mathbb{S}$ () to $\mathbb{S}$, sending $-\frac{d}{c}$ to ∞ and ∞ to $\frac{a}{c}$, or sending ∞ to ∞ if $c = 0$. (When thought of this way one does not have to worry about removable singularities.)

(g) A fractional linear transformation sends lines and circles to lines and circles (circles to circles if a line is regarded as a circle through ∞).

(h) If $\{z_1, z_2, z_3\}$ and $\{w_1, w_2, w_3\}$ are two sets of distinct points in $\mathbb{S}$, then there is a unique fractional linear transformation T with $T(z_j) = w_j$ for $1 \leq j \leq 3$.

(i) $T_{a,b,c,d}$ $(ad - bc = 1)$ sends $\mathbb{R} \cup \{\infty\}$ to $\mathbb{R} \cup \{\infty\}$ if and only if $a, b, c, d \in \mathbb{R}$. Determine when it sends the upper half plane to the upper half plane. T sends $\mathbb{D}$ onto $\mathbb{D}$ if and only if it is of the form

$$T(z) = \alpha \frac{z - z_0}{1 - \bar{z}_0 z}$$

for some $z_0 \in \mathbb{D}$ and $|\alpha| = 1$.

(j) Every conformal bijection from $\mathbb{D}$ to $\mathbb{D}$ is a fractional linear transformation. The same is true between any Ω and Λ each conformally equivalent to $\mathbb{D}$ via a fractional linear transformation (e.g. a half plane).

Caution: In some texts, fractional linear transformations (or "linear fractional transformations") are called "linear transformations." But most are not linear in the linear algebra sense, or even affine. More commonly, fractional linear transformations are called "bilinear," which is also not good terminology since they are not bilinear in any sense similar to III.11.13.1..

XII.8.6.4. Use fractional linear transformations to prove the following generalization of the Schwarz Lemma (*Pick's Theorem*):

THEOREM. Let f be an analytic function from $\mathbb{D}$ to $\mathbb{D}$, and $z_0 \in \mathbb{D}$. Then either f is a conformal bijection (fractional linear transformation of the form in XII.8.6.3.(i)), or, for all $z \in \mathbb{D}$, $z \neq z_0$,

$$\left|\frac{f(z)-f(z_0)}{1-\overline{f(z_0)}f(z)}\right| < \left|\frac{z-z_0}{1-\bar{z}_0 z}\right|$$

and

$$|f'(z_0)| < \frac{1-|f(z_0)|^2}{1-|z_0|^2} < \frac{1}{1-|z_0|^2}\ .$$

More generally, if f is an analytic function on $\{z : |z| < R\}$ and $|f(z)| < S$ for all such z, and $|z_0| < R$, then either f is a conformal bijection (which must be a fractional linear transformation), or

$$\left|S\frac{f(z)-f(z_0)}{S^2-\overline{f(z_0)}f(z)}\right| < \left|R\frac{z-z_0}{R^2-\bar{z}_0 z}\right|$$

for all z with $|z| < R$, $z \neq z_0$, and

$$|f'(z_0)| < \frac{R}{S}\frac{S^2-|f(z_0)|^2}{R^2-|z_0|^2}\ .$$

XII.8.6.5. Conformally Rigid Sets. Let Ω be $\mathbb{D}$ with finitely many points removed.

(a) Show that any conformal equivalence f from Ω to Ω extends to a conformal equivalence from $\mathbb{D}$ to $\mathbb{D}$, hence is a fractional linear transformation. [All the singularities are removable.]

(b) If Ω has three points z_1, z_2, z_3 removed, then f must permute $\{z_1, z_2, z_3\}$. There is at most one such f for any such permutation. [Use XII.8.6.3..] If z_1, z_2, z_3 are collinear, or lie on a circle not contained in $\mathbb{D}$, the permutation can only be the identity or the one interchanging z_1 and z_3.

(c) In the last case of (b), give a necessary and sufficient condition that there is an f that reverses order. This condition is rarely satisfied, and if not, the only conformal equivalence of Ω with itself is the identity. In particular, the only conformal equivalence of $\mathbb{D} \setminus \{0, 1/2, 3/4)\}$ with itself is the identity. (If Ω is $\mathbb{D}$ with more than three points removed, it is even harder for Ω to have a self-equivalence other than the identity.)

(d) More generally, two regions consisting of $\mathbb{D}$ with finitely many points removed are rarely conformally equivalent (for one thing, they cannot be if different numbers of points have been removed – they are not even homeomorphic!), and a conformal equivalence, if it exists, is usually unique. Give a necessary and sufficient condition that two regions consisting of $\mathbb{D}$ with three points removed are conformally equivalent. Contrast with the case where only two points have been removed.

XII.8.6.6. Let Ω and Λ be bounded simply connected open sets in $\mathbb{C}$ (so there is a homeomorphism, even a conformal bijection, from Ω to Λ).

(a) If $\partial\Omega$ is homeomorphic to $\partial\Lambda$, are $\bar{\Omega}$ and $\bar{\Lambda}$ necessarily homeomorphic under a homeomorphism sending Ω to Λ? (Taking Ω and Λ to be two of the Lakes of Wada may give a counterexample depending on how the construction is done.)

(b) If there is a homeomorphism from $\bar{\Omega}$ to $\bar{\Lambda}$ sending Ω to Λ (and hence sending $\partial\Omega$ to $\partial\Lambda$), does a conformal bijection from Ω to Λ necessarily extend to $\bar{\Omega}$? If the answer is no in general, give necessary and sufficient conditions for an extension.

(c) What if Ω and Λ are connected but not simply connected? (If Ω and Λ are not connected, the answer to (a) is no in general: let Ω be one of the Lakes of Wada and Λ the union of two of the lakes. And if the answer to (a) is yes, there is not a conformal bijection from Ω to Λ in general (XII.8.6.5.(d) or annuli XII.8.2.4.). The question in (b) asks: if there is a homeomorphism from $\bar{\Omega}$ to $\bar{\Lambda}$ sending Ω to Λ *and* there is a conformal bijection from Ω to Λ, does it extend?)

XII.8.6.7. Let Ω be a bounded simply connected open set in $\mathbb{C}$, and $\partial_r\Omega$ and $\partial_i\Omega$ as in XII.8.5.9.. Then $\partial\Omega$ is the disjoint union of $\partial_r\Omega$ and $\partial_i\Omega$; $\partial_r\Omega$ is closed, but $\partial_i\Omega$, if nonempty, is not closed.

(a) Show that $\partial_i\Omega$ is locally connected. [It is relatively open in $\partial\Omega$.] Note that $\partial_r\Omega$ need not be locally connected (XII.8.5.10.(vii)).

(b) Show that $\partial_i\Omega$ can contain no Jordan curves. [Ω is connected.] Note that $\partial_r\Omega$ can contain Jordan curves, even of arbitrarily small diameter (XII.8.5.10.(vi)).

(c) Let X be a connected (hence path-connected) component of $\partial_i\Omega$. Show that X is not closed, and $\bar{X} \setminus X$ consists of either one or two points of $\partial_r\Omega$ and if it is two, they must be in different connected components of $\partial_r\Omega$. Conclude that $\bar{X}$ is a dendrite ().

XII.8.6.8. Use the Jordan Curve Theorem XIII.19.1.20., Theorem XII.8.3.2.[(x) $\Rightarrow$ (iv)], and Theorem XII.8.5.12. to prove the Jordan-Schönflies Theorem XIII.19.1.21.. [Some additional argument is needed to match up the homeomorphisms on the inside and outside of the curve.]

XII.8.6.9. If X is a connected topological space, a point $p \in X$ is a *cut point* of X if $X \setminus \{p\}$ is not connected.

(a) If Ω is a bounded simply connected open set in $\mathbb{C}$, show that $\partial\Omega$ is a Jordan curve if and only if it is locally connected and has no cut points.

(b) There are one-dimensional continua in the plane which are locally connected with no cut points which are not Jordan curves, for example the letter θ. There are even one-dimensional continua in the plane which are locally connected with no "local cut points" which are not Jordan curves, such as the Sierpiński Gasket (XIII.19.5.10.) and Sierpiński Carpet (XIII.19.5.11.).

XII.8.6.10. Adapt the arguments in this section to the Riemann sphere to handle boundary behavior if Ω is unbounded.

XII.9. Analytic Continuation and Riemann Surfaces

In this section we will assume all open sets we work on are connected. We will use the term *region* to mean a nonempty connected open subset of $\mathbb{C}$.

XII.9.1. Analytic Function Elements

The Rigidity Theorem implies that if Ω and $\tilde{\Omega}$ are regions in $\mathbb{C}$, whose intersection is nonempty, and f is holomorphic on Ω, then there is at most one function $\tilde{f}$ which is holomorphic on $\tilde{\Omega}$ and agrees with f on the intersection. There may or may not be such an $\tilde{f}$; but if there is, f and $\tilde{f}$ can be reasonably considered to be "pieces" of the same function which is holomorphic on some unspecified domain containing both Ω and $\tilde{\Omega}$.

Things can be more complicated, however. The intersection of Ω and $\tilde{\Omega}$ is not necessarily connected, and the functions f and $\tilde{f}$ can agree on part of the intersection but not all. An example is two branches of $\log z$ () corresponding to α and β with $|\alpha - \beta| < 2\pi$.

A related difficulty which actually provides a solution to the first difficulty is that if Ω_1, Ω_2, and Ω_3 are regions, and f_j is holomorphic on Ω_j, if $f_1 = f_2$ on $\Omega_1 \cap \Omega_2$ and $f_2 = f_3$ on $\Omega_2 \cap \Omega_3$, then f_1 and f_3 should be regarded as "pieces" of the same function even if Ω_1 and Ω_3 are disjoint, or if they overlap but f_1 and f_3 do not agree on $\Omega_1 \cap \Omega_3$, as can happen, e.g. with suitable branches of the logarithm. The solution is to regard f on Ω and $\tilde{f}$ on $\tilde{\Omega}$ as "pieces" of the same function if there is a finite chain of intermediate "pieces" f_j on Ω_j which agree on consecutive overlaps. Using this extension of equivalence, we may regard any two branches of $\log z$, even ones whose angles differ by more than 2π, to be "pieces" of the same big function. The domain of this big function is not a subset of $\mathbb{C}$, but a large abstract set made up of overlapping pieces which can be identified with regions in $\mathbb{C}$ (technically a complex 1-manifold ()). This domain is called the *Riemann surface* of the function.

We now discuss the details.

XII.9.1.1. Definition. An *analytic function element* is a pair (Ω, f), where Ω is a region (nonempty connected open set) in $\mathbb{C}$ and f is holomorphic on Ω.

Two analytic function elements (Ω, f) and $(\tilde{\Omega}, \tilde{f})$ are *equivalent* if there is a finite chain (Ω_j, f_j) $(1 \le j \le n)$ such that $(\Omega_1, f_1) = (\Omega, f)$, $(\Omega_n, f_n) = (\tilde{\Omega}, \tilde{f})$, and $\Omega_j \cap \Omega_{j+1} \neq \emptyset$ and $f_j = f_{j+1}$ on $\Omega_j \cap \Omega_{j+1}$ for $1 \le j < n$.

A *total analytic function* is an equivalence class of analytic function elements.

XII.9.1.2. It is obvious that equivalence of analytic function elements is indeed an equivalence relation. Every analytic function element determines a unique total analytic function, namely its equivalence class. Equivalent analytic function elements determine the same total analytic function.

XII.9.1.3. Proposition. (i) If (Ω, f) and $(\tilde{\Omega}, \tilde{f})$ are analytic function elements, $\Omega \cap \tilde{\Omega} \neq \emptyset$, and $f = \tilde{f}$ on $\Omega \cap \tilde{\Omega}$, then (Ω, f) and $(\tilde{\Omega}, \tilde{f})$ are equivalent.

(ii) If (Ω, f) is an analytic function element, $\tilde{\Omega}$ a subregion of Ω, and $\tilde{f} = f|_{\tilde{\Omega}}$, then the analytic function element $(\tilde{\Omega}, \tilde{f})$ is equivalent to (Ω, f).

(ii) If $\{(\Omega_k, f_k) : k \in K\}$ are analytic function elements, such that $f_j = f_k$ on $\Omega_j \cap \Omega_k$ for all j and k, and $\Omega = \cup_k \Omega_k$ is connected (e.g. if $\cap_k \Omega_k \neq \emptyset$), set $f = f_k$ on Ω_k for each k. Then f is a well-defined holomorphic function on Ω, and the analytic function element (Ω, f) is equivalent to each (Ω_k, f_k).

XII.9.2. The Riemann Surface of a Total Analytic Function

XII.9.2.1. We can put the domains of the elements of a total analytic function together to get a "surface" which is the natural domain of the function. Informally, we take the "union" of the domains of the elements, with points in overlapping elements identified *provided* the function agrees around these points. More precisely:

XII.9.2.2. DEFINITION. Let $\boldsymbol{f} = \{(\Omega_k, f_k) : k \in K\}$ be a total analytic function, i.e. the (Ω_k, f_k) are equivalent analytic function elements. Let D_f be the disjoint union () of the Ω_k (even if $\Omega_j = \Omega_k$ as subsets of $\mathbb{C}$, if $j \neq k$ they are disjoint subsets of D_f). Put an equivalence relation on D_f as follows. If $z_j \in \Omega_j$, $z_k \in \Omega_k$, set $z_j \sim z_k$ if $z_j = z_k \in \Omega_j \cap \Omega_k \subseteq \mathbb{C}$ and $f_j(z) = f_k(z)$ for all z in a neighborhood of $z_j = z_k$. Write $\hat{\Omega}_k = \{[z] : z \in \Omega_k\}$. Let S_f be the set of equivalence classes. S_f is the *Riemann surface* of the total analytic function $\boldsymbol{f}$.

The total analytic function $\boldsymbol{f}$ gives a well-defined function f from S_f to $\mathbb{C}$ by $f([z]) = f_k(z)$ for $z \in \Omega_k$. The function f is called the *(complete) analytic function* defined by $\boldsymbol{f}$. Each (Ω_k, f_k) is a *branch* of f or $\boldsymbol{f}$.

XII.9.2.3. There is a natural injective map ι_k from Ω_k to S_f for each k, and the restriction of f to the image $\hat{\Omega}_k$ of Ω_k is exactly f_k.

We topologize S_f by taking the $\hat{\Omega}_k$ as a base for the topology. Then each $\hat{\Omega}_k$ is an open subset of S_f, and the inclusion of Ω_k into S_f is a homeomorphism onto its image. The function $f : S_f \to \mathbb{C}$ is continuous.

XII.9.2.4. The natural identifications of the subsets $\hat{\Omega}_k$ of S_f with the corresponding subsets Ω_k of $\mathbb{C}$ give an atlas defining the structure of a complex analytic 1-manifold on S_f (). This atlas has the special property that the transition functions between charts are identity maps on open sets in $\mathbb{C}$. (This natural atlas is not a maximal atlas.)

The next proposition is an immediate corollary of ().

XII.9.2.5. PROPOSITION. Let $\boldsymbol{f}$ be a total analytic function, and (Ω_j, f_j) and (Ω_k, f_k) analytic function elements in $\boldsymbol{f}$. If $z_0 \in \Omega_j \cap \Omega_k$, then either $\iota_j(z) = \iota_k(z)$ for all z in a neighborhood of z_0 (if $\iota_j(z_0) = \iota_k(z_0)$), or $f_j(z) \neq f_k(z)$ for all z in a deleted neighborhood of z_0 and in particular $\iota_j(z) \neq \iota_k(z)$ for all z in a neighborhood of z_0 (if $\iota_j(z_0) \neq \iota_k(z_0)$).

XII.9.2.6. COROLLARY. Let $\boldsymbol{f}$ be a total analytic function with Riemann surface S_f. Then S_f is Hausdorff.

XII.9.2.7. PROPOSITION. Let $\boldsymbol{f}$ be a total analytic function with Riemann surface S_f. Then S_f is path-connected.

PROOF: Suppose (Ω_j, f_j) and $\Omega_k, f_k)$ are elements of $\boldsymbol{f}$, and $z_j \in \Omega_j$, $z_k \in \Omega_k$. Let $(\Omega_1, f_1), \ldots, (\Omega_n, f_n)$ be a chain with $(\Omega_1, f_1) = (\Omega_j, f_j)$, $(\Omega_n, f_n) = (\Omega_k, f_k)$, and $\Omega_m \cap \Omega_{m+1} \neq \emptyset$ and $f_m = f_{m+1}$ on $\Omega_m \cap \Omega_{m+1}$ for $1 \leq m < n$. For each m, $1 \leq m \leq n-1$, choose $z_m \in \Omega_m \cap \Omega_{m+1}$. We have $\iota_m(z_m) = \iota_{m+1}(z_m)$ for each

m. There is a path from z_j to z_1 in Ω_1, a path from z_m to z_{m+1} in Ω_{m+1} for $1 \leq m \leq n-2$, and a path from z_{n-1} to z_k in Ω_n. The corresponding paths in the $\hat{\Omega}_m$ match up at the endpoints and give a path in S_f from $\iota_j(z_j)$ to $\iota_k(z_k)$. 👍

XII.9.2.8. EXAMPLES. (i) The Riemann surface of a total analytic function can sometimes be identified with a subset of $\mathbb{C}$. The simplest case is when f is an entire function. Then $(\mathbb{C}, f)$ is an analytic function element, and the analytic function elements equivalent to it are precisely of the form $(\Omega, f|_\Omega)$, where Ω is a region in $\mathbb{C}$. Since the functions in any two elements of the equivalence class agree on the intersection of the regions, every region in S_f is identified with itself as a subset of $\mathbb{C}$. Thus $S_f \cong \mathbb{C}$.

(ii) Similarly, if f is holomorphic on $\mathbb{C}$ except for isolated non-removable singularities, the set P of (non-removable) singularities is a countable subset of $\mathbb{C}$ with no limit point. Then $(\mathbb{C} \setminus P, f)$ is an analytic function element, and as before every equivalent analytic function element is of the form $(\Omega, f|_\Omega)$, where Ω is a region in $\mathbb{C} \setminus P$, and $S_f \cong \mathbb{C} \setminus P$. (If f also has removable singularities, then S_f is the domain of f with the removable singularities removed.)

(iii) Here is one of the most important examples, of a total analytic function whose Riemann surface is not a subset of $\mathbb{C}$. If Ω is $\mathbb{C}$ with a branch cut (ray out from 0) removed (), then there are infinitely many branches of $\log z$ defined on Ω. For each such f, (Ω, f) is an analytic function element, and the copies of Ω corresponding to different branches are disjoint. If $\tilde{\Omega}$ is $\mathbb{C}$ with a different branch cut removed, then $\Omega \cap \tilde{\Omega}$ is not connected, and the pieces are identified with parts of different copies of Ω in S_f. The Riemann surface for $\log z$ can be visualized by taking a sequence of copies of Ω, and connecting each sheet along the branch cut with the sheet above, giving a helical surface (Figure XII.1, from http://upload.wikimedia.org/wikipedia/commons/4/41/Riemann_surface_log.jpg). Choosing a branch cut just allows the surface to be constructed or visualized in this way; the branch cut has no intrinsic significance as part of the Riemann surface, and any other branch cut would work as well and give the same surface.

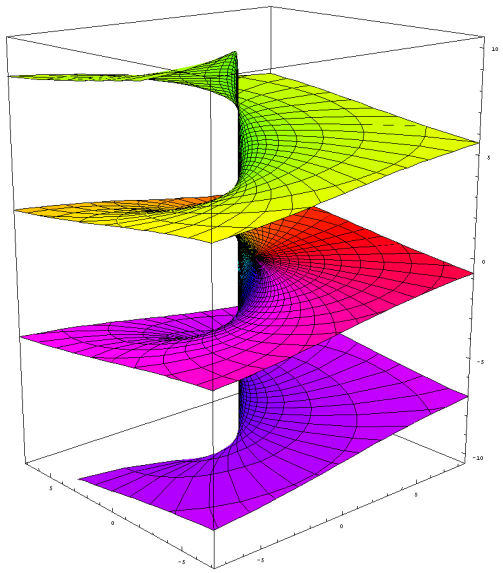

Figure XII.1: Riemann Surface for $\log z$ (Three levels shown)

(iv) Similarly, the Riemann surface for $\sqrt{z}$ can be constructed by again taking a branch cut out from 0. This time, there are only two branches for each branch cut. The Riemann surface is obtained by gluing each copy of the plane with branch cut removed to the other copy along the branch cut (this cannot be physically accomplished in $\mathbb{R}^3$ since the surfaces would have to pass through each other along the branch cut, but can be done in $\mathbb{R}^4$ or $\mathbb{C}^2$; see Figure XII.2, from http://en.wikipedia.org/wiki/File:Riemann_sqrt.jpg).

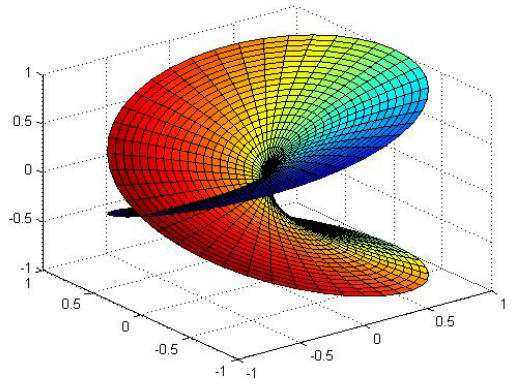

Figure XII.2: Riemann Surface for $\sqrt{z}$

The Riemann surface for $\sqrt[n]{z}$ is similar, with n sheets, each attached to the next one along the branch cut and the last attached to the first.

(v) If (Ω_j, f_j) and (Ω_k, f_k) are branches of a total analytic function $\boldsymbol{f}$, and $z \in \Omega_j \cap \Omega_k$, we may have $\iota_j(z) \neq \iota_k(z)$ even though $f_j(z) = f_k(z)$: the function with elements $(\Omega, g(z)[g(z) - 2\pi i])$, where Ω is a simply connected open set in $\mathbb{C} \setminus \{0\}$ and g is a branch of $\log z$ holomorphic on Ω, has two distinct branches over neighborhoods of 1 both taking the value 0 at 1. (These branches differ at all points of a deleted neighborhood of 1.)

XII.9.2.9. If $\boldsymbol{f}$ is a total analytic function with Riemann surface S_f, there is a projection map p_f from S_f to $\mathbb{C}$ which sends each $\hat{\Omega}$ on the surface to the corresponding subset Ω of $\mathbb{C}$. This projection is continuous and open, its range is an open subset of $\mathbb{C}$, and may be either one-to-one (e.g. in cases XII.9.2.8.(i)–(ii)) or many-to-one (e.g. in cases XII.9.2.8.(iii)–(iv)). If p_f is one-to-one, it is a homeomorphism onto its image, and S_f can be identified with an open set in $\mathbb{C}$; in this case, $\boldsymbol{f}$ is said to be *single-valued*; if p_f is not one-to-one, $\boldsymbol{f}$ is said to be *multivalued*.

In cases XII.9.2.8.(iii)–(v), the map p_f is a covering map, but this is not true in general, and the preimage of different points can even have different cardinality () (each point preimage is always finite or countable since it is relatively discrete in S_f ()). The range of p_f is always a region in $\mathbb{C}$, but it may be quite small ().

XII.9.2.10. Any analytic function element (Ω, f) defines a unique total analytic function $\boldsymbol{f}$ and hence a Riemann surface S_f, which is the "largest domain" f can be extended to as a holomorphic function. But if f is defined on a small open set Ω, e.g. on a finite disk by a power series with finite radius of convergence, it can

be difficult if not impossible to determine the full Riemann surface of f, or indeed whether $\boldsymbol{f}$ is single-valued or multivalued.

XII.9.3. Analytic Continuation

XII.9.3.1. We now change our point of view slightly, and discuss the problem from XII.9.2.10. in more detail. Suppose f is a holomorphic function on a region Ω (i.e. (Ω, f) is an analytic function element). How far outside Ω can f be extended as a holomorphic function, and to what degree is the extension unique?

XII.9.3.2. The first question to discuss is: if z is a boundary point of Ω, can a (necessarily unique) holomorphic function g be defined on an open disk centered at z which agrees with f on the part of the disk contained in Ω? If not, z is called a *singular point* of the boundary (for f). The set of singular points is a closed subset of the boundary of Ω. In some cases, it can be shown that there must be singular boundary points, e.g.:

XII.9.3.3. PROPOSITION. Let

$$\sum_{k=0}^{\infty} a_k (z - z_0)^k$$

be a power series with radius of convergence R, $0 < R < \infty$, and let Ω be the open disk of radius R centered at z_0. If f is the holomorphic function on Ω defined by the power series, then there is at least one singular point for f on the boundary of Ω.

PROOF: Suppose not. Then for any z on the boundary circle there is an open disk D_z of radius ϵ_z centered at z and a holomorphic function g_z on this disk agreeing with f on the part of the disk inside Ω. By the Rigidity Theorem, any two g_z must agree on the intersection of the D_z. Thus there is a well-defined holomorphic function g on $U = \Omega \cup \cup_z D_z$ which extends f. But U is an open neighborhood of $\bar{\Omega}$, which is compact, so U contains a disk of radius $R + \epsilon$ centered at z_0, for some $\epsilon > 0$ (). Then by XII.4.4.6. the Taylor series for f around z_0 has radius of convergence at least $R + \epsilon$, a contradiction. 👍

XII.9.3.4. EXAMPLES. (i) There may be only one singular boundary point. The power series

$$\sum_{k=0}^{\infty} z^k$$

converges to $f(z) = \frac{1}{1-z}$ on the open unit disk $\mathbb{D}$. This function can be extended holomorphically to every boundary point of $\mathbb{D}$ except $z = 1$. In fact, it extends to a function holomorphic on $\mathbb{C} \setminus \{1\}$.

(ii) At the other extreme, all boundary points can be singular points. The power series

$$\sum_{k=0}^{\infty} z^{2^k}$$

has radius of convergence 1, hence defines a holomorphic function on $\mathbb{D}$. But if θ is a dyadic rational multiple of 2π, then it is easily checked that

$$\lim_{r \to 1-} |f(re^{i\theta})| = +\infty$$

so $e^{i\theta}$ is a singular point of the boundary. Since such points are dense in the unit circle and the set of singular points is closed, every boundary point is a singular point.

(iii) Here is an interesting variation of (ii), a holomorphic function on $\mathbb{D}$ which can be extended continuously, even smoothly, to the boundary, but for which all boundary points are nonetheless singular. The power series

$$\sum_{k=1}^{\infty} 2^{-k^2} z^{2^k}$$

has radius of convergence 1 and converges uniformly on the closed unit disk $\bar{\mathbb{D}}$, as do the derived series of all orders. Thus the function

$$f(z) = 1 + 2z + \sum_{k=1}^{\infty} 2^{-k^2} z^{2^k}$$

is a smooth function (in the vector calculus sense) on $\bar{\mathbb{D}}$ which is holomorphic on $\mathbb{D}$. But nonetheless all boundary points are singular by the Hadamard gap theorem. (It turns out that f is one-to-one on $\bar{\mathbb{D}}$, the reason for including the $2z$ term. Including the constant term 1 is conventional.)

Examples (ii) and (iii) are *lacunary series*, power series where the gaps between the indices of consecutive nonzero coefficients become arbitrarily large. There is a discussion of these and related series in [Rem98], where the comment is made that "The gap theorem is in some sense a paradox: power series that, because of their gaps, converge especially fast in the interior of their disk of convergence have singularities almost everywhere on the boundary precisely on account of these gaps."

We now consider analytic continuation along a path.

XII.9.3.5. DEFINITION. Let Ω be a region in $\mathbb{C}$, and f a holomorphic function on Ω. Let γ a path in $\mathbb{C}$ from z_0 to z_1, with $z_0 \in \Omega$, parametrized by $\zeta : [a, b] \to \mathbb{C}$. Then f can be *analytically continued along* γ if, for every $t \in [a, b]$, there is an open disk D_t centered at $\zeta(t)$ and a function f_t holomorphic on D_t such that, for every $t_0 \in [a, b]$, $f_t = f_{t_0}$ on $D_t \cap D_{t_0}$ for all t sufficiently close to t_0, and such that $f_a = f|_{D_a}$.

The essential point is that the path γ begins in Ω but may pass or end outside Ω. In fact this is the only interesting situation: if γ lies inside Ω, then f can be analytically continued along γ simply by restriction.

If $\{(D_t, f_t) : t \in [a, b]\}$ is an analytic continuation of f along γ, then each (D_t, f_t) is an analytic function element.

XII.9.3.6. PROPOSITION. If $\{(D_t, f_t) : t \in [a, b]\}$ is an analytic continuation of f along γ, all analytic function elements (D_t, f_t) are equivalent.

PROOF: It is clear that for any t_0, the function elements (D_t, f_t) are equivalent to (D_{t_0}, f_{t_0}) for t sufficiently close to t_0. Thus the set of t in each equivalence class is open in $[a, b]$. Since the complement of an equivalence class is the union of the other equivalence classes, the set of t in each equivalence class is also closed in $[a, b]$. Thus there can be only one equivalence class since $[a, b]$ is connected. 👍

XII.9.3.7. Analytic continuation along a path γ can be alternately considered a finite process: if $\{(D_t, f_t)\}$ is an analytic continuation, there is a finite partition $\{a = t_0, t_1, \ldots, t_n = b\}$ of $[a, b]$ such that $\zeta(t) \in D_{t_k} \cup D_{t_{k+1}}$ for $t_k \leq t \leq t_{k+1}$, and $f_{t_k} = f_{t_{k+1}}$ on $D_{t_k} \cap D_{t_{k+1}}$ for $0 \leq k < n$. Conversely, if there is such a partition, disks D_k centered at ζ_{t_k} such that $\zeta(t) \in D_{t_k} \cup D_{t_{k+1}}$ for $t_k \leq t \leq t_{k+1}$, and functions f_k holomorphic on D_k agreeing on the consecutive overlaps, then (D_t, f_t) can be defined for each t by restricting f_k or f_{k+1} for $t_k \leq t \leq t_{k+1}$ to a disk D_t centered at $\zeta(t)$ contained in $D_k \cup D_{k+1}$.

XII.9.3.8. PROPOSITION. Let Ω be a region in $\mathbb{C}$, and f a holomorphic function on Ω. Let γ a path in $\mathbb{C}$ from z_0 to z_1, with $z_0 \in \Omega$, parametrized by $\zeta : [a, b] \to \mathbb{C}$. Then an analytic continuation of f along γ, if it exists, is unique: if $\{(D_t, f_t)\}$ and $\{\tilde{D}_t, g_t)\}$ are analytic continuations of f along γ, then $f_t = g_t$ on $D_t \cap \tilde{D}_t$ for all t.

PROOF: Let S be the set of $t \in [a, b]$ such that $f_t = g_t$ on $D_t \cap \tilde{D}_t$. Then $a \in S$ since both f_a and g_a must agree with f on a neighborhood of z_0, hence everywhere on $D_a \cap \tilde{D}_a$ by the Rigidity Theorem. S is obviously (relatively) open in $[a, b]$, again by the Rigidity Theorem. If t_0 is a limit point of S, then $f_{t_0} = g_{t_0}$ on a sequence of points in S converging to t_0, and thus $f_{t_0} = g_{t_0}$ on all of $D_{t_0} \cap \tilde{D}_{t_0}$ by the Rigidity Theorem, i.e. $t_0 \in S$. Thus S is also closed. So $S = [a, b]$ since $[a, b]$ is connected. 👍

XII.9.3.9. Thus, if f can be analytically continued along γ, the value of $f(\zeta(t))$ is uniquely determined for each t, and in particular a branch of f at z_1 is uniquely determined by the analytic continuation. Note, however, that the curve γ may cross itself, and at crossing or repeated points the value of f obtained can be different at different times. This is particularly common and important if γ is a closed curve. A good example is $f(z) = \log z$, $z_0 = z_1 = 1$, γ the unit circle parametrized once around counterclockwise. This example also shows that the parametrization (or at least its equivalence class) is essential: if γ is parametrized once around clockwise, or more than once around, different values of f at z_1 are obtained.

XII.9.3.10. PROPOSITION. Let Ω be a region in $\mathbb{C}$, and f a holomorphic function on Ω. If γ is a (parametrized) curve in $\mathbb{C}$ from $z_0 \in \Omega$ to $z_1 \in \mathbb{C}$, then f can be analytically continued along γ if and only if there is a (necessarily unique) curve $\hat{\gamma}$ in S_f from the point $\hat{z}_0$ corresponding to z_0 on the branch (Ω, f) to another point $\hat{z}_1$, such that $p(\hat{\gamma}) = \gamma$.

PROOF: If there is such a $\hat{\gamma}$, f can clearly be analytically continued along γ. Conversely, if f can be analytically continued along γ, there is a partition $\{a = t_0, t_1, \ldots, t_n = b\}$ of the interval $[a, b]$ such that the disks D_{t_k} cover γ and $f_{t_k} = f_{t_{k+1}}$ on $D_{t_k} \cap D_{t_{k+1}}$ for each k. The pieces of γ for $t_k \leq t \leq t_{k+1}$ can be successively lifted to $\hat{D}_{t_k} \subseteq S_f$ in a unique way via the local homeomorphisms so that the entire lifted path is continuous. 👍

XII.9.3.11. As a result, if f can be analytically continued along γ, there is a "largest" analytic continuation (D_t, f_t), where D_t is the open disk of convergence of the Taylor series for f_t around $\zeta(t)$. We can use this analytic continuation as the standard one.

XII.9.3.12. If f can be analytically continued along γ, and γ is not entirely contained inside Ω, then there is a smallest t, say $t = t_1$, for which $\zeta(t_1) \in \partial\Omega$. Then $\zeta(t_1)$ is not a singular point of $\partial\Omega$. There is then a smallest $t_2 > t_1$ such that $\zeta(t_2) \in \partial(\Omega \cup D_{t_1})$ (unless $\gamma \subseteq \Omega \cup D_{t_1}$), and this point is not a singular point. The process can be continued.

Conversely, if f cannot be analytically continued along γ, then there is a smallest $c \in [a, b]$ such that f cannot be analytically continued along the restriction γ_c of γ to $[a, c]$. We have $c > a$ since f can be analytically continued along γ_d for $d > a$ small enough that $\gamma_d \subseteq \Omega$. Then $\zeta(c)$ can be regarded as a singular point of f along γ. For example, if $z_0 \in \Omega$, $z_1 \in \partial\Omega$, and γ is a path from z_0 to z_1 with $\zeta(t) \in \Omega$ for $a \leq t < b$, then z_1 is a singular point of f along γ if and only if z_1 is a singular point of $\partial\Omega$ in the sense of XII.9.3.2.. (There is not always such a path for every $z_1 \in \partial\Omega$ if $\partial\Omega$ is not well behaved topologically.)

XII.9.3.13. If f is holomorphic on Ω, and γ is a path beginning in Ω ending in a point z_1 outside Ω along which f can be analytically continued, then there is a well-defined value for f at z_1 (and for all z in some neighborhood of z_1) given by the analytic continuation along γ. But if $\tilde{\gamma}$ is another path beginning in Ω and ending at z_1, the value of f at z_1 defined by analytic continuation along this path need not be the same. A simple example is the principal branch of $\log z$ defined on the right half plane Ω, and the upper and lower unit semicircles from 1 to -1. However, homotopic paths give the same result:

XII.9.3.14. Theorem. [Monodromy Theorem] Let f be holomorphic on a region Ω, $z_0 \in \Omega$, $z_1 \in \mathbb{C}$. Let γ_0 and γ_1 be paths in $\mathbb{C}$ from z_0 to z_1, which are homotopic by a homotopy $h : [0, 1] \times [a, b]$ (XII.3.5.1.). For each s, let γ_s be the path parametrized by ζ_s, where $\zeta_s(t) = h(s, t)$. Suppose f can be analytically continued along γ_s for every s. Then the values of f at z_1 defined by analytic continuation along γ_0 and γ_1 are the same.

XII.9.4. The Regular Riemann Surface of a Function

XII.9.4.1. If $\boldsymbol{f}$ is a total analytic function with Riemann surface S_f, and $f : S_f \to \mathbb{C}$ is the corresponding complete analytic function, then f has a well-defined derivative at each point of S_f obtained from a local function element representative, and in fact well-defined derivatives of all orders (hence a well-defined Taylor series representation) at each point.

Viewed another way, if (Ω_k, f_k) is a function element of $\boldsymbol{f}$, then (Ω, f') is also an analytic function element, and the corresponding total analytic function $\boldsymbol{f'}$ can be regarded as the derivative of the total analytic function $\boldsymbol{f}$.

Although there is a natural map from S_f to $S_{f'}$, which is surjective (), the Riemann surface $S_{f'}$ is not the same as the Riemann surface S_f in general; it is only a quotient. (Consider the case of $\log z$; cf. Exercise ().) The map from S_f to $S_{f'}$ is a covering map in general ().

XII.9.4.2. If $\boldsymbol{f}$ is a total analytic function with Riemann surface S_f, and $\boldsymbol{f}$ is not constant, then the set of points of S_f where f' is zero is a closed subset Z_f which is discrete in the relative topology (). Thus the complement $R_f = S_f \setminus Z_f$ is a dense open subset of S_f, called the *regular Riemann surface of* $\boldsymbol{f}$.

XII.9.4.3. If $\zeta \in R_f$, then there is a function element (Ω, g) of $\boldsymbol{f}$ such that $\hat{\Omega}$ is a neighborhood of ζ and f is one-to-one on $\hat{\Omega}$, i.e. g is one-to-one on Ω (). Then $(g(\Omega), g^{-1})$ is an analytic function element which is a "branch" of $\boldsymbol{f}^{-1}$. It is not hard to see that any two such function elements corresponding to small open sets

in R_f are equivalent, so the total analytic function defined by them can be called $\boldsymbol{f}^{-1}$. The correspondence $\Omega \mapsto g(\Omega)$ gives a conformal bijection between R_f and $R_{f^{-1}}$; thus f can be regarded as a conformal bijection from R_f onto $R_{f^{-1}}$.

XII.9.4.4. Another way of viewing this is: if R_f and $R_{f^{-1}}$ are identified in this way, and p and q are the natural projections from R_f and $R_{f^{-1}}$ to $\mathbb{C}$, then f is completely determined by the two projections p and q. Thus an analytic function can be thought of as consisting of a Riemann surface and two projections to $\mathbb{C}$.

XII.9.5. Branch Points

XII.9.5.1. The regular Riemann surface R_f naturally sits as a dense subset of S_f, and the (isolated) points in $Z_f = S_f \setminus R_f$ do not appear in the Riemann surface $S_{f^{-1}}$. Conversely, there may be points in $S_{f^{-1}}$ not corresponding to points of S_f. The points of Z_f and $Z_{f^{-1}}$ can all be added to $R_f \cong R_{f^{-1}}$ to make a larger Riemann surface, and both f and f^{-1} can be extended in a meaningful way to these points. Such added points are called *branch points*.

XII.9.5.2. Example. Here is a simple example. Let $f(z) = \sqrt{z}$. Then the Riemann surface $S_f = R_f$ is a two-sheeted surface which projects to $\mathbb{C} \setminus \{0\}$ (XII.9.2.8.(iv)). The inverse function $f^{-1}(z) = z^2$ has $S_{f^{-1}} = \mathbb{C}$ and $R_{f^{-1}} = \mathbb{C} \setminus \{0\}$. The point 0 can be added to R_f, and f can be defined to be 0 at this added point, so S_f can be extended by adding a branch point. There are in this case no branch points to be added to $R_{f^{-1}}$. The roles of f and f^{-1} can of course be interchanged.

XII.9.5.3. There is an intrinsic way to describe branch points. To motivate this, it is simplest to describe branch points of $\boldsymbol{f}^{-1}$ corresponding to points of Z_f. Suppose $\zeta_0 \in Z_f$. Set $z_0 = p(\zeta_0)$. Then there is a small disk Ω centered at z_0 such that the corresponding function element (Ω, g) of $\boldsymbol{f}$ has $g'(z_0) = 0$ and no other zeroes of g'. Then z_0 is a zero of g of finite order n, and g is exactly n-to-one on $\Omega \setminus \{z_0\}$. The open set U in $R_{f^{-1}}$ corresponding to $\Omega \setminus \{z_0\}$ evenly covers a deleted neighborhood V of $g(z_0)$ n times via q, so there are locally n corresponding branches of $\boldsymbol{f}^{-1}$ over V which fit together like the branches of $\sqrt[n]{z}$ around 0. (Note that there is no reason there cannot be other branches of $\boldsymbol{f}^{-1}$ over points of V corresponding to different branches of $\boldsymbol{f}$ near z_0 than the one corresponding to ζ_0.)

If C is a small circle in V centered at $g(z_0)$, w_1 a point of C, and γ_k is C parametrized k times around counterclockwise beginning and ending at w_1, and h is any of the n corresponding branches of g^{-1} in a small neighborhood of w_1, then h can be analytically continued along γ_k for any k. For $1 \leq k < n$ the terminal branch of g^{-1} around w_1 differs from the initial branch chosen, but for $k = n$ the terminal branch is the same as the initial branch. As the diameter of C approaches 0, all the values on the branches at w_1 approach z_0. So we can "unwind" U, which is homeomorphic to a punctured disk, and add a center point where g^{-1} takes the value z_0.

XII.9.5.4. In general, a branch point of $\boldsymbol{f}$ corresponds to an open set U in S_f homeomorphic to to a punctured disk, such that p gives an even covering () from U onto a punctured disk $D \setminus \{z_0\}$ centered at a point z_0, and such that

$$w_0 = \lim_{p(\zeta) \to z_0} f(\zeta)$$

exists in the sense that for every $\epsilon > 0$ there is a $\delta > 0$ such that $|f(\zeta) - w_0| < \epsilon$ whenever $\zeta \in U$ and $|p(\zeta) - z_0| < \delta$ (it actually suffices that f just be bounded on U because of ()). Then there is an $n \in \mathbb{N}$ such that $p|_U$ is exactly n-to-one, and the image of every simple closed curve in U not homotopic to 0 has winding number $\pm n$ around z_0. If $n = 1$, there will be a point ζ_0 in the closure of U in S_f such that $p(\zeta_0) = z_0$ and p maps $U \cup \{\zeta_0\}$ homeomorphically onto D; and $f(\zeta_0) = w_0$. If $n > 1$, there is no such point on S_f; but we can then add a point ζ_0 to S_f, and topologize $S_f \cup \{\zeta_0\}$ by taking sets of the form

$$\{\zeta_0\} \cup \left[U \cap p^{-1}\left(\{z : |z - z_0| < \delta\}\right)\right]$$

for $\delta > 0$ as a local base at ζ_0. Extend f to $S_f \cup \{\zeta_0\}$ by setting $f(\zeta_0) = w_0$.

XII.9.5.5. The extended surface $S_f \cup \{\zeta_0\}$ is a topological 2-manifold with a natural structure as a complex 1-manifold, defined around ζ_0 by taking a "local uniformizing variable." Consider the map $h(s) = z_0 + s^n$ from a disk $\tilde{D}$ centered at 0 onto D. Fix an $s_1 \in \tilde{D}$, $s_1 \neq 0$, and let $z_1 = h(s_1)$ be the corresponding point of D. Define a holomorphic function G on $\tilde{D}$ as follows. Fix a branch g of f on a neighborhood Ω of z_1 corresponding to a point ζ_1 of U lying above it. If $s \in \tilde{D} \setminus \{0\}$, let γ be a path from s_1 to s in $\tilde{D} \setminus \{0\}$; then $h(\gamma)$ is a path from z_1 to $h(s)$ within $D \setminus \{z_0\}$, and g can be analytically continued along $h(\gamma)$ by () and XII.9.3.10.. Let $G(s)$ be the value of the analytic continuation at the terminal point $h(s)$. Then G is well defined on $\tilde{D} \setminus \{0\}$ (cf. [Ahl78, p. 221-222]). We have

$$\lim_{s \to 0} G(s) = w_0$$

so G has a removable singularity at 0. There is then an obvious induced homeomorphism ϕ from $\tilde{D}$ to $U \cup \{\zeta_0\}$ sending 0 to ζ_0 and s_1 to ζ_1, for which $G = f \circ \phi$, and this homeomorphism can be used to transfer the analytic structure on $\tilde{D}$ to $U \cup \{z_0\}$. This analytic structure agrees with the one already defined on U as a subset of S_f. It is easily seen that this analytic structure does not depend on the choices made in the construction of G. If the branch point arises from a point of $S_{f^{-1}}$ as in XII.9.5.3., this procedure gives the same analytic structure as the usual analytic structure from $S_{f^{-1}}$.

XII.9.5.6. Example. Not all branch points of $\boldsymbol{f}$ arise from $\boldsymbol{f}^{-1}$. Consider $f(z) = z^{2/3}$. The Riemann surface S_f has three sheets over $\mathbb{C} \setminus \{0\}$, and $\boldsymbol{f}$ has a branch point of order 3 at 0. The inverse function is $f^{-1}(z) = z^{3/2}$, whose Riemann surface has two sheets over $\mathbb{C} \setminus \{0\}$ and a branch point of order 2 at 0.

XII.9.6. Points at Infinity and Meromorphic Functions

Essentially everything done so far in this section works identically if we replace the complex plane $\mathbb{C}$ with the Riemann sphere $\bar{\mathbb{C}}$ and the words *analytic* and *holomorphic* with *meromorphic*.

XII.9.6.1. Definition. A *meromorphic function element* is a pair (Ω, f), where Ω is a region in $\mathbb{C}$ and f is a meromorphic function on Ω. Two meromorphic function elements (Ω, f) and $(\tilde{\Omega}, \tilde{f})$ are *equivalent* if there is a finite chain (Ω_j, f_j) $(1 \leq j \leq n)$ such that $(\Omega_1, f_1) = (\Omega, f)$, $(\Omega_n, f_n) = (\tilde{\Omega}, \tilde{f})$, and $\Omega_j \cap \Omega_{j+1} \neq \emptyset$ and $f_j = f_{j+1}$ on $\Omega_j \cap \Omega_{j+1}$ for $1 \leq j < n$.

A meromorphic function on Ω can be regarded as an analytic function from Ω to $\bar{\mathbb{C}}$ in the sense of (). Any analytic function element is a meromorphic function element.

XII.9.6.2. A total meromorphic function can be thought of as an equivalence class of meromorphic function elements (we will later () give a slightly different definition, allowing meromorphic function elements including the point at infinity also).

If $\boldsymbol{f} = \{(\Omega_k, f_k)\}$ is an equivalence class of meromorphic function elements, we can form a Riemann surface S_f as in the holomorphic case, where $z_j \in \Omega_j$ is identified with $z_k \in \Omega_k$ if $z_j = z_k$ in $\mathbb{C}$ and $f_j = f_k$ on a deleted neighborhood of $z_j = z_k$. (If we regard f_j and f_k as maps to $\bar{\mathbb{C}}$, they then agree on a neighborhood of $z_j = z_k$). There is an induced function from S_f to $\bar{\mathbb{C}}$. Thus every meromorphic function element gives a well-defined Riemann surface in this way corresponding to its equivalence class.

XII.9.6.3. Note that each analytic function element (Ω, f) defines a Riemann surface S_f^h as in XII.9.2.2. when thought of as an analytic function element, and a Riemann surface S_f^m when thought of as a meromorphic function element. These are not the same in general. S_f^h is naturally a subset of S_f^m; S_f^h is exactly the preimage of $\mathbb{C}$ in S_f^m under the induced function from S_f^m to $\bar{\mathbb{C}}$. Thus S_f^m can be regarded as S_f^h with points added where the extended f has poles. For example, if $f(z) = \frac{1}{z}$, then $S_f^h \cong \mathbb{C} \setminus \{0\}$ and $S_f^m \cong \mathbb{C}$.

XII.9.6.4. We can incorporate the point at infinity more fully into this picture. A meromorphic function element (Ω, f), where Ω is a region in $\mathbb{C}$ with bounded complement and f is a meromorphic function on $\mathbb{C}$ which has a removable singularity or pole at ∞ in the sense of () (this implies that f is holomorphic in the complement of a bounded set), can be regarded as a region in $\bar{\mathbb{C}}$ containing ∞ and an analytic function from this set to $\bar{\mathbb{C}}$, and will be called a *meromorphic function element at infinity*.

For each meromorphic function element (Ω, f) at infinity, for which $0 \notin \Omega$, define a meromorphic function element $(\bar{\Omega}, g)$, where

$$\bar{\Omega} = \{0\} \cup \left\{ \frac{1}{z} : z \in \Omega \right\}$$

$$g(z) = f\left(\frac{1}{z}\right) \text{ for } z \in \Omega, \quad g(0) = \lim_{z \to \infty} f(z) \in \bar{\mathbb{C}} \ .$$

We incorporate $(\bar{\Omega}, g)$ into the construction of S_f by identifying $w \in \bar{\Omega} \setminus \{0\}$ with $\frac{1}{w} \in \Omega$. This effectively adds a "point at infinity" to S_f, at which f takes the value $g(0)$. There may be many such points at infinity added corresponding to different branches of $\boldsymbol{f}$.

There is then a natural projection map p from the extended S_f to $\bar{\mathbb{C}}$.

XII.9.6.5. Branch points can then be defined and added as in the holomorphic case. A branch point corresponds to an open set U in S_f for which p is an even covering from U onto a deleted open disk $D \setminus \{z_0\}$ in $\bar{\mathbb{C}}$, where $z_0 = \infty$ is allowed in which case $D \setminus \{\infty\}$ is the complement of a closed disk in $\mathbb{C}$ centered at 0, and

$$w_0 = \lim_{p(\zeta) \to z_0} f(\zeta)$$

exists in $\bar{\mathbb{C}}$, i.e. $w_0 = \infty$ is allowed.

When all points at infinity and branch points have been added, a Riemann surface $\bar{S}_f$ is obtained which is called the *total Riemann surface* of $\boldsymbol{f}$. If $\boldsymbol{f}$ is not constant, the total Riemann surfaces of $\boldsymbol{f}$ and $\boldsymbol{f}^{-1}$ are conformally equivalent ().

XII.9.7. Germs of Analytic Functions

XII.9.7.1. We now go to the opposite extreme from considering the Riemann surface of a total analytic function. If $z_0 \in \mathbb{C}$ is a fixed point of $\mathbb{C}$, and if $\boldsymbol{f}$ is a total analytic function containing an analytic function element (Ω, f) with $z_0 \in \Omega$, then the restriction of f to any neighborhood of z_0 completely determines $\boldsymbol{f}$. Thus every function holomorphic in a neighborhood of z_0 determines a unique total analytic function, and two holomorphic functions agreeing on a neighborhood of z_0 determine the same total analytic function. (But two different holomorphic functions on small neighborhoods of z_0 can give different branches of the same total analytic function.)

XII.9.7.2. Definition. Let $z_0 \in \mathbb{C}$. A *germ* of an analytic function at z_0 is an equivalence class of functions holomorphic in neighborhoods of z_0, where two such functions are equivalent if they agree on some neighborhood of z_0.

Thus the exact domain of a germ of an analytic function at z_0 is not specified or relevant.

XII.9.7.3. The algebraic operations of addition, multiplication, and scalar multiplication are well defined on germs. If f and g are holomorphic on neighborhoods U and V of z_0, then $f+g$ is defined and holomorphic on $U \cap V$. If $\tilde{f}$ is holomorphic near z_0 and agrees with f on $\tilde{U} \subseteq U$, and $\tilde{g}$ agrees with g on $\tilde{V} \subseteq V$, then $\tilde{f} + \tilde{g}$ agrees with $f + g$ on $\tilde{U} \cap \tilde{V}$, so addition is well defined. The argument for multiplication and scalar multiplication is almost identical.

XII.9.7.4. Thus the set $\mathcal{G}(z_0)$ of germs of analytic functions has a natural structure as a ring, actually an algebra over $\mathbb{C}$.

XII.9.7.5. The algebra $\mathcal{G}(z_0)$ can be described in a different way. If f is holomorphic in a neighborhood of z_0, then the Taylor series of f around z_0 determines f on at least a small disk centered at z_0. Conversely, any power series centered at z_0 with a positive radius of convergence defines a holomorphic function on a disk centered at z_0. Thus there is a one-one correspondence between germs of analytic functions at z_0 and power series centered at z_0 with a positive radius of convergence (we will call such a series a *convergent power series* centered at z_0). This correspondence preserves addition, multiplication, and scalar multiplication, i.e. is an algebra isomorphism.

Up to isomorphism, the algebra $\mathcal{G}(z_0)$ does not depend on z_0; the map $f(z) \mapsto f(z+z_0)$ is an isomorphism of $\mathcal{G}(z_0)$ onto $\mathcal{G}(0)$, which is isomorphic to the algebra of convergent power series centered at 0. So $\mathcal{G}(0)$ can be identified with a subalgebra of the algebra $\mathbb{C}[[X]]$ of formal power series over $\mathbb{C}$ ().

XII.9.7.6. Proposition. The algebra $\mathcal{G}(z_0)$ has no zero divisors: if $[f], [g]$ are nonzero elements of $\mathcal{G}(z_0)$, then $[f][g] \neq 0$. That is, $\mathcal{G}(z_0)$ is an integral domain ().

Proof: This can be seen in at least two ways. $\mathcal{G}(z_0)$ is isomorphic to a subring of the integral domain $\mathbb{C}[[X]]$. Alternatively, if $[f]$ and $[g]$ are germs of analytic functions f and g respectively, neither of which are identically zero in a neighborhood of z_0, then f and g have at most an isolated zero at z_0, i.e. there is a deleted neighborhood U of z_0 on which both f and g are never zero. Thus fg is nonzero on U, i.e. $[fg] = [f][g] \neq 0$ in $\mathcal{G}(z_0)$. 👍

Germs of Meromorphic Functions

We can extend the notion of germ to functions holomorphic on a neighborhood of z_0 except possibly for a pole at z_0.

XII.9.7.7. DEFINITION. Let $z_0 \in \mathbb{C}$. A *germ* of a meromorphic function at z_0 is an equivalence class of functions holomorphic in deleted neighborhoods of z_0 with a removable singularity or pole at z_0, where two such functions are equivalent if they agree on some deleted neighborhood of z_0.

XII.9.7.8. As before, the set $\mathcal{M}(z_0)$ of germs of meromorphic functions at z_0 is a complex algebra. There is an obvious injective homomorphism from $\mathcal{G}(z_0)$ to $\mathcal{M}(z_0)$, so we may identify $\mathcal{G}(z_0)$ with a subalgebra of $\mathcal{M}(z_0)$. We again have $\mathcal{M}(z_0) \cong \mathcal{M}(0)$.

There is a one-one correspondence (algebra isomorphism) between $\mathcal{M}(z_0)$ and the algebra of Laurent series () centered at z_0 which converge on a deleted neighborhood of z_0 (*convergent Laurent series*). Thus $\mathcal{M}(z_0)$ is isomorphic to a subalgebra of the algebra $\mathbb{C}((X))$ of formal Laurent series with complex coefficients ().

XII.9.7.9. PROPOSITION. The algebra $\mathcal{M}(z_0)$ is a field; in fact, it is the quotient field of the ring $\mathcal{G}(z_0)$.

PROOF: If f is holomorphic on a deleted neighborhood of z_0 and has a pole at z_0, then $\frac{1}{f}$ has a removable singularity at z_0, so agrees on a deleted neighborhood of z_0 with a function holomorphic in a neighborhood of z_0. Thus $[f]$ is invertible in $\mathcal{M}(z_0)$, and its reciprocal is in $\mathcal{G}(z_0)$. And if $[g] \in \mathcal{G}(z_0)$, $[g]$ not the zero element (i.e. g not identically zero near z_0), then either $g(z_0) \neq 0$, in which case $[g]$ is already invertible in $\mathcal{G}(z_0)$, or g has an isolated zero at z_0, in which case $\frac{1}{g}$ is holomorphic in a deleted neighborhood of z_0 and has a pole at z_0, i.e. $[g]$ is invertible in $\mathcal{M}(z_0)$. 👍

XII.9.7.10. Note that this proposition cannot be proved simply by using the isomorphism with a subring of the field $\mathbb{C}((X))$, since it is not obvious (although it turns out to be true) that the inverse Laurent series to a convergent Laurent series is also convergent.

XII.9.8. General Riemann Surfaces

XII.9.9. Exercises

XII.9.9.1. (a) (H. Looman) For $z \in \mathbb{C}$, define $f(z) = e^{-1/z^4}$ if $z \neq 0$, and set $f(0) = 0$. Show that the partial derivatives of the real and imaginary parts of f exist and satisfy the Cauchy-Riemann equations everywhere on $\mathbb{R}^2$, but f is not complex differentiable, or even continuous, at 0.

(b) (D. Menchoff) Set $f(z) = \frac{z^5}{|z|^4}$ for $z \neq 0$, and $f(0) = 0$. Show that f is continuous and has first-order partials everywhere on $\mathbb{C}$, and the first-order partials at 0 satisfy the Cauchy-Riemann equations, but f is not complex differentiable at 0.

XII.9.9.2. Let $\mathbb{D}$ be the open unit disk in $\mathbb{C}$.

(a) Show that the power series $\displaystyle\sum_{k=1}^{\infty} \frac{z^k}{k^2}$ converges uniformly on $\mathbb{D}$.

(b) Show that the series $\displaystyle\sum_{k=1}^{\infty} \frac{z^{k-1}}{k}$ of term-by-term derivatives converges u.c. but not uniformly on $\mathbb{D}$.

XII.9.9.3. (Another proof of the Fundamental Theorem of Algebra, the "standard" one) Let f be a polynomial with complex coefficients and no root in $\mathbb{C}$, and let $g = \frac{1}{f}$. Then g is an entire function.

(a) Use Lemma XII.1.4.1. to show that g is bounded.

(b) Apply Liouville's Theorem () to conclude that g, and hence f, is constant.

XII.9.9.4. (Yet another proof of the Fundamental Theorem of Algebra [Boa64]) Suppose f is a polynomial of degree $n \geq 1$ with no root in $\mathbb{C}$.

(a) Set $p(z) = f(z)\bar{f}(z)$, where $\bar{f}$ is the polynomial obtained from f by replacing each coefficient by its complex conjugate. Then p is a polynomial of degree $2n$ with no root in $\mathbb{C}$, taking strictly positive values on the real axis.

(b) Set $I = \displaystyle\int_{-\pi}^{\pi} \frac{1}{p(2\cos\theta)}\, d\theta$. Then $I > 0$.

(c) Show that $I = -i \displaystyle\int_{\gamma} \frac{1}{\zeta p(\zeta + \zeta^{-1})}\, d\zeta$, where γ is the unit circle.

(d) Show that $p(z + z^{-1}) = z^{-2n} q(z)$ for a polynomial q with no roots in $\mathbb{C}$.

(e) Conclude from Cauchy's Theorem that $I = -i \int_{\gamma} \frac{\zeta^{2n-1}}{q(\zeta)}\, d\zeta = 0$, contradicting (b).

XII.9.9.5. Prove the following complex analog of Rolle's Theorem for polynomials:

Theorem. Let $f(z)$ be a polynomial with complex coefficients. Then the roots of f' are contained in the (necessarily closed) convex hull K of the roots of f.

(a) Since K is an intersection of closed half planes, it suffices to show that if H is a closed half plane containing all the roots of f, then H also contains all the roots of f'. Show that it suffices to prove this if H is the closed upper half plane.

(b) We may assume f is monic without loss of generality. Use the Fundamental Theorem of Algebra to write

$$f(z) = (z - z_1)^{m_1}(z - z_2)^{m_2} \cdots (z - z_n)^{m_n}$$

where $z_1, \ldots, z_n \in \mathbb{C}$ and $m_1, \ldots, m_n \in \mathbb{N}$.

(c) Use either the Product Rule or logarithmic differentiation to show that

$$\frac{f'(z)}{f(z)} = \frac{m_1}{z - z_1} + \frac{m_2}{z - z_2} + \cdots + \frac{m_n}{z - z_n}$$

for $z \in \mathbb{C} \setminus \{z_1, \ldots, z_n\}$.

(d) Under the assumption that $Im(z_k) \geq 0$ for all k, show that if $Im(z) < 0$, then $Im\left(\frac{f'(z)}{f(z)}\right) > 0$ and hence $f'(z) \neq 0$.

(e) Explain why the theorem is a complex analog of Rolle's Theorem.

XII.9.9.6. The aim of this problem is to further justify the definition of the complex exponential function (XII.1.1.8.(iii)).

(a) Let $f(z) = e^z$. If g is holomorphic on a connected region Ω, and satisfies $g' = g$ on Ω, then $g = cf$ for some $c \in \mathbb{C}$. [Apply the Quotient Rule to $\frac{g}{f}$.] If $0 \in \Omega$ and $g(0) = 1$, then $g = f$.

(b) Similarly characterize the complex trigonometric and hyperbolic functions.

XII.9.9.7. Discuss the Riemann surface for the function $\log \log z$.

XII.9.9.8. Discuss the validity of the following formulas, where all letters denote complex numbers, and interpret them in terms of Riemann surfaces:

(a) $\log(zw) = \log z + \log w$.

(b) $\log(z^c) = c \log z$.

(c) $z^{c+d} = z^c z^d$.

(d) $(z^c)^d = z^{cd}$.

(e) $(zw)^c = z^c w^c$.

XII.9.9.9. Develop the argument in the last part of the proof of XII.3.5.4. to show that if γ_0 and γ_1 are piecewise-smooth contours from p to q which are homotopic in an open set Ω, then they are homotopic in Ω via a piecewise-smooth homotopy. [Choose partitions $\mathcal{P}$ and $\mathcal{Q}$ as in the proof; for $1 < j < m$ let $H(s_j, t)$ be piecewise-linear in t with $H(s_j, t_k) = h(s_j, t_k)$ for each k, and then extend H by making it piecewise-linear in s for fixed t.]

XII.9.9.10. (a) Let Ω be a connected open set in $\mathbb{C}$ containing an interval I on the real axis. Show that the complex exponential function is the only function which is holomorphic on Ω and which agrees with the usual real exponential function on I. [Use the Rigidity Theorem.] Do the same for the sine and cosine functions.

(b) Show that the power series

$$\sum_{k=0}^{\infty} \frac{z^k}{k!}$$

converges u.c. on all of $\mathbb{C}$ to the function e^z. Similarly, show that the series expansions

$$\cos z = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k)!} z^{2k}$$

$$\sin z = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)!} z^{2k+1}$$

are valid for all $z \in \mathbb{C}$. Give similar series representations for $\cosh z$ and $\sinh z$.

Thus the usual power series representations of the real exponential, trigonometric, and hyperbolic functions are valid also for the complex ones. This problem provides additional justification for why the extensions we gave of the exponential function, etc., to $\mathbb{C}$ are reasonable (and indeed are the *only* reasonable ones.) In fact, in many references these functions are defined using the power series.

XII.9.9.11. [**?**] Here is an example of an improper real integral which can be computed by a more complicated contour integration. Consider the integral

$$\int_0^{\infty} \frac{x^{-k}}{1+x}\, dx$$

(where k is a real constant and x^{-k} is interpreted in the usual real sense, i.e. as a positive real number for $x > 0$).

(a) Show that this improper integral converges if and only if $0 < k < 1$.

We make this restriction in the rest of the problem. Define

$$f(z) = \frac{z^{-k}}{1+z}$$

where z^{-k} is defined using a branch cut along the positive real axis and taking the argument between 0 and 2π. Thus the argument of z^{-k} lies between $-2\pi k$ and 0.

We also consider the contour $\gamma = \gamma_1 + \gamma_2 + \gamma_3 + \gamma_4$:
where γ_1 and γ_3 are line segments along the ray of points with argument ϵ and $2\pi - \epsilon$ respectively, and γ_2 and γ_4 are circle arcs of radius R and r respectively.

(b) Show that if $0 < r < 1$, $R > 1$, and $0 < \epsilon < \pi$ we have

$$\int_{\gamma} f = 2\pi i\, Res(f, -1) = 2\pi i e^{-\pi i k}\ .$$

(c) Show that

$$\int_{\gamma_2} f \to 0$$

as $R \to +\infty$ and

$$\int_{\gamma_4} f \to 0$$

as $r \to 0$, uniformly in ϵ.

(d) Show that, for fixed r and R, as $\epsilon \to 0+$ we have

$$\int_{\gamma_1} f \to \int_r^R \frac{x^{-k}}{1+x}\,dx$$

and that

$$\int_{\gamma_3} f \to -e^{-2\pi ik} \int_r^R \frac{x^{-k}}{1+x}\,dx$$

[The integrals do not approach the same limit because of the branch cut.]

(e) Conclude that

$$\int_0^\infty \frac{x^{-k}}{1+x}\,dx = \frac{2\pi i e^{-\pi ik}}{1-e^{-2\pi ik}}\ .$$

(f) Show that

$$1 - e^{-2\pi ik} = 2ie^{-\pi ik}\sin \pi k$$

so that

$$\int_0^\infty \frac{x^{-k}}{1+x}\,dx = \frac{\pi}{\sin \pi k}\ .$$

XII.9.9.12. Suppose f has a singularity at z_0, and that f is bounded in a deleted neighborhood of z_0. Mimic the proof of (iv) $\Rightarrow$ (i) in XII.5.2.7. to show that the singularity is removable, by showing directly that for fixed z near z_0,

$$\lim_{\delta \to 0+} \left[\int_{\gamma_\delta} \frac{f(\zeta)}{\zeta - z}\,d\zeta \right] = 0$$

by estimating the size of the integral.

XII.9.9.13. (a) Show that the implication (ii) $\Rightarrow$ (i) in XII.5.2.7. is equivalent to the following:

THEOREM. Let D be an open disk in $\mathbb{C}$ centered at z_0, and $f : D \to \mathbb{C}$. If f is continuous on D and holomorphic on $D \setminus \{z_0\}$, then f is holomorphic on D (i.e. differentiable at z_0).

(b) Prove this theorem by showing that the integral of f around any triangle in D is zero and applying Morera's Theorem.

XII.9.9.14. Using the Big Picard Theorem (XII.5.2.19.) and XII.5.3.5., prove the Little Picard Theorem (XII.3.3.12.). Do the case of a polynomial separately using the Fundamental Theorem of Algebra.

XII.9.9.15. For $z \in \mathbb{C}$ set $f(z) = e^{e^z}\,(= e^{(e^z)})$. Then f is an entire function.

What is wrong with the following argument? Since e^z is never 0, f never takes either the value 0 or the value 1. Thus f is a counterexample to the Little Picard Theorem (XII.3.3.12.).

XII.9.9.16. Let f be a continuous function from $\mathbb{C}$ to $\mathbb{C}$ such that the range of f contains the unit circle but not 0 (e.g. $f(z) = e^z$). Give a topological proof that f cannot be one-to-one.

XII.9.9.17. Convergent Power Series. This problem is a continuation of III.5.3.2., III.5.3.7.,and III.5.3.8.. Let F be a nondiscrete normed field. The prototype example is $\mathbb{C}$, but F could be $\mathbb{R}$ or $\mathbb{Q}_p$. We do not assume F is complete, so F could be any subfield of $\mathbb{C}$ or $\mathbb{Q}_p$ such as $\mathbb{Q}$ with either the usual absolute value or the p-norm. (There are many other possibilities too.) Denote the norm on F by $|\cdot|$.

(a) Let $\sum_{k=0}^{\infty} a_k X^k \in F[[X]]$. Show that the following conditions are equivalent:

(i) $\sup_k |a_k|^{1/k} < \infty$.

(ii) There is an $x \in F$, $x \neq 0$, such that $(|a_k x^k|)$ is bounded. [Since F is nondiscrete, there are nonzero x's in F of arbitrarily small norm.]

(iii) There is an $R > 0$ such that the partial sums of the series $\sum_{k=0}^{\infty} a_k x^k$ form a Cauchy sequence in F for all $x \in F$, $|x| < R$. [The norm on a normed field F satisfies $|xy| = |x||y|$ for all $x, y \in F$.]

A power series satisfying these conditions will be said to have a *positive radius of convergence*. The theoretical radius of convergence is

$$R = \frac{1}{\limsup |a_k|^{1/k}} .$$

If $F = \mathbb{C}$, these conditions are equivalent to having a positive radius of convergence in the usual sense. But since F is not required to be complete, a power series with positive radius of convergence will not necessarily converge (in F) for any nonzero elements of F. And the exact "radius of convergence" may not be well defined since the norm on a normed field does not necessarily take a dense set of values in $\mathbb{R}$.

(b) Let $\mathcal{G}_F[[X]]$ be the subset of $F[[X]]$ consisting of the power series with positive radius of convergence. (There does not seem to be standard notation for this set; we use this notation since $\mathcal{G}_{\mathbb{C}}[[X]]$ can be identified with the set $\mathcal{G}(0)$ of germs of analytic functions around 0.) $\mathcal{G}_F[[X]]$ can be thought of as the set of germs of "analytic" functions from F to F around 0, although this does not make literal sense in general. Show that $\mathcal{G}_F[[X]]$ is a subring (subalgebra) of $F[[X]]$. The polynomial ring $F[X]$ is a subring (subalgebra) of $\mathcal{G}_F[[X]]$. (The subalgebra $\mathcal{G}_F[[X]]$ of $F[[X]]$ depends on the norm used: if $F = \mathbb{Q}$, it is different for the usual absolute value and for the various p-norms.)

(c) Using the notation of III.5.3.7., if $f \in \mathcal{G}_F[[X]]$ and $f(0) \neq 0$, show that f is invertible in $\mathcal{G}_F[[X]]$, i.e. show that the inverse $\frac{1}{f}$ in $F[[X]]$ is in $\mathcal{G}_F[[X]]$. Show that $\mathcal{G}_F[[X]]$ has exactly one maximal ideal, the set of f with $f(0) = 0$, which is the principal ideal generated by $f(X) = X$.

(d) Define the set $\mathcal{G}_F((X))$ of Laurent series with positive radius of convergence. $\mathcal{G}_{\mathbb{C}}((X))$ can be identified with the set of germs of meromorphic functions around 0 (). Show that $\mathcal{G}_F((X))$ is a subfield of $F((X))$ and is the quotient field of $\mathcal{G}_F[[X]]$.

(e) Give an appropriate definition of positive radius of convergence for power series of several variables, and define $\mathcal{G}_F[[X_1, \ldots, X_n]]$ and $\mathcal{G}_F((X_1, \ldots, X_n))$. Formulate and prove analogs of the constructions of III.5.3.7.–III.5.3.8.: composition and the Implicit and Inverse Function Theorems, i.e. show in the results of III.5.3.7.–III.5.3.8., if the given functions have positive radius of convergence, so do the various functions asserted to exist in III.5.3.7.–III.5.3.8. (III.5.3.7.(a) does not work unrestrictedly).

If $F = \mathbb{C}$ (or $F = \mathbb{R}$), these theorems have analytic proofs. But there are direct proofs valid if F is any nondiscrete normed field. In proving the theorems, one may assume F is complete: if $\bar{F}$ is the completion, and the asserted functions are in $\mathcal{G}_{\bar{F}}[[X_1, \ldots, X_n]]$, they are actually in $F[[X_1, \ldots, F_n]] \cap \mathcal{G}_{\bar{F}}[[X_1, \ldots, X_n]] = \mathcal{G}_F[[X_1, \ldots, X_n]]$.

XII.10. Analytic Functions of Several Variables

We now describe the basic theory of complex analytic functions of several variables. Some aspects of the theory are virtually identical to the one-variable case, but there are also significant differences.

This is a large and active subject, and we only cover the most elementary aspects of it; even [BM48] gives a far more comprehensive treatment. The standard general reference for the theory of several complex variables is [GR09]. See [Gun90a]–[Gun90c] for a more modern and detailed study. See also [H90] and [AW98].

XII.10.1. Elementary Theory

XII.10.1.1. Definition. Let U be an open set in $\mathbb{C}^n$. A function $f : U \to \mathbb{C}$ is *analytic* if, for every $\boldsymbol{c} \in U$, f is represented in a neighborhood of $\boldsymbol{c}$ by a multivariable power series (VIII.8.1.4.) centered at $\boldsymbol{c}$. A function $\boldsymbol{f} = (f_1, \ldots, f_m) : U \to \mathbb{C}^m$ is analytic if each f_k is analytic.

XII.10.1.2. As in the one-variable case, this definition is a local one: a function f on an open set U is analytic on U if and only if it is analytic on a neighborhood of $\boldsymbol{c}$ for each $\boldsymbol{c} \in U$. In particular, if $U = \cup_j U_j$ is a union of open sets, then f is analytic on U if and only if it is analytic on each U_j.

An immediate corollary of VIII.8.1.13. is:

XII.10.1.3. Corollary. Let U be an open set in $\mathbb{C}^n$, and f analytic on U. Then f is $\mathcal{C}^\infty$ on U, and for any multi-index α, $\frac{\partial^\alpha f}{\partial z_\alpha}$ is analytic on U.

XII.10.1.4. An analytic function f is "jointly analytic" in its variables. If all but one variable is fixed, it is analytic in the remaining variable in the usual sense of (), since the multivariable power series for f around any point has a drastic revision obtained by collecting together all terms of like power in the remaining variable, which will converge in a neighborhood of the point. (More generally, if some of the variables are fixed, the function is analytic in the remaining variables.) Thus an analytic function is "separately analytic" in its variables. Conversely, one of the major theorems of the subject is that a separately analytic function is (jointly) analytic:

XII.10.1.5. Theorem. [Hartogs' Theorem] Let U be an open set in $\mathbb{C}^n$, and $f : U \to \mathbb{C}$. Suppose f is analytic (holomorphic) on U in each variable separately when the other variables are held fixed, i.e. all first-order partials of f (in the complex sense) exist everywhere on U. Then f is analytic on U.

We will prove the theorem only under the additional assumption that f is continuous (which is of course a consequence of the theorem); for the considerably more difficult proof without this assumption, see [BM48].

XII.10.1.6. THEOREM. [OSGOOD'S LEMMA] Let U be an open set in $\mathbb{C}^n$, and $f : U \to \mathbb{C}$. Suppose f is continuous on U, and analytic (holomorphic) on U in each variable separately when the other variables are held fixed, i.e. all first-order partials of f (in the complex sense) exist everywhere on U. Then f is analytic on U.

PROOF: The proof is a multidimensional version of the proof of XII.4.4.6.. Let $\boldsymbol{c} = (c_1, \ldots, c_n) \in U$, and let $R = \{(z_1, \ldots, z_n) : |z_k - c_k| \leq r_k\}$ be a closed polydisk around $\boldsymbol{c}$ contained in U. Fix $(z_1, \ldots, z_n)$ in the interior R° of R, i.e. $|z_k - c_k| < r_k$ for all k. We have, by repeated application of the Cauchy Integral Formula (),

$$f(z_1, \ldots, z_n) = \frac{1}{2\pi i} \int_{\gamma_n} \frac{f(z_1, \ldots, z_{n-1}, \zeta_n)}{\zeta_n - z_n}\, d\zeta_n$$

$$= \frac{1}{2\pi i} \int_{\gamma_{n-1}} \left[\frac{1}{2\pi i} \int_{\gamma_n} \frac{f(z_1, \ldots, z_{n-2}, \zeta_{n-1}, \zeta_n)}{\zeta_n - z_n}\, d\zeta_n \right] \frac{1}{\zeta_{n-1} - z_{n-1}}\, d\zeta_{n-1}$$

$$= \cdots = \frac{1}{(2\pi i)^n} \int_{\gamma_1} \int_{\gamma_2} \cdots \int_{\gamma_n} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - z_1) \cdots (\zeta_n - z_n)}\, d\zeta_n \cdots d\zeta_2\, d\zeta_1$$

where γ_k is the circle $\{z_k : |z_k - c_k| = r_k\}$ parametrized once around counterclockwise.

By parametrizing the integrals, $f(z_1, \ldots, z_n)$ becomes an iterated integral of a complex-valued continuous function over a rectangle in $\mathbb{R}^n$. By Fubini's Theorem (), this integral can be converted to a multiple integral (or computed as an iterated integral in any order). We will symbolically denote this multiple integral by

$$f(z_1, \ldots, z_n) = \frac{1}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - z_1) \cdots (\zeta_n - z_n)}\, d\zeta \ .$$

For each k set $b_k = \frac{|z_k - c_k|}{r_k} < 1$. We have, for $(\zeta_1, \ldots, \zeta_n) \in \partial R$,

$$\frac{1}{\zeta_k - z_k} = \frac{1}{\zeta_k - c_k} \frac{1}{1 - \frac{z_k - c_k}{\zeta_k - c_k}} = \frac{1}{\zeta_k - c_k} \sum_{m=0}^{\infty} \left[\frac{z_k - c_k}{\zeta_k - c_k} \right]^m$$

and the terms in the series are dominated in absolute value by the terms of $\sum_{m=0}^{\infty} b_k^m$, so the series converges absolutely and uniformly on ∂R. Iterating, the iterated sum

$$\sum_{m_1=0}^{\infty} \sum_{m_2=0}^{\infty} \cdots \sum_{m_n=0}^{\infty} \frac{(z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}}$$

converges absolutely and uniformly on ∂R to $\frac{1}{(\zeta_1 - z_1) \cdots (\zeta_n - z_n)}$. Thus the unordered sum

$$\sum_{(m_1, \ldots, m_n) \in \mathbb{N}_0^n} \frac{(z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}}$$

converges uniformly on ∂R to $\frac{1}{(\zeta_1 - z_1) \cdots (\zeta_n - z_n)}$. So we have

$$f(z_1, \ldots, z_n) = \frac{1}{(2\pi i)^n} \int_{\partial R} f(\zeta_1, \ldots, \zeta_n) \left[\sum_{(m_1, \ldots, m_n) \in \mathbb{N}_0^n} \frac{(z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}} \right] d\zeta$$

$$= \frac{1}{(2\pi i)^n} \int_{\partial R} \left[\sum_{(m_1,\ldots,m_n)\in\mathbb{N}_0^n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n} \frac{f(\zeta_1,\ldots,\zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}} \right] d\zeta \ .$$

Since f is bounded on R, by comparison the unordered sum

$$\sum_{(m_1,\ldots,m_n)\in\mathbb{N}_0^n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n} \frac{f(\zeta_1,\ldots,\zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}}$$

converges uniformly on ∂R, and hence the summation can be moved past the integral (). Thus

$$f(z_1,\ldots,z_n) = \sum_{(m_1,\ldots,m_n)\in\mathbb{N}_0^n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n} \left[\frac{1}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1,\ldots,\zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}} \, d\zeta \right]$$

$$= \sum_{(m_1,\ldots,m_n)\in\mathbb{N}_0^n} a_{m_1,\ldots,m_n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}$$

where

$$a_{m_1,\ldots,m_n} = \frac{1}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1,\ldots,\zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}} \, d\zeta$$

(where the last integral can be interpreted as an iterated contour integral in any order). Thus, since $(z_1,\ldots,z_n)$ is arbitrary in R°, the multivariable power series

$$\sum_{(m_1,\ldots,m_n)\in\mathbb{N}_0^n} a_{m_1,\ldots,m_n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}$$

converges to f on R°, a neighborhood of $\boldsymbol{c}$. Since $\boldsymbol{c} \in U$ is arbitrary, f is analytic on U. 👍

XII.10.1.7. Corollary. Let U be an open set in $\mathbb{C}^n$, and $f : U \to \mathbb{C}$ a function. Then f is analytic on U if and only if f, when regarded as a function $f(x_1, y_1, \ldots, x_n, y_n)$ from $\mathbb{R}^{2n}$ to $\mathbb{R}^2$ with coordinate functions u and v, is differentiable in the vector calculus sense on U and the Cauchy-Riemann equations hold for each pair (x_k, y_k), i.e. for all k,

$$\frac{\partial u}{\partial x_k} = \frac{\partial v}{\partial y_k} \quad \text{and} \quad \frac{\partial u}{\partial y_k} = -\frac{\partial v}{\partial x_k} \ .$$

Proof: If f is analytic, it is differentiable in the vector calculus sense and separately analytic, so by XII.1.1.5. the Cauchy-Riemann equations are satisfied. Conversely, if it is differentiable, hence continuous, and the Cauchy-Riemann equations are satisfied, apply XII.1.1.5. to conclude that f is separately analytic. 👍

XII.10.1.8. Using the Looman-Menchoff Theorem (XII.1.1.6.), the assumption that f be differentiable in the vector calculus sense can be relaxed to just assuming f is continuous, and that the first-order partial derivatives of u and v (in the vector calculus sense) all exist everywhere on U and satisfy the Cauchy-Riemann equations. The assumptions can be further relaxed using Hartogs' Theorem, but they cannot be relaxed to simply assuming the partials exist everywhere and satisfy the Cauchy-Riemann equations (this does not imply analyticity even when $n = 1$; cf. XII.9.9.1.).

As a corollary of the proof, we obtain a multidimensional version of the Cauchy Integral Formula and of XII.4.4.6.:

XII.10.1.9. Corollary. Let U be an open set in $\mathbb{C}^n$, and $f : U \to \mathbb{C}$ an analytic function. For any $\boldsymbol{c} = (c_1, \ldots, c_n) \in U$, we have:

(i) If R is any closed polydisk in U containing $\boldsymbol{c}$ in its interior, we have

$$f(\boldsymbol{c}) = \frac{1}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - c_1) \cdots (\zeta_n - c_n)}\, d\zeta$$

where the multiple integral can be regarded as an iterated contour integral in any order.

(ii) The multivariable power series

$$\sum_{(m_1,\ldots,m_n)\in\mathbb{N}_0^n} a_{m_1,\ldots,m_n} (z_1 - c_1)^{m_1} \cdots (z_n - c_n)^{m_n}$$

in standard form representing f in a neighborhood of $\boldsymbol{c}$ is unique and converges u.c. to f on any open polydisk centered at $\boldsymbol{c}$ contained in U; we have, for any $(m_1, \ldots, m_n) \in \mathbb{N}_0^n$,

$$\frac{\partial^{m_1+\cdots+m_n} f}{\partial z_1^{m_1} \cdots \partial z_n^{m_n}}(\boldsymbol{c}) = (m_1!) \cdots (m_n!) a_{m_1,\ldots,m_n} = \frac{(m_1!) \cdots (m_n!)}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}}\, d\zeta$$

for any closed polydisk R contained in U and containing $\boldsymbol{c}$ in its interior. Thus

$$a_{m_1,\ldots,m_n} = \frac{1}{(2\pi i)^n} \int_{\partial R} \frac{f(\zeta_1, \ldots, \zeta_n)}{(\zeta_1 - c_1)^{m_1+1} \cdots (\zeta_n - c_n)^{m_n+1}}\, d\zeta$$

where the multiple integral can be regarded as an iterated contour integral in any order.

XII.10.2. Exercises

XII.10.2.1. Prove the complex version of Clairaut's Theorem: if f is analytic on $\Omega \subseteq \mathbb{C}^n$, then for any j and k we have

$$\frac{\partial^2 f}{\partial z_j \partial z_k} = \frac{\partial^2 f}{\partial z_k \partial z_j}$$

on Ω, and more generally that higher mixed partials are independent of the order of differentiation.

XII.11. Harmonic Functions

Harmonic functions form a bridge between complex analysis, partial differential equations, and mathematical physics. They are solutions to a PDE with wide applications in physics, and in the two-dimensional case are intimately connected with complex analytic functions.

XII.11.1. Definitions and Basic Properties

XII.11.1.1. Definition. Let Ω be a region (open set) in $\mathbb{R}^n$. A *harmonic function* on Ω is a $\mathcal{C}^2$ function $u : \Omega \to \mathbb{R}$ satisfying the *Laplace equation*

$$\frac{\partial^2 u}{\partial x_1^2} + \frac{\partial^2 u}{\partial x_2^2} + \cdots + \frac{\partial^2 u}{\partial x_n^2} = 0$$

or

$$u_{x_1 x_1} + u_{x_2 x_2} + \cdots + u_{x_n x_n} = 0$$

which can be written more compactly as

$$\Delta u = 0 \text{ or } \nabla^2 u = 0$$

where $\Delta = \nabla^2$ is the *Laplace operator*

$$\Delta = \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} + \cdots + \frac{\partial^2}{\partial x_n^2} \ .$$

XII.11.1.2. We will almost exclusively concern ourselves with the case $n = 2$, which has close connections with complex analytic functions; in fact, this case can almost be considered to be the same as the theory of analytic functions. In this case the Laplace operator can be written

$$\Delta = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$$

and a function u is harmonic if $u_{xx} + u_{yy} = 0$.

XII.11.1.3. Examples. (i) Any linear or affine function (in particular, any constant function) is harmonic.

(ii) The function $u(x, y) = x^2 - y^2$ is harmonic on $\mathbb{R}^2$. More generally, if $\alpha_1, \ldots, \alpha_n$ satisfy $\sum_{k=1}^n \alpha_k = 0$, then $u(x_1, \ldots, x_n) = \alpha_1 x_1^2 + \cdots + \alpha_n x_n^2$ is harmonic on $\mathbb{R}^n$.

(iii) The function $u(x, y) = \log \sqrt{x^2 + y^2} = \frac{1}{2} \log(x^2 + y^2)$ is harmonic on $\mathbb{R}^2 \setminus \{(0, 0)\}$. This is a particularly important example (cf. XII.11.5.1.).

(iv) If Ω is a region in $\mathbb{C} \cong \mathbb{R}^2$, and f is a complex-analytic function on Ω, then the Cauchy-Riemann equations, plus the fact that f is $\mathcal{C}^\infty$, imply that the real and imaginary parts of f are harmonic. (This includes (ii), since u is the real part of $f(z) = z^2$, and also essentially includes (iii) since u is the real part of $f(z) = \log z$.)

XII.11.1.4. A function which is harmonic on Ω is, of course, also harmonic on any subregion. Conversely, a real-valued function on Ω which is harmonic on an open neighborhood of each point of Ω is harmonic on Ω (harmonicity is a *local property*).

XII.11.1.5. Proposition. Let Ω be a region in $\mathbb{R}^n$. Any linear combination of harmonic functions on Ω is harmonic (Δ is a *linear operator*).

XII.11.1.6. A simple formal calculation using Clairaut's Theorem seems to show that any partial derivative of a harmonic function is harmonic. But there is a technicality: a harmonic function is only assumed to have continuous second-order partials, so a partial derivative is not obviously $\mathcal{C}^2$. But harmonic functions are actually automatically $\mathcal{C}^\infty$, even real-analytic (see XII.11.2.4. for the two-dimensional case), so partial derivatives of any order of harmonic functions are harmonic.

XII.11.2. Harmonic and Analytic Functions

In this section, we will only consider harmonic functions on regions in $\mathbb{R}^2$, which we can (and will) identify with $\mathbb{C}$.

XII.11.2.1. XII.11.1.3.(iv) shows that there is a connection between harmonic and analytic functions. The connection is much more intimate: the converse also essentially holds (holds locally). This provides a powerful tool for analyzing harmonic functions.

XII.11.2.2. The converse is not unrestrictedly true: the function $u(x,y) = \log\sqrt{x^2+y^2}$ of XII.11.1.3.(iii) is harmonic on $\mathbb{C}\setminus\{0\}$, but is not the real part of an analytic function on all of $\mathbb{C}\setminus\{0\}$. Thus we have to work locally.

XII.11.2.3. Theorem. Let Ω be a region in $\mathbb{C}$. If u is harmonic on Ω, then in a neighborhood of each point of Ω there is a harmonic function v, unique up to adding a constant, such that $f(x+iy) = u(x,y) + iv(x,y)$ is analytic. (The function v is called the *harmonic conjugate* of u.) Thus u is locally the real part of an analytic function on Ω. If Ω is simply connected, there is a harmonic conjugate for u on all of Ω, i.e. u is the real part of an analytic function on Ω.

Proof: The Cauchy-Riemann equations imply that v, if it exists, is unique up to adding a constant. For existence, first suppose Ω is simply connected. Define $f(x+iy) = \frac{\partial u}{\partial x}(x,y) - i\frac{\partial u}{\partial y}(x,y)$ on Ω. Then the real and imaginary parts of f have continuous first-order partials, so f is differentiable in the vector calculus sense, and the partials satisfy the Cauchy-Riemann equations by harmonicity of u and Clairaut's Theorem. Thus f is holomorphic on Ω. By (), f has an antiderivative $F = U + iV$ on Ω. We have

$$F' = \frac{\partial U}{\partial x} - i\frac{\partial U}{\partial y} = f = \frac{\partial u}{\partial x} - i\frac{\partial u}{\partial y}$$

by XII.1.1.5., so U has the same partials as u, and hence differs from u by a (real) constant. Correcting F by subtracting this constant, we have $U = u$, and we may take $v = V$.

Since every point of a general region Ω has a simply connected open neighborhood (e.g. a disk) contained in Ω, the first statement follows. 👍

Here are some crucial consequences:

XII.11.2.4. Corollary. Let Ω be a region in $\mathbb{R}^2$. Any harmonic function on Ω is real-analytic, and in particular $\mathcal{C}^\infty$.

XII.11.2.5. Corollary. Let Λ and Ω be regions in $\mathbb{C}$. If $u : \Omega \to \mathbb{R}$ is harmonic and $\phi : \Lambda \to \Omega$ is (complex-)analytic, then $u \circ \phi$ is harmonic on Λ.

Proof: Let $w_0 \in \Lambda$, and $z_0 = \phi(w_0)$. Let D be an open disk around z_0 contained in Ω, and $W = \phi^{-1}(D)$. Then W is an open neighborhood of w_0. There is an analytic function ψ on D with real part $u|_D$. So $\psi \circ \phi$ is analytic on W, and its real part is the restriction of $u \circ \phi$ to W. Thus $u \circ \phi$ is locally harmonic, hence harmonic. 👍

XII.11.3. The Mean Value Property and Local Extrema

We continue to only work in regions of $\mathbb{R}^2$. Using XII.11.2.3., we have the following important consequence of XII.3.3.3.:

XII.11.3.1. Theorem. Let u be harmonic in $\Omega \subseteq \mathbb{R}^2$, and let γ be a circle centered at $z_0 = (x_0, y_0) \in \Omega$ such that γ and its interior are contained in Ω. Then $u(x_0, y_0)$ is the average value of u around γ, i.e. if γ has radius r, then

$$u(x_0, y_0) = \frac{1}{2\pi} \int_0^{2\pi} u(z_0 + re^{i\theta})\, d\theta$$

and $u(x_0, y_0)$ is also the average value of u over the disk D bounded by γ, i.e.

$$u(x_0, y_0) = \frac{1}{\pi r^2} \iint_D u(x, y)\, dx\, dy \ .$$

Proof: The function u is the real part of an analytic function f on a slightly larger disk containing γ, and so the first formula follows from XII.3.3.3. by taking the real part. For the second part, integrating using polar coordinates and applying the first part to each circle inside γ, we have

$$\frac{1}{\pi r^2} \iint_D u(x, y)\, dx\, dy = \frac{1}{\pi r^2} \int_0^r \left[\int_0^{2\pi} u(z_0 + se^{i\theta})\, d\theta \right] s\, ds = \frac{1}{\pi r^2} \int_0^r [2\pi u(x_0, y_0)]\, s\, ds$$

$$= \frac{2\pi u(x_0, y_0)}{\pi r^2} \int_0^r s\, ds = \frac{2u(x_0, y_0)}{r^2} \frac{r^2}{2} = u(x_0, y_0) \ .$$

👍

XII.11.3.2. A continuous real-valued function u on $\Omega \subseteq \mathbb{R}^2$ satisfying the conclusion of the theorem for each circle γ is said to have the *mean value property*. (Note we do not assume a function with the mean value property is differentiable). There is a converse to XII.11.3.1.: a (continuous) function from Ω to $\mathbb{R}$ with the mean value property is necessarily harmonic (XII.11.4.8.) (and in particular $\mathcal{C}^\infty$).

Since the average value of a nonconstant real-valued continuous function over a closed bounded region is strictly less than the maximum in the region (), we have:

XII.11.3.3. Corollary. Let u have the mean value property on a region $\Omega \subseteq \mathbb{R}^2$. If u has a local maximum or minimum at a point $(x_0, y_0) \in \Omega$, then u is constant in a neighborhood of (x_0, y_0).

Proof: If u has a local maximum at (x_0, y_0), then there is a closed disk D centered at (x_0, y_0) with $u(x_0, y_0) = \max\{u(x, y) : (x, y) \in D\}$, and it follows that u is constant on D. The statement for local minima follows by considering $-u$, which also has the mean value property. 👍

Using the Rigidity Theorem, we get a vast extension (given XII.11.4.8.):

XII.11.3.4. Theorem. Let u be harmonic on a connected region $\Omega \subseteq \mathbb{R}^2$. If u has a local maximum or minimum at a point $(x_0, y_0) \in \Omega$, then u is constant on Ω.

Proof: Let $u(x_0, y_0) = \alpha$. Let

$$W = \{(x, y) \in \Omega : u \equiv \alpha \text{ in a neighborhood of } (x, y)\} .$$

Then W is open, and nonempty since $(x_0, y_0) \in W$. Let $(x_1, y_1) \in \partial W \cap \Omega$, and let D be an open disk centered at (x_1, y_1) contained in Ω. Then u is the real part of an analytic function f on D. Since the real part of f is constant on $D \cap W$, by the Cauchy-Riemann equations f is constant on $D \cap W$. Thus by the Rigidity Theorem f, and therefore u, is constant on D, and so $(x_1, y_1) \in W$. Therefore W is ralatively closed in Ω. Since Ω is connected, $W = \Omega$. 👍

This argument does not work directly if u just has the mean value property. But by a similar argument we get the following corollary of XII.11.3.4.:

XII.11.3.5. Corollary. Let Ω be a connected region in $\mathbb{C}$. Let u be continuous on $\bar{\Omega}$, with the mean value property (e.g. harmonic) on Ω, and not constant. If u has a maximum [resp. minimum] on $\bar{\Omega}$ (which will be automatic if Ω is bounded), then the maximum [resp. minimum] of u on $\bar{\Omega}$ can occur only on $\partial\Omega$.

Proof: Suppose α is the maximum value of u on $\bar{\Omega}$, and suppose $(x_0, y_0) \in \Omega$ with $u(x_0, y_0) = \alpha$. Set $W = \{(x, y) \in \Omega : u(x, y) = \alpha\}$. Then W is nonempty and relatively closed in Ω since u is continuous. If $(x_1, y_1) \in W$, then by XII.11.3.4. u is constant in a neighborhood of (x_1, y_1), so W is open. Since Ω is connected, $W = \Omega$. For the minimum, use $-u$. 👍

XII.11.3.6. Corollary. Let Ω be a region in $\mathbb{C}$. Let u and v be continuous on $\bar{\Omega}$, with the mean value property (e.g. harmonic) on Ω. If $u \equiv v$ on $\partial\Omega$, then $u \equiv v$ on all of $\bar{\Omega}$.

Proof: If Ω_0 is a connected component of Ω, then $u - v$ is identically 0 on $\partial\Omega_0$, hence is identically 0 on Ω_0. 👍

We also get a harmonic analog of the Rigidity Theorem. The proof is very similar to the proof of XII.11.3.4..

XII.11.3.7. Theorem. [Rigidity Theorem for Harmonic Functions] Let Ω be a connected region in $\mathbb{R}^2$, and let u and v be harmonic on Ω. If there is a sequence (x_n, y_n) in Ω with $(x_n, y_n) \to (x, y) \in \Omega$ and $u(x_n, y_n) = v(x_n, y_n)$ for all n, then $u \equiv v$ on all of Ω.

XII.11.4. The Dirichlet Problem

The Dirichlet Problem is a PDE boundary-value problem with many applications in physics:

XII.11.4.1. Problem. [Dirichlet Problem] Let Ω be a (usually bounded) region in $\mathbb{R}^n$, and let f be a real-valued continuous function on $\partial\Omega$. Does there exist a function $u : \bar{\Omega} \to \mathbb{R}$ which is continuous on $\bar{\Omega}$, harmonic on Ω, with $u|_{\partial\Omega} = f$? (In other words, can f be extended to $\bar{\Omega}$ to be harmonic on its interior?)

XII.11.4.2. XII.11.3.6. implies that if there is a solution, it is unique.

We will again restrict to the case $n = 2$.

XII.11.4.3. The Dirichlet Problem is not always solvable. Let Ω be the open unit disk with the origin removed. Then $\partial\Omega$ is the union of $\{0\}$ and the unit circle. If $f(0) = 1$ and f is identically 0 on the unit circle, the problem is not solvable [by uniqueness, a solution would have to be rotationally symmetric; apply XII.11.5.1.(c)].

In this example, Ω is not a regular open set, i.e. the interior of $\bar{\Omega}$ is larger than Ω. It is harder to give an example of a regular Ω for which the problem is not solvable ($\partial\Omega$ must be very complicated ()).

The Dirichlet Problem can be solved on $\mathbb{D}$, by explicit formula:

XII.11.4.4. Theorem. Let $f : [0, 2\pi] \to \mathbb{R}$ be a continuous function with $f(0) = f(2\pi)$. Then the function

$$u(re^{i\phi}) = \int_0^{2\pi} f(\theta) \frac{1 - r^2}{2\pi[1 - 2r\cos(\theta - \phi) + r^2]}\, d\theta$$

is harmonic on $\mathbb{D}$, and

$$\lim_{re^{i\phi} \to e^{i\theta}} u(re^{i\phi}) = f(\theta)$$

for all $\theta \in [0, 2\pi]$, i.e. u extends to a continuous function on $\bar{\mathbb{D}}$ agreeing with f on the unit circle. So u is the unique solution to the Dirichlet Problem on $\mathbb{D}$ for f.

See e.g. () for a proof. More generally, the Dirichlet Problem is solvable on any disk just by scaling.

XII.11.4.5. If Ω is a bounded simply connected region, and some (hence any) conformal bijection ϕ from Ω to $\mathbb{D}$ extends to a homeomorphism from $\bar{\Omega}$ to $\bar{\mathbb{D}}$, then the Dirichlet problem on Ω can be transferred to $\mathbb{D}$ via ϕ, so is solvable for any f. This condition is satisfied if $\partial\Omega$ is reasonably nice, e.g. a smooth curve or a polygon. But for this argument $\partial\Omega$ must be at least homeomorphic to a circle, and even this is not sufficient. See () for a precise description of the regions on which the problem is solvable.

XII.11.4.6. The Dirichlet Problem is also solvable if the boundary function is "not too discontinuous" ().

XII.11.4.7. Here is a simple but important example of a physical situation leading to the Dirichlet Problem. Let P be a thin metal plate whose boundary is kept at a known temperature which varies around the edge (but is constant in time). If the plate has reached steady-state temperature, the temperature at interior points is a harmonic function which is the solution to the Dirichlet Problem for the known boundary temperatures.

The Converse of the Mean Value Property

Using the fact that the Dirichlet Problem is solvable on a disk, we can obtain a converse to XII.11.3.1.:

XII.11.4.8. PROPOSITION. Let Ω be a region in $\mathbb{R}^2$, and let u be a (continuous) real-valued function on Ω with the mean value property. Then u is harmonic on Ω.

PROOF: Let $(x_0, y_0) \in \Omega$, and let D be an open disk centered at (x_0, y_0) with $\bar{D} \subseteq \Omega$. Let f be the restriction of u to ∂D. Then f is continuous, so there is a continuous function v on $\bar{D}$ which is harmonic on D and which agrees with f on ∂D. Then u and v are continuous functions on $\bar{D}$ with the mean value property, and $u \equiv v$ on ∂D, so $u \equiv v$ on $\bar{D}$ by XII.11.3.6.. In particular, u is harmonic on the open neighborhood D of (x_0, y_0). Since $(x_0, y_0) \in \Omega$ is arbitrary, u is harmonic on Ω. 👍

XII.11.4.9. Note that the analogous statement about complex-valued functions is false. If Ω is a region in $\mathbb{C}$ and f a complex-valued function on $\mathbb{C}$, then f has the mean value property if and only if its real and imaginary parts are harmonic, with no necessary relation between them, so f need not be analytic (indeed, the imaginary part may be zero, so f is just harmonic!)

XII.11.5. Exercises

XII.11.5.1. Let Ω be a region in $\mathbb{R}^2$ not containing the origin, and let u be a real-valued function $u(r, \theta)$ on Ω written in polar coordinates.
(a) Show that $\Delta u(r, \theta) = \frac{1}{r}(ru_r)_r + \frac{1}{r^2}u_{\theta\theta} = u_{rr} + \frac{1}{r}u_r + \frac{1}{r^2}u_{\theta\theta}$.

(b) Show that if u is a function of r alone (i.e. its value is "rotationally symmetric"), and harmonic, then $u(r) = a \log r + b$, where a and b are (real) constants. This function with $a = \frac{1}{2\pi}$ and $b = 0$ is called the *fundamental solution* of Laplace's equation (in two variables). It can be used to give explicit formulas for solutions to the Dirichlet and Neumann problems. (In some references, this u is described as having a "pole" at 0. But this is potentially misleading since u is not the real part of an analytic function with a pole at 0, or any other kind of isolated singularity.)

(c) If u is a nonconstant rotationally symmetric harmonic function on the unit disk with the origin removed, then u cannot be extended to a function continuous at 0.

XII.11.5.2. This problem is a continuation of Problem XII.11.5.1.. Give an alternate description of the solution to the Dirichlet problem on the unit disk $\mathbb{D}$, as follows.

(a) Show directly that the functions $u(r,\theta) = r^k \cos k\theta$, $u(r,\theta) = r^k \sin k\theta$, and more generally $u(r,\theta) = r^k \cos(k\theta + \alpha)$, for $k \in \mathbb{Z}$ and $\alpha \in \mathbb{R}$, is harmonic on $\mathbb{C} \setminus \{0\}$ (all of $\mathbb{C}$ if $k \geq 0$). [A simple indirect proof: this function is the real part of $f(z) = cz^k$ for some $c \in \mathbb{C}$, $|c| = 1$.]

(b) Let f be a real-valued continuous function on the unit circle in $\mathbb{C}$, thought of as a function on $[0, 2\pi]$ with $f(2\pi) = f(0)$. Suppose the Fourier series

$$f(\theta) = \sum_{k=0}^{\infty} a_k \cos k\theta + \sum_{k=1}^{\infty} b_k \sin k\theta$$

converges in an appropriate sense (cf. ()). Show that the series

$$u(r,\theta) = \sum_{k=0}^{\infty} a_k r^k \cos k\theta + \sum_{k=1}^{\infty} b_k r^k \sin k\theta$$

gives the solution to the Dirichlet problem on $\mathbb{D}$ for f.

XII.11.5.3. Give alternate proofs of the results of this section without using complex analysis, and formulate and prove analogous theorems for harmonic functions on regions in $\mathbb{R}^n$. (See e.g. ().)

XII.12. Differential Algebra

Differential algebra is, roughly speaking, the algebraic theory of calculus. Versions appear in quite different contexts. A basic application concerns solutions of differential equations, in particular answering questions about whether antiderivatives or other solutions to differential equations have elementary closed formulas. A quite different context is the study of one-parameter automorphism groups of operator algebras, and in forms of amenability.

XII.12.1. Derivations

A derivation on a ring is an algebraic operation which abstracts the essential properties of the derivative, specifically the product rule.

XII.12.1.1. DEFINITION. Let R be a ring. A *derivation* on R is a function $\delta : R \to R$ with the properties

$$\delta(x+y) = \delta(x) + \delta(y)$$

$$\delta(xy) = \delta(x)y + x\delta(y)$$

for all $x, y \in R$. If R is an algebra over a field $\mathbb{F}$, we often (but not always) expand the first condition to require that δ be $\mathbb{F}$-linear, i.e. we add the requirement

$$\delta(\alpha x) = \alpha\delta(x)$$

for all $\alpha \in \mathbb{F}$, $x \in R$ (cf. XII.12.1.5.(iii)).

A *differential subring* of a differential ring (R, δ) is a subring S which is closed under δ; the restriction of δ to S is thus a derivation on S.

XII.12.1.2. Note that R need not be commutative; if R is not commutative, it is crucial to respect the order of the factors in the product rule terms (since addition is always commutative, the order of the terms does not matter).

Derivations can be defined more generally from a ring R to an R-bimodule M with the same properties; but we will primarily stick to the case of derivations from R to R, which are general enough for most purposes.

XII.12.1.3. EXAMPLES. (i) Let I be an interval in $\mathbb{R}$, and R be a ring of real-valued differentiable functions on I which is closed under differentiation, e.g. $\mathcal{C}^\infty(I)$ or the set of polynomials, and set $\delta(f) = f'$. Then δ is a derivation on R. This is the prototype example.

R must be closed under differentiation: a ring such as $\mathcal{C}^1(I)$ will not work, since the derivative of a $\mathcal{C}^1$ function is not in $\mathcal{C}^1$ in general. We could more generally define differentiation as a derivation from $\mathcal{C}^p(I)$ to the $C^p(I)$-bimodule $C^{p-1}(I)$ for any $p \geq 1$.

(ii) Similarly, if U is an open set in $\mathbb{R}^2$ and $R = \mathcal{C}^\infty(U)$, set $\delta_x(f) = \frac{\partial f}{\partial x}$ and $\delta_y(f) = \frac{\partial f}{\partial y}$. Then δ_x and δ_y are derivations on R.

(iii): Let $\mathbb{F}$ be a commutative ring, usually a field. On either the polynomial ring $\mathbb{F}[X]$ or the ring of formal power series $\mathbb{F}[[X]]$ (III.5.3.2.) define δ by

$$\delta\left(\sum_{k=0}^{\infty} a_k X^k\right) = \sum_{k=1}^{\infty} k a_k X^{k-1}$$

(the sum is finite in the $\mathbb{F}[X]$ case). Then δ is a derivation. This derivation on $\mathbb{F}[X]$ can be extended to the field $\mathbb{F}(X)$ of rational functions using the "quotient rule." An extension to the field of formal Laurent series $\mathbb{F}((X))$ (III.5.3.3.) can be made in the evident way. Similarly, on $\mathbb{F}[X,Y]$ or $\mathbb{F}[[X,Y]]$, derivations δ_X and δ_Y can be defined in the same way.

(iv): Let $\mathbb{F}$ be a unital commutative ring, usually a field, and let $X, X_1, X_2, \ldots$ be a sequence of indeterminates. Form the polynomial ring

$$R = \mathbb{F}[X, X_1, X_2, \ldots] \ .$$

We will regard X_n as the "n'th derivative" of X (we may think of X as X_0). Specifically, we define a derivation δ on R with $\delta(X_k) = X_{k+1}$ for all $k \geq 0$. Linearity and the product rule then dictates the following formula for δ:

$$\delta\left(\sum_{k,n} \alpha_{kn} X_k^n\right) = \sum_{k,n} n\alpha_{k,n} X_k^{n-1} X_{k+1}$$

(the sum is a finite sum). It is easily checked that δ is a derivation on R. The ring R with this derivation is called the *ring of differential polynomials* in X, over $\mathbb{F}$, denoted $\mathbb{F}\{X\}$. We may similarly form rings of differential polynomials in more than one variable, e.g. $\mathbb{F}\{X,Y\}$, with "partial derivatives" δ_X, δ_Y.

(v) Here is an important class of derivations of interest only on noncommutative rings. Let R be a ring, and $a \in R$. Set

$$\delta_a(x) = [a,x] = ax - xa \ .$$

Then δ_a is a derivation on R, called the *inner derivation* defined by a. It is the zero derivation if and only if a is in the center of R (e.g. if R is commutative).

More generally, if M is an R-bimodule and $a \in M$, then δ_a is a derivation from R to M. Amenability is characterized by certain types of derivations always being inner ().

(vi) We illustrate the connection between inner derivations and derivatives with the following example, which is a (very) special case of the theory to be developed in (). Let $\mathcal{H}$ be a (complex) Hilbert space, and let H be a self-adjoint operator in $\mathcal{B}(\mathcal{H})$. For each $t \in \mathbb{R}$, let $U_t = e^{itH}$. Then U_t is a unitary operator on $\mathcal{H}$, $U_{s+t} = U_s U_t$ for all s,t, and $t \mapsto U_t$ is norm-continuous. Consider the inner derivation $\delta = \delta_H$ on $\mathcal{B}(\mathcal{H})$, i.e. $\delta(X) = HX - XH$. Then δ is a derivation on $\mathcal{B}(\mathcal{H})$, and is also a bounded operator on $\mathcal{B}(\mathcal{H})$, i.e. $\delta \in \mathcal{B}(\mathcal{B}(\mathcal{H}))$. Thus we may form the operator

$$\alpha_t = e^{t\delta} \in \mathcal{B}(\mathcal{B}(\mathcal{H}))$$

for any $t \in \mathbb{R}$. Then α_t is a *-automorphism of $\mathcal{B}(\mathcal{H})$ for each t, $\alpha_{s+t} = \alpha_s \circ \alpha_t$ for all s,t, and $t \mapsto \alpha_t$ is norm-continuous ($\{\alpha_t\}$ is a *norm-continuous one-parameter group of automorphisms* of $\mathcal{B}(\mathcal{H})$). We have

$$\alpha_t(X) = U_t X U_t^*$$

$$H = \lim_{t\to 0} \frac{U_t - I}{t}$$

$$\delta(X) = \lim_{t\to 0} \frac{\alpha_t(X) - X}{t}$$

for all $X \in \mathcal{B}(\mathcal{H})$. Every norm-continuous one-parameter automorphism group of $\mathcal{B}(\mathcal{H})$ is of this form (), i.e. every bounded *-derivation on $\mathcal{B}(\mathcal{H})$ is inner.

The formal relation between derivations and one-parameter automorphism groups is quite simple (if convergence questions are ignored): if (α_t) is a one-parameter automorphism group and we define

$$\delta(X) = \lim_{t\to 0} \frac{\alpha_t(X) - X}{t}$$

(assuming the limit exists for all X), then for any X and Y we have

$$\delta(XY) = \lim_{t\to 0} \frac{\alpha_t(XY) - I}{t} = \lim_{t\to 0} \frac{\alpha_t(X)\alpha_t(Y) - X\alpha_t(Y) + X\alpha_t(Y) - I}{t}$$

$$= \lim_{t\to 0} \frac{\alpha_t(X) - I}{t} Y + X \lim_{t\to 0} \frac{\alpha_t(Y) - I}{t} = \delta(X)Y + X\delta(Y)$$

so δ is a derivation. Conversely, if δ is a derivation, a formal power-series calculation (assuming the appropriate series converge) shows that e^δ is an automorphism. Thus derivations are "derivatives" of one-parameter automorphism groups.

One-parameter groups of automorphisms of $\mathcal{B}(\mathcal{H})$ which are only point-norm continuous (strongly continuous) are more important in applications, e.g. in the time evolution of a dynamical system, and have a similar description except that the H is unbounded and only densely defined in general, as is the derivation δ.

Constants

XII.12.1.4. Let δ be a derivation on a ring R. An element $x \in R$ is a *constant* (for δ) if $\delta(x) = 0$. Write R_0 for the set of constants for δ.

XII.12.1.5. Proposition. Let δ be a derivation on a ring R, and R_0 the set of constants for δ. Then

(i) R_0 is a subring of R.

(ii) If R is a unital ring, then $1 \in R_0$, i.e. R_0 is a unital subring of R.

(iii) If K is a subring of R_0 which is contained in the center of R, and R is regarded as an algebra over K, then δ is K-linear, i.e.

$$\delta(\alpha x) = \alpha\delta(x)$$

for all $\alpha \in K$, $x \in R$.

Proof: Parts (i) and (iii) are obvious. For (ii), we have

$$\delta(1) = \delta(1 \cdot 1) = \delta(1)1 + 1\delta(1) = 2\delta(1)$$

so $\delta(1) = 0$. 👍

XII.12.1.6. If δ is a derivation on a ring R, and $\alpha \in R_0$ is in the center of R, then $\alpha\delta$ is also a derivation on R, where $(\alpha\delta)(x) = \delta(\alpha x)$:

$$(\alpha\delta)(xy) = \delta(\alpha xy) = \delta(\alpha)\delta(xy) + \alpha\delta(xy) = \alpha\delta(x)y + \alpha x\delta(y) = \alpha\delta(x)y + x\alpha\delta(y)\ .$$

XII.12.1.7. EXAMPLES. (i) In XII.12.1.3.(i), the constants are exactly the constant functions.

(ii) In XII.12.1.3.(ii), if U is connected, the constants for δ_x are just the functions whose value depends only on y. But if U is not connected, the constants for the derivation are a little more complicated (functions of only y on each component of U).

(iii)–(iv) In XII.12.1.3.(iii)–(iv), the constants are just the elements of $\mathbb{F}$.

(v) In XII.12.1.3.(v), the constants for the inner derivation δ_a are exactly the elements of R which commute with a.

(vi) The ring of constants is not necessarily commutative. In the extreme case, if δ is the zero derivation on any ring R, then $R_0 = R$.

XII.12.2. Differential Fields

In the subject of differential algebra, derivations on fields are usually considered. In this subsection, all rings will be commutative.

XII.12.2.1. DEFINITION. A *differential field* is a pair $(\mathbb{F}, \delta)$, where $\mathbb{F}$ is a field of characteristic zero (III.4.3.2.) and δ a derivation on $\mathbb{F}$. (In some references the characteristic zero requirement is omitted.)

The restriction to fields is rather natural, due to the following result:

XII.12.2.2. THEOREM. Let R be a unital commutative ring, and D a subset of R closed under multiplication, $1 \in D$, which contains neither 0 nor any zero divisors. If δ is a derivation on R, then δ extends uniquely to a derivation $\bar{\delta}$ on the ring $D^{-1}R$ of quotients (III.4.3.4.). The extension is given by the "quotient rule"

$$\bar{\delta}\left(\frac{x}{y}\right) = \frac{y\delta(x) - x\delta(y)}{y^2}$$

for all $x \in R$, $y \in D$. In particular, if R is an integral domain and δ is a derivation on R, then δ extends uniquely to the quotient field of R. If $x \in R$ and $y \in D$ are constants for δ, then $\frac{x}{y}$ is a constant for $\bar{\delta}$.

PROOF: Recall that elements of $D^{-1}R$ can be symbolically written as $\frac{x}{y}$ with $x \in R$, $y \in D$, with $\frac{x}{y} = \frac{z}{w}$ if and only if $xw = yz$. (We should really write $\left[\frac{x}{y}\right]$ or $[(x, y)]$ instead of $\frac{x}{y}$.)

To motivate the definition of $\bar{\delta}$ and prove uniqueness, suppose $\tilde{\delta}$ is a derivation on $D^{-1}R$ extending δ. For each $y \in D$, we have, by XII.12.1.5.(ii),

$$0 = \tilde{\delta}(1) = \tilde{\delta}\left(y\frac{1}{y}\right) = y\tilde{\delta}\left(\frac{1}{y}\right) + \frac{1}{y}\tilde{\delta}(y) = y\tilde{\delta}\left(\frac{1}{y}\right) + \frac{1}{y}\delta(y)$$

$$\tilde{\delta}\left(\frac{1}{y}\right) = -\frac{1}{y^2}\delta(y)$$

and if $x \in R$, we have

$$\tilde{\delta}\left(\frac{x}{y}\right) = \tilde{\delta}\left(x\frac{1}{y}\right) = \frac{1}{y}\tilde{\delta}(x) + x\tilde{\delta}\left(\frac{1}{y}\right) = \frac{1}{y}\delta(x) - \frac{x}{y^2}\delta(y) = \frac{y\delta(x) - x\delta(y)}{y^2} \ .$$

We now show that $\bar{\delta}$ is well defined. We first suppose $x \in \mathbb{R}$ and $y, z \in D$. Then

$$\bar{\delta}\left(\frac{xz}{yz}\right) = \frac{yz\delta(xz) - xz\delta(yz)}{y^2z^2} = \frac{yz(x\delta(z) + z\delta(x)) - xz(y\delta(z) + z\delta(y))}{y^2z^2}$$

$$= \frac{yz^2\delta(x) - xz^2\delta(y)}{y^2z^2} = \frac{y\delta(x) - x\delta(y)}{y^2} = \bar{\delta}\left(\frac{x}{y}\right) .$$

Now if $\frac{x}{y} = \frac{z}{w}$, i.e. $xw = yz$, we have

$$\bar{\delta}\left(\frac{x}{y}\right) = \bar{\delta}\left(\frac{xyw^2}{y^2w^2}\right) = \bar{\delta}\left(\frac{y^2zw}{y^2w^2}\right) = \bar{\delta}\left(\frac{z}{w}\right) .$$

The embedding of R into $D^{-1}R$ sends x to $\frac{x}{1}$, and

$$\bar{\delta}\left(\frac{x}{1}\right) = \frac{1 \cdot \delta(x) - x\delta(1)}{1^2} = \delta(x)$$

since $\delta(1) = 0$. Thus $\bar{\delta}$ extends δ.

To show that $\bar{\delta}$ is a derivation, let $x, z \in R$ and $y, w \in D$. Then

$$\bar{\delta}\left(\frac{x}{y} \cdot \frac{z}{w}\right) = \bar{\delta}\left(\frac{xz}{yw}\right) = \frac{yw\delta(xz) - xz\delta(yw)}{y^2w^2} = \frac{yw(x\delta(z) + z\delta(x)) - xz(y\delta(w) + w\delta(y))}{y^2w^2}$$

$$= \frac{ywz\delta(x) - xzw\delta(y) + xyw\delta(z) - xyz\delta(w)}{y^2w^2} = \frac{yz\delta(x) - xz\delta(y)}{y^2w} + \frac{xw\delta(z) - xz\delta(w)}{yw^2} = \frac{z}{w}\bar{\delta}\left(\frac{x}{y}\right) + \frac{x}{y}\bar{\delta}\left(\frac{z}{w}\right)$$

so $\bar{\delta}$ is a derivation.

The last statement is obvious from the formula for $\bar{\delta}$. 👍

A corollary of the first part of the proof is:

XII.12.2.3. Corollary. Let δ be a derivation on a unital ring R. If $y \in R$ is invertible, then

$$\delta(y^{-1}) = -y^{-1}\delta(y)y^{-1} .$$

In particular, if y is a constant for δ, so is y^{-1}. So if $(\mathbb{F}, \delta)$ is a differential field, the ring of constants for δ is a subfield of $\mathbb{F}$.

Here are the most important examples of differential fields for our purposes:

XII.12.2.4. EXAMPLES. (i) Let $\mathbb{F}$ be a field of characteristic zero (e.g. $\mathbb{Q}$, $\mathbb{R}$, or $\mathbb{C}$). The polynomial ring $\mathbb{F}[X]$ in one variable over $\mathbb{F}$ becomes a differential ring under the derivation

$$\delta\left(\sum_{k=0}^{n}\alpha_k X^k\right)=\sum_{k=1}^{n}k\alpha_k X^{k-1}$$

and the quotient field $\mathbb{F}(X)$ of rational functions in one variable over $\mathbb{F}$ becomes a differential field with the unique extension from XII.12.2.2. given by the quotient rule.

There is a minor but technically important point about this example and the succeeding ones which is glossed over in many references on differential fields. The elements of $\mathbb{F}(X)$ are called "rational functions," but they are not exactly functions from $\mathbb{F}$ (or a fixed subset) to $\mathbb{F}$ since functions which agree except at finitely many points are identified. Thus, for example, $f(X)=X+1$, $g(X)=\frac{X^2-1}{X-1}$, and $h(X)=\frac{X^2-X-2}{X-2}$ all represent the same element of $\mathbb{F}(X)$ even though they represent different functions since their domains are different.

It is customary in differential algebra to play a little fast and loose with domains of "functions" since it turns out that the domains and other functional properties are not really relevant to the algebra, but one should be careful in the process.

(ii) Let Ω be a connected open set in $\mathbb{C}$. Let $\mathbb{M}(\Omega)$ be the set of meromorphic functions on Ω, complex-valued functions which are differentiable on Ω except for isolated poles (or removable singularities). We again identify two functions if they agree when all removable singularities have been filled in, i.e. if the functions agree on a nonempty open subset of Ω, or more generally on a subset of Ω with a limit point in Ω (XII.5.1.4.). The reciprocal of a meromorphic function on Ω which is not identically zero is again a meromorphic function on Ω, so $\mathbb{M}(\Omega)$ is a field. The usual complex differentiation is a derivation on $\mathbb{M}(\Omega)$ making it into a differential field. $\mathbb{C}(X)$ may be regarded as a differential subfield of $\mathbb{M}(\Omega)$ for any Ω. If $\Omega_1\subseteq\Omega_2$, then restriction gives a natural embedding of $\mathbb{M}(\Omega_2)$ into $\mathbb{M}(\Omega_1)$, so $\mathbb{M}(\Omega_2)$ can be regarded as a subfield of $\mathbb{M}(\Omega_1)$. (It is a proper subfield if $\Omega_2\neq\Omega_1$: for example, if $z_0\in\Omega_2\setminus\Omega_1$, then $f(z)=e^{1/(z-z_0)}$ is in $\mathbb{M}(\Omega_1)$ but not $\mathbb{M}(\Omega_2)$.) The field of constants in these differential fields is $\mathbb{C}$ (i.e. the usual constant functions).

If Ω is not connected, then $\mathbb{M}(\Omega)$ has zero divisors and is not a field: a function which is identically zero on one component of Ω but not on all of Ω is a zero divisor.

Differential Function Fields

These examples lead to a convenient definition of the principal objects of study in elementary differential algebra:

XII.12.2.5. DEFINITION. A *differential function field* or *dff* is a differential subfield of $\mathbb{M}(\Omega)$ containing $\mathbb{C}(X)$, for some nonempty connected open subset Ω of $\mathbb{C}$.

As mentioned earlier, the exact set Ω will turn out to be unimportant, and we will feel free to reduce it whenever necessary. The next convenient result illustrates the technique:

XII.12.2.6. PROPOSITION. Let $\mathbb{F}$ be a differential function field, and $\mathbb{K}$ a finite extension of $\mathbb{F}$. Then $\mathbb{K}$ is isomorphic to a differential function field, and the derivation on $\mathbb{K}$ is uniquely determined by the derivation on $\mathbb{F}$.

PROOF: Identify $\mathbb{F}$ with a subfield of $\mathbb{M}(\Omega)$ for some $\Omega \subseteq \mathbb{C}$. Suppose $\mathbb{K} = \mathbb{F}(\phi)$ for some $\phi \in \mathbb{K}$ ($\mathbb{K}$ can be constructed from $\mathbb{F}$ by finitely many such steps; in fact, it can be done in one step by the Primitive Element Theorem of algebra). Then ϕ is a root of an irreducible polynomial $p(Y)$ with coefficients in $\mathbb{F}$. Regard p as a function $p(z, w)$ from $\Omega \times \mathbb{C}$ to $\mathbb{C}$ which is analytic except where z is a pole of a coefficient function of p. By the Analytic Implicit Function Theorem (VIII.5.10.4.), there is an open set $\Omega' \subseteq \Omega$ and an analytic function g on Ω' such that $p(z, g(z)) = 0$ for all $z \in \Omega'$. The embedding of $\mathbb{K}$ into $\mathbb{M}(\Omega')$ which is restriction on $\mathbb{F}$ and which sends ϕ to g represents $\mathbb{K}$ as a differential function field. 👍

Algebraic Extensions of Derivations

The uniqueness of the derivation follows from a more general version of this result:

XII.12.2.7. PROPOSITION. Let $(\mathbb{F}, \delta)$ be a differential field, and $\mathbb{K}$ an algebraic extension of $\mathbb{F}$. Then δ extends uniquely to a derivation on $\mathbb{K}$.

PROOF: [Ros72] Define two derivations δ_0, δ_1 on $\mathbb{F}[X]$ by

$$\delta_0\left(\sum_{k=0}^{n} \alpha_k X^k\right) = \sum_{k=0}^{n} \delta(\alpha_k) X^k$$

$$\delta_1\left(\sum_{k=0}^{n} \alpha_k X^k\right) = \sum_{k=1}^{n} k\alpha_k X^{k-1}$$

(it is routine to check that δ_0 and δ_1 are derivations). Let $\tilde{\delta}$ be a derivation on $\mathbb{K}$ extending δ. If $p(X) = \sum_{k=0}^{n} \alpha_k X^k$, then for any $z \in \mathbb{K}$,

$$0 = \tilde{\delta}(p(z)) = \sum_{k=0}^{n} \tilde{\delta}(\alpha_k z^k) = \sum_{k=0}^{n} \tilde{\delta}(\alpha_k) z^k + \sum_{k=1}^{n} \alpha_k z^{k-1} \tilde{\delta}(z) = (\delta_0(p))(z) + (\delta_1(p))(z)\tilde{\delta}(z) \ .$$

Let f be the irreducible polynomial of z over $\mathbb{F}$. Taking $p = f$, we have

$$0 = \tilde{\delta}(0) = \tilde{\delta}(f(z)) = (\delta_0(f))(z) + (\delta_1(f))(z)\tilde{\delta}(z)$$

$$(\delta_1(f))(z)\tilde{\delta}(z) = -(\delta_0(f))(z) \ .$$

But $\delta_1(f)$ is the "derivative" of f in the usual algebraic sense. Since $\mathbb{F}$ has characteristic zero, z is not a root of $\delta_1(f)$ (), i.e. $(\delta_1(f))(z) \neq 0$, and hence

$$\tilde{\delta}(z) = -\frac{(\delta_0(f))(z)}{(\delta_1(f))(z)} \ .$$

Thus an extension of δ to $\mathbb{K}$ (if one exists) is unique, and for any $z \in \mathbb{K}$, we have that $\tilde{\delta}(z) \in \mathbb{F}(z)$.

To show existence, we may assume $\mathbb{K} = \mathbb{F}(z)$ for some z. We have $\mathbb{K} = \mathbb{F}(z) \cong \mathbb{F}[X]/(f(X))$, where $f(X)$ is the irreducible polynomial of z over $\mathbb{F}$. We need only show that the derivation

$$\bar{\delta} = \delta_0 - \frac{(\delta_0(f))(z)}{(\delta_1(f))(z)}\delta_1$$

of $\mathbb{F}[X]$ drops to a derivation of $\mathbb{F}[X]/(f(X))$ (XII.12.4.5.), since this drop will extend δ. Thus we only need to show that $\bar{\delta}$ maps the ideal $(f(X))$ into itself, i.e. that $\delta(f)$ is a multiple of f, or equivalently that z is a root of $\bar{\delta}(f)$. But

$$(\bar{\delta}(f))(z) = (\delta_0(f))(z) - \frac{(\delta_0(f))(z)}{(\delta_1(f))(z)}(\delta_1(f))(z) = 0 \ .$$

Exponentials and Logarithms

XII.12.2.8. Definition. Let $(\mathbb{F}, \delta)$ be a differential field, and $x, y \in \mathbb{F}$, $y \neq 0$. Then y is an *exponential* of x, and x is a *logarithm* of y, if $\delta(y) = y\delta(x)$, or equivalently $\delta(x) = \frac{\delta(y)}{y}$.

XII.12.2.9. Proposition. (i) If y_1 is an exponential of x, then y_2 is an exponential of x if and only if $y_2 = cy_1$ for some nonzero constant c.
(ii) If x_1 is a logarithm for y, then x_2 is a logarithm for y if and only if $x_2 = x_1 + c$ for some constant c.

Proof: (ii) is trivial since $\delta(x_2) = \delta(x_1)$ if and only if $\delta(x_1 - x_2) = 0$.
(i): The following statements are equivalent for $y_2 \neq 0$:

$$\frac{\delta(y_2)}{y_2} = \frac{\delta(y_1)}{y_1} (= \delta(x))$$

$$y_2\delta(y_1) = y_1\delta(y_2)$$

$$\frac{y_2\delta(y_1) - y_1\delta(y_2)}{y_2^2} = \delta\left(\frac{y_1}{y_2}\right) = 0 \ .$$

XII.12.2.10. Example. Let $f \in \mathbb{M}(\Omega)$ for some connected open set $\Omega \subseteq \mathbb{C}$. An exponential for f is a function g of the form ce^f for some nonzero $c \in \mathbb{C}$. The function g is meromorphic (holomorphic) on any subregion $\Omega' \subseteq \Omega$ containing no poles of f, i.e. a subset on which f is holomorphic.

If f is not identically zero, a logarithm for f is a function h of the form $c + \log f$ for some $c \in \mathbb{C}$. The function h can be chosen meromorphic (holomorphic) on any simply connected $\Omega' \subseteq \Omega$ not containing any zeroes or poles of f.

Thus, if $\mathbb{F}$ is any differential function field, and $f \in \mathbb{F}$, there is a dff $\mathbb{K}$ containing $\mathbb{F}$ containing an exponential for f; if f is nonzero there is also such a $\mathbb{K}$ containing a logarithm for f. The smallest such dff is well defined up to isomorphism, and is called the dff obtained from $\mathbb{F}$ by adding an exponential [logarithm] of $\mathbb{F}$; it is isomorphic to an evident quotient of the universal differential algebra $\mathbb{F}\{X\}$ (by the differential ideal generated by $X_1 - fX$ in the exponential case and $fX_1 - f'$ in the logarithm case).

XII.12.2.11. Proposition. [Logarithmic Differentiation Formula] Let $(\mathbb{F}, \delta)$ be a differential field, $a_1, \ldots, a_n$ nonzero elements of $\mathbb{F}$, and $r_1, \ldots, r_n \in \mathbb{N}$. Set $a = a_1^{r_1} a_2^{r_2} \cdots a_n^{r_n}$. Then

$$\frac{\delta(a)}{a} = r_1 \frac{\delta(a_1)}{a_1} + r_2 \frac{\delta(a_2)}{a_2} + \cdots + r_n \frac{\delta(a_n)}{a_n} \ .$$

Proof: This is an easy proof by induction on $r_1 + \cdots + r_n$, using the product rule. 👍

XII.12.3. Integration in Finite Terms

The name of this section has been the title of at least two important publications on the subject ([Rit48], [Ros72]). The general problem is: if δ is a derivation on a ring R, what is the range of δ, and in particular is δ surjective? If $x \in R$, can δ be extended to a well-behaved larger ring with x in the range of the extended derivation?

Rather than treating the general problem, we will have the much more modest goal of examining the question for differential function fields. In other words, we will determine conditions for when there is, or is not, a differentiable function g with an elementary formula whose derivative is a given function f which has an elementary formula, or equivalently whether

$$\int f(x)\, dx$$

has a formula in terms of standard functions.

We must first carefully determine what it means for a function to have an "elementary formula."

Elementary Formulas

XII.12.3.1. We will informally say a function has an elementary formula if it can be written in terms of algebraic operations and exponential, logarithm, trigonometric, and inverse trigonometric functions, which are defined on some common interval. (We could include hyperbolic and inverse hyperbolic functions too, but these functions can be written in terms of exponential and logarithm functions so they come for free.)

XII.12.3.2. It is convenient and useful to pass to complex functions. Each of the "building block" functions (algebraic, exponential, logarithm, trigonometric, inverse trigonometric) can be regarded as a holomorphic function on large regions of the complex plane, and hence any real-valued function defined on a real interval which has an elementary formula in the above sense will be holomorphic on a large region in $\mathbb{C}$. In addition, when we expand to complex functions, we get the pleasant fact that trigonometric and inverse trigonometric functions can also be written in terms of exponential and logarithm functions () and thus do not have to be separately considered. We can thus reduce the problem to consideration of only functions which can be written with formulas involving only algebraic operations and exponential and logarithm functions.

XII.12.3.3. Definition. Let $(\mathbb{F}, \delta)$ be a differential field. A differential field $\mathbb{K}$ containing $\mathbb{F}$ is an *elementary extension* of $\mathbb{F}$ if there is a finite chain

$$\mathbb{F} = \mathbb{F}_1 \subseteq \mathbb{F}_2 \subseteq \cdots \subseteq \mathbb{F}_n = \mathbb{K}$$

of field extensions where, for each k, $\mathbb{F}_{k+1}$ is either a finite extension of $\mathbb{F}_k$ or is obtained by adding to $\mathbb{F}_k$ an exponential or logarithm of an element of $\mathbb{F}_k$.

An *elementary function field* is an elementary extension of the field $\mathbb{C}(X)$ of rational functions over $\mathbb{C}$. A function f which is meromorphic on a region in $\mathbb{C}$ is an *elementary function* if it lies in some elementary function field.

XII.12.3.4. By XII.12.2.6.and XII.12.2.10., an elementary function field is a differential function field. Any elementary extension of an elementary extension of a differential field $\mathbb{F}$ is an elementary extension of $\mathbb{F}$; in particular, an elementary extension of an elementary function field is an elementary function field.

XII.12.3.5. Example. A function with a formula like

$$f(z) = \frac{\sqrt[3]{e^{\cos(z^2+1)} - \log(\sin^{-1} z))}}{z^5 - iz + 1}$$

is an elementary function. The reader can find a finite chain of exponentials, logarithms, and roots (beginning with $e^{i(z^2+1)}$) which when successively added to the field of rational functions include this function.

The problem of integration in finite terms thus becomes the following specific problem:

XII.12.3.6. Question. Let f be an elementary function. Is there an elementary function g with $g' = f$?

XII.12.3.7. It would be clean to take the field of all elementary functions, with its natural derivative (derivation), and ask what the range of this derivation is. However, it is not clear that this version of the question is well defined. (There is certainly no region in $\mathbb{C}$ on which all elementary functions are meromorphic.) Thus we have to work locally in elementary function fields.

A more general version of the question is thus:

XII.12.3.8. Question. Let $(\mathbb{F}, \delta)$ be a differential field, and $x \in \mathbb{F}$. Under what conditions is there an elementary extension $(\mathbb{K}, \tilde{\delta})$ of $\mathbb{F}$ and an element $y \in \mathbb{K}$ with $x = \tilde{\delta}(y)$?

XII.12.3.9. In 1835, Liouville gave a necessary and sufficient condition (XII.12.3.11.) for elements of elementary function fields, which was abstracted by Ostrowski [**?**] in 1946 (cf. [Ros72]):

XII.12.3.10. THEOREM. Let $(\mathbb{F}, \delta)$ be a differential field, and $x \in \mathbb{F}$. Then there is an elementary extension $(\mathbb{K}, \tilde{\delta})$ of $(\mathbb{F}, \delta)$ with the same field of constants as $(\mathbb{F}, \delta)$, and an element $y \in \mathbb{K}$ with $x = \tilde{\delta}(y)$, if and only if there are constants $c_1, \ldots, c_n$ and elements $u_1, \ldots, u_n, v$ of $\mathbb{F}$ such that

$$x = \sum_{k=1}^{n} c_k \frac{\delta(u_k)}{u_k} + \delta(v) \ .$$

XII.12.3.11. COROLLARY. Let $(\mathbb{F}, \delta)$ be an elementary function field, and $f \in \mathbb{F}$. Then there is an elementary function g with $f = g'$ if and only if there are constants $c_1, \ldots, c_n$ and functions $h_1, \ldots, h_n, \phi$ in $\mathbb{F}$ such that

$$f = \sum_{k=1}^{n} c_k \frac{h_k'}{h_k} + \phi' \ .$$

XII.12.3.12. To obtain the corollary from the theorem, it suffices to note that all differential function fields have the same field of constants, namely the constant functions. One direction of the theorem is very easy: if x is of the given form, one only needs to add logarithms $z_1, \ldots, z_n$ of $u_1, \ldots, u_n$ to $\mathbb{F}$, and then

$$y = c_1 z_1 + \cdots + c_n z_n + v$$

is an antiderivative of x. Thus the conclusion of the theorem can be strengthened, since $\mathbb{K}$ is obtained by just adding logarithms.

The other direction is a more involved argument requiring some elementary field theory, and is omitted. See e.g. [Ros72]. The requirement that $\mathbb{K}$ have the same constants as $\mathbb{F}$ is necessary: if $\mathbb{F} = \mathbb{R}(X)$, and $f(x) = \frac{1}{x^2+1}$, then f is not of the given form in $\mathbb{F}$ even though it has an elementary antiderivative in an extension of $\mathbb{C}(X)$ (which is a finite, hence elementary, extension of $\mathbb{F}$) by a logarithm. (It does have such an expression in $\mathbb{C}(X)$, to which the theorem applies.)

Applications

We now discuss some simple functions which have no elementary antiderivatives.

XII.12.3.13. We first examine integrals of the form

$$\int \frac{1}{\sqrt{p(x)}}\, dx$$

where p is a polynomial with complex coefficients of degree ≥ 3 and with no multiple roots. Integrals of this type include *elliptic integrals*, which arise in computing the arc length of an ellipse. Of course, what we want is an elementary function g whose derivative is $f(z) = \frac{1}{\sqrt{p(z)}}$ (say, on some subregion of $\mathbb{C}$; it could be the preimage under $1/p$ of any simply connected region not containing 0).

XII.12.3.14. We now examine integrals of the form

$$\int f(x)e^{g(x)}\,dx$$

where f and g are rational functions. LIOUVILLE showed:

XII.12.3.15. THEOREM. Let f and g be in $\mathbb{C}(X)$, with $f \neq 0$ and g not constant. Then there is an elementary function h such that $h'(z) = f(z)e^{g(z)}$ if and only if there is a rational function r such that

$$r'(X) + g'(X)r(X) = f(X)$$

in $\mathbb{C}(X)$. If there is such an r, then $h(z) = r(z)e^{g(z)}$ is an elementary antiderivative of fe^g.

XII.12.3.16. Note that the condition is considerably stronger than simply asserting that the differential equation

$$y' + g'(t)y = f(t)$$

has a solution, which will always be the case from existence theorems for differential equations (at least if f and g have real coefficients); the condition requires that it have a *rational* solution. A corollary (equivalent version) of the theorem is that if the differential equation does not have a rational solution, it does not have an elementary solution.

XII.12.3.17. For example, consider the integral

$$\int \frac{e^x}{x}\,dx\ .$$

Applying the theorem with $f(X) = \frac{1}{X}$ and $g(X) = X$, this integral has an elementary formula if and only if the differential equation

$$r'(X) + r(X) = \frac{1}{X}$$

has a rational solution. Suppose $r(X) = \frac{p(X)}{q(X)}$ is a solution with $p(X)$, $q(X)$ polynomials which are relatively prime. We have

$$\frac{q(X)p'(X) - p(X)q'(X)}{[q(X)]^2} + \frac{p(X)}{q(X)} = \frac{q(X)p'(X) - p(X)q'(X) + p(X)q(X)}{[q(X)]^2} = \frac{1}{X}$$

in $\mathbb{C}(X)$, and hence X divides $[q(X)]^2$ and therefore $q(X)$. Thus

$$q(X) = X^n\phi(X)$$

for some $n \geq 1$ and some polynomial $\phi(X)$ not divisible by X. Note that X does not divide $p(X)$. We have

$$\frac{X^n\phi(X)p'(X) - p(X)[nX^{n-1}\phi(X) + X^n\phi'(X)]}{X^{2n}[\phi(X)]^2} + \frac{p(X)}{X^n\phi(X)}$$

$$= \frac{X^n[\phi(X)p'(X) - \phi'(X)p(X) + \phi(X)p(X)] - nX^{n-1}\phi(X)p(X)}{X^{2n}[\phi(X)]^2}$$
$$= \frac{X[\phi(X)p'(X) - \phi'(X)p(X) + \phi(X)p(X)] - n\phi(X)p(X)}{X^{n+1}[\phi(X)]^2} = \frac{1}{X}$$

in $\mathbb{C}(X)$. The denominator is divisible by X^{n+1}, so the numerator must be divisible by X^n, and in particular by X. Thus $n\phi(X)p(X)$ must be divisible by X. But X does not divide $p(X)$, so it must divide $\phi(X)$, a contradiction. Thus there is no rational solution, and no elementary formula for the antiderivative.

The substitution $x = \log u$ converts this integral into

$$\int \frac{1}{\log u}\, du$$

which therefore also does not have an elementary formula. This integral arises in the Prime Number Theorem ().

XII.12.3.18. Now we turn to the best-known example of this type:

$$\int e^{-x^2}\, dx$$

which is important in probability (). The arguments for

$$\int e^{x^2}\, dx$$

are essentially identical.

Applying the theorem with $f(X) = 1$ and $g(X) = -X^2$, we need to show that there is no rational function $r(X)$ satisfying

$$r'(X) - 2Xr(X) = 1\ .$$

Clearly there is no polynomial satisfying this equation, since if $r(X)$ is a polynomial of degree d, the left side is a polynomial of degree $d+1$. Thus we may write $r(X) = \frac{p(X)}{q(X)}$ in lowest terms with q not constant. Then q has a root $z_0 \in \mathbb{C}$, i.e. r has a pole of some finite order $n \geq 1$ at z_0, so r can be written

$$r(X) = \frac{h(X)}{(X - z_0)^n}$$

with $h(X) \in \mathbb{C}(X)$ defined and nonzero at z_0, and h and h' are continuous at z_0. Set

$$\phi(X) = r'(X) - 2Xr(X) = \frac{(X - z_0)^n h'(X) - n(X - z_0)^{n-1}h(X)}{(X - z_0)^{2n}} - \frac{2Xh(X)}{(X - z_0)^n}$$
$$= \frac{(X - z_0)^n[h'(X) - 2Xh(X)] - n(X - z_0)^{n-1}h(X)}{(X - z_0)^{2n}} = \frac{(X - z_0)[h'(X) - 2Xh(X)] - nh(X)}{(X - z_0)^{n+1}}$$

and thus, if ϕ is regarded as a meromorphic function on $\mathbb{C}$, we have

$$\lim_{z \to z_0} (z - z_0)^{n+1}\phi(z) = \lim_{z \to z_0} [(z - z_0)[h'(z) - 2zh(z)] - nh(z)] = nh(z_0) \neq 0$$

which contradicts that $\phi(X) = 1$ in $\mathbb{C}(X)$.

Thus there is no rational solution to the differential equation, and no elementary formula for the antiderivative.

XII.12.4. Exercises

XII.12.4.1. Let δ be the derivation of $\mathbb{F}[X]$ defined as in XII.12.1.3.(iii). Show that the automorphism e^δ (XII.12.1.3.(vi)) is defined, and that $[e^\delta(f)](X) = f(X+1)$. Show why this does not work on $\mathbb{F}[[X]]$. But it does work on $\mathbb{F}\{X\}$ (XII.12.1.3.(iv)); give an explicit formula.

XII.12.4.2. Let (R,δ) and $(\tilde{R},\tilde{\delta})$ be differential rings. A ring-homomorphism $\phi : R \to \tilde{R}$ is a *differential homomorphism*, or *diffomorphism*, if ϕ intertwines δ and $\tilde{\delta}$, i.e. $\tilde{\delta}(\phi(x)) = \phi(\delta(x))$ for all $x \in R$. [The term "diffomorphism" is to "diffeomorphism" exactly as "homomorphism" is to "homeomorphism".]

Show that if (R,δ) is a commutative differential ring and $z \in R$, there is a unique diffomorphism from the differential polynomial ring $R_0\{X\}$ (XII.12.1.3.(iv)) to R sending X to z. Thus $R_0\{X\}$ is the "universal" differential algebra with one generator over the ring R_0 of constants.

XII.12.4.3. Generalize the construction of the differential polynomial ring as follows. Let $(\mathbb{F},\delta)$ be a commutative differential ring, and let $X, X_1, X_2, \dots$ be a sequence of indeterminates. Form the polynomial ring

$$R = \mathbb{F}[X, X_1, X_2, \dots] \ .$$

Define a map $\tilde{\delta} : R \to R$ by

$$\delta\left(\sum_{k,n} \alpha_{kn} X_k^n\right) = \sum_{k,n} \delta(\alpha_{k,n}) X_k^n + \sum_{k,n} n\alpha_{k,n} X_k^{n-1} X_{k+1} \ .$$

(i) Show that $\tilde{\delta}$ is a derivation on R which extends the derivation δ on the subring $\mathbb{F}$ of "constant polynomials" (which is not the ring of constants for $\tilde{\delta}$ in general!) Denote the ring R by $\mathbb{F}\{X\}$. Note that if δ is the zero derivation on $\mathbb{F}$, then this definition agrees with the previous definition of $\mathbb{F}\{X\}$.

(ii) Show that if $(\mathbb{K},\bar{\delta})$ is another commutative differential ring and $\phi : \mathbb{F} \to \mathbb{K}$ is a diffomorphism, and $z \in \mathbb{K}$, then there is a unique extension $\tilde{\phi}$ of ϕ to a diffomorphism from $\mathbb{F}\{X\}$ to $\mathbb{K}$ sending X to z. Thus $\mathbb{F}\{X\}$ is the "universal" differential algebra in one variable over the differential ring $(\mathbb{F},\delta)$.

XII.12.4.4. Let $\mathbb{F}$ be a unital commutative ring, and $\mathbb{F}\{X,Y\}$ the universal differential algebra in two variables over $\mathbb{F}$ (XII.12.1.3.(iv)). Give a careful description of $\mathbb{F}\{X,Y\}$, δ_X, and δ_Y, and prove the algebraic version of Clairaut's Theorem: δ_X and δ_Y commute, i.e. $\delta_X \circ \delta_Y = \delta_Y \circ \delta_X$. In fact, show that $\mathbb{F}\{X,Y\}$, $[\mathbb{F}\{X\}]\{Y\}$, and $[\mathbb{F}\{Y\}]\{X\}$ are naturally isomorphic, where the last two are defined as in XII.12.4.3.. Show that the automorphisms e^{δ_X} and e^{δ_Y} of $\mathbb{F}\{X,Y\}$ exist, give formulas, and show they commute.

XII.12.4.5. Let (R,δ) be a differential ring, and J a closed two-sided ideal of R (). If J is invariant under δ, i.e. if $\delta(J) \subseteq J$, show that δ drops to a derivation $\bar{\delta}$ on the quotient ring R/J satisfying $\bar{\delta}(\pi(x)) = \pi(\delta(x))$ for all $x \in R$, where $\pi : R \to R/J$ is the quotient map (i.e. π is a diffomorphism). An ideal of R invariant under δ is called a *differential ideal*.

XII.12.4.6. Let $(\mathbb{K},\delta)$ be a differential field, and $\mathbb{F}$ a subfield of $\mathbb{K}$ closed under δ. If $y \in \mathbb{K} \setminus \mathbb{F}$ is an exponential or logarithm of an element of $\mathbb{F}$, is y necessarily transcendental over $\mathbb{F}$? What if $\mathbb{F}$ contains all constants of $\mathbb{K}$?

XII.12.4.7. Define a one-parameter automorphism group of $\mathcal{C}_c^\infty(\mathbb{R})$ () by

$$[\alpha_t(f)](x) = f(x+t) \ .$$

Show that α_t is an automorphism for each t, that $\alpha_{t+s} = \alpha_t \circ \alpha_s$ for all t, s. Discuss continuity of this one-parameter automorphism group and how the "derivative" in the sense of XII.12.1.3.(vi) is the derivation given by ordinary differentiation.

XII.12.4.8. (a) Find an elementary closed formula for

$$\int \sqrt{\tan x}\ dx$$

(a computer algebra system is very helpful).

(b) (Liouville, 1835) Show that

$$\int \sqrt{\sin x}\ dx$$

has no elementary closed formula.

Chapter XIII

Topology

Topology is a part of mathematics which provides a general setting for the notions of limits and continuity.

Topology is a huge subject, and goes far beyond the parts which form an essential tool for analysis and other parts of mathematics. Our treatment of topology will mostly just cover the basic tools of the subject, with an eye to applications in analysis.

In his classic topology book [Kel75], J. Kelley described the contents as "what every young analyst should know." While his judgment was of course subjective, it can be taken as a good guide. The topology covered in this book largely represents my own judgment of What Every Analyst Should Know, but I admit some idiosyncracies due to my own personal interests.

The idea behind topology is to describe what it means for points of a set to be "close together." There are at least four standard and commonly used equivalent ways to define, specify, or think of a topology on a set X (usually called a *space*):

(1) Specifying what the neighborhoods of each point of X are, i.e. specifying which subsets of X are open.

(2) Specifying the closure of each subset of X.

(3) Specifying which sequences (or generalized sequences) in X converge, and what their limits are.

(4) Specifying which functions into or out of X are continuous.

A good way of doing (1) is to specify a metric on X, and hence open balls in X, but there are other ways to do (1) also.

Approach (1) is normally taken as the definition of a topology. We will in due course describe all four approaches and how to go from each to the others.

Topology as used by topologists (or as presented in most elementary topology classes) has a rather different emphasis than topology as used by analysts. Topologists by and large consider spaces which have only one obvious or natural topology (except sometimes for exotic topologies artificially constructed primarily to provide counterexamples; there are other exceptions too). When a topologist considers convergence of a sequence or continuity of a function, there is a natural interpretation, and it is not necessary to go back and worry about "with respect to what topology?" The topology tends to be taken for granted.

An analyst must quickly overcome this mindset. Spaces arising in analysis, notably function spaces, often have more than one *natural* topology, sometimes a great many, with varying properties. Convergence in one sense does not generally imply convergence in another sense, and some properties (e.g. continuity of functions) are preserved under certain kinds of limits but not others. Thus, for example, an analyst should never say of functions that $f_n \to f$ without carefully specifying what is meant, because such a statement is totally ambiguous otherwise. An analyst needs to be acutely aware of which topology is being considered in a given situation, and that there is usually a multitude of reasonable candidates.

Topology is a subject which is full of definitions; in fact, the density of definitions in topology may be the highest in all the parts of mathematics. This situation arises because of the great generality of the subject and the enormous variety of topological spaces with varied properties. Most definitions in topology are of little direct interest to analysts. We will for the most part stick to those definitions relevant to analysis to try to avoid getting too bogged down in terminology.

Figure XIII.1: Rumored original source of topology in Serbia

XIII.1. Topological Spaces

The most important tool used in the study of limits and continuity in Euclidean spaces and metric spaces is the notion of "open set." The idea behind the definition of a topological space is to abstract the notion of open set directly, without working through intermediate structures like metrics. Thus a topological space will just be an abstract set X together with a specified collection of subsets which we arbitrarily call "open" sets in X; the term "open" does not have any intrinsic or geometric meaning in this context. We only require that the "open" sets have some simple union and intersection properties which hold for open sets in Euclidean space, and which are necessary to make a reasonable theory of limits and continuity.

XIII.1.1. Definitions

XIII.1.1.1. DEFINITION. A *topology* on a set X is a subset $\mathcal{T}$ of $\mathcal{P}(X)$ with the following properties:

(i) $\emptyset, X \in \mathcal{T}$.

(ii) $\mathcal{T}$ is closed under finite intersections.

(iii) $\mathcal{T}$ is closed under arbitrary unions.

The sets in $\mathcal{T}$ are called the *open sets* (or $\mathcal{T}$-*open sets*) in X.

A *topological space* is a pair $(X, \mathcal{T})$, where X is a set and $\mathcal{T}$ is a topology on X.

There is a technical question whether a topological space is required to be nonempty (the pair $(\emptyset, \mathcal{P}(\emptyset))$ satisfies the definition). We will generally assume topological spaces are nonempty, but explicitly state this when it is important.

XIII.1.1.2. A set can have many different topologies. For example, the function spaces studied in analysis typically have several different natural topologies, and it is necessary to carefully distinguish between them. In some settings, there is one standard topology which is obvious from the context, so by abuse of language we often make statements like "let X be a topological space." However, it should be carefully noted and always kept in mind that the specification of a topology is an essential part of the definition of a topological space.

Topological spaces are the natural abstract setting for the notions of limits and continuity. We typically refer to elements of a topological space as "points." In this connection, it is convenient to think of an open set containing a point as a "neighborhood" of the point. Slightly more generally:

XIII.1.1.3. DEFINITION. Let $(X, \mathcal{T})$ be a topological space, and $x \in X$. A *neighborhood* (or $\mathcal{T}$-*neighborhood*) of x is a set containing an open set which contains x.

Note that by this definition, a neighborhood of a point in X is not necessarily an open set. It is sometimes convenient to work with neighborhoods which are not open. But the most important neighborhoods of points are open neighborhoods; every neighborhood of a point x contains an open neighborhood of x, which is simply an open set containing x. We will try to always specify "open neighborhood" when open sets are required, even though this sometimes becomes a little pedantic.

Topologies and Metrics.

XIII.1.1.4. EXAMPLES.

(i) If X is any set, then $\mathcal{P}(X)$ is a topology on X, called the *discrete topology*.

(ii) If X is any set, then $\{\emptyset, X\}$ is a topology on X, called the *indiscrete topology*.

(iii) The most important examples of topologies are those defined by metrics. If (X, ρ) is a metric space, as usual define a subset of X to be *open* (or *ρ-open*) if it contains an open ball around each of its points. The set $\mathcal{T}_\rho$ of ρ-open sets is a topology on X, called the *topology defined by* (or *underlying topology of*) the metric space (X, ρ). Equivalent metrics define the same topology.

The discrete topology on a set X comes from a metric (the *discrete metric*) ρ, where $\rho(x, y) = 1$ if $x \neq y$.

The usual notions of convergence of sequences and closure of a set in a metric space, or of continuity of functions between metric spaces, depend only on the underlying topology and can all be phrased in terms of the topology. See () and Problem () for continuity, and () for the other notions.

XIII.1.1.5. There are, however, many examples of topological spaces which do not come from metric spaces (e.g. the indiscrete topology on a set with more than one element), some of which are important in applications. Even a metrizable topological space (one whose topology comes from a metric) need not have any *natural* metric defining the topology, and it is often unnatural to artificially pick one of the many possible metrics defining a topology which is given in another way. Thus it is useful to work directly with topological spaces rather than metric spaces in many situations.

XIII.1.1.6. Although topologies, even interesting topologies, do not come from metrics in general, most interesting topologies share some of the properties of metric spaces: there are "enough" open sets that points have "small" neighborhoods, and in particular distinct points have disjoint neighborhoods. There are varying degrees of similarity to metrizable spaces which are useful, described by the separation axioms developed in ().

XIII.1.2. Bases and Subbases

XIII.1.2.1. If $\{\mathcal{T}_\alpha\}$ is a family of topologies on a set X, then $\cap_\alpha \mathcal{T}_\alpha$ is also a topology on X (Exercise XIII.1.6.2.). In particular, if $\mathcal{S}$ is any subset of $\mathcal{P}(X)$, there is a smallest topology containing $\mathcal{S}$, called the *topology generated by* $\mathcal{S}$ (there is always at least one topology containing $\mathcal{S}$, the discrete topology).

Bases

It is usually convenient to use a smaller collection of "nice" open sets to describe a topology. For example, in a topology defined by a metric, the open balls generate the topology as in XIII.1.2.1.. We abstract this situation in the notion of base:

XIII.1.2.2. DEFINITION. Let $(X, \mathcal{T})$ be a topological space, and $p \in X$. A subset $\mathcal{B}$ of $\mathcal{T}$ is a *local base* for $\mathcal{T}$ at p if, whenever $U \in \mathcal{T}$ and $p \in U$, there is a $V \in \mathcal{B}$ with $p \in V$ and $V \subseteq U$.

A subset $\mathcal{B}$ of $\mathcal{T}$ is a *base* for $\mathcal{T}$ if it is a local base at every point, i.e. whenever $U \in \mathcal{T}$ and $x \in U$, there is a $V \in \mathcal{B}$ with $x \in V$ and $V \subseteq U$. In other words, if $U \neq \emptyset$, $U = \cup_{\substack{V \in \mathcal{B} \\ V \subseteq U}} V$, i.e. every nonempty open set in $\mathcal{T}$ is a union of sets in $\mathcal{B}$.

In particular, if $\mathcal{B}$ is a base for $\mathcal{T}$, then $\mathcal{T}$ is the topology generated by $\mathcal{B}$.

When a base or local base $\mathcal{B}$ is specified, the sets in $\mathcal{B}$ are usually called *basic open sets*. Some authors use the term *basis* instead of *base*, in analogy with the use of "basis" for a vector space; but this is potentially misleading, since a base for a topology does not necessarily have any type of minimality condition like a basis for a vector space: for example, any collection of open sets containing a base for $\mathcal{T}$ is also a base for $\mathcal{T}$.

XIII.1.2.3. EXAMPLES. (i) If (X, ρ) is a metric space, and $p \in X$, the open balls centered at p form a local base for the topology at p. The set of all open balls in X forms a base for $\mathcal{T}_\rho$.

(ii) If X has the discrete topology, and $p \in X$, then $\{\{p\}\}$ is a local base for the topology at p. The collection of all singleton subsets of X is a base for the discrete topology.

(iii) If $\mathcal{T}$ is a topology on X, then the collection of all sets in $\mathcal{T}$, or the collection of all nonempty sets in $\mathcal{T}$, is a (not very interesting) base for $\mathcal{T}$.

XIII.1.2.4. There is nothing unique about a base for a given topology. For example, if ρ_1 and ρ_2 are equivalent metrics on a set X, the open *balls* from ρ_1 and ρ_2 may be quite different, but the open *sets* they generate will be the same. See () for an example.

It is useful to know when a collection $\mathcal{B}$ of open subsets of X forms a base for the topology it generates.

XIII.1.2.5. PROPOSITION. Let X be a set and $\mathcal{B} \subseteq \mathcal{P}(X)$, and let $\mathcal{T}$ be the topology generated by $\mathcal{B}$. Then $\mathcal{B}$ is a base for $\mathcal{T}$ if and only if

(i) $\cup_{V \in \mathcal{B}} V = X$ and

(ii) If $V_1, \ldots, V_n \in \mathcal{B}$ and $x \in \cap_{j=1}^n V_j$, there is a $V \in \mathcal{B}$ with $x \in V$ and $V \subseteq \cap_{j=1}^n V_j$.

XIII.1.2.6. Note that a base for a topology need not be closed under finite intersections. For example, an intersection of open balls with different centers in a metric space is generally not an open ball. (For XIII.1.2.5.(ii), it obviously *suffices* that $\mathcal{B}$ be closed under finite intersections, as is frequently the case.)

First and Second Countability

Most interesting topological spaces have uncountably many open sets. But frequently there is a countable base for the topology, or at least a countable local base at each point, and if so the topology is more easily describable and tends to behave more nicely.

XIII.1.2.7. DEFINITION. Let $(X, \mathcal{T})$ be a topological space.

(i) $(X, \mathcal{T})$ satisfies the *first axiom of countability*, or is *first countable*, if there is a countable local base for $\mathcal{T}$ at each point.

(ii) $(X, \mathcal{T})$ satisfies the *second axiom of countability*, or is *second countable*, if there is a countable base for $\mathcal{T}$.

The "first" and "second" are used for historical reasons, but the terminology persists because it is both appropriate and useful. A second countable space is first countable.

XIII.1.2.8. EXAMPLES.

(i) The discrete topology on a set X is always first countable; it is second countable if and only if X is countable.

(ii) The indiscrete topology on a set X is always second countable.

(iii) The usual topology on $\mathbb{R}^n$ is second countable: balls with rational radii around points with rational coordinates form a base for the topology. More generally, the topology of a metric space is always first countable (for any point p, balls of rational radius centered at p form a local base at p), and is second countable if and only if the metric space is separable (XIII.2.3.15.).

(iv) Let X be a set. The *finite complement topology* on X is the topology consisting of $\emptyset$ and all subsets of X with finite complement. (It is easily checked that this is a topology; cf. Exercise XIII.1.6.4..) If X is countable, then this topology is second countable: in fact, there are only countably many open sets in all. But if X is uncountable, then the finite complement topology is not first countable, and in fact no point has a countable neighborhood base. For if $p \in X$ and $\{U_n : n \in \mathbb{N}\}$ is a countable collection of open neighborhoods of p, set $E = \cap_{n=1}^{\infty} U_n$. Then E has countable complement and is therefore uncountable, and in particular contains a point $q \neq p$. Then $X \setminus \{q\}$ is an open neighborhood of p not containing any U_n, so the U_n cannot form a local base at p. (This argument requires the Countable AC.)

Topological spaces which are not first countable are rather unusual, but they do arise naturally in analysis; see (). First countability is important since it is essentially just in first countable topological spaces that the topology can be entirely described by convergence of sequences (although see XIII.3.5.2. and XXII.2.1.21.); in spaces which are not first countable it is usually necessary to work with generalizations of sequences called *nets*.

XIII.1.2.9. **Caution:** For a topological space to be first countable, it is not sufficient that every singleton subset be a countable intersection of open sets (which may be assumed to be decreasing since a finite intersection of open sets is open), i.e. that every singleton subset is a G_δ: there are countable (Hausdorff, even normal) topological spaces which are not first countable (Exercise XIII.11.14.10.). (The condition that singletons are G_δ's is not necessary either: the indiscrete topology on any set is even second countable. In a first countable T_1 space (), every singleton subset is a G_δ (XIII.7.3.3.). In fact, see XIII.7.10.2..)

XIII.1.2.10. PROPOSITION. Let $(X, \mathcal{T})$ be a second countable topological space, and $\mathcal{B}$ be a base for $\mathcal{T}$. Then $\mathcal{B}$ contains a countable base for $\mathcal{T}$. In particular, every $U \in \mathcal{T}$ is a *countable* union of sets in $\mathcal{B}$.

PROOF: Let $\mathcal{D} = \{V_n : n \in \mathbb{N}\}$ be a countable base for $\mathcal{T}$. Let S be the set of $(n, m) \in \mathbb{N}^2$ such that there is a $W_{n,m} \in \mathcal{B}$ with $V_m \subseteq W_{n,m} \subseteq V_n$. Let $U \in \mathcal{T}$. For each $x \in U$, there is an n such that $x \in V_n$ and $V_n \subseteq U$ since $\mathcal{D}$ is a base for $\mathcal{T}$. Since $\mathcal{B}$ is a base, there is a $W \in \mathcal{B}$ with $x \in W$ and $W \subseteq V_n$; then, since $\mathcal{D}$ is a base, there is an m with $x \in V_m$ and $V_m \subseteq W$. Thus $(n, m) \in S$ and $x \in W_{n,m} \subseteq U$. So $\{W_{n,m} : (n, m) \in S\}$ is a countable subset of $\mathcal{B}$ which is a base for $\mathcal{T}$. (This argument uses the Countable AC.) 👍

XIII.1.2.11. We can more generally define the *weight* $w(X)$ of a topological space X to be the minimum cardinality of a base for the topology of X (this is only well defined in general if the AC is assumed). Thus X is second countable if and only if $w(X) \leq \aleph_0$. Weight is an example of a *cardinal invariant* for topological spaces. The simplest cardinal invariant for X is $card(X)$; another cardinal invariant is *density* $d(X)$ (XIII.2.3.16.). There are many other cardinal invariants, such as:

(i) *character* $\chi(X)$, minimum cardinal κ such that every point of X has a local base of cardinality $\leq \kappa$, e.g. X is first countable if and only if $\chi(X) \leq \aleph_0$.

(ii) *Lindelöf number* $L(X)$, the smallest cardinal κ such that every open cover of X has a subcover (XIII.1.3.3.) of cardinality $\leq \kappa$, e.g. X is Lindelöf (XIII.1.3.4.) if and only if $L(X) \leq \aleph_0$.

(iii) *cellularity* $c(X)$, minimum cardinal κ such that every family of pairwise disjoint nonempty open subsets of X has cardinality $\leq \kappa$. X has the *Countable Chain Condition* if $c(X) \leq \aleph_0$.

The invariants $w(X)$, $d(X)$, $L(X)$, and $c(X)$ coincide for metrizable spaces, but differ in general. A thorough discussion of cardinal invariants can be found in [KV84], and there is also extensive discussion in [Eng89].

Subbases

It is sometimes convenient to work with a less restrictive set of generators:

XIII.1.2.12. DEFINITION. Let $(X, \mathcal{T})$ be a topological space, and $\mathcal{S} \subseteq \mathcal{T}$. Then $\mathcal{S}$ is a *subbase* for $\mathcal{T}$ if the collection of finite intersections of sets in $\mathcal{S}$ forms a base for $\mathcal{T}$.

XIII.1.2.13. EXAMPLE. In $\mathbb{R}^2 = \mathbb{R} \times \mathbb{R}$, let $\mathcal{S}$ be the collection of all sets of the form $I \times \mathbb{R}$ or $\mathbb{R} \times I$, where I is an open interval in $\mathbb{R}$. Then $\mathcal{S}$ is a subbase for the usual topology on $\mathbb{R}^2$.

More generally, the topology generated by a family of pseudometrics is naturally defined by a subbase. See ().

XIII.1.2.14. It is sometimes convenient to extend the notion of base to allow sets which are not open. We say that a collection $\mathcal{B}$ of not necessarily open subsets of X is a base for the topology $\mathcal{T}$ if, whenever $U \in \mathcal{T}$ and $x \in U$, there is an $E \in \mathcal{B}$ which is a neighborhood of x for which $E \subseteq U$. For example, the set of closed balls of positive radius in a metric space is a base for the topology in this extended sense. We can similarly extend the notion of local base and subbase. Thus, for example, we can in some cases (e.g. in $\mathbb{R}^n$) take a base for a topology consisting of compact sets ().

If $\mathcal{B}$ is a base for the topology $\mathcal{T}$ in this sense, then the interiors (XIII.2.3.17.) of the sets in $\mathcal{B}$ form a base for the topology consisting of open sets. Thus if X has a countable base in this sense, it is second countable. The same applies to local bases; in particular, if every point of X has a countable local base in this sense, then X is first countable.

XIII.1.3. Covers and Subcovers

It is often convenient to cover a topological space with "small" subsets, particularly small open sets.

XIII.1.3.1. Definition. Let X be a set, and $\mathcal{U} = \{U_i : i \in I\}$ a collection of subsets of X. If $Y \subseteq X$, then $\mathcal{U}$ *covers* Y, or is a *cover of* Y, if $Y \subseteq \cup_{i\in I} U_i$. $\mathcal{U}$ covers X if $\cup_{i\in I} U_i = X$.
If X is a topological space, each U_i is open in X, and $\mathcal{U}$ covers X, then $\mathcal{U}$ is an *open cover* of X.

XIII.1.3.2. Examples. (i) Any base or subbase for the topology of X is an open cover of X.
(ii) If (X, ρ) is a metric space and $\epsilon > 0$ is fixed, then the open balls of radius ϵ form an open cover of X.

XIII.1.3.3. Definition. Let X be a set, $Y \subseteq X$, and $\mathcal{U}$ a cover of Y. A *subcover* of $\mathcal{U}$ is a subcollection of $\mathcal{U}$ which also covers Y.

Any subcover of an open cover is also an open cover. Although the terminology is imprecise, one must specify the set Y to discuss subcovers; normally one uses "subcover" only for covers of the whole set X.

XIII.1.3.4. Definition. Let X be a topological space.
(i) X is a *Lindelöf space* if every open cover of X has a countable subcover.
(ii) X is *compact* if every open cover of X has a finite subcover.

Compact spaces are discussed in detail in (). Obviously every compact space is Lindelöf; the converse is far from true.

XIII.1.3.5. Proposition. Every second countable topological space is Lindelöf.

Proof: Let $\{V_n : n \in \mathbb{N}\}$ be a countable base for the topology of X. Let $\mathcal{U}$ be an open cover of X. Fix a $U_0 \in \mathcal{U}$. For each $n \in \mathbb{N}$, if V_n is contained in some $U \in \mathcal{U}$, choose $U_n \in \mathcal{U}$ with $V_n \subseteq U_n$; if $V_n \subseteq U$ for no $U \in \mathcal{U}$, set $U_n = U_0$. We claim $\{U_n : n \in \mathbb{N}\}$ is a subcover of $\mathcal{U}$ (it is obviously countable). If $p \in X$, then there is a $U \in \mathcal{U}$ with $p \in U$ since $\mathcal{U}$ is a cover of X. Then there is an n such that $p \in V_n$ and $V_n \subseteq U$ since $\{V_n\}$ is a base for the topology. Then $p \in U_n$. Thus $\cup_{n\in\mathbb{N}} U_n = X$. 👍

Note that this proof requires the Countable AC.

XIII.1.3.6. In particular, $\mathbb{R}^n$ is Lindelöf for any n by XIII.1.2.8.(iii).

We can sharpen this result:

XIII.1.3.7. Definition. A topological space X is *locally second countable* if every $x \in X$ has an open neighborhood which is second countable in the relative topology.

Since every subspace of a second countable space is second countable, we may eliminate "open" from the definition without changing its meaning.

XIII.1.3.8. Proposition. Let X be a topological space. Then X is second countable if and only if it is Lindelöf and locally second countable.

Proof: If X is second countable, then it is obviously locally second countable, and Lindelöf by XIII.1.3.5.. Conversely, for each $x \in X$ let U_x be an open neighborhood of x which is second countable. Let $\{U_n : n \in \mathbb{N}\}$ be a countable subcover of $\{U_x : x \in X\}$. For each n, let $\mathcal{V}_n = \{V_{n1}, V_{n2}, \dots\}$ be a countable base for the relative topology on U_n. Then $\cup_n \mathcal{V}_n$ is a countable base for the topology on X. (Note that each V_{nk} is open in U_n, and U_n is open in X, so V_{nk} is open in X.) 👍

This proof uses the Countable AC.

XIII.1.4. Relative Topology on a Subspace

If $(X, \mathcal{T})$ is a topological space and Y is a subset of X, then there is one, and only one, reasonable way to put a topology on Y which is compatible with the topology on X:

XIII.1.4.1. Definition. Let $(X, \mathcal{T})$ and $Y \subseteq X$. The *relative topology*, or *subspace topology*, on Y from $\mathcal{T}$ is

$$\mathcal{T}_Y = \{U \cap Y : U \in \mathcal{T}\}$$

i.e. the open sets in Y are the intersections with Y of the open sets in X. Y with this topology is called a *subspace* of X.

XIII.1.4.2. Proposition. $\mathcal{T}_Y$ is a topology on Y.

Here is the proof as it appears in many standard references:
Proof: We have $\emptyset = \emptyset \cap Y$ and $Y = X \cap Y$, so $\emptyset, Y \in \mathcal{T}_Y$. If $V_1, \dots, V_n \in \mathcal{T}_Y$, then, for each k, $V_k = U_k \cap Y$ for some $U_k \in \mathcal{T}$; so

$$V_1 \cap \cdots \cap V_n = (U_1 \cap Y) \cap \cdots \cap (U_n \cap Y) = (U_1 \cap \cdots \cap U_n) \cap Y \in \mathcal{T}_Y$$

since $U_1 \cap \cdots \cap U_n \in \mathcal{T}$. If $\{V_i : i \in I\}$ is a collection of sets in $\mathcal{T}_Y$, then, for each i, $V_i = U_i \cap Y$ for some $U_i \in \mathcal{T}$; then

$$\bigcup_{i \in I} V_i = \bigcup_{i \in I} (U_i \cap Y) = \left(\bigcup_{i \in I} U_i \right) \cap Y \in \mathcal{T}_Y$$

since $\cup_{i \in I} U_i \in \mathcal{T}$. 👍

XIII.1.4.3. Note that the AC is used in this proof to choose the U_i. (Most standard references seem to overlook this point! See XIII.1.6.5..) But the result does not depend on the AC, because there is actually a systematic way to choose the U_i: for each i let U_i be the union of all $W \in \mathcal{T}$ such that $V_i = W \cap Y$ (I am indebted to S. Jabuka for this argument). There is also an alternate approach which does not use the AC (XIII.1.4.7.).

XIII.1.4.4. If $A \subseteq Y$, the phrase "A is open" is ambiguous since also $A \subseteq X$: does it mean that A is open in Y (i.e. $A \in \mathcal{T}_Y$) or that A is open in X (i.e. that $A \in \mathcal{T}$)? To avoid ambiguity, we use the term *relatively open* for the first: $A \subseteq Y$ is relatively open in Y if $A \in \mathcal{T}_Y$, i.e. $A = U \cap Y$ for some $U \in \mathcal{T}$. If Y is open in X, i.e. $Y \in \mathcal{T}$, there is no ambiguity: a subset of Y is relatively open if and only if it is open in X (the converse holds also).

XIII.1.4.5. Since $(X \setminus A) \cap Y = Y \setminus (A \cap Y)$ for any $A \subseteq X$, the closed sets in $(Y, \mathcal{T}_Y)$ are precisely the sets of the form $F \cap Y$ for F closed in X. These sets are called the *relatively closed* subsets of Y. If Y is closed in X, then a subset of Y is relatively closed if and only if it is closed in X.

If $A \subseteq Y$, the phrase "closure of A" is also ambiguous: we could mean the closure $\tilde{A}$ of A in $(Y, \mathcal{T}_Y)$ or the closure $\bar{A}$ in $(X, \mathcal{T})$. But the situation is well behaved:

XIII.1.4.6. Proposition. We have $\tilde{A} = \bar{A} \cap Y$ for any $A \subseteq Y$.

Proof: Let $y \in \tilde{A}$. Then for any $V \in \mathcal{T}_Y$ with $y \in V$ there is a $z \in A \cap V$. If $U \in \mathcal{T}$ with $y \in U$, set $V = U \cap Y$. If $z \in A \cap V$, then $z \in A \cap U$, so $y \in \bar{A}$. Conversely, if $y \in \bar{A} \cap Y$ and $V \in \mathcal{T}_Y$ with $y \in V$, then there is a $U \in \mathcal{T}$ with $V = U \cap Y$. Since $y \in \bar{A}$, there is a $z \in A \cap U$. Since $A \subseteq Y$, $z \in Y \cap U = V$. Thus $y \in \tilde{A}$.

The set $\tilde{A}$ is called the *relative closure* of A in Y.

In light of this result, we can give an alternate construction of the relative topology:

XIII.1.4.7. Proposition. Let $(X, \mathcal{T})$ be a topological space, and $Y \subseteq X$. For $A \subseteq Y$, define $\tilde{A} = \bar{A} \cap Y$ ($\bar{A}$ denotes the closure of A in X). Then $A \mapsto \tilde{A}$ is a Kuratowski closure operator (XIII.2.4.1.) on Y, and the closed sets in the corresponding topology are precisely the sets of the form $F \cap Y$ for F closed in X, i.e. is the relative topology on Y.

The proof is very simple and is left to the reader. It does not depend on the AC, and hence gives an alternate proof of XIII.1.4.2. not using the AC.

The relative topology also has other properties which make it the only reasonable choice:

XIII.1.4.8. Proposition. Let $(X, \mathcal{T})$ be a topological space, $Y \subseteq X$, and $\mathcal{T}_Y$ the relative topology on Y. Then

(i) If (y_i) is a net in Y and $y \in Y$, then $y_i \to y$ in $(Y, \mathcal{T}_Y)$ if and only if $y_i \to y$ in $(X, \mathcal{T})$.

(ii) If Z is another topological space and $f : X \to Z$ is continuous, then $f|_Y : Y \to Z$ is also continuous.

(iii) The topology $\mathcal{T}_Y$ is the weakest topology on Y making the inclusion map into X continuous.

(iv) If $(Z, \mathcal{S})$ is a topological space and $f : Z \to Y$ is a function, then f is continuous as a function from $(Z, \mathcal{S})$ to $(Y, \mathcal{T}_Y)$ if and only if it is continuous as a function from $(Z, \mathcal{S})$ to $(X, \mathcal{T})$.

XIII.1.4.9. Note that (i) does *not* say that if a net in Y converges in X, then it converges in Y. This will only be true if Y is closed in X.

XIII.1.4.10. Proposition. Let $(X, \mathcal{T})$ be a topological space, and $Z \subseteq Y \subseteq X$. Then the relative topology on Z as a subspace of $(Y, \mathcal{T}_Y)$ is the same as the relative topology as a subspace of $(X, \mathcal{T})$, i.e. $(\mathcal{T}_Y)_Z = \mathcal{T}_Z$.

Bases

XIII.1.4.11. If $(X, \mathcal{T})$ is a topological space and $(Y, \mathcal{T}_Y)$ is a subspace, and if $\mathcal{B}$ is a base for $\mathcal{T}$, then it is easily checked that $\mathcal{B}_Y = \{B \cap Y : B \in \mathcal{B}\}$ is a base for $\mathcal{T}_Y$. Similarly, if $y \in Y$ and $\mathcal{B}$ is a local base for $\mathcal{T}$ at y, then $\mathcal{B}_Y$ is a local base for $\mathcal{T}_Y$ at y. We thus obtain:

XIII.1.4.12. Proposition. Let $(X, \mathcal{T})$ be a topological space and $(Y, \mathcal{T}_Y)$ a subspace. Then

(i) If $(X, \mathcal{T})$ is first countable, so is $(Y, \mathcal{T}_Y)$.

(ii) If $(X, \mathcal{T})$ is second countable, so is $(Y, \mathcal{T}_Y)$.

XIII.1.4.13. It is not true that if $(X, \mathcal{T})$ is separable, then $(Y, \mathcal{T}_Y)$ is necessarily separable. There are many counterexamples, e.g. XIII.7.10.14.(h), XIII.7.10.18.(d), XIII.11.14.4..

XIII.1.5. Separated Union

There are many operations making new topological spaces from old ones. One of the simplest is separated union.

XIII.1.5.1. Definition. Let $(X, \mathcal{T})$ be a topological space, and $\{X_i : i \in I\}$ a collection of pairwise disjoint nonempty subsets of X whose union is X (i.e. a partition of X). Then X is the *separated union* of the X_i if a subset U of X is open (i.e. $U \in \mathcal{T}$) if and only if $U \cap X_i$ is relatively open in X_i for every $i \in I$.

XIII.1.5.2. If $U \in \mathcal{T}$, then by definition $U \cap X_i$ is relatively open in X_i for each i. So the important condition is the converse, which is not automatic [consider a partition of X into singleton sets; then X is the separated union if and only if its topology is the discrete topology.] Some authors call a separated union a *disjoint union*, but the term "separated union" seems clearer and more descriptive.

A subset U of a topological space X is called *clopen* if both U and $X \setminus U$ are open in X. ("Clopen" means "both open and closed"; cf. ().)

XIII.1.5.3. PROPOSITION. Let $\{X_i : i \in I\}$ be a partition of a topological space X. Then X is the separated union of the X_i if and only if each X_i is a clopen subset of X.

PROOF: Suppose X is the separated union of the X_i. For each fixed $j \in I$, $X_j \cap X_i$ is either X_j (if $i = j$) or $\emptyset$ (if $i \neq j$). Thus $X_j \cap X_i$ is relatively open in X_i for each i; hence X_j is open in X. So for any $J \subseteq I$, $\cup_{j\in J} X_j$ is open in X. In particular, for each j, $X \setminus X_j = \cup_{i\neq j} X_i$ is open in X, hence X_j is clopen in X. More generally, if $J \subseteq I$, $X \setminus \cup_{j\in J} X_j = \cup_{i\in I\setminus J} X_i$ is open in X; so $\cup_{j\in J} X_j$ is clopen in X.

Conversely, suppose each X_i is clopen (and in particular open) in X. Let U be a subset of X such that $U \cap X_i$ is relatively open in X_i for each i. Then, since X_i is open in X, $U \cap X_i$ is open in X for each i (), and hence $U = \cup_{i\in I}(U \cap X_i)$ is open in X. 👍

XIII.1.5.4. We can reverse the process. Suppose we are given a family $\{(X_i, \mathcal{T}_i) : i \in I\}$ of topological spaces. Form the set-theoretic disjoint union $X = \sqcup_{i\in I} X_i$ (). Let $\mathcal{T}$ be the collection of all subsets U of X such that $U \cap X_i \in \mathcal{T}_i$ for all i. It is easily checked that $\mathcal{T}$ is a topology on X and $(X, \mathcal{T})$ is the separated union of the $(X_i, \mathcal{T}_i)$.

XIII.1.6. Exercises

XIII.1.6.1. Give a logical critique of the following statement which can be found in many books:

> "A metric space is a topological space."

As part of your answer, you might consider, if ρ and σ are equivalent metrics on a set X, whether the spaces (X, ρ) and (X, σ) are the "same" or "different."

XIII.1.6.2. Show that if $\{\mathcal{T}_\alpha\}$ is a family of topologies on a set X, then $\cap_\alpha \mathcal{T}_\alpha$ is also a topology on X.

XIII.1.6.3. Prove Proposition XIII.1.2.5..

XIII.1.6.4. (a) Show that the finite complement topology (XIII.1.2.8.(iv)) on a set X is a topology. Show that it is the discrete topology if and only if X is finite.

(b) Let X be a set. The *countable complement topology* on X consists of $\emptyset$ and all subsets of X with countable complement. Show that this is a topology on X, which is the discrete topology if and only if X is countable. If X is uncountable, show that the countable complement topology is not first countable.

XIII.1.6.5. Explain why the following argument (which appears or is implicit in many books and does not use the AC) is not adequate to prove that the set $\mathcal{T}_Y$ defined in XIII.1.4.1. is closed under arbitrary unions and is thus a topology:

"Let $\{U_i \cap Y : i \in I, U_i \in \mathcal{T}\}$ be an indexed collection of relatively open sets (sets in $\mathcal{T}_Y$). Then

$$\bigcup_{i\in I}(U_i \cap Y) = \left(\bigcup_{i\in I} U_i\right) \cap Y \in \mathcal{T}_Y$$

since $\cup_{i\in I} U_i \in \mathcal{T}$."

XIII.1.6.6. Show that XIII.1.3.5. can be rephrased as follows:

PROPOSITION. Let X be a second countable topological space, and $\mathcal{U} = \{U_i : i \in I\}$ a collection of open sets in X with union U. Then there is a countable subcollection of $\mathcal{U}$ whose union is U.

XIII.1.6.7. Let $(X, \mathcal{T})$ be a topological space. A *pseudo-base* for $\mathcal{T}$ is a collection $\{U_i : i \in I\}$ of nonempty open sets such that every nonempty open set contains at least one U_i.

(i) Show that a base for a topology (consisting of nonempty sets) is a pseudo-base. In particular, a second countable topological space has a countable pseudo-base. (But a pseudo-base is not necessarily a base: the union of the sets in a pseudo-base is not necessarily even all of X in general, although it is dense.)

(ii) Show that every topological space with a countable pseudo-base is separable.

(iii) Show that a topological space which is separable and first countable has a countable pseudo-base (more generally, only a countable dense set of points which each have a countable local base is needed). Since there are even compact Hausdorff spaces which are separable and first countable but not second countable (XIII.11.14.4.), a space with a countable pseudo-base is not necessarily second countable. There are also separable compact Hausdorff spaces which do not have a countable pseudo-base ().

(iv) If $(X, \mathcal{T})$ is a topological space, and X has a dense open subspace Y which has a countable pseudo-base in the relative topology, then X has a countable pseudo-base. Thus if X is locally compact and has a countable pseudo-base, then any compactification of X (e.g. the Stone-Čech compactification βX) has a countable pseudo-base. In particular, $\beta\mathbb{N}$ and $\beta\mathbb{R}$ have countable pseudo-bases but are not even first countable (this also follows from the general version of (iii).)

(The Countable AC is needed for (ii) and (iii).)

XIII.2. Closed Sets and Limit Points

XIII.2.1. Closed Sets

Complements of open sets in a topological space are called closed sets:

XIII.2.1.1. DEFINITION. Let $(X, \mathcal{T})$ be a topological space. A subset A of X is *closed* in the topology $\mathcal{T}$, or $\mathcal{T}$-*closed*, if $A^c = X \setminus A \in \mathcal{T}$.

There is an important alternate description of closed sets (XIII.2.3.6.).

XIII.2.1.2. EXAMPLES. (i) A subset of $\mathbb{R}$ is closed in the usual topology if and only if it is closed in the sense of ().

(ii) If X has the discrete topology, then every subset of X is closed.

(iii) If X has the indiscrete topology, then the only closed subsets of X are $\emptyset$ and X.

XIII.2.1.3. It is important to note that being closed is *not* the opposite of being open: on the one hand, a subset of X can be both open and closed (cf. XIII.2.1.2.(ii)), and on the other hand a subset of X need not be either open or closed – in fact typically "most" subsets of a topological space are neither open nor closed.

From de Morgan's laws we immediately obtain the following properties of closed sets:

XIII.2.1.4. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space, and $\mathcal{E}$ the collection of $\mathcal{T}$-closed sets. Then

(i) $\emptyset, X \in \mathcal{E}$.

(ii) $\mathcal{E}$ is closed under finite unions.

(iii) $\mathcal{E}$ is closed under arbitrary intersections.

XIII.2.1.5. Conversely, if X is a set and $\mathcal{E}$ is a collection of subsets of X satisfying XIII.2.1.4.(i)–(iii), then the complements of the sets in $\mathcal{E}$ form a topology $\mathcal{T}$ for which $\mathcal{E}$ is precisely the collection of closed sets. Thus a topology can be equally well defined by specifying the closed sets instead of the open sets.

XIII.2.1.6. There is an asymmetry between unions and intersections for both open sets and closed sets. An arbitrary union of closed sets is not closed in general: for example, in $\mathbb{R}$ with its usual topology, points (singleton subsets) are closed, and every subset of $\mathbb{R}$ is a union of singleton sets. Correspondingly, an arbitrary intersection of open sets is not open in general. In fact, this asymmetry is the crucial underlying feature of topology, and it is what gives the subject its power and usefulness.

XIII.2.2. Limit Points of a Set

One of the most fundamental notions in topology is limit point. Roughly speaking, a point x in a topological space X is a limit point of a set A if there are points of A "arbitrarily close" to x. More specifically:

XIII.2.2.1. DEFINITION. Let $(X, \mathcal{T})$ be a topological space, $A \subseteq X$, and $x \in X$. Then x is a *limit point* of A (in the topology $\mathcal{T}$) if every open neighborhood of x contains at least one point of A.

Note that if $x \in A$, then x is trivially a limit point of A since every neighborhood of x contains at least one point of A, namely x itself. But the importance of the notion of limit point is that limit points of A are not necessarily in A. For example, 0 and 1 are limit points of the open interval $(0, 1)$ in $\mathbb{R}$ with its usual topology. Whether a point x is a limit point of a subset A can depend crucially on the topology used (if $x \notin A$); if there is a possibility of confusion we will use the terminology $\mathcal{T}$-limit point.

There is a closely related but distinct notion:

XIII.2.2.2. DEFINITION. Let $(X, \mathcal{T})$ be a topological space, $A \subseteq X$, and $x \in X$. Then x is an *accumulation point* of A (in the topology $\mathcal{T}$) if every deleted open neighborhood of x contains at least one point of A, i.e. if every open neighborhood of x contains at least one point of A other than x.

Accumulation points are called *cluster points* by some authors, but for clarity we will only use the term "cluster point" in reference to sequences or nets (where the meaning is somewhat different, cf. XIII.3.1.7.), not subspaces.

XIII.2.2.3. Unlike for limit points, a point in A is not necessarily an accumulation point of A; a point of A which is not an accumulation point of A is called an *isolated point* of A. A point of X which is not in A is a limit point of A if and only if it is an accumulation point of A. There is some nonuniformity of terminology in the literature: some authors take "limit point" to mean what we call "accumulation point." It will sometimes be convenient to have separate terms for the two notions, and for the purposes of this section limit points are more important. See XIII.2.5. for a discussion of accumulation points and isolated points.

XIII.2.3. Closure of a Set

XIII.2.3.1. If $(X, \mathcal{T})$ is a topological space and $A \subseteq X$, then there is a smallest closed subset of X containing A, namely the intersection of all closed subsets of X containing A (there is at least one such set, X; recall that any intersection of closed sets is closed).

XIII.2.3.2. DEFINITION. Let $(X, \mathcal{T})$ be a topological space and $A \subseteq X$. The smallest $\mathcal{T}$-closed subset of X containing A is called the *closure* of A in X (or $\mathcal{T}$-closure of A).

The standard notation for the closure of A is $\bar{A}$; the notation $Cl(A)$ is also common. The closure of A depends on X and $\mathcal{T}$; when this needs to be made explicit we will use the notation $Cl_X(A)$, $Cl_{\mathcal{T}}(A)$, or $Cl_{(X,\mathcal{T})}(A)$.

Here are some elementary properties of closure:

XIII.2.3.3. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space and $A, B \subseteq X$. Then

(i) $A \subseteq \bar{A}$.

(ii) A is closed if and only if $A = \bar{A}$.

(iii) $\bar{\bar{A}} = \bar{A}$.

(iv) If $A \subseteq B$, then $\bar{A} \subseteq \bar{B}$.

(v) $\overline{A \cup B} = \bar{A} \cup \bar{B}$.

(vi) $\bar{\emptyset} = \emptyset$ and $\bar{X} = X$.

PROOF: (i) and (ii) are trivial from the definition, and (iii) and (vi) follow immediately from (ii). (iv) is also immediate from the definition [$\bar{B}$ is a closed set containing A]. For (v), note that $\bar{A} \cup \bar{B}$ is a union of two closed sets, hence closed, and contains $A \cup B$, so $\overline{A \cup B} \subseteq \bar{A} \cup \bar{B}$. On the other hand, $A \subseteq A \cup B$, so $\bar{A} \subseteq \overline{A \cup B}$ by (iv), and similarly $\bar{B} \subseteq \overline{A \cup B}$. 👍

XIII.2.3.4. If $A, B \subseteq X$, it is not generally true that $\overline{A \cap B} = \bar{A} \cap \bar{B}$. For example, if $A = (0, 1)$ and $B = (1, 2)$ in $\mathbb{R}$ (with its usual topology), then $\bar{A} \cap \bar{B} = \{1\}$. But $A \cap B = \emptyset$, so $\overline{A \cap B} = \emptyset$.

However, we do always have $\overline{A \cap B} \subseteq \bar{A} \cap \bar{B}$, since the set on the right is a closed set containing $A \cap B$. More generally, for any collection $\{A_i : i \in I\}$ of subsets of X, we have $\overline{\cap_{i \in I} A_i} \subseteq \cap_{i \in I} \bar{A}_i$ by the same argument. A similar argument shows that $\cup_{i \in I} \bar{A}_i \subseteq \overline{\cup_{i \in I} A_i}$, but we do not have equality in general if I is infinite.

The definition of closure is precise but often hard to apply directly. There is a more generally useful characterization of closure:

XIII.2.3.5. THEOREM. Let $(X, \mathcal{T})$ be a topological space and $A \subseteq X$. Then the closure of A is exactly the set of all limit points (XIII.2.2.1.) of A.

PROOF: Let U be the complement of $\bar{A}$; then U is open. Suppose x is a limit point of A. If $x \notin \bar{A}$, then U is an open neighborhood of x containing no points of A, contradicting that x is a limit point of A. Thus $x \in \bar{A}$.

Now suppose x is not a limit point of A. Then there is an open neighborhood V of x containing no point of A. So V^c is a closed set with $A \subseteq V^c$, and hence $\bar{A} \subseteq V^c$, $x \notin \bar{A}$. 👍

XIII.2.3.6. COROLLARY. Let $(X, \mathcal{T})$ be a topological space. A subset of X is closed if and only if it contains all its limit points.

Dense Sets and Separability

XIII.2.3.7. Definition. Let $(X, \mathcal{T})$ be a topological space, and $D \subseteq X$. Then D is *dense* in X if $\bar{D} = X$.

XIII.2.3.8. Proposition. Let X be a topological space, and $D \subseteq X$. Then D is dense in X if and only if every nonempty open subset of X contains a point of D.

An intersection of two dense subsets is not necessarily dense, or even nonempty: both $\mathbb{Q}$ and $\mathbb{J}$ are dense in $\mathbb{R}$. But if at least one of the sets is open, the intersection is dense:

XIII.2.3.9. Proposition. Let X be a topological space, and U and V dense subsets of X. If U is open, then $U \cap V$ is dense in X.

Proof: Let W be a nonempty open set in X. Then $U \cap W$ is an open set in X, which is nonempty since U is dense. Then $W \cap (U \cap V) = (U \cap W) \cap V$ is nonempty since V is dense. 👍

XIII.2.3.10. Corollary. Let X be a topological space. The intersection of any finite number of dense open subsets of X is a dense open subset of X.

In some, but not all, topological spaces, an intersection of a *countable* number of dense open sets is always dense (but not necessarily open). See XIII.12.2.1..

Some topological spaces have "small" dense subsets, which can cause better behavior:

XIII.2.3.11. Definition. A topological space is *separable* if it has a countable dense subset.

Note that separability in this sense has nothing to do with the separation axioms of XIII.7.. The coincidence of terminology is regrettable, but well established. ✋

XIII.2.3.12. Examples. (i) If X has the indiscrete topology, then any nonempty subset of X is dense. Thus X is separable.

(ii) If X has the discrete topology, no proper subset of X is dense in X. Thus X is separable if and only if it is countable. In fact, a countable set with any topology is separable.

(iii) If X is an infinite set with the finite complement topology, any infinite subset of X is dense. Thus X is separable if and only if it contains a countably infinite subset (this will always be true if the Countable AC is assumed).

(iv) If $\mathbb{R}$ has the usual topology, $\mathbb{Q}$ is a countable dense subset, so $\mathbb{R}$ is separable. More generally, the points of $\mathbb{R}^n$ with rational coordinates form a countable dense set (for the usual topology), so $\mathbb{R}^n$ is separable.

XIII.2.3.13. Separability seems to be related to first or (especially) second countability. There are some connections, as the next two results show. But a topological space can be separable without being first countable (an uncountable set with the finite complement topology; cf. also XIII.6.3.2.–XIII.6.3.4.), first countable without being separable (an uncountable set with the discrete topology), and both first countable and separable without being second countable (XIII.11.14.4.).

XIII.2.3.14. PROPOSITION. A second countable topological space is separable.

PROOF: If $\{U_n : n \in \mathbb{N}\}$ is a countable base for the topology consisting of nonempty sets, choose $x_n \in U_n$ for each n. Then $\{x_n : n \in \mathbb{N}\}$ is a countable dense set in X. 👍

This proof requires the Countable AC, and the result cannot be proved in ZF.

XIII.2.3.15. THEOREM. A metrizable topological space is second countable if and only if it is separable.

PROOF: Let (X, ρ) be a metric space. If X is second countable, it is separable by XIII.2.3.14.. Conversely, suppose X has a countable dense set $D = \{x_n : n \in \mathbb{N}\}$. Let $\mathcal{B}$ be the collection of all open balls of the form $B_r(x_n)$, where $x_n \in D$ and $r \in \mathbb{Q}$. Then $\mathcal{B}$ is a countable collection of open sets in X. We claim $\mathcal{B}$ is a base for the topology. To show this, we need only show that if $x \in X$ and $\epsilon > 0$, there is an n and r such that $x \in B_r(x_n)$ and $B_r(x_n) \subseteq B_\epsilon(x)$. Choose n such that $\rho(x, x_n) < \frac{\epsilon}{3}$ and $r \in \mathbb{Q}$ such that $\frac{\epsilon}{3} < r < \frac{2\epsilon}{3}$. Then $x \in B_r(x_n)$, and $B_r(x_n) \subseteq B_\epsilon(x)$ by the triangle inequality. 👍

The implication proved in this proof does not require any form of Choice, since only finitely many choices must be made.

XIII.2.3.16. More generally, we can define the *density* $d(X)$ of a topological space X to be the minimum cardinality of a dense subset of X (this is only well defined in general if the AC is assumed). X is separable if and only if $d(X) \leq \aleph_0$. A slight variation of the proof of XIII.2.3.14. shows that $d(X) \leq w(X)$ (XIII.1.2.11.) for any X. We can have $d(X) < w(X)$ (a separable space is not necessarily second countable), but if X is regular we have $w(X) \leq 2^{d(X)}$ (XIII.7.10.7.).

Interior of a Set

There is a dual notion to closure:

XIII.2.3.17. DEFINITION. Let $(X, \mathcal{T})$ be a topological space, and $A \subseteq X$. The *interior* of A (in X, in the topology $\mathcal{T}$) is the largest open ($\mathcal{T}$-open) subset of X contained in A.

There is a largest such open set, the union of all open sets contained in A; there is always one such set, the empty set. The interior of A can very well be empty. The standard notation for the interior of A is A^o; the notation $Int(A)$ is also used.

XIII.2.3.18. Note that the interior of a subset A of X is a relative notion, not intrinsic to A (if A is given the relative topology, the interior of A with respect to A is all of A!) The interior of A is also dependent on the topology $\mathcal{T}$, although the notation A^o does not reflect this; the notation $Int(A)$ is thus more flexible, since it can be embellished as $Int_X(A)$, $Int_{\mathcal{T}}(A)$, or $Int_{(X,\mathcal{T})}(A)$ when necessary.

XIII.2.3.19. Example. Let $X = \mathbb{R}$ with its usual topology, $A = [0, 1]$. Then $A^o = (0, 1)$. If, however, $X = \mathbb{R}^2$ and A is the interval $[0, 1]$ on the x-axis, then $A^o = \emptyset$.

The relation between interior and closure is:

XIII.2.3.20. Proposition. Let X be a topological space, and $A \subseteq X$. Then $(A^o)^c = (A^c)^-$, i.e. $A^o = [(A^c)^-]^c$.

From this, de Morgan's laws, and XIII.2.3.3. we obtain the basic properties of interior:

XIII.2.3.21. Proposition. Let $(X, \mathcal{T})$ be a topological space and $A, B \subseteq X$. Then

(i) $A^o \subseteq A$.

(ii) A is open if and only if $A^o = A$.

(iii) $(A^o)^o = A^o$.

(iv) If $A \subseteq B$, then $A^o \subseteq B^o$.

(v) $(A \cap B)^o = A^o \cap B^o$.

(vi) $\emptyset^o = \emptyset$ and $X^o = X$.

XIII.2.3.22. We always have $A^o \cup B^o \subseteq (A \cup B)^o$, but equality does not hold in general. A dramatic example is to take $X = \mathbb{R}$, $A = \mathbb{Q}$, and $B = \mathbb{J}$; then $A^o = B^o = \emptyset$ but $(A \cup B)^o = X$.

Boundary of a Subset

XIII.2.4. Specification of a Topology via Closure

Instead of defining a topology by specifying the open sets, we can define it by specifying the closure of each set (this will determine the closed sets). This procedure can be axiomatized by a list of properties of the closure operation. This approach to topology is generally attributed to Kuratowski, although he himself in [Kur66] credited the procedure to F. Riesz.

XIII.2.4.1. DEFINITION. Let X be a set. A *Kuratowski closure operation* on X is an assignment to each subset A of X a subset $\bar{A}$ of X, called the *closure* of A, with the following properties:

(i) $\bar{\emptyset} = \emptyset$.

(ii) $A \subseteq \bar{A}$ for all $A \subseteq X$.

(iii) $\bar{\bar{A}} = \bar{A}$ for all $A \subseteq X$.

(iv) $\overline{A \cup B} = \bar{A} \cup \bar{B}$ for all $A, B \subseteq X$.

XIII.2.4.2. EXAMPLES. (i) Let $(X, \mathcal{T})$ be a topological space. For $A \subseteq X$, let $\bar{A}$ be the closure of A in the topological sense (XIII.2.3.2.). Then $A \mapsto \bar{A}$ is a Kuratowski closure operation (XIII.2.3.3.). We will show the converse: if $A \mapsto \bar{A}$ is a Kuratowski closure operation on X, then there is a unique topology on X such that the closure operation is closure with respect to the topology (XIII.2.4.4.).

(ii) If X is a nonempty set, set $\bar{A} = X$ for every $A \subseteq X$. Then this operation satisfies XIII.2.4.1.(ii), (iii), and (iv), but not (i).

(iii) If X is a nonempty set, set $\bar{A} = \emptyset$ for all $A \subseteq X$. Then this operation satisfies XIII.2.4.1.(i), (iii), and (iv), but not (ii).

(iv) Let $X = \{1, 2, 3\}$. Set $\bar{\emptyset} = \emptyset$, $\overline{\{1\}} = \{1, 2\}$, and $\bar{A} = X$ for every other A. Then this operation satisfies XIII.2.4.1.(i), (ii), and (iv), but not (iii).

(v) Let $X = \{1, 2, 3\}$. Set $\bar{\emptyset} = \emptyset$, $\overline{\{1, 2\}} = \{1, 2\}$, and $\bar{A} = X$ for every other A. Then this operation satisfies XIII.2.4.1.(i), (ii), and (iii), but not (iv).

(ii)–(v) show that the axioms in XIII.2.4.1. are independent, and hence all are necessary to specify a topology.

The most powerful of the axioms is (iv):

XIII.2.4.3. PROPOSITION. Let $A \mapsto \bar{A}$ be an operation on X satisfying (iv). Then

(i) If $A \subseteq B \subseteq X$, then $\bar{A} \subseteq \bar{B}$.

(ii) If $\{A_i : i \in I\}$ is a collection of subsets of X, then $\cup_{i \in I} \bar{A}_i \subseteq \overline{\cup_{i \in I} A_i}$.

(iii) If $\{A_i : i \in I\}$ is a collection of subsets of X, then $\overline{\cap_{i \in I} A_i} \subseteq \cap_{i \in I} \bar{A}_i$.

PROOF: (i): If $A \subseteq B$, then

$$\bar{B} = \overline{A \cup B} = \bar{A} \cup \bar{B}$$

which implies that $\bar{A} \subseteq \bar{B}$.

(ii): For each $j \in I$, $A_j \subseteq \cup_{i \in I} A_i$, so $\bar{A}_j \subseteq \overline{\cup_{i \in I} A_i}$ by (i).

(iii): For each $j \in I$, $\cap_{i \in I} A_i \subseteq A_j$, so $\overline{\cup_{i \in I} A_i} \subseteq \bar{A}_j$ by (i).

XIII.2.4.4. THEOREM. Let $A \mapsto \bar{A}$ be a Kuratowski closure operation on a set X. Then there is a unique topology $\mathcal{T}$ on X such that the closure operation is precisely closure in the topology $\mathcal{T}$.

PROOF: If there is such a topology, then the closed sets for the topology must be precisely the sets A for which $A = \bar{A}$ by axiom (iii), so there is at most one such topology. So we must show that the collection of such sets defines a topology (i.e. the complements of such sets form a topology on X). Call such sets *closed*. By XIII.2.1.5., we must show that $\emptyset$ and X are closed, and that the collection of closed sets is closed under finite unions and arbitrary intersections.
We have $\bar{\emptyset} = \emptyset$ by axiom (i), and $X \subseteq \bar{X}$ by axiom (ii), hence $X = \bar{X}$.
Suppose $A = \bar{A}$ and $B = \bar{B}$. Then $\overline{A \cup B} = \bar{A} \cup \bar{B} = A \cup B$ by axiom (iv), so $A \cup B$ is closed. By iteration (or induction), the collection of closed sets is closed under finite unions.
Suppose $A_i = \bar{A}_i$ for each $i \in I$. Then $\overline{\cap_{i\in I} A_i} \subseteq \cap_{i\in I} \bar{A}_i = \cap_{i\in I} A_i$ by XIII.2.4.3.(iii), and the opposite inclusion follows from axiom (ii). Thus the collection of closed sets is closed under arbitrary intersections. 👍

XIII.2.4.5. Suppose $A \mapsto \bar{A}$ is an operation on a set X satisfying axiom (iv) and also

(v) $\overline{\{p\}} = \{p\}$ for every $p \in X$.

Then the operation satisfies axiom (ii) by XIII.2.4.3.(ii) since any subset of X is a union of singleton subsets. If X has two distinct points p and q, then $\bar{\emptyset} \subseteq \overline{\{p\}} = \{p\}$ by XIII.2.4.3.(i), and similarly $\bar{\emptyset} \subseteq \{q\}$, so the operation also satisfies axiom (i). Thus if it also satisfies axiom (iii), it is a Kuratowski closure operation. A Kuratowski closure operation satisfies axiom (v) if and only if the corresponding topology is T_1 ().

XIII.2.5. Isolated Points and Derived Sets

We now look at isolated points and accumulation points (XIII.2.2.2.) in more detail. In order to avoid some cardinal-theoretic difficulties, we will assume the AC.

XIII.2.5.1. A point p in a topological space X is an *isolated point* of X if it is not in the closure of $X \setminus \{p\}$, i.e. if $\{p\}$ is an open set in X. (In some references, an isolated point is also required to be closed, which is automatic in a T_1 space; but we will not make this restriction.) A topological space is *dense-in-itself* if it contains no isolated points. A topological space X is *scattered* if every nonempty subset of X contains an isolated point in the relative topology, i.e. if no (nonempty) subset of X is dense-in-itself.

Any subset of a scattered space is scattered. A subset of a space which is dense-in-itself is not necessarily dense-in-itself (it could even be scattered); but an open subset of a space which is dense-in-itself must also be dense-in-itself.

XIII.2.5.2. If A is a subset of a topological space X, denote by A' the set of accumulation points of A in X. A' is called the *derived set* of A in X. A subset A of X is closed if and only if $A' \subseteq A$. We say A is a *perfect* subset of X if $A' = A$. A is perfect in X if and only if it is closed and dense-in-itself.

Note that the properties of being scattered or dense-in-itself are intrinsic properties of a space (or subspace), but being perfect is a relative property.

The next theorem, the main result of this section, is often stated in references in much less generality than necessary (the proof does not even become simpler for these special cases!) Recall (XIII.1.2.11.) that the weight $w(X)$ of a topological space X is the smallest cardinality of a base for the topology of X.

XIII.2.5.3. Theorem. [General Cantor-Bendixson Theorem] Let X be a topological space. Then there is a unique decomposition of X as a disjoint union of a perfect subset X^p and a (necessarily open) scattered subset X^s. We have $card(X^s) \leq \min(card(X), w(X))$.

Note that X^p or X^s can be empty: $X^s = \emptyset$ if (and only if) X is dense-in-itself, and $X^p = \emptyset$ if (and only if) X is scattered.

Proof: The proof will actually show more than the stated result; the additional conclusions will be formalized at the end of the proof.

Define a decreasing collection of closed subsets of X by transfinite induction as follows. Set $X^{(0)} = X$. For any ordinal α, if $X^{(\alpha)}$ has been defined, set $X^{(\alpha+1)} = (X^{(\alpha)})'$. If α is a limit ordinal, set $X^{(\alpha)} = \cap_{\beta<\alpha} X^{(\beta)}$. We have $X^{(\alpha)} \subseteq X^{(\beta)}$ if $\beta < \alpha$. Note that $X^{(1)}$ is X with the isolated points removed; since each isolated point is open, $X^{(1)}$ is closed in X. By the same argument, $X^{(\alpha+1)}$ is relatively closed in $X^{(\alpha)}$; thus by transfinite induction $X^{(\alpha)}$ is a closed subset of X for all α.

The $X^{(\alpha)}$ cannot continue to strictly decrease (it will stabilize before $card(\alpha) > card(X)$); there must be a smallest α for which $X^{(\alpha+1)} = X^{(\alpha)}$. If $X^p = X^{(\alpha)}$ for this α, then X^p is a perfect subset of X.

Set $X^s = X \setminus X^p$; then X^s is open in X. Suppose Y is a subset of X which is dense-in-itself. If $Y \cap X^s \neq \emptyset$, then there is a largest β such that $Y \subseteq X^{(\beta)}$, and $\beta < \alpha$. Thus there is a $y \in Y \cap (X^{(\beta)} \setminus X^{(\beta+1)})$. But then y is an isolated point of $X^{(\beta)}$ and hence an isolated point of Y, a contradiction. Thus every dense-in-itself subset of X is contained in X^p, and X^s is scattered.

For uniqueness, suppose $X = Z \cup W$, where Z is perfect and W scattered. We have seen that $Z \subseteq X^p$. If $X^p \cap W \neq \emptyset$, it is a relatively open subset of X^p which contains an isolated point, a contradiction.

For the cardinality assertion, let $\mathcal{B}$ be a base for the topology of X with $card(\mathcal{B}) = w(X)$. First note that if p is an isolated point of X, then $\{p\} \in \mathcal{B}$. By a similar argument, for each $x \in X^{(\alpha)} \setminus X^{(\alpha+1)}$ there is an open set $U_x \in \mathcal{B}$ with $U_x \cap X^{(\alpha)} = \{x\}$. It is clear that $x \mapsto U_x$ is an injective map from X^s to $\mathcal{B}$, so $card(X^s) \leq w(X)$. The assertion $card(X^s) \leq card(X)$ is trivial. 👍

The next corollary, or special cases of it, is usually called the "Cantor-Bendixson Theorem." Actually Cantor and Bendixson (who worked independently) only stated the result for subsets of $\mathbb{R}^n$ since the formalism of general topology had not yet been developed.

XIII.2.5.4. Corollary. [Cantor-Bendixson Theorem] Let X be a second countable topological space. Then X can be written uniquely as a disjoint union of a perfect subset X^p and a (necessarily open) scattered subset X^s. In addition, X^s is countable.

XIII.2.5.5. The set $X^{(\alpha)}$ is called the *α'th derived set* of X, and the smallest α for which $X^{(\alpha+1)} = X^{(\alpha)} = X^p$ is called the *(Cantor-Bendixson) height* $ht(X)$ of X. The chain of derived subsets and the height are homeomorphism invariants of X. The height is an ordinal invariant of X, not a cardinal invariant; if X is second countable, then $ht(X)$ is a countable ordinal, but it is not always a finite ordinal or even ω. In fact, every countable ordinal α occurs as the height of a compact subset X_α of $\mathbb{R}$ (). More generally, every ordinal occurs as the height of a compact Hausdorff space.

XIII.2.6. Exercises

XIII.2.6.1. (cf. [Dug78, III.5]) (a) Define a notion of "interior operation" on a set in analogy with the definition of a Kuratowski closure operation, using the properties from XIII.2.3.21., and prove the analog of XIII.2.4.4. that a topology can be specified by such an interior operation.

(b) Do the same for "boundary operation," using the properties of ().

(c) Do the same for the "derived set" operation $A \mapsto A'$ (XIII.2.5.2.).

XIII.2.6.2. (a) Show that if X is a T_1 topological space and $A \subseteq X$, then A' is closed in X.

(b) Show by example that if X is just T_0, A' need not be closed in X.

XIII.2.6.3. Let X be a topological space. A *block* in X is the closure of an open set in X. (Some authors call such a set *canonically closed*, but this is poor terminology since there is nothing canonical about a block.)

(a) Show that a block is the closure of its interior.

(b) Show that any finite union of blocks is a block. What about a finite intersection of blocks?

(c) An open set in X is a *regular open set* if it is the interior of its closure, i.e. the interior of a block. Show that every open set U is contained in a smallest regular open set, whose closure is the same as the closure of U.

XIII.3. Convergence

One of the most important uses of a metric is to define limits of sequences. Limits of sequences can be defined nicely in any topological space, although not all properties of limits of sequences in metric spaces carry over to this case. And it turns out that for (most – cf. XIII.3.5.2.) topological spaces which are not first countable, the theory of limits of sequences is not adequate to fully describe convergence and continuity in the space, and one must use a generalized version of sequences known as *nets*. An alternate equivalent point of view with some technical advantages uses filters in place of nets.

XIII.3.1. Limits of Sequences

Limits of sequences in topological spaces are defined just as in metric spaces, replacing open balls by open neighborhoods:

XIII.3.1.1. DEFINITION. Let $(X, \mathcal{T})$ be a topological space, and let (x_n) be a sequence in X, and $x \in X$. Then (x_n) *converges to* x in $(X, \mathcal{T})$, denoted $x_n \to x$ or $\lim\limits_{n\to\infty} x_n = x$, if for every open neighborhood U of x there is an N such that $x_n \in U$ for all $n \geq N$. (We say that x_n is *eventually in* U.)

If there is any possible ambiguity about which topology is used on X, we write $x_n \to_{\mathcal{T}} x$ or $\mathcal{T}\text{-}\lim\limits_{n\to\infty} x_n = x$.

XIII.3.1.2. The word "open" can be deleted from this definition without changing its meaning, since every neighborhood of x contains an open neighborhood. Similarly, the existence of an N need only be shown for U's in a fixed local base for the topology at x.

XIII.3.1.3. Unlike in metric spaces, limits of sequences need not be unique: for example, in a space with the indiscrete topology every sequence converges to every point. This undesirable situation does not occur in Hausdorff spaces (XIII.7.4.1.).

Subsequences and Tails

Subsequences and tails of sequences are defined just as in (). Convergence of a sequence depends only on the tails of the sequence, and implies convergence of each subsequence, just as in the metric case (the proof is essentially identical):

XIII.3.1.4. PROPOSITION. Let X be a topological space, and (x_n) a sequence in X, $x \in X$.

(i) $x_n \to x$ if and only if some tail of (x_n) converges to x.

(ii) If $x_n \to x$, then every subsequence of (x_n) converges to x. In particular, every tail of (x_n) converges to x.

There is a sort of converse to (ii), which is almost harder to state than to prove:

XIII.3.1.5. PROPOSITION. Let X be a topological space, and (x_n) a sequence in X, $x \in X$. If (x_n) does not converge to x, then there is a subsequence of (x_n), no subsequence of which converges to x.

PROOF: If (x_n) does not converge to x, then there is an open neighborhood U of x such that $x_n \notin U$ for infinitely many n. These x_n form a subsequence with no terms in U, so no subsequence of it can converge to x. 👍

The result is often stated in the contrapositive:

XIII.3.1.6. COROLLARY. Let X be a topological space, and (x_n) a sequence in X, $x \in X$. If every subsequence of (x_n) has a subsequence which converges to x, then $x_n \to x$.

Cluster Points of Sequences

XIII.3.1.7. DEFINITION. Let X be a topological space, and (x_n) a sequence in X, $x \in X$. Then x is a *cluster point* of (x_n) if every open neighborhood U of x contains x_n for infinitely many n (we say x_n is *frequently in* U).

The proof of the next Proposition is essentially identical to the proof of ().

XIII.3.1.8. PROPOSITION. Let X be a topological space, and (x_n) a sequence in X. For each n, let F_n be the closure in X of $\{x_k : k \geq n\}$. Then $\cap_n F_n$ is exactly the set of cluster points of (x_n). In particular, the set of cluster points of a sequence is a closed set.

If $x_n \to x$, or more generally if there is a subsequence of (x_n) which converges to x, then x is a cluster point of (x_n). The converse is not true in general (), but is true if the topological space is first countable:

XIII.3.1.9. PROPOSITION. Let X be a topological space, (x_n) a sequence in X, and $x \in X$. If x is a cluster point of (x_n), and there is a countable local base for the topology at x (in particular, if X is first countable), then there is a subsequence of (x_n) which converges to x.

PROOF: Let (U_n) be a decreasing sequence of open neighborhoods of x forming a local base (). Let $x_{k_1} \in U_1$, and inductively choose $k_{n+1} > k_n$ with $x_{k_{n+1}} \in U_{n+1}$; this is possible since $x_k \in U_{n+1}$ for infinitely many k. (For definiteness and to avoid use of the Countable AC, choose k_{n+1} to be the smallest $k > k_n$ for which $x_k \in U_{n+1}$.) Then (x_{k_n}) is a subsequence of (x_n), and $x_{k_n} \in U_m$ for $n \geq m$. If V is any neighborhood of x, then $U_m \subseteq V$ for some m, so $x_{k_n} \in V$ for all $n \geq m$. Thus $x_{k_n} \to x$. 👍

XIII.3.1.10. If A is a subset of a topological space X, $x \in X$, and there is a sequence (x_n) in A with $x_n \to x$, then x is obviously a limit point of A, so $x \in \bar{A}$. The converse is not true in general (), but is true if the topological space is first countable:

XIII.3.1.11. PROPOSITION. Let A be a subset of a topological space X and $x \in X$. If there is a countable local base for the topology at x (in particular, if X is first countable), then $x \in \bar{A}$ if and only if there is a sequence (x_n) of points of A which converges to x.

PROOF: The proof is very similar to the proof of XIII.3.1.9.. One direction is noted above, and does not require a countable local base. Conversely, suppose $x \in \bar{A}$. Let (U_n) be a decreasing sequence of open neighborhoods of x forming a local base. Then $A \cap U_n$ is nonempty for every n. Choose $x_n \in A \cap U_n$ for each n. If V is any neighborhood of x, then $U_m \subseteq V$ for some m, so $x_n \in V$ for all $n \geq m$. Thus $x_n \to x$. 👍

Note that the Countable AC is needed for this proof.

XIII.3.1.12. Thus, if X is a first countable topological space, then (assuming the Countable AC) convergence of sequences tells the whole story about the topology.

Iterated Limits

There is another property of convergent sequences in first countable topological spaces:

XIII.3.1.13. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space and $\{x_{k,n} : k, n \in \mathbb{N}\}$ be a doubly indexed set of points in X. Suppose $\lim_{n\to\infty} x_{k,n} = x_k$ for each k and $\lim_{k\to\infty} x_k = x$. If x has a countable local base (in particular, if X is first countable), then there are strictly increasing sequences $(k_m), (n_m)$ in $\mathbb{N}$ such that $\lim_{m\to\infty} x_{k_m,n_m} = x$.

The sequence (x_{k_m,n_m}) is a sort of "diagonal" sequence, and this property of limits is sometimes called the *diagonal property*.

PROOF: Let (U_m) be a countable decreasing local neighborhood base at x. Then for each m there is a K_m such that $x_k \in U_m$ for all $k \geq K_m$. Then for each $k \geq K_m$ there is an $N_{k,m}$ such that $x_{k,n} \in U_m$ for all $n \geq N_{k,m}$. Inductively choose $k_1 = n_1 = 1$ and $k_m = \max(k_{m-1} + 1, K_m)$ and $n_m = \max(n_{m-1} + 1, N_{k_m,m})$ for $m > 1$. It is routine to check that $x_{k_m,n_m} \to x$. 👍

XIII.3.1.14. This result can fail if x does not have a countable local base (). But the net version holds in general ().

XIII.3.2. Nets and Limits

In a topological space which is not first countable, sequences are generally inadequate to completely describe the behavior of the topology and convergence. But there is a deceptively simple way to generalize sequences, which in complete analogy does fully describe the topology. These generalized sequences are called nets. On the surface, the results of the preceding subsection work for general topological spaces by simply substituting "net" for "sequence" and "subnet" for "subsequence"; however, below the surface there are some subtleties involved, especially with the notion of a subnet.

XIII.3.2.1. DEFINITION. Let X be a topological space (or just a set). A *net* in X is a function from a directed set $(I, \leq)$ to X. The set I is called the *index set* of the net.

A sequence is just a net whose index set is $\mathbb{N}$. If $\phi : I \to X$ is a net with index set I, we usually denote the net by $(x_i)_{i \in I}$ or just by (x_i) if I is understood, where $x_i = \phi(i)$. This notation is a simple extension of sequence notation. However, this notation does not reflect the direction on I, which is part of the definition of the net.

XIII.3.2.2. Note that the index set of a net does not have to be partially ordered. One can in principle restrict to partially ordered index sets in the theory of nets (cf. XIII.3.2.4., XIII.3.2.5., II.4.4.11.). However, it is often convenient to use nets whose index sets are not partially ordered.

XIII.3.2.3. DEFINITION. Let X be a topological space, (x_i) a net in X, and $x \in X$. Then (x_i) *converges to* x, denoted $x_i \to x$ or $\lim_i x_i = x$, if for every open neighborhood U of X there is an $i_0 \in I$ such that $x_i \in U$ whenever $i_0 \leq i$. (We say the net (x_i) is *eventually in* U.)

As for sequences, the word "open" can be deleted, and it suffices to let the U range over a local base at x.

XIII.3.2.4. If the index set of a net is not properly directed (i.e. has a largest element), convergence of the net is pretty trivial: if there is exactly one largest element i_1 in I, then the net automatically converges to x_{i_1}. If there is more than one largest element in I, then the net rarely converges (only if every neighborhood of x_i for each largest element i contains x_j for all the other largest j; this cannot happen in a T_0-space () unless $x_i = x_j$ for all largest i and j, in which case the net converges to this element). The theory of convergence of nets is only interesting if the index set is properly directed.

The convergence of a net depends on the ordering (direction) of I only up to equivalence, i.e. only on the "cofinal behavior" of the direction:

XIII.3.2.5. PROPOSITION. Let $(I, \leq)$ be a directed set, X a topological space, and $(x_i)_{i \in I}$ a net in X with index set I. Let $\precsim$ be another direction on I which is equivalent to $\leq$. If $x \in X$, then $x_i \to x$ using the direction $\leq$ on I if and only if $x_i \to x$ using the direction $\precsim$ on I.

This is obvious using the definition of equivalence of directions ().

Subnets

The definition of a subnet is not an obvious one. Experience has shown that the following definition is appropriate, and flexible enough to be useful:

XIII.3.2.6. DEFINITION. Let X be a topological space, $(I, \leq)$ a directed set, and $\phi : I \to X$ a net in X. A *subnet* of ϕ is a net $\phi \circ f$, where f is a directed function from a directed set $(J, \precsim)$ to $(I, \leq)$. The index set of the subnet is $(J, \precsim)$.

Thus the index set of a subnet of a net is not necessarily the same as the index set of the net.

XIII.3.2.7. A subnet of a sequence is not necessarily a subsequence, for two reasons. First of all, the index set of the subnet is not necessarily $\mathbb{N}$. And even if it is, the function $f : \mathbb{N} \to \mathbb{N}$ defining the subnet is not necessarily injective or increasing. A subnet of a sequence is a subsequence if and only if its index set is $\mathbb{N}$ and its function $f : \mathbb{N} \to \mathbb{N}$ is strictly increasing.

XIII.3.2.8. **Notation:** If we denote the net $\phi : I \to X$ by $(x_i)_{i\in I}$, the net $\phi \circ f$ for $f : J \to I$ will be denoted $(x_{f(j)})_{j\in J}$ or $(x_{i_j})_{j\in J}$, sometimes just $(x_j)_{j\in J}$, where $x_i = \phi(i)$ and $i_j = f(j)$. The "$j \in J$" may be omitted if J is understood. This notation is a little ambiguous, since f is not necessarily injective; we must regard $x_{i_{j_1}}$ and $x_{i_{j_2}}$ as distinct terms in the subnet if $j_1 \neq j_2$, even if $f(j_1) = f(j_2)$. (Note that terms of the original net may be "repeated" in the subnet, although only to a limited extent since f is directed. This really causes no more complication than the fact that x_{i_1} can equal x_{i_2} in the original net even if $i_1 \neq i_2$, i.e. ϕ need not be injective.)

XIII.3.2.9. The most obvious subnets of a net (x_i) are formed by letting J be a cofinal subset () of I and f the inclusion of J into I. We will call a subnet of this kind a *subtail* (a nonstandard name; there appears to be no standard one). A *tail* of a net is a subtail where J is of the form $\{i \in I : i_0 \leq i\}$ for a fixed $i_0 \in I$. A subtail of a sequence is exactly just a subsequence, and a tail of a sequence in this sense is the same as a tail as previously defined.

For purposes of describing topologies and convergence, subtails are inadequate in general, just as in the sequence case. Thus it is necessary to use the more complicated but more general and flexible notion of subnet as we have defined it.

XIII.3.2.10. Proposition. Let X be a topological space and (x_i) a net in X. Any subnet of a subnet of (x_i) is a subnet of (x_i). Any subtail of a subtail of (x_i) is a subtail, and any tail of a tail is a tail.

Proof: If $\phi : I \to X$ defines (x_i), and $f : J \to I$ the subnet, a subnet of $(x_{f(j)})$ consists of a directed set K and a directed function $g : K \to J$, with function $(\phi \circ f) \circ g$. Then $f \circ g$ is a directed function from K to I (II.4.4.8.), and $\phi \circ (f \circ g)$ gives the subsubnet as a subnet of (x_i). The last statement is obvious. 👍

The proofs of the next two results are almost identical to the sequence versions:

XIII.3.2.11. Proposition. Let X be a topological space, and (x_i) a net in X, $x \in X$.

(i) $x_i \to x$ if and only if some tail of (x_i) converges to x.

(ii) If $x_i \to x$, then every subnet of (x_i) converges to x. In particular, every tail of (x_i) converges to x.

Proof: We give the proof of (ii), leaving the simpler proof of (i) to the reader. Suppose $(x_{f(j)})_{j\in J}$ is a subnet of (x_i), and let U be an open neighborhood of x. There is an i_0 such that $x_i \in U$ for all $i \geq i_0$. Fix $j_0 \in J$ so that $f(j) \geq i_0$ for all $j \geq j_0$. Then $x_{f(j)} \in U$ for all $j \geq j_0$, so the subnet converges to x. 👍

The net version of XIII.3.1.5. is the hard-to-state "converse" to (ii):

XIII.3.2.12. PROPOSITION. Let X be a topological space, and (x_i) a net in X, $x \in X$. If (x_i) does not converge to x, then there is a subnet of (x_i) (in fact a subtail), no subnet of which converges to x.

PROOF: If (x_i) does not converge to x, then there is an open neighborhood U of x such that $J = \{i \in I : x_i \notin U\}$ is cofinal in I. This J gives a subtail with no terms in U, so no subnet of it can converge to x. 👍

The result is often stated in the contrapositive:

XIII.3.2.13. COROLLARY. Let X be a topological space, and (x_i) a net in X, $x \in X$. If every subnet of (x_i) has a subnet which converges to x, then $x_i \to x$.

Weak Subnets

We can extend XIII.3.2.12. in an interesting way.

XIII.3.2.14. DEFINITION. Let (x_i) be a net in X with index set I defined by $\phi : I \to X$. A *weak subnet* of (x_i) is a net defined by $\phi \circ f$, where f is a not necessarily directed function from a directed set J to I.

XIII.3.2.15. Any subnet is a weak subnet, but there are many weak subnets which are not subnets: for example, f could be a constant function. Even if f is strictly increasing, the weak subnet is not necessarily a subnet since the range of f may not be cofinal in I (this cannot happen for sequences).

The proof of XIII.3.2.12. actually shows the following considerably stronger result:

XIII.3.2.16. PROPOSITION. Let X be a topological space, and (x_i) a net in X, $x \in X$. If (x_i) does not converge to x, then there is a subnet of (x_i) (in fact a subtail), no weak subnet of which converges to x.

XIII.3.2.17. COROLLARY. Let X be a topological space, and (x_i) a net in X, $x \in X$. If every subnet of (x_i) has a weak subnet which converges to x, then $x_i \to x$.

Cluster Points of Nets

XIII.3.2.18. DEFINITION. Let X be a topological space, and (x_i) a net in X, $x \in X$. Then x is a *cluster point* of (x_i) if every open neighborhood U of x contains x_i for a cofinal set of i (we say x_i is *frequently in* U).

The proof of the next Proposition is essentially identical to the proof of (). This result motivates the theory of convergence via filters ().

XIII.3.2.19. PROPOSITION. Let $(x_i)_{i\in I}$ be a net in a topological space X. For each $i \in I$, set

$$T_i = \{x_j : j \geq i\} .$$

Then $\cap_{i\in I}\bar{T}_i$ is precisely the set of cluster points of the net (x_i). In particular, the set of cluster points of a net is closed.

The set T_i is called the *tail set* of the net (x_i) corresponding to i. Thus the convergence of a net depends only weakly on the actual directed set I but only on the collection of tail sets of the net.

PROOF: If x is a cluster point of (x_i), then any neighborhood of x contains point of T_i for arbitrarily large i, hence $x \in \cap_{i\in I}\bar{T}_i$. Conversely, if $x \in \cap_{i\in I}\bar{T}_i$ and U is an open neighborhood of x, then for each i we have $T_i \cap U \neq \emptyset$, and any element of this intersection is of the form x_j for some $j \geq i$. Thus x is a cluster point of (x_i). 👍

If $x_i \to x$, or more generally if there is a subnet of (x_i) which converges to x, then x is a cluster point of (x_i). Unlike in the sequence case, the converse is true in general, showing the universal applicability of nets to convergence. The proof is a good example of how nets are used in practice, and beautifully and graphically demonstrates the utility of the subnet definition.

XIII.3.2.20. THEOREM. Let X be a topological space, (x_i) a net in X, and $x \in X$. If x is a cluster point of (x_i), then there is a subnet of (x_i) which converges to x.

PROOF: Let J be the set of all pairs (U, i), where U is an open neighborhood of x, $i \in I$, and $x_i \in U$. Put a preorder $\precsim$ on J by setting $(U_1, i_1) \precsim (U_2, i_2)$ if $U_2 \subseteq U_1$ and $i_1 \leq i_2$.

We show that $(J, \precsim)$ is directed. Suppose (U_1, i_1) and (U_2, i_2) are in J. Set $V = U_1 \cap U_2$ and let i_3 be an upper bound for $\{i_1, i_2\}$ in I. Then since x is a cluster point of (x_i), there is an $i \geq i_3$ with $x_i \in V$. Then $(V, i) \in J$, and (V, i) is an upper bound for $\{(U_1, i_1), (U_2, i_2)\}$.

Define $f : J \to I$ by $f(U, i) = i$. We show that f is directed. Let $i_0 \in I$. We must find $(U_1, i_1) \in J$ such that $(V, i) \in J$, $(U_1, i_1) \precsim (V, i)$ implies $i \geq i_0$. Just take $U_1 = X$ and $i_1 = i_0$. (Note that f is in fact order-preserving.)

Finally, we show that the subnet $(x_{(U,i)})$ converges to x. Let V be an open neighborhood of x, and fix i_0 such that $x_{i_0} \in V$. Then $(V, i_0) \in J$, and $x_{(U,i)} \in V$ whenever $(V, i_0) \precsim (U, i)$. 👍

Similarly, we get a net version of XIII.3.1.11. which is valid in complete generality. The proof shows the utility of considering directed sets which are not partially ordered.

XIII.3.2.21. THEOREM. Let A be a subset of a topological space X and $x \in X$. Then $x \in \bar{A}$ if and only if there is a net (x_i) of points of A which converges to x.

PROOF: If there is a net in A converging to x, then every neighborhood of x contains a term of the net, hence a point of A. Thus $x \in \bar{A}$. Conversely, suppose $x \in \bar{A}$. Let I be the set of all pairs (U, y), where U is an open neighborhood of x and $y \in U \cap A$. (We have $U \cap A \neq \emptyset$ for all U.) Put a preorder $\leq$ on I by $(U, y) \leq (V, z)$ if $V \subseteq U$. (Note that this is rarely a partial order.)

We show that $(I, \leq)$ is directed. If (U_1, y_1) and (U_2, y_2) are in I, set $V = U_1 \cap U_2$, and let $z \in V \cap A$. Then (V, z) is an upper bound for $\{(U_1, y_1), (U_2, y_2)\}$.

Define a net $(x_i)_{i \in I}$ by setting $x_{(U,y)} = y$. Then $x_i \in A$ for all i. If U is any open neighborhood of x, let $y \in U \cap A$, and set $i_0 = (U, y) \in I$. Then for any $(V, z) \geq (U, y)$ in I, $x_{(V,z)} = z \in V \subseteq U$, i.e. if $i \geq i_0$, $x_i \in U$. Thus $x_i \to x$. 👍

Note that unlike in the sequence case, no form of Choice is needed for this result. This again shows the versatility of the theory of nets and subnets.

Interleaving Nets

XIII.3.2.22. It is technically useful to be able to "interleaf" or "intertwine" two nets into a single net. This is easily done for sequences: if (x_n) and (y_n) are sequences in X, simply alternate the terms to form the sequence

$$(x_1, y_1, x_2, y_2, \ldots, x_n, y_n, \ldots)$$

which will converge to a limit x if and only if $x_n \to x$ and $y_n \to x$ (cf. ()).

It is unclear how to do this in the case of nets. There are two technical difficulties:

(i) The two nets need not even have the same index set.

(ii) Even if the index sets are the same, it is not obvious what "alternating" terms means.

The difficulty is in the generality of the indexing for nets, but the generality and flexibility of indexing is also the key to the solution.

XIII.3.2.23. We first show how to modify two nets to new nets with the same index set. Suppose (x_i) is a net in X with index set I, and suppose J is another directed set; we will use $\prec$ for the direction in both I and J. Set $K = I \times J$, and give K the product ordering: $(i_1, j_1) \prec (i_2, j_2)$ if and only if $i_1 \prec i_2$ and $j_1 \prec j_2$ (cf. ()). For $k = (i, j)$, set $x_k = x_i$.

XIII.3.2.24. PROPOSITION. The net (x_k) converges to $x \in X$ if and only if $x_i \to x$.

PROOF: Let U be a neighborhood of x. If $x_k \to x$, there is an $k_0 = (i_0, j_0)$ such that $x_k \in U$ whenever $k_0 \prec k$; then $x_i \in U$ whenever $i_0 \prec i$. Conversely, if $x_i \to x$, there is an i_0 such that $x_i \in U$ whenever $i_0 \prec i$; if j_0 is any fixed element of J, then $x_k \in U$ whenever $k_0 = (i_0, j_0) \prec k$. 👍

In fact, the modified net (x_k) is a subnet of (x_i) via the projection from $I \times J$ onto I.

XIII.3.2.25. If (x_i) and (y_j) are nets in X with index sets I and J respectively, both can be modified to nets with index set $K = I \times J$; convergence of the nets is unaffected by the reindexing.

XIII.3.2.26. Now suppose (x_k) and (y_k) are nets with the same index set K. Define a new net $(z_{k,n})$ with index set $K \times \{1, 2\}$ with ordering $(k_1, n_1) \prec (k_2, n_2)$ if and only if $k_1 \prec k_2$, by taking $z_{k,1} = x_k$ and $z_{k,2} = y_k$ for all k (cf. ()). The net $(z_{k,n})$ is called the *interleaving* of (x_k) and (y_k). We have:

XIII.3.2.27. PROPOSITION. The interleaved net $(z_{k,n})$ converges to $x \in X$ if and only if $x_k \to x$ and $y_k \to x$.

The simple proof is almost identical to the proof of XIII.3.2.24., and is left to the reader (Exercise ()). Note that (x_k) and (y_k) are subnets of $(z_{k,n})$ via the maps $k \mapsto (k,1)$ and $k \mapsto (k,2)$ respectively, giving one direction.

Moore-Smith Convergence

XIII.3.2.28. The theory of convergence of nets is often called the theory of *Moore-Smith convergence*, since it was originated in [**?**]. The term "net" was coined by KELLEY.

The Moore of Moore-Smith was E. H. MOORE, not R. L. MOORE. Both Moores (who were not related) were very important and influential in American mathematics. Both were first-rate mathematicians, but their importance went far beyond their own mathematical work. Both served as presidents of the American Mathematical Society and were instrumental in the development of the AMS.

E. H. MOORE was probably more responsible than any other individual for the rise of American mathematics in general, and the University of Chicago in particular, to world-class status. A considerable percentage of current American mathematicians, including the author, are mathematical descendents of his (the Mathematics Genealogy Project https://genealogy.math.ndsu.nodak.edu/ lists at least 25,722 mathematical descendents of E. H. MOORE).

R. L. MOORE, in addition to being one of the principal founders of the American school of topology, was a gifted and energetic teacher who trained a large percentage of the leading American topologists of the mid-twentieth century. He also developed the "Moore method" of pedagogy (cf. I.6.7.), which is much admired and emulated, although it is not without its detractors. Unfortunately, he was also a virulent racist.

There have been a number of other mathematicians named Moore, including the author's advisor, C. C. MOORE, who is apparently unrelated to either E. H. or R. L.

XIII.3.3. Specification of a Topology via Convergence

It is often desirable to define a topology by specifying which sequences or nets converge. This is particularly convenient when considering function spaces, where we often want to discuss the "topology of pointwise convergence," the "topology of uniform convergence," etc. This can be done rather cleanly, although there are some subtleties.

This approach to topology was developed by FRÉCHET [], ALEKSANDROV and URYSOHN [], [], and BIRKHOFF [Bir37]. See [Kur66, §20] and [Kel75] for details.

XIII.3.3.1. It is clear that a topology cannot be completely determined by convergence of sequences in general in the non-first-countable case; in fact, two distinct topologies on a set can have the same convergent sequences, such as the usual topology and the discrete topology on $\beta\mathbb{N}$ (XIII.11.9.16.(v); see also () for a natural and important example, and Exercise XIII.7.10.16. for a simple one). We have a much better chance of success working with nets, but we will use sequences as much as possible since in applications it is very convenient to use sequences.

XIII.3.3.2. The general setup is: X is a set, and $\mathcal{C}$ a collection of sequences (or nets) in X which we will declare to converge, each with a specified limit. More precisely, $\mathcal{C}$ will be a set of pairs (s, x), where s is a sequence or net in X and $x \in X$; we will declare that the sequence s converges to x. We want a topology $\mathcal{T}$ on X such that $s \to x$ in the topology $\mathcal{T}$ for every pair (s, x) in $\mathcal{C}$; ideally, we want $\mathcal{C}$ to be the *complete* set of convergent sequences (or nets) with respect to $\mathcal{T}$.

We will be primarily interested in the case where a sequence cannot have more than one limit (this was an explicit assumption in [], [], [], [Bir37]), but we will not make this a blanket assumption.

XIII.3.3.3. To make the process work, we make the modest assumption on $\mathcal{C}$ that any subsequence of a sequence in $\mathcal{C}$ is also in $\mathcal{C}$, with the same limit, i.e. that if $(s, x) \in \mathcal{C}$ and s' is a subsequence of s, then $(s', x) \in \mathcal{C}$. This subsequence property must be satisfied for $\mathcal{C}$ to have any claim to completeness. ("Sequence" and "subsequence" can be replaced by "net" and "subnet" here.)

XIII.3.3.4. There are two possible approaches to defining $\mathcal{T}$:

(1) We could declare a subset E of X *closed* if, whenever $(s, x) \in \mathcal{C}$ and s is a sequence in E, then $x \in E$. (If $\mathcal{T}$ is a topology on X under which the sequences in $\mathcal{C}$ converge, then any $\mathcal{T}$-closed set has this property.)

(2) We could define a closure operation on X by saying that if $A \subseteq X$, then $\bar{A}$ consists of all $x \in X$ such that there exists $(s, x) \in \mathcal{C}$ with s a sequence in A. (If $\mathcal{T}$ is a topology on X under which the sequences in $\mathcal{C}$ converge, then any such x must be a limit point of A.) If $A \mapsto \bar{A}$ is a Kuratowski closure operator (), it defines a suitable topology $\mathcal{T}$.

Procedure (2) is more constructive. It turns out that procedure (1) works quite nicely, but procedure (2) is more problematic.

First consider procedure (1). Half the answer is almost immediate:

XIII.3.3.5. Proposition. Let X be a set and $\mathcal{C}$ a set of sequences as above, with the subsequence property. Let $\mathcal{E}$ be the collection of closed subsets of X as defined in (1). Then $\mathcal{E}$ is the collection of closed sets in a topology $\mathcal{T}$ which is the strongest topology on X for which $s \to x$ for every $(s, x) \in \mathcal{C}$.

Proof: We need to show that $\mathcal{E}$ satisfies the conditions of XIII.2.1.4.. It is obvious that $\emptyset$ and X are in $\mathcal{E}$, and that $\mathcal{E}$ is closed under arbitrary intersections. So suppose A and B are in $\mathcal{E}$ and $(s, x) \in \mathcal{C}$ with s a sequence in $A \cup B$. Then s either has a subsequence s' in A or a subsequence s'' in B. In the first case $(s', x) \in \mathcal{C}$, so $x \in A \subseteq A \cup B$ since $A \in \mathcal{E}$, and similarly in the second case $x \in B \subseteq A \cup B$. Thus $A \cup B \in \mathcal{E}$ and $\mathcal{E}$ is closed under finite unions.
It is clear from the last observation in (1) that the topology defined by $\mathcal{E}$ is the strongest possible topology on X giving the desired convergence. 👍

XIII.3.3.6. This result and its proof hold if "sequence" is replaced by "net" and "subsequence" by "subnet" throughout (i.e. the subsequence property is replaced by the subnet property, and the definition of "closed" in (1) uses nets).

XIII.3.3.7. However, it will rarely be true that $\mathcal{C}$ is the complete set of sequences which converge with respect to $\mathcal{T}$. For one thing, for $\mathcal{C}$ to be complete it must have the following property (cf. XIII.3.1.6.):

> If s is a sequence in X, $x \in X$, and every subsequence s' of s has a subsequence s'' such that $(s'', x) \in \mathcal{C}$, then $(s, x) \in \mathcal{C}$.

$\mathcal{C}$ must also contain all constant sequences (with limit equal to the constant term).

Even these additional assumptions on $\mathcal{C}$ are not enough in general. Before discussing this further, we will examine procedure (2), beginning with the net version.

XIII.3.3.8. So, given a collection $\mathcal{C}$ of nets, let us define a closure operation on X as in (2). If $\mathcal{C}$ is to be the set of convergent nets for a topology , we must have the diagonal property:

It turns out this property along with the previous ones is sufficient to obtain a Kuratowski closure operation:

XIII.3.3.9. PROPOSITION. Let X be a set and $\mathcal{C}$ a collection of pairs (s, x) where s is a net in X and $x \in X$. Suppose $\mathcal{C}$ has the following properties:

(i) If $x \in X$ and s is a constant net with all terms x, then $(s, x) \in \mathcal{C}$.

(ii) If $(s, x) \in \mathcal{C}$ and s' is a subnet of s, then $(s', x) \in \mathcal{C}$.

(iii) Diagonal property

For $A \subseteq X$, let $\bar{A}$ be the set of all $x \in X$ such that there exists a pair $(s, x) \in \mathcal{C}$ with s a net in A. Then $A \mapsto \bar{A}$ is a Kuratowski closure operation on X. The corresponding topology on X is the strongest topology $\mathcal{T}$ on X with the property that $s \to x$ in $\mathcal{T}$ for every $(s, x) \in \mathcal{C}$, and coincides with the topology defined in XIII.3.3.5..

PROOF: Obviously $\bar{\emptyset} = \emptyset$, and $\bar{X} = X$ since $\mathcal{C}$ contains all constant nets. If $A \subseteq X$, then $A \subseteq \bar{A}$ by the same argument, and $\bar{\bar{A}}$ by (iii). Now suppose $A, B \subseteq X$, and $x \in X$. If $x \in \bar{A}$ or $x \in \bar{B}$, then obviously $x \in \overline{A \cup B}$. Conversely, if $x \in \overline{A \cup B}$, let $s = (x_i)$ be a net in $A \cup B$ with $(s, x) \in S$. Then s either has a subnet s' in A or a subnet s'' in B (). In the first case $(s', x) \in \mathcal{C}$, so $x \in \bar{A}$, and in the second case $x \in \bar{B}$. In either case, $x \in \bar{A} \cup \bar{B}$. Thus $\overline{A \cup B} = \bar{A} \cup \bar{B}$. 👍

XIII.3.3.10. From either XIII.3.3.5. or XIII.3.3.9. we are left with two questions:

(1) Is the topology $\mathcal{T}$ so defined the *unique* topology on X for which $s \to x$ for all $(s, x) \in \mathcal{C}$?

(2) Is $\mathcal{C}$ the collection of *all* convergent sequences or nets with respect to $\mathcal{T}$?

The answer to (1) is clearly no in general: we have $s \to x$ for all $(x, s) \in \mathcal{C}$ for any weaker topology too, e.g. the indiscrete topology.

For question (2) to have a positive answer, it is necessary that $\mathcal{C}$ have the net version of the property of XIII.3.3.7., as well as (i)–(iii) of XIII.3.3.9.. This suffices:

XIII.3.3.11. THEOREM. (cf. [Bir37]) Let X be a set and $\mathcal{C}$ a collection of pairs (s, x) where s is a net in X and $x \in X$. Suppose $\mathcal{C}$ has the following properties:

(i) If $x \in X$ and s is a constant net with all terms x, then $(s, x) \in \mathcal{C}$.

(ii) If $(s, x) \in \mathcal{C}$ and s' is a subnet of s, then $(s', x) \in \mathcal{C}$.

(iii) Diagonal property

(iv) If s is a net in X, $x \in X$, and every subnet s' of s has a weak subnet s'' with $(s'', x) \in \mathcal{C}$, then $(s, x) \in S$.

Let $\mathcal{T}$ be the topology defined by $\mathcal{C}$ as in XIII.3.3.7. or XIII.3.3.9.. Then $\mathcal{C}$ is precisely the set of nets in X which converge in $\mathcal{T}$.

PROOF: We need only to show that if s is a net in X with $s \to x$, then $(s, x) \in \mathcal{C}$. Suppose $(s, x) \notin \mathcal{C}$. Then by (iv) there is a subnet s' of s such that $(s'', x) \notin \mathcal{C}$ for all weak subnets s'' of s'. Set

$$E = \{y \in X | (s'', y) \in \mathcal{C} \text{ for some weak subnet } s'' \text{ of } s'\} .$$

The set E is exactly the closure of the set of terms in s', hence is a closed subset of X. Since all terms of s' are in E, we cannot have $s' \to x$ and hence s does not converge to x. 👍

XIII.3.3.12. Hypotheses (iii) and (iv) may be somewhat difficult to check in some cases, but they are indeed necessary conditions for the conclusion (),(). By a somewhat more complicated argument (cf. [Kel75, p. 74]), it can be shown that hypothesis (iv) can be slightly weakened by replacing "weak subnet" with "subnet." The proof of this in [Kel75] (implicitly) uses the AC (note that the proof of XIII.3.3.11. above does not use any Choice). A class of nets satisfying (i)–(iii) and this version of (iv) is called a *convergence class*.

XIII.3.3.13. It is suggested in [**?**, p. 19] that hypothesis (iv) is redundant. However, at least some weak version of (iv) is necessary; otherwise, we could take $\mathcal{C}$ to be the class of constant nets. The topology on X determined by this $\mathcal{C}$ is the discrete topology, but if X has more than one element $\mathcal{C}$ is not the entire class of convergent nets in X (the class of eventually constant nets).

The following weak version of (iv) might suffice:

(iv′) If s is a net in X, $x \in X$, and there is a tail s' of s with $(s', x) \in \mathcal{C}$, then $(s, x) \in \mathcal{C}$.

XIII.3.3.14. There is also a set-theoretic problem: the collection of all subnets of a net does not form a set. One might be able to get around this problem by only considering nets whose index set is a subset of some fixed set whose cardinality is large compared to $|X|$, although construction of diagonal nets may cause difficulty. One really needs a notion of equivalence of nets and that every net on X is equivalent to a net with an index set of bounded cardinality. This is effectively accomplished using the theory of filter convergence (), which avoids these set-theoretic difficulties.

XIII.3.3.15. Unfortunately, there is no simple version of XIII.3.3.11. for sequences. The sequence version of (iii) does not hold in general (). If the generated topology is assumed to be first countable, the theorem holds with sequences in place of nets; but there is no simple criterion in terms of convergence of sequences which will characterize when the generated topology is first countable.

XIII.3.4. Convergence via Filters

There is another approach to convergence in a topological space which uses filters instead of nets. This approach is somewhat more complicated and less familiar at first, but has some technical advantages once set up. The theories of convergence via nets and filters are entirely equivalent logically, and there is a way of translating directly from one to the other, and it is largely a matter of taste (and, unfortunately, sometimes of national pride, since the theory of net convergence was developed in the United States and the theory of filter convergence in France) which approach is used; but some things are done more easily or efficiently from one of the points of view instead of the other, so it is valuable to be familiar with both approaches.

The theory of convergence via filters was developed by H. CARTAN for BOURBAKI around 1940. More details can be found in [**?**] and [Dug78].

XIII.3.4.1. Recall (XVI.1.8.1.) that a *filter* on X is a nonempty collection $\mathcal{F}$ of subsets of X such that

(i) $\mathcal{F}$ is closed under finite intersections.

(ii) $\mathcal{F}$ has the *superset property*: if $A \in \mathcal{F}$ and $A \subseteq B \subseteq X$, then $B \in \mathcal{F}$.

(iii) $\emptyset \notin \mathcal{F}$.

XIII.3.4.2. DEFINITION. A collection $\mathcal{D}$ of nonempty subsets of a set X is *centered* if, for every $A, B \in \mathcal{D}$ there is a $C \in \mathcal{D}$ with $C \subseteq A \cap B$. A centered collection of subsets of X is called a *filterbase* in X.

XIII.3.4.3. A collection of nonempty subsets of a set X is centered if and only if it is directed by inverse inclusion, i.e. $A \leq B$ if $B \subseteq A$. A filterbase $\mathcal{D}$ has the finite intersection property (XVI.1.8.9.), and hence is contained in a unique smallest filter $\mathcal{F}$ (XVI.1.8.10.) called the *filter generated by* $\mathcal{D}$; $\mathcal{D}$ is called a *filterbase for* $\mathcal{F}$. In fact, $\mathcal{F}$ consists precisely of all subsets of X which contain a subset in $\mathcal{D}$.

Here are the most important examples of filterbases for topology:

XIII.3.4.4. EXAMPLES. (i) Let $(X, \mathcal{T})$ be a topological space and $p \in X$. The set of all $\mathcal{T}$-neighborhoods of p is a filter, called the *neighborhood filter*, or *$\mathcal{T}$-neighborhood filter*, of p in X, denoted $\mathcal{N}_p$. The collection of open neighborhoods of p is a filterbase for $\mathcal{N}_p$; more generally, any local base for $\mathcal{T}$ at p is a filterbase for $\mathcal{N}_p$.
(ii) Let X be a set, and $(x_i)_{i \in I}$ a net in X. The tail set $\{T_i : i \in I\}$ (XIII.3.2.19.) is a filterbase in X.

XIII.3.4.5. Example XIII.3.4.4.(ii) is actually universal: if $\mathcal{D}$ is a filterbase in X, let I be the set of pairs (A, x), where $A \in \mathcal{D}$ and $x \in A$. Set $(A, x) \leq (B, y)$ if $B \subseteq A$. Then I is a directed set since $\mathcal{D}$ is centered. If $x_{(A,z)} = z$, then $(x_{(A,z)})$ is a net in X with index set I, with $T_{(A,z)} = A$ for each (A, z). There is thus a one-one correspondence between filterbases in X and equivalence classes of nets in X, where two nets are regarded as equivalent if their corresponding filterbases are identical (see Exercise XIII.3.5.3.; cf. XIII.3.3.14.).

Convergence of Filters

The definition of convergence of a filter is very simple:

XIII.3.4.6. DEFINITION. Let $(X, \mathcal{T})$ be a topological space. A filter $\mathcal{F}$ in X *converges* to a point $p \in X$ if $\mathcal{N}_p \subseteq \mathcal{F}$.

XIII.3.4.7. Because of the superset property of filters, a filter $\mathcal{F}$ converges to a point p if and only if, whenever U is a neighborhood of p, there is an $A \in \mathcal{F}$ with $A \subseteq U$. Thus we extend the notion of filter convergence to filterbases:

XIII.3.4.8. DEFINITION. Let $(X, \mathcal{T})$ be a topological space. A filterbase $\mathcal{D}$ in X *converges* to a point $p \in X$ if whenever U is a neighborhood of p, there is an $A \in \mathcal{D}$ with $A \subseteq U$.

Thus a filterbase converges to p if and only if the filter it generates converges to p.

XIII.3.4.9. This is consistent with convergence of nets: a net $(x_i)_{i \in I}$ converges to p if and only if the corresponding filterbase $\{T_i : i \in I\}$ converges to p.

Closure via Filters

We can give a characterization of the closure of a set using filters. It is cleanest to express it in terms of filterbases, since if A is a subset of X and $\mathcal{D}$ is a filterbase in A, $\mathcal{D}$ is also a filterbase in X (this is false for filters).

XIII.3.4.10. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space and $A \subseteq X$. The $\mathcal{T}$-closure of A in X consists precisely of all points x with the property that there is a filterbase $\mathcal{D}$ in A converging to x. In particular, A is $\mathcal{T}$-closed if and only if, whenever $\mathcal{D}$ is a filterbase in A converging to $x \in X$, then $x \in A$.

XIII.3.4.11. To state the result using filters, we make the following definition. We say a filter $\mathcal{F}$ in a set X is *eventually in* $A \subseteq X$ if $A \in \mathcal{F}$ (or, equivalently, some subset of A is in $\mathcal{F}$). We can then state:

XIII.3.4.12. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space and $A \subseteq X$. The $\mathcal{T}$-closure of A in X consists precisely of all points x with the property that there is a filter $\mathcal{F}$ which is eventually in A and converges to x. In particular, A is $\mathcal{T}$-closed if and only if, whenever $\mathcal{F}$ is a filter in X which is eventually in A and converges to $x \in X$, then $x \in A$.

XIII.3.4.13. Similarly, we say a filterbase $\mathcal{D}$ in X is *eventually in* $A \subseteq X$ if there is a $D \in \mathcal{D}$ with $D \subseteq A$.

Cluster Points of Filters

XIII.3.4.14. DEFINITION. Let $\mathcal{D}$ be a filterbase in a set X and $A \subseteq X$. We say $\mathcal{D}$ is *frequently in* A if $A \cap D \neq \emptyset$ for all $D \in \mathcal{D}$. A point x is a *cluster point* for a filterbase $\mathcal{D}$ in X if $\mathcal{D}$ is frequently in every neighborhood of x.

This terminology is consistent with the corresponding definition for nets (). There is no modification needed to replace "filterbase" by "filter" (in fact, the statement for filters is a special case since every filter is a filterbase).

XIII.3.4.15. If a filter or filterbase converges to x, then x is a cluster point. We have the following filter version of XIII.3.2.19.:

XIII.3.4.16. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space, and let $\mathcal{D}$ be a filterbase in X. A point $x \in X$ is a cluster point of $\mathcal{D}$ if and only if $x \in \cap_{D \in \mathcal{D}} \bar{D}$.

Subfilters

What is the right filter or filterbase analog of a subnet? The following definition is reasonable:

XIII.3.4.17. DEFINITION. Let $\mathcal{D}$ and $\mathcal{D}'$ be filterbases in a set X. Then $\mathcal{D}'$ is *subordinate* to $\mathcal{D}$, written $\mathcal{D}' \vdash \mathcal{D}$, if for every $A \in \mathcal{D}$ there is a $B \in \mathcal{D}'$ with $B \subseteq A$.

XIII.3.4.18. It is easily seen that if $\mathcal{F}$ and $\mathcal{F}'$ are the filters generated by $\mathcal{D}$ and $\mathcal{D}'$ respectively, then $\mathcal{D}' \vdash \mathcal{D}$ if and only if $\mathcal{F} \subseteq \mathcal{F}'$, i.e. the subordinate filter is *larger*. If $\mathcal{F} \subseteq \mathcal{F}'$, we say the filter $\mathcal{F}'$ is *finer* than $\mathcal{F}$. Thus it is not appropriate to call $\mathcal{D}'$ a "subfilterbase" of $\mathcal{D}$ (which is a mouthful anyway.) However, if $(x_i)_{i \in I}$ is a net in X and $(y_j)_{j \in J}$ is a subnet, then the tail filterbase of (y_j) is subordinate to the tail filterbase of (x_i) (the converse is false).

We have:

XIII.3.4.19. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space, and let $\mathcal{D}$, $\mathcal{D}'$ be filterbases in X, with $\mathcal{D}' \vdash \mathcal{D}$.

(i) If $\mathcal{D}$ converges to $x \in X$, then $\mathcal{D}'$ converges to x.

(ii) If $x \in X$ is a cluster point of $\mathcal{D}'$, it is a cluster point of $\mathcal{D}$.

We next obtain a generalization of XIII.3.2.20.:

XIII.3.4.20. PROPOSITION. Let $\mathcal{D}$ be a filterbase in a set X, and $(x_i)_{i \in I}$ a net in X which is frequently in D for every $D \in \mathcal{D}$. Then there is a subnet of (x_i) which is eventually in every $D \in \mathcal{D}$.

PROOF: Let J be the set of all pairs (D, i) where $D \in \mathcal{D}$, $i \in I$, and $x_i \in D$. Set $(D_1, i_1) \leq (D_2, i_2)$ if $D_2 \subseteq D_1$ and $i_1 \leq i_2$. Then J is directed: if $(D_1, i_1), (D_2, i_2) \in J$, there is a $D_3 \in \mathcal{D}$, $D_3 \subseteq D_1 \cap D_2$, and an $i_0 \in I$ with $i_1, i_2 \leq i_0$, and an $i_3 \geq i_0$ such that $x_{i_3} \in D_3$ since (x_i) is frequently in D_3, so $(D_3, i_3) \in J$ and $(D_1, i_1), (D_2, i_2) \leq (D_3, i_3)$. Define $f : J \to I$ by $f(D, i) = i$. Then f is directed: if $i_0 \in I$, fix $D_1 \in \mathcal{D}$ and $i_1 \geq i_0$ with $x_{i_1} \in D_1$; then $f(D, i) \geq i_0$ whenever $(D, i) \geq (D_1, i_1)$. If $\phi : I \to X$ gives $\phi(i) = x_i$, then $\phi \circ f$ defines a subnet $(x_{f(j)})$. If $D_0 \in \mathcal{D}$, then there is an $i_0 \in I$ with $(D_0, i_0) \in J$. If $(D_0, i_0) \leq (D, i) = j \in J$, then $x_{f(j)} \in D \subseteq D_0$, so the subnet $(x_{f(j)})$ is eventually in D_0. 👍

Rephrasing, we get:

XIII.3.4.21. Corollary. Let $\mathcal{D}$ be a filterbase in a set X, and $(x_i)_{i\in I}$ a net in X. If the tail set filterbase $\mathcal{D}'$ of (x_i) satisfies $\mathcal{D} \vdash \mathcal{D}'$, then there is a subnet of (x_i) whose tail set filterbase $\mathcal{D}''$ satisfies $\mathcal{D}'' \vdash \mathcal{D}$.

We also have the following analog of XIII.3.2.12.:

XIII.3.4.22. Proposition. Let $(X, \mathcal{T})$ be a topological space, $\mathcal{D}$ a filterbase in X, and $x \in X$. If $\mathcal{D}$ does not converge to x, then there is a filterbase $\mathcal{D}' \vdash \mathcal{D}$ such that no filterbase $\mathcal{D}'' \vdash \mathcal{D}'$ converges to x.

Ultrafilters and Maximal Filterbases

XIII.3.4.23. By XIII.3.4.18., larger means "finer" for filters. The largest filters are ultrafilters (XVI.1.8.1.), which are therefore the "finest" filters. By XVI.1.8.15. (which uses AC), every filter is contained in an ultrafilter. By XVI.1.8.12., a filter $\mathcal{F}$ in a set X is an ultrafilter if and only if for every $A \subseteq X$, either $A \in \mathcal{F}$ or $A^c \in \mathcal{F}$, i.e. $\mathcal{F}$ is either eventually in A or eventually in A^c.

XIII.3.4.24. A filterbase which generates an ultrafilter is called a *maximal filterbase*; "ultrafilterbase" would be a better name but too cumbersome ("maximal filterbase" is an abuse of language since a maximal filterbase is not maximal among all filterbases under inclusion unless it is already an ultrafilter; but see Exercise XIII.3.5.5.). A filterbase $\mathcal{D}$ in X is maximal if and only if for each $A \subseteq X$, there is a $D \in \mathcal{D}$ such that either $D \subseteq A$ or $D \subseteq A^c$.

XIII.3.4.25. Proposition. Let $(X, \mathcal{T})$ be a topological space, $\mathcal{D}$ a maximal filterbase in X, and $x \in X$. If x is a cluster point of $\mathcal{D}$, then $\mathcal{D}$ converges to x.

Proof: Let U be a neighborhood of x. Then there is a $D \in \mathcal{D}$ with either $D \subseteq U$ or $D \subseteq U^c$. But $D \cap U \neq \emptyset$ since x is a cluster point of $\mathcal{D}$, so $D \subseteq U^c$ is impossible and $D \subseteq U$. 👍

XIII.3.4.26. Proposition. Let X and Y be sets, $f : X \to Y$ any function, and $\mathcal{D}$ a maximal filterbase in X. Then $f(\mathcal{D}) = \{f(D) : D \in \mathcal{D}\}$ is a maximal filterbase in Y.

Proof: It is clear that $f(\mathcal{D})$ is a filterbase in Y. If $B \subseteq Y$ and $A = f^{-1}(B)$, then $A^c = f^{-1}(B^c)$. Since $\mathcal{D}$ is maximal, there is a $D \in \mathcal{D}$ such that either $D \subseteq f^{-1}(B)$ or $D \subseteq f^{-1}(B^c)$, hence either $f(D) \subseteq B$ or $f(D) \subseteq B^c$. Thus $f(\mathcal{D})$ is maximal. 👍

Universal Nets

XIII.3.4.27. Definition. A net (x_i) in a set X is a *universal net* if its tail set filterbase is maximal.

The simple verification of the next proposition is left to the reader.

XIII.3.4.28. PROPOSITION. A net (x_i) in a set X is universal if and only if, for every subset A of X, either (x_i) is eventually in A or (x_i) is eventually in A^c.

XIII.3.4.29. The existence of universal nets is an immediate consequence of the existence of ultrafilters. But we can do better:

XIII.3.4.30. THEOREM. Let X be a set, and (x_i) a net in X. Then (x_i) has a universal subnet.

PROOF: Let $\mathcal{D}$ be the tail set filterbase corresponding to (x_i). Let $\mathcal{F}$ be an ultrafilter containing $\mathcal{D}$ (i.e. containing the filter generated by $\mathcal{D}$). Since $\mathcal{D} \subseteq \mathcal{F}$, if $F \in \mathcal{F}$ we have $F \cap D \neq \emptyset$ for all $D \in \mathcal{D}$, and it follows that (x_i) is frequently in $\mathcal{F}$. Since $\mathcal{F}$ is itself a filterbase, by XIII.3.4.20. there is a subnet $(x_{f(j)})$ of (x_i) which is eventually in F for any $F \in \mathcal{F}$. If $A \subseteq X$, then either $A \in \mathcal{F}$ or $A^c \in \mathcal{F}$, so $(x_{f(j)})$ is either eventually in A or eventually in A^c. Thus $(x_{f(j)})$ is a universal net. 👍

This result requires some version of Choice, and is not a theorem of ZF. In fact, it is equivalent to the fact that every filter on a set is contained in an ultrafilter, hence to BPI ().

XIII.3.5. Exercises

XIII.3.5.1. Let X be a topological space.

(a) Let (x_n) be a sequence in X. If (y_n) is a rearrangement of (x_n), i.e. $y_n = x_{\phi(n)}$ for a bijection (permutation) $\phi : \mathbb{N} \to \mathbb{N}$, show that (y_n) converges if and only if (x_n) converges, and $\lim_{n\to\infty} y_n = \lim_{n\to\infty} x_n$ (if X is not Hausdorff, then (x_n) and (y_n) converge to the same limits).

(b) Show that the analogous statement for nets is false in general.

XIII.3.5.2. Let X be a topological space. Make the following definitions:

(i) A subset A of X is *sequentially closed* if, whenever (x_n) is a sequence in A with $x_n \to x \in X$, then $x \in A$.

(ii) If A is a subset of X, then the *sequential closure* of A is the set of all $x \in X$ for which there is a sequence (x_n) in A with $x_n \to x$.

These definitions, from [Fra65], are standard, but somewhat inconsistent: the sequential closure of a set is not sequentially closed in general. Sequential closure can be applied repeatedly, even transfinitely. Every closed set is sequentially closed, and the sequential closure of a set is contained in its closure. ✋

(iii) The space X is *sequential* if every sequentially closed subset of X is closed.

(iv) The space X is a *Fréchet-Urysohn space* if the sequential closure of every subset of X equals its closure (i.e. is closed).

(a) Show that every first countable topological space is Fréchet-Urysohn, and every Fréchet-Urysohn space is sequential. The simplest example of a Fréchet-Urysohn space which is not first countable is the one-point compactification of an uncountable discrete space (so even a compact Hausdorff Fréchet-Urysohn space need

not be first countable). See XIII.9.5.7. for another example, and [Eng89, 1.6.19] for a sequential space which is not Fréchet-Urysohn.

(b) Show that the space in XIII.11.14.10. is not sequential, even though every singleton subset is a G_δ. (In fact, "most" topological spaces which are not first countable fail to be sequential.)

(c) Show that every quotient of a sequential space is sequential. In particular, every quotient of a first countable space is sequential.

(d) Show that every sequential Hausdorff space is a quotient of a locally compact metrizable space. [Consider the separated union of the spaces consisting of convergent sequences in the space and their limits, i.e. a separated union of copies of $\mathbb{N}^\dagger$ and singletons.] This is a strong converse to (c).

(e) Show that a topological space X is sequential if and only if the sequential criterion for continuity holds for functions from X, i.e. if Y is any topological space and $f : X \to Y$ is a function, then f is continuous if and only if, whenever $x_n \to x$ in X, we have $f(x_n) \to f(x)$.

(f) If X is a Fréchet-Urysohn space, (x_n) is a sequence in X, and $x \in X$, then x is a cluster point of (x_n) if and only if there is a subsequence of (x_n) converging to X. Show that this property characterizes Fréchet-Urysohn spaces among sequential spaces (but not among all topological spaces).

(g) Show that a topological space X is Fréchet-Urysohn if and only if every subspace of X is sequential in the relative topology.

For more on these spaces, see [Eng89] (where Fréchet-Urysohn spaces are called *Fréchet spaces*). Both notions (sequential and Fréchet-Urysohn) are reasonable precise versions of the condition "the topology of X is completely determined by convergence of sequences."

XIII.3.5.3. Let $(x_i)_{i\in I}$ and $(y_j)_{j\in J}$ be two nets in a set X. Here are various possible notions of equivalence for the nets. Show each is an equivalence relation and compare them.

(a) The nets generate the same filterbase (XIII.3.4.5.).

(b) The corresponding filterbases generate the same filter.

(c) Each net is a subnet of the other.

(d) Every subnet of each net has a subnet which is also a subnet of the other net.

[To compare (a) with (c) and (d), consider constant nets with index sets $\mathbb{N}$ and the first uncountable ordinal.]

XIII.3.5.4. In what sense is XIII.3.4.20. a generalization of XIII.3.2.20.?

XIII.3.5.5. Let X be a set, and $\mathcal{D}$, $\mathcal{D}'$ filterbases in X.

(a) Show that we can have $\mathcal{D}' \vdash \mathcal{D}$ and $\mathcal{D} \vdash \mathcal{D}'$ even if $\mathcal{D} \neq \mathcal{D}'$. Thus $\vdash$ is only a preorder and not a partial order on filterbases.

(b) If $\mathcal{D}$ is a maximal filterbase and $\mathcal{D}' \vdash \mathcal{D}$, then also $\mathcal{D} \vdash \mathcal{D}'$, and any $\mathcal{D}$ with this property is maximal.

XIII.4. Continuous Functions

XIII.4.1. Definition and Properties

XIII.4.2. Topological Continuity vs. Metric Continuity

XIII.5. Comparison of Topologies

XIII.5.1. Stronger and Weaker Topologies

XIII.5.1.1. DEFINITION. Let $\mathcal{T}$ and $\mathcal{S}$ be topologies on the same set X. Then $\mathcal{S}$ is *stronger* (*larger, finer*) than $\mathcal{T}$, and $\mathcal{T}$ is *weaker* (*smaller, coarser*) than $\mathcal{S}$, if $\mathcal{T} \subseteq \mathcal{S}$, i.e. if every $\mathcal{T}$-open set is also $\mathcal{S}$-open.

The philosophy behind the names reflects the intuitive idea that a topology gives a notion of "closeness" for points, and a stronger or finer topology gives a more discriminating notion of "closeness" than a weaker or coarser one, i.e. makes it easier to distinguish between points using open sets.

A topology is stronger than itself, and also weaker than itself. In fact, a common and useful way to prove that two potentially different topologies are the same is to show that each is stronger than the other. We sometimes use the terms *strictly stronger*, *strictly weaker*, etc., when we mean to specify that the topologies are distinct.

XIII.5.1.2. It can happen, and often does, that if $\mathcal{T}$ and $\mathcal{S}$ are topologies on a set X, then neither topology is stronger than the other. In this case the topologies are said to be *incomparable*.

XIII.5.1.3. EXAMPLES. (i) On every set X, the discrete topology is the strongest topology: every topology on X is weaker than the discrete topology. Similarly, every topology on X is stronger than the indiscrete topology, so the indiscrete topology on X is the weakest topology on X.

(ii) The finite complement topology (XIII.1.2.8.(iv)) on a set X is the weakest T_1 topology () on X. For in any T_1 topology on X, the singleton subsets are closed, hence finite sets are closed, so complements of finite subsets must be open. In particular, the finite complement topology on $\mathbb{R}$ is weaker than the ordinary topology.

(iii) Let $X = \{a, b\}$, and let $\mathcal{T} = \{\emptyset, \{a\}, X\}$, $\mathcal{S} = \{\emptyset, \{b\}, X\}$. Then $\mathcal{T}$ and $\mathcal{S}$ are incomparable.

(iv) On $C([0,1])$, the topology of pointwise convergence () is strictly weaker than the topology of uniform convergence (). The topology of mean convergence () is strictly weaker than uniform convergence but incomparable with pointwise convergence. In fact, for every p, $0 < p \leq \infty$, there is an L^p topology on $C([0,1])$ (), with $p = 1$ giving mean convergence and $p = \infty$ uniform convergence; the L^p topology is weaker than the L^r topology if and only if $p \leq r$ (). So there is an uncountable family of natural topologies on $C([0,1])$, all distinct and all comparable; only the strongest of these (uniform convergence) is comparable with pointwise convergence. (There are very many other topologies on $C([0,1])$ too, most of which are incomparable to these.)

(v) On $C_c(\mathbb{R})$, the set of real-valued continuous functions on $\mathbb{R}$ of compact support, i.e. zero outside a finite interval, there is also an L^p topology for $0 < p \leq \infty$ (). In this case no two of the topologies are comparable ().

XIII.5.1.4. When the topology is changed, all the ancillary things associated with a topological space potentially change. If the topology on a space X is made stronger, i.e. with more open sets, then

> Since closed sets are complements of open sets, there are *more* closed sets. (Recall that being closed is not the opposite of being open!) Thus it is *easier* for a subset of X to be closed.

It is *harder* for a point x to be a limit point of a subset E, since there are *more* open neighborhoods of x which must have nonempty intersection with E. Thus E has *fewer* limit points and the closure of E is *smaller*.

Similarly, it is *harder* for a point x to be the limit of a sequence or net (x_i), since there are *more* open neighborhoods of x which must eventually contain the sequence or net. Thus there are *fewer* convergent sequences and nets. Similarly, a sequence or net has *fewer* cluster points.

It is *harder* for a subset F of X to be compact, since there are *more* open covers of F which must each have finite subcovers.

It is *easier* for X to be T_0, T_1, or Hausdorff, since there are *more* open sets to choose from.

However, it is unclear whether regularity or normality becomes easier when the topology becomes stronger, since on the one hand for a given point p and closed set F it is easier to find disjoint neighborhoods, but on the other hand there are more pairs (p, F) to consider. Similarly, normality does not obviously become easier. In fact, regularity and normality are not preserved under making the topology stronger or weaker (cf. XIII.7.10.17.; for the other direction, consider weakening the discrete topology). In a similar way, one might expect paracompactness, like compactness, to be preserved when weakening a topology, since there are *fewer* open covers to consider; but on the other hand an open cover has *fewer* refinements. Paracompactness is in fact not preserved under either strengthening or weakening the topology (XIII.7.10.17. and weakening the discrete topology are again counterexamples).

It is *harder* for a subset of X to be connected, since there are more potential separations.

If Y is another space and $f : X \to Y$, and the topology on Y is kept fixed and the topology on X strengthened, it is *easier* for f to be continuous since it is easier for $f^{-1}(V)$ to be open for any given open set $V \subseteq Y$. However, if the topology on X is kept fixed and the topology on Y is strengthened, it is *harder* for f to be continuous since the preimages of more open sets must be considered. If the topologies on both X and Y are strengthened, it may be neither easier nor harder for f to be continuous. In particular, if the topology on X is strengthened, functions from X to X may change from continuous to discontinuous or vice versa; the set of continuous functions from X to X will normally be different, although neither larger nor smaller (cf. Exercise XIII.7.10.15.).

Of course, there are analogous statements if the topology on X is weakened.

XIII.5.1.5. The following chart summarizes the main features of stronger and weaker topologies:

Stronger (larger, finer) topology	Weaker (smaller, coarser) topology
More open sets	Fewer open sets
More closed sets	Fewer closed sets
Fewer limit points	More limit points
Smaller closures	Larger closures
Fewer compact subsets	More compact subsets
Fewer connected subsets	More connected subsets
Fewer convergent sequences (nets)	More convergent sequences (nets)
More continuous functions out	Fewer continuous functions out
Fewer continuous functions in	More continuous functions in

The easiest way to remember what happens under strengthening or weakening of the topology is to think of the extreme cases of the discrete or indiscrete topology. (In fact, one good way to analyze many mathematical situations and guess what happens is to pass to the most extreme case.)

XIII.5.1.6. Our use of "stronger" and "weaker" in comparing topologies is the standard one, especially in analysis, particularly functional analysis (weak and weak-* topologies (), strong and weak operator topologies ()). However, it should be noted that a few topology references use these terms in the opposite sense.

XIII.5.1.7. Another sometimes convenient way to describe stronger and weaker topologies is: if $\mathcal{S}$ and $\mathcal{T}$ are topologies on a set X, then $\mathcal{S}$ is stronger than $\mathcal{T}$ if and only if the identity map from $(X, \mathcal{S})$ to $(X, \mathcal{T})$ is continuous.

Strongest and Weakest Topologies Defined by a Family of Functions

XIII.5.1.8. If X is a set, and $(Y, \mathcal{S})$ is a topological space, and $f : X \to Y$ is a function, then there is a weakest topology on X such that f is continuous. In fact,

$$\mathcal{T} = \{f^{-1}(V) : V \in \mathcal{S}\}$$

is a topology on X, as is easily checked since preimages respect unions and intersections, and $\mathcal{T}$ is obviously the weakest topology on X making f continuous.

XIII.5.1.9. More generally, if X is a set, $\{(Y_j, \mathcal{S}_j) : j \in J\}$ is a family of topological spaces (not necessarily distinct), and $f_j : X \to Y_j$ is a function for each $j \in J$, then there is a weakest topology on X making all the f_j continuous. The set

$$\{f_j^{-1}(V) : j \in J,\ V \in \mathcal{S}_j\}$$

is not usually a topology on X; however, it is a subbase for a topology $\mathcal{T}$ which is obviously the weakest topology on X making all the f_j continuous.

XIII.5.1.10. The topology $\mathcal{T}$ can also be characterized as the intersection of all topologies on X making each f_j continuous (there is always at least one such topology, the discrete topology). However, it is usually better to describe $\mathcal{T}$ constructively as in XIII.5.1.9..

XIII.5.1.11. The topology $\mathcal{T}$ can be described in terms of convergence: a net (x_i) in X converges to x in $(X, \mathcal{T})$ if and only if $f_j(x_i) \to f_j(x)$ in $(Y_j, \mathcal{S}_j)$ for every $j \in J$. Thus $\mathcal{T}$ is often called the *weak topology* on X defined by the f_j.

XIII.5.1.12. One of the most important examples of a weak topology defined by a family of functions is the product topology (), i.e. the case where $X = \prod_j Y_j$ and the f_j are the coordinate projections. The general situation can also be reduced to the case of one target space using the product topology: if X is a set, $\{(Y_j, \mathcal{S}_j) : j \in J\}$ is a family of topological spaces (not necessarily distinct), and $f_j : X \to Y_j$ is a function for each $j \in J$, let $Y = \prod_j Y_j$ and $f : X \to Y$ the induced map, i.e. $(f(x))_j = f_j(x)$ for all j. Give Y the product topology. Then the weak topology on X from the f_j is the weak topology on X from f ().

XIII.5.1.13. If all the Y_j are Hausdorff and the f_j separate points of X, then the weak topology on X defined by the f_j is also Hausdorff: if $p, q \in X$, $p \neq q$, choose j with $f_j(p) \neq f_j(q)$, and choose disjoint neighborhoods U and V of $f_j(p)$ and $f_j(q)$ in Y_j; then $f_j^{-1}(U)$ and $f_j^{-1}(V)$ are disjoint neighborhoods of p and q. The same statement is true if all the Y_j are regular or completely regular ().

XIII.5.1.14. Similarly, if Y is a set, $\{(X_j, \mathcal{T}_j) : j \in J\}$ is a set of topological spaces, and $f_j : X_j \to Y$ is a function for each j, then there is a strongest topology on Y making all the f_j continuous:

$$\mathcal{S} = \{V \subseteq Y : f_j^{-1}(V) \in \mathcal{T}_j \text{ for all } j\} .$$

It is easy to verify that $\mathcal{S}$ is a topology on Y, and it is obviously the strongest one making all the f_j continuous. However, this topology is often very weak (frequently even the indiscrete topology). The quotient topology (XIII.8.1.1.) is an example of this construction, probably the most important example.

The Lattice of Topologies

Fix a set X. We consider all topologies on X, partially ordered by containment.

XIII.5.1.15. If $\{\mathcal{T}_i : i \in I\}$ is a set of topologies on X, then $\bigcap_{i\in I} \mathcal{T}_i$ is a topology on X, which is the strongest topology on X weaker than all the $\mathcal{T}_i$. Denote this topology by $\bigwedge_{i\in I} \mathcal{T}_i$. If $I = \{1, \ldots, n\}$, write $\mathcal{T}_1 \wedge \cdots \wedge \mathcal{T}_n$ for $\bigwedge_{i\in I} \mathcal{T}_i$.

Define a family $(X_i, \mathcal{T}_i)$ of topological spaces, where $X_i = X$ for all i. For each i let f_i be the identity map on X, regarded as a map from X_i to X. Then $\bigwedge_{i\in I} \mathcal{T}_i$ is the strongest topology on X making all the f_i continuous.

XIII.5.1.16. If $\{\mathcal{T}_i : i \in I\}$ is a set of topologies on X, then $\bigcup_{i\in I} \mathcal{T}_i$ is not usually a topology on X. But it is a subbase for a topology on X, which is the weakest topology on X stronger than all the $\mathcal{T}_i$. Denote this topology by $\bigvee_{i\in I} \mathcal{T}_i$. If $I = \{1, \ldots, n\}$, write $\mathcal{T}_1 \vee \cdots \vee \mathcal{T}_n$ for $\bigvee_{i\in I} \mathcal{T}_i$. If $\mathcal{S}_i$ is a subbase for $\mathcal{T}_i$ for each i, then $\bigcup_{i\in I} \mathcal{S}_i$ is a subbase for $\bigvee_{i\in I} \mathcal{T}_i$.

Define a family $(X_i, \mathcal{T}_i)$ of topological spaces, where $X_i = X$ for all i. For each i let g_i be the identity map on X, regarded as a map from X to X_i. Then $\bigvee_{i\in I} \mathcal{T}_i$ is the weakest topology on X making all the g_i continuous.

XIII.5.1.17. Thus the set of all topologies on X is a complete lattice under containment. There is a largest element, the discrete topology, and a smallest element, the indiscrete topology. It turns out that this lattice is complemented: for every topology $\mathcal{T}$ there is a unique topology $\mathcal{T}'$ such that $\mathcal{T} \vee \mathcal{T}'$ is the discrete topology and $\mathcal{T} \wedge \mathcal{T}'$ the indiscrete topology. This was not proved until 1966 ([Ste66], cf. [vR68]).

XIII.6. Products and the Product Topology

One of the most important constructions in topology is the topological product.

XIII.6.1. Finite Products

We begin with the product of two topological spaces, which by iteration gives a product for finitely many.

XIII.6.1.1. Let $(X, \mathcal{T})$ and $(Y, \mathcal{S})$ be topological spaces. If $U \in \mathcal{T}$ and $V \in \mathcal{S}$, then $U \times V \subseteq X \times Y$ should be an open set in $X \times Y$ in any reasonable compatible topology; such a subset of $X \times Y$ is called an *open rectangle*. In particular, all sets of the form $U \times Y$ or $X \times V$ ($U \in \mathcal{T}$, $V \in \mathcal{S}$) are open rectangles.

"Compatible topology" is not well defined, but one reasonable requirement is that the coordinate projections $\pi_X : X \times Y \to X$ and $\pi_Y : X \times Y \to Y$ should be continuous. Since if $U \subseteq X$ and $V \subseteq Y$, then $\pi_X^{-1}(U) = U \times Y$ and $\pi_Y^{-1}(V) = X \times V$, so for π_X to be continuous $U \times X$ must be open in $X \times Y$ for every $U \in \mathcal{T}$, and similarly $X \times V$ must be open in $X \times Y$ for every $V \in \mathcal{S}$; since $U \times V = (U \times Y) \cap (X \times V)$, every open rectangle must be open in $X \times Y$ (and conversely).

XIII.6.1.2. Definition. Let $(X, \mathcal{T})$ and $(Y, \mathcal{S})$ be topological spaces. The *product topology* $\mathcal{T} \times \mathcal{S}$ is the set of all unions of open rectangles in $X \times Y$.

XIII.6.1.3. Since the intersection of two open rectangles is another open rectangle, it is easily checked that $\mathcal{T} \times \mathcal{S}$ is a topology, and is the smallest topology on $X \times Y$ making π_X and π_Y continuous.

Note that the union of two open rectangles is rarely an open rectangle, however; thus $\mathcal{T} \times \mathcal{S}$ consists of far more than just the open rectangles, or even finite unions of open rectangles, in general. We should really write $\mathcal{T} \otimes \mathcal{S}$ for the product topology in analogy with () and (); however, the notation $\mathcal{T} \times \mathcal{S}$ is standard.

The set of open rectangles does form a base for the topology $\mathcal{T} \times \mathcal{S}$, and thus open rectangles are often called *basic open sets*. More generally, we have:

XIII.6.1.4. Proposition. Let $\mathcal{B}$ be a base for the topology $\mathcal{T}$ on X, and $\mathcal{C}$ a base for the topology $\mathcal{S}$ on Y. Then

$$\mathcal{B} \times \mathcal{C} = \{B \times C : B \in \mathcal{B}, C \in \mathcal{C}\}$$

is a base for the topology $\mathcal{T} \times \mathcal{S}$ on $X \times Y$.

Proof: Let $(p, q) \in X \times Y$ and $W \in \mathcal{T} \times \mathcal{S}$ with $(p, q) \in W$. Then there are $U \in \mathcal{T}$ and $V \in \mathcal{S}$ with $p \in U$, $q \in V$, and $U \times V \subseteq W$. There is a $B \in \mathcal{B}$ with $p \in B \subseteq U$, and $C \in \mathcal{C}$ with $q \in C \subseteq V$. Then

$$(p, q) \in B \times C \subseteq U \times V \subseteq W \ .$$

XIII.6.1.5. EXAMPLES. (i) Let X and Y be sets, and $\mathcal{T} = \mathcal{P}(X)$ and $\mathcal{S} = \mathcal{P}(Y)$ be the discrete topologies on X and Y. Then the singleton subsets of X and Y form a base for the discrete topologies on X and Y. The product of two singleton sets is a singleton set and an open rectangle. Every subset of $X \times Y$ is a union of singletons, hence in $\mathcal{T} \times \mathcal{S}$; thus $\mathcal{T} \times \mathcal{S}$ is the discrete topology on $X \times Y$.

This shows the problem with using the notation $\mathcal{T} \times \mathcal{S}$ for the product topology: we get $\mathcal{P}(X) \times \mathcal{P}(Y) = \mathcal{P}(X \times Y)$ in this notation, but this equation only holds in usual set-theoretic notation if X or Y is itself a singleton.

(ii) Let $\mathcal{T}$ be the usual topology on $\mathbb{R}$, i.e. the set of unions of open intervals. Then the product topology $\mathcal{T}^{(2)} = \mathcal{T} \times \mathcal{T}$ on $\mathbb{R}^2$ consists of all unions of open rectangles (in the usual geometric sense) with sides parallel to the coordinate axes. Every open set in $\mathbb{R}^2$ in the usual sense is a union of open rectangles, although "most" open sets in $\mathbb{R}^2$ (e.g. an open disk) are not open rectangles or even finite unions of open rectangles. Conversely, any union of open rectangles is an open set in the usual sense. Thus $\mathcal{T}^{(2)}$ is the usual topology on $\mathbb{R}^2$, defined by the usual metric.

More generally, we have:

XIII.6.1.6. PROPOSITION. Let (X, ρ) and (Y, σ) be metric spaces, and $\mathcal{T}$ and $\mathcal{S}$ the topologies defined by ρ and σ respectively. Then $\mathcal{T} \times \mathcal{S}$ is the topology defined by any of the metrics $\rho \times_1 \sigma$, $\rho \times_2 \sigma$, $\rho \times_\infty \sigma$ on $X \times Y$, where

$$\rho \times_1 \sigma((x,y),(x',y')) = \rho(x,x') + \sigma(y,y')$$

$$\rho \times_2 \sigma((x,y),(x',y')) = [\rho(x,x')^2 + \sigma(y,y')^2]^{1/2}$$

$$\rho \times_\infty \sigma((x,y),(x',y')) = \max\{\rho(x,x'), \sigma(y,y')\}$$

For $x, x' \in X$, $y, y' \in Y$.

PROOF: It is easily checked that these are metrics (although the triangle inequality for $\rho \times_2 \sigma$ takes some work, cf. ()), and that they are equivalent, so it suffices to work with $\rho \times_\infty \sigma$. The open $(\rho \times_\infty \sigma)$-balls are open rectangles, hence in $\mathcal{T} \times \mathcal{S}$; conversely, if $(x,y) \in X \times Y$ and $W \in \mathcal{T} \times \mathcal{S}$ with $(x,y) \in W$, there are $U \in \mathcal{T}$ and $V \in \mathcal{S}$ with $(x,y) \in U \times V \subseteq W$, and there is an $\epsilon > 0$ such that $B^\rho_\epsilon(x) \subseteq U$ and $B^\sigma_\epsilon(y) \subseteq V$; thus

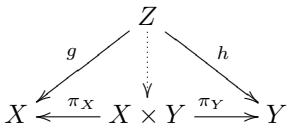
$$B^{\rho \times_\infty \sigma}_\epsilon((x,y)) = B^\rho_\epsilon(x) \times B^\sigma_\epsilon(y) \subseteq U \times V \subseteq W$$

so the open $(\rho \times_\infty \sigma)$-balls are a base for $\mathcal{T} \times \mathcal{S}$. 👍

Convergence

Since open rectangles form a base for the product topology, the following is obvious:

XIII.6.1.7. PROPOSITION. Let $(X, \mathcal{T})$ and $(Y, \mathcal{S})$ be topological spaces, and $((x_i, y_i)_{i \in I})$ be a net in $X \times Y$, $(x,y) \in X \times Y$. Then $(x_i, y_i) \to (x,y)$ in $(X \times Y, \mathcal{T} \times \mathcal{S})$ if and only if $x_i \to x$ in $(X, \mathcal{T})$ and $y_i \to y$ in $(Y, \mathcal{S})$.



Because of this, convergence in the product topology is often called *coordinatewise convergence*.

Universal Property

Because $\mathcal{T} \times \mathcal{S}$ is the weakest topology on $X \times Y$ for which the coordinate projections are continuous, the following universal property is obvious:

XIII.6.1.8. PROPOSITION. Let $(X, \mathcal{T})$, $(Y, \mathcal{S})$, $(Z, \mathcal{R})$ be topological spaces, and $f : Z \to X \times Y$ a function. Then f is $(\mathcal{R}, \mathcal{T} \times \mathcal{S})$-continuous if and only if $\pi_X \circ f$ is $(\mathcal{R}, \mathcal{T})$-continuous and $\pi_Y \circ f$ is $(\mathcal{R}, \mathcal{S})$-continuous. Conversely, if $g : Z \to X$ is $(\mathcal{R}, \mathcal{T})$-continuous and $h : R \to Y$ is $(\mathcal{R}, \mathcal{S})$-continuous, then $(g, h) : Z \to X \times Y$ is $(\mathcal{R}, \mathcal{T} \times \mathcal{S})$-continuous.

XIII.6.1.9. In other words, the following diagram has a unique completion in the category $\mathcal{C}$ of topological spaces and continuous functions:

i.e. $(X \times Y, \mathcal{T} \times \mathcal{S})$ is a *product* of $(X, \mathcal{T})$ and $(Y, \mathcal{S})$ in $\mathcal{C}$ ().

Finite Products

XIII.6.1.10. All the results of this subsection hold equally for products of finitely many topological spaces $\{(X_k, \mathcal{T}_k) : 1 \leq k \leq n\}$. Products of open sets are called *open rectangles*, *open boxes*, or *basic open sets*. The product topology on $\prod_{k=1}^n X_k$ is conventionally denoted $\prod_{k=1}^n \mathcal{T}_k$, although the notation $\bigotimes_{k=1}^n \mathcal{T}_k$ would be better. Details are left to the reader.

XIII.6.2. General Products

We now consider the topological product of an arbitrary indexed family of topological spaces $\{(X_i, \mathcal{T}_i) : i \in I\}$.

XIII.6.2.1. In the absence of the Axiom of Choice, there may be a set-theoretic problem: we could have $\prod_{i \in I} X_i = \emptyset$. But if the product is nonempty, it is fairly large (). (We implicitly assume that each X_i is nonempty, and that I is nonempty.) We will not assume the AC, but we will assume, usually without explicit mention, that the product is nonempty.

XIII.6.2.2. In analogy with the case of finitely many X_i, we could expect we want any set of the form $\prod_{i \in I} U_i$ to be open in $\prod_i X_i$, where $U_i \in \mathcal{T}_i$ for each i. Such a subset of $\prod_i X_i$ is called an *open box*. The set of all unions of open boxes is a topology on $\prod_i X_i$, called the *box topology*. However, it turns out that if I is infinite, the box topology has pathological properties (cf. XIII.6.3.8.) and is not very useful, although it is occasionally considered.

XIII.6.2.3. The proper definition of the product topology is a little less obvious. We say that an open box $\prod_{i \in I} U_i$ is an *open rectangle*, or *basic open set*, if U_i is the whole space X_i for all but finitely many i. (This means that membership in an open rectangle depends on only finitely many coordinates.)

XIII.6.2.4. DEFINITION. Let $\{(X_i, \mathcal{T}_i) : i \in I\}$ be an indexed collection of topological spaces, with $\prod_{i\in I} X_i \neq \emptyset$. The *product topology* on $\prod_i X_i$ is the set of unions of open rectangles.

The product topology on $\prod_{i\in I} X_i$ is conventionally denoted $\prod_{i\in I} \mathcal{T}_i$, although the notation $\bigotimes_{i\in I} \mathcal{T}_i$ would be better.

XIII.6.2.5. This definition makes more sense if coordinate projections are considered. Let $X = \prod_{i\in I} X_i$, and fix $i \in I$, and let π_i be the coordinate projection from X to X_i. If $U \in \mathcal{T}_i$, then $\pi_i^{-1}(U) = U \times \prod_{j\neq i} X_j$, so for π_i to be continuous such sets must be open in X. These sets (for various i) form a subbase for the weakest topology on X making each π_i continuous. Open rectangles are just finite intersections of such sets, and hence form a base for this topology which is therefore exactly the product topology. In the language of XIII.5.1.9., the product topology is the weak topology on X defined by the π_i.

XIII.6.2.6. The product topology is weaker than the box topology. The two coincide if I is finite, but not usually if I is infinite. The product topology is much more useful than the box topology in general, and when products are considered we will always assume we use the product topology without explicit mention to the contrary.

XIII.6.2.7. PROPOSITION. Let $\{(X_i, \mathcal{T}_i) : i \in I\}$ be an indexed collection of topological spaces, with $X = \prod_i X_i \neq \emptyset$, and for each i let $\mathcal{B}_i$ be a base for $\mathcal{T}_i$. Let $\mathcal{B}$ be the collection of all subsets of X of the form $\prod_{i\in F} B_i \times \prod_{i\in I\setminus F} X_i$, where F is a finite subset of I and $B_i \in \mathcal{B}_i$ for $i \in F$. Then $\mathcal{B}$ is a base for the product topology on X.

Convergence

The analog of XIII.6.1.7. holds for general products (i.e. the product topology is the topology of coordinate-wise convergence, or "pointwise convergence on I"), immediate from the fact that open rectangles form a base:

XIII.6.2.8. PROPOSITION. Let $\{(X_i, \mathcal{T}_i) : i \in I\}$ be an indexed collection of topological spaces, with $X = \prod_i X_i \neq \emptyset$. Give X the product topology $\mathcal{T}$. Let $(x_\lambda)_{\lambda\in\Lambda}$ be a net in X, and for each i and λ let $x_{\lambda,i} = \pi_i(x_\lambda)$, where $\pi_i : X \to X_i$ is the i'th coordinate projection. If $x = (\cdots x_i \cdots) \in X$, then $x_\lambda \to x$ in $(X, \mathcal{T})$ if and only if the net $(x_{\lambda,i})$ converges to x_i in $(X_i, \mathcal{T}_i)$ for each $i \in I$.

The analog of XIII.6.1.8. holds:

XIII.6.2.9. PROPOSITION. Let $\{(X_i, \mathcal{T}_i) : i \in I\}$, $(Z, \mathcal{R})$ be topological spaces, with $X = \prod_{i\in I} X_i \neq \emptyset$, and $f : Z \to X$ a function. Give X the product topology $\mathcal{T}$. Then f is $(\mathcal{R}, \mathcal{T})$-continuous if and only if $\pi_i \circ f$ is $(\mathcal{R}, \mathcal{T}_i)$-continuous for each i. Conversely, if $g_i : Z \to X_i$ is $(\mathcal{R}, \mathcal{T}_i)$-continuous for each i, then $(\cdots g_i \cdots) : Z \to X$ is $(\mathcal{R}, \mathcal{T})$-continuous.

XIII.6.3. Exercises

XIII.6.3.1. Let $(X, \mathcal{T})$ be the Sierpinski space (). What are the open sets in $(X \times X, \mathcal{T} \times \mathcal{T})$? Is every open set an open rectangle? [There are six open sets.]

XIII.6.3.2. Let I be an uncountable index set, and $\{X_i : i \in I\}$ a collection of topological spaces. Suppose for each i there is a point $p_i \in X_i$ which has an open neighborhood U_i which is not all of X_i (there will be such a p_i unless X_i has the indiscrete topology). Let $X = \prod_{i\in I} X_i$ with the product topology, and $p = (\cdots p_i \cdots) \in X$. Show that p does not have a countable neighborhood base, and hence X is not first countable. [If $\{V_n : n \in \mathbb{N}\}$ is a sequence of open neighborhoods of p, then for each n there is a finite subset F_n of I and nonempty open sets W_{ni} such that V_n contains $\prod_{i\in F_n} W_{ni} \times \prod_{i\notin F_n} X_i$. If $j \in I \setminus (\cup_{n=1}^{\infty} F_n)$, then $U_j \times \prod_{i\neq j} X_i$ does not contain any V_n.] This result requires the AC.

XIII.6.3.3. Let $\{X_i : i \in I\}$ be a collection of topological spaces, and let $X = \prod_{i\in I} X_i$ with the product topology. Suppose each X_i is separable and $card(I) \leq 2^{\aleph_0}$. Show that X is separable. [Let $\{p_{in} : n \in \mathbb{N}\}$ be a countable dense set in X_i for each i. Identify I with a subset of $\mathbb{R}$. For each finite set $S = \{(a_1, b_1), \ldots, (a_m, b_m)\}$ of disjoint open intervals in $\mathbb{R}$ with rational endpoints, and every corresponding tuple $N = (n_1, \ldots, n_m)$ of natural numbers, let $p_{(S,N)}$ be the point of x whose i'th coordinate is p_{in_k} if $i \in (a_k, b_k)$ and p_{i1} otherwise. Show that the set of all $p_{(S,N)}$ is a countable dense set in X.]

This result requires the AC for index sets of cardinality $2^{\aleph_0}$.

XIII.6.3.4. Let D be a countable dense set in $[0, 1]^{\mathfrak{c}}$. Then D, with the relative topology, is a countable normal topological space in which no point has a countable local base.

XIII.6.3.5. Let $\{X_i : i \in I\}$ be a collection of topological spaces, and let $X = \prod_{i\in I} X_i$ with the product topology. Suppose each X_i has two disjoint nonempty open sets U_i and V_i (this will happen if X_i is Hausdorff and has more than one point), and that X is separable. Show that $card(I) \leq 2^{\aleph_0}$. [If $\{p_n : n \in \mathbb{N}\}$ is dense in X, for each i let $S(i)$ be the set of all n such that the i'th coordinate of p_n is in U_i. Show that $S(i)$ and $S(j)$ are distinct subsets of $\mathbb{N}$ for $i \neq j$.]

XIII.6.3.6. Let X be an arbitrary product of copies of $\mathbb{N}$ with the finite complement topology. Show that X is separable in the product topology. [For each $n \in \mathbb{N}$ let p_n be the point of X with all coordinates n.]

XIII.6.3.7. (a) ([Sto48]; cf. [Eng89, 2.3.E]) Show that $\mathbb{N}^{\aleph_1}$ is not normal. [For $j = 1, 2$ let A_j be the set of all points for which, for each $k \neq j$, at most one coordinate is k. Show that A_1 and A_2 are closed and disjoint, but do not have disjoint neighborhoods.]

(b) Conclude from XIII.11.14.11. that if I is an index set with $card(I) \geq \aleph_1$, and, for each $i \in I$, X_i is a topological space which is not countably compact, then $\prod_{i\in I} X_i$ is not normal. In particular, if X is a topological space which is not countably compact, then $X^{\aleph_1}$ is not normal.

XIII.6.3.8. Let X be the product of countably many copies of $\mathbb{R}$, and $\mathcal{T}$ the box topology on X from the ordinary topology on $\mathbb{R}$. For each $t \in \mathbb{R}$, let $\boldsymbol{t}$ be the point of X with all coordinates t, and $Y = \{\boldsymbol{t} : t \in \mathbb{R}\} \subseteq X$. Then $\phi : \mathbb{R} \to Y$, $\phi(t) = \boldsymbol{t}$, is a bijection. Show that the relative box topology on Y is the discrete topology, and ϕ is not continuous.

XIII.6.3.9. Let $\{X_i : i \in i\}$ be an indexed collection of sets, with $X = \prod_i X_i \neq \emptyset$. For each i let $\mathcal{T}_i$ be the discrete topology on X_i. Show that the box topology on X is the discrete topology, but the product topology is not unless I is finite or all but finitely many X_i are singletons.

XIII.7. Separation Axioms

The notion of topological space is so general that practically nothing can be said about all topological spaces. All nontrivial results in topology require additional restrictions, usually including *separation axioms*. Separation axioms roughly insure that there are "enough" open sets in the topology. There are several important separation axioms of varying strength, described in this section. Virtually all topological spaces arising in applications, particularly in analysis, including any metrizable space, satisfy all these separation axioms.

Note that the separation axioms have nothing to do with separability in the sense of XIII.2.3.11..

XIII.7.1. The T-Axioms

The first five separation axioms first appeared together in [AH74], where they were called T_0–T_4 (T for *Trennungsaxiom*); the authors attributed each property to someone else (Kolmogorov, Fréchet, Hausdorff, Vietoris, and Tietze respectively), and most date back to the early 1920s (cf. [Tie23], [Ury25a]). Alternate names for T_2–T_4 predate [AH74] and are usually used today. There are also a $T_{3\frac{1}{2}}$ (XIII.7.8.3.), and a T_5, discussed in XIII.10.1.2.; some add $T_{2\frac{1}{2}}$ (XIII.7.10.21.) and T_6 (XIII.10.6.11.).

XIII.7.1.1. Definition. Let X be a topological space. Then

(o) X is T_0 if, whenever p and q are distinct points of X, there is an open neighborhood of at least one of the points not containing the other.

(i) X is T_1 if each singleton subset of X is closed.

(ii) X is T_2 if any two distinct points of X have disjoint open neighborhoods.

(iii) X is T_3 if whenever E is a closed set in X and p a point of X not in E, then p and E have disjoint open neighborhoods.

(iv) X is T_4 if disjoint closed sets in X have disjoint open neighborhoods.

X is *Hausdorff* if it is T_2.
X is *regular* if it is T_3 and Hausdorff.
X is *normal* if it is T_4 and Hausdorff.

Each of these separation axioms is discussed in more detail below.

XIII.7.1.2. There is some nonuniformity of use of the terminology in this definition. Some references define "regular" and "normal" to mean what we have called T_3 and T_4, and define T_3 to mean "T_2 and regular", and similarly for T_4. Our definition reflects the original historical usage of the terms. We will regard "T_3" and "regular" as essentially synonymous since they differ only in the case of spaces which are not T_0 (XIII.7.5.2.), and similarly "T_4" and "normal" are essentially equivalent. (In fact, Hausdorff's definition of topological space in [Hau49] included the T_2 axiom, and his definition was generally used by others in the 1920s.)

Some references use the term *separated* as a synonym for "Hausdorff." But this term is too easily confused with "separable" as defined in XIII.2.3.11..

XIII.7.2. T_0-Spaces

XIII.7.2.1. PROPOSITION. Let X be a topological space, and p and q distinct points of X. The following are equivalent:

(i) $\{p\}$ and $\{q\}$ have identical closures.

(ii) p is in the closure of $\{q\}$ and q is in the closure of $\{p\}$.

(iii) Any open set containing p also contains q, and vice versa.

X is T_0 if and only if none of these occur for any distinct p and q.

PROOF: (i) $\Rightarrow$ (iii): if U is an open set containing p but not q, then U^c is a closed set containing q and hence containing the closure of $\{q\}$, so the closure of $\{q\}$ is not the same as the closure of $\{p\}$ (in fact, does not contain p). The same argument works with p and q interchanged.

(iii) $\Rightarrow$ (ii): If p is not in the closure of $\{q\}$, the complement of the closure of $\{q\}$ is an open set containing p but not q. The same argument works if p and q are interchanged.

(ii) $\Rightarrow$ (i) is trivial.

It is obvious that the T_0 condition is precisely the negation of (iii). 👍

XIII.7.2.2. COROLLARY. A T_1 topological space is T_0.

There are T_0 spaces which are not T_1, e.g. the Sierpiński space.

The T_0 property is a local property. Say that a topological space X is *locally* T_0 if every point of X has an open neighborhood which is T_0 in the relative topology. Every T_0 space is obviously locally T_0. The converse is also true:

XIII.7.2.3. PROPOSITION. A locally T_0 space is T_0.

PROOF: Let X be a locally T_0 space, and p, q distinct points of X. We must find an open set containing one of p and q and not the other. Let U be an open neighborhood of p which is T_0 in the relative topology. If $q \notin U$, then U is the desired set. If $q \in U$, there is a relatively open subset V of U containing one of p and q but not the other. Since U is open in X, V is also open in X (), and is the desired subset. 👍

XIII.7.2.4. Every topological space has a maximal T_0 quotient, which captures all the topological information of the space (XIII.8.3.10.).

XIII.7.2.5. There seems to be no reason to consider topological spaces which are not at least T_0 (especially in light of XIII.8.3.10.). Many authors feel the same about restricting to T_1 or T_2 spaces; indeed, topological spaces which are not Hausdorff are rather bizarre and are rarely encountered. In analysis almost all spaces encountered are even completely regular. However, there are topological spaces arising in applications in algebra and logic, such as spectra of rings (XIII.7.10.20., XX.16.4.39.), which are T_0 but not necessarily even T_1, so such spaces cannot be completely ignored.

And there is one situation in analysis where spaces which are not T_0 arise naturally: certain natural topological groups () and topological vector spaces () are not T_0. In this case, taking the maximal T_0 quotient amounts to dividing out by the closure of the identity (), hence the T_0 quotient is also naturally a topological group or topological vector space.

XIII.7.3. T_1-Spaces

The T_1 property has an alternate characterization, which was actually the original definition:

XIII.7.3.1. Proposition. A topological space X is T_1 if and only if, whenever p and q are distinct points of X, each of p and q has an open neighborhood not containing the other.

Proof: If X is T_1 and p and q are distinct points of X, then $X\setminus\{q\}$ and $X\setminus\{p\}$ are the desired neighborhoods of p and q. Conversely, let $p \in X$. For each $q \in X\setminus\{p\}$, there is an open neighborhood U_q of q not containing p. The union of the U_q is open, and equals $X \setminus \{p\}$, so $\{p\}$ is closed. 👍

This characterization gives a simpler proof that a T_1 space is T_0, and also immediately implies that a Hausdorff space is T_1. We used the definition we did for T_1 since it is the version which is usually verified and used in applications.

XIII.7.3.2. Note that the condition in XIII.7.3.1. can be rephrased: whenever p and q are distinct points of X, then p has an open neighborhood not containing q. For if this statement is true for any p and q (in that order), it is also true for q and p, i.e. each of p and q has a neighborhood not containing the other.

XIII.7.3.3. Corollary. A topological space X is T_1 if and only if every singleton subset of X is an intersection of open sets.

XIII.7.3.4. Like the T_0 property, the T_1 property is a local property. Say that a topological space X is *locally* T_1 if every point of X has an open neighborhood which is T_1 in the relative topology. Every T_1 space is obviously locally T_1. The converse is also true:

XIII.7.3.5. Proposition. A locally T_1 space is T_1.

The proof is a slightly simplified version of the argument in the proof of XIII.7.2.3., and is left to the reader.

XIII.7.4. Hausdorff Spaces

The Hausdorff property is probably the most widely used separation axiom. Here is one of the main reasons. One of the most basic facts about limits in $\mathbb{R}$ or $\mathbb{R}^n$, or in general metric spaces, is that limits are unique (). This property only holds in Hausdorff spaces:

XIII.7.4.1. PROPOSITION. Let X be a topological space. Then X is Hausdorff if and only if every convergent net in X has a unique limit.

PROOF: Suppose X is Hausdorff, and (x_i) is a net in X with $x_i \to x$ and $x_i \to y$ with $x \neq y$. Let U and V be disjoint neighborhoods of x and y respectively. Then there is an i_1 such that $x_i \in U$ for all $i \geq i_1$, and there is an i_2 such that $x_i \in V$ for all $i \geq i_2$. If $i \geq i_1$ and $i \geq i_2$ (there is such an i since the index set is directed), then $x_i \in U \cap V$, a contradiction. Thus the limit of a convergent net is unique.

Conversely, suppose X is not Hausdorff, and let x and y be distinct points which do not have disjoint neighborhoods. Let $I = \{(U, V, z)\}$, where U is a neighborhood of x, V is a neighborhood of y, and $z \in U \cap V$. Put a preorder on I by setting $(U_1, V_1, z_1) \leq (U_2, V_2, z_2)$ if $U_2 \subseteq U_1$ and $V_2 \subseteq V_1$. Then I is a directed set. Set $x_{(U,V,z)} = z$; this defines a net with index set I, and this net converges to both x and y. So limits of convergent nets are not unique. 👍

XIII.7.4.2. Note that the "if" part can be false if "net" is replaced by "sequence" if the space is not first countable (Exercise XIII.7.10.16.). In a first countable space, the sequence version is true ().

The (equivalent) filter version of XIII.7.4.1. is especially easy to prove:

XIII.7.4.3. PROPOSITION. Let X be a topological space. Then X is Hausdorff if and only if every convergent filter in X has a unique limit.

PROOF: If X is Hausdorff and $x, y \in X$, $x \neq y$, then the neighborhood filters of x and y cannot be contained in a single filter since x and y have disjoint neighborhoods. Conversely, if X is not Hausdorff, let x and y be distinct points of X which do not have disjoint neighborhoods, and let $\mathcal{D}$ be the collection of all sets of the form $U \cap V$, where U is a neighborhood of x and V a neighborhood of y. Then $\mathcal{D}$ is a filterbase in X which converges to both x and y. 👍

XIII.7.4.4. Unlike the T_0 and T_1 properties, the Hausdorff property is not a local property. Say that a topological space X is *locally Hausdorff* if every point of X has an open neighborhood which is Hausdorff in the relative topology. A Hausdorff space is obviously locally Hausdorff. But a locally Hausdorff space need not be Hausdorff (XIII.20.1.3.(v)), although it is T_1 (XIII.7.3.5.). However, see XIII.7.10.5..

XIII.7.5. Regular Spaces

The T_3 separation axiom has a simple reformulation which reinforces the utility of the axiom:

XIII.7.5.1. PROPOSITION. Let X be a topological space. Then X is a T_3 space if and only if, whenever p is a point of X and U is an open neighborhood of p, there is an open neighborhood V of p with $\bar{V} \subseteq U$.

PROOF: Suppose X is T_3, and U is an open neighborhood of p. Then U^c is a closed set not containing p, so p and U^c have disjoint open neighborhoods V and W. Then $\bar{V}$ is contained in the closed set W^c, hence in U. Conversely, suppose X has the property in the statement, and E is a closed set in X and p is a point of X not in E. Then $U = E^c$ is an open neighborhood of p, so there is an open neighborhood V of p with $\bar{V} \subseteq U$. Then V and $(\bar{V})^c$ are disjoint open neighborhoods of p and E, so X is a T_3 space. 👍

In the presence of T_3, only the T_0 axiom is needed to give the Hausdorff property and thus regularity:

XIII.7.5.2. PROPOSITION. Let X be a topological space which is T_3 and T_0. Then X is Hausdorff, and thus regular.

PROOF: Let p and q be distinct points of X. Suppose p is not in the closure E of $\{q\}$. Then p and E have disjoint open neighborhoods, which are disjoint open neighborhoods of p and q. The same proof works if q is not in the closure of $\{p\}$. Apply XIII.7.2.1.. 👍

A set with the indiscrete topology and more than one point is an example of a T_3 space which is not T_0.

XIII.7.6. Normal Spaces

XIII.7.6.1. In the presence of T_4, the T_1 condition gives T_2, hence normality, as is obvious. However, unlike with regularity, T_0 is not enough: the Sierpiński space is T_0 and vacuously T_4, but not T_1. It is also obvious that normality implies regularity, although T_4 does not imply T_3 in the absence of T_1 (the Sierpiński space is again a counterexample).

There is an analog of XIII.7.5.1. for normal spaces. The proof is virtually identical.

XIII.7.6.2. PROPOSITION. Let X be a topological space. Then X is a T_4 space if and only if, whenever E is a closed set in X and U is an open neighborhood of E, there is an open neighborhood V of E with $\bar{V} \subseteq U$.

XIII.7.6.3. PROPOSITION. A closed subspace of a T_4 space is T_4. Hence a closed subspace of a normal space is normal.

PROOF: If A is a closed subspace of a T_4 space X, and Y, Z are (relatively) closed subsets of A, then Y and Z are closed in X, hence have disjoint neighborhoods U, V in X. Then $A \cap U$ and $A \cap V$ are disjoint neighborhoods in A. 👍

A general subspace of a normal space is not necessarily normal (XIII.11.14.7.). However, an F_σ in a normal space is normal (XIII.7.10.8.).

An alternate way of phrasing normality is using partitions:

XIII.7.6.4. Definition. Let X be a topological space, and Y, Z disjoint closed subsets of X. A *partition* between Y and Z in X is a (necessarily closed) subset P of X such that there are open sets $U, V \subseteq X$ with $Y \subseteq U$, $Z \subseteq V$, $U \cap V = \emptyset$, and $X \setminus (U \cup V) = P$.

Note that there can be many partitions between disjoint subsets. A partition can be empty: $\emptyset$ is a partition between Y and Z in X if (and only if) there is a clopen set U in X with $Y \subseteq U$ and $Z \subseteq (X \setminus U)$.

XIII.7.6.5. Proposition. Let X be a topological space. Then X is T_4 if and only if every pair of disjoint closed subsets of X has a partition in X.

Proof: If every pair of disjoint closed subsets of X has a partition in X, and Y, Z are disjoint closed subsets of X, let P be a partition between Y and Z in X; the associated U and V are disjoint neighborhoods of Y and Z. Thus X is T_4. Conversely, suppose X is T_4 and Y and Z are disjoint closed subsets of X. Let U and V be disjoint neighborhoods of Y and Z in X; then $P = X \setminus (U \cup V)$ is a partition between Y and Z in X. 👍

XIII.7.6.6. Proposition. A metrizable topological space is normal.

See XIII.7.10.25.. In fact, a metrizable space has a stronger property called *complete normality*. See XIII.10.1.1. for a definition and proof. In particular, a metrizable space is regular and Hausdorff.

Every compact Hausdorff space is also normal (XIII.11.4.3.).

Here is a useful refinement of the definition of normality:

XIII.7.6.7. Definition. Let X be a topological space, and $\mathcal{U} = \{U_i : i \in I\}$ an open cover of X. A *shrinking* of $\mathcal{U}$ is an open cover $\mathcal{V} = \{V_i : i \in I\}$ (same index set) with $\bar{V}_i \subseteq U_i$ for all i.

XIII.7.6.8. Proposition. Let X be a topological space. Then X is T_4 if and only if every finite open cover of X has a shrinking.

Proof: If X is not T_4, let Y and Z be disjoint closed sets in X which do not have disjoint neighborhoods. Then the open cover $\{X \setminus Y, X \setminus Z\}$ does not have a shrinking.

Conversely, suppose X is T_4. We show by induction on the number of sets in the cover that every finite open cover of X has a shrinking. First suppose $\mathcal{U} = \{U_1, U_2\}$ is an open cover of X. Then $X \setminus U_1$ and $X \setminus U_2$ are disjoint closed sets in X, and so have disjoint open neighborhoods V_1, V_2. By XIII.7.6.2. there are open neighborhoods W_1, W_2 with $\bar{W}_k \subseteq V_k$. Then $\{X \setminus \bar{W}_1, X \setminus \bar{W}_2\}$ is a shrinking of $\mathcal{U}$.

Now suppose every open cover with n sets has a shrinking, and let $\mathcal{U} = \{U_1, \ldots, U_{n+1}\}$ be an open cover of X. There is a shrinking $\{V_1, \ldots, V_{n-1}, W\}$ for the open cover $\{U_1, \ldots, U_{n-1}, U_n \cup U_{n+1}\}$. Then $F = \bar{W}$ is a closed subset of X, hence T_4, so the open cover $\{F \cap U_n, F \cap U_{n+1}\}$ of F has a shrinking $\{W_n, W_{n+1}\}$. Set $V_n = W \cap W_n$, $V_{n+1} = W \cap W_{n+1}$. Then $\{V_1, \ldots, V_{n+1}\}$ is a shrinking of $\mathcal{U}$. 👍

XIII.7.6.9. Proposition XIII.7.6.8. uses no form of Choice, i.e. is a theorem of ZF. Using the AC (Well-ordering), one direction can be extended to show that every point-finite open cover of a normal (T_4) space has a shrinking (Exercise XIII.7.10.24.). This is used e.g. in XIII.11.10.6..

There is a nice "dual" fact about normal spaces. We first make a definition:

XIII.7.6.10. Definition. Let X be a topological space, and $A_1, \ldots, A_n$ closed subsets of X. A *swelling* of $\{A_1, \ldots, A_n\}$ is a collection $\{U_1, \ldots, U_n\}$ of open sets in X with $A_k \subseteq U_k$ for each k and $U_{k_1} \cap U_{k_2} \cap \cdots \cap U_{k_m} = \emptyset$ for any $k_1, \ldots, k_m$ with $A_{k_1} \cap A_{k_2} \cap \cdots \cap A_{k_m} = \emptyset$.

XIII.7.6.11. Proposition. Let X be a T_4 topological space, and $A_1, \ldots, A_n$ closed subsets of X. Then $\{A_1, \ldots, A_n\}$ has a swelling.

Proof: Let B_1 be the union of all sets of the form $A_{k_1} \cap A_{k_2} \cap \cdots \cap A_{k_m}$ for which

$$A_1 \cap A_{k_1} \cap A_{k_2} \cap \cdots \cap A_{k_m} = \emptyset \ .$$

Since this is a finite union, B_1 is closed; and A_1 and B_1 are disjoint. By normality there are disjoint open neighborhoods U_1 and V_1 of A_1 and B_1, so that $\bar{U}_1$ is disjoint from B_1.

Now repeat the process with A_2, with A_1 replaced by $\bar{U}_1$: let B_2 be the union of all finite intersections of $\{\bar{U}_1, A_3, \ldots, A_n\}$ which are disjoint from A_2, and obtain an open neighborhood U_2 of A_2 with $\bar{U}_2$ disjoint from B_2. Repeating the process n times (at the k'th step A_j is replaced by $\bar{U}_j$ for all $j < k$), we obtain a swelling $\{U_1, \ldots, U_n\}$. 👍

There are two important theorems about normality with nontrivial proofs. The first is due to ():

XIII.7.6.12. Theorem. A T_3 Lindelöf space is T_4. Thus a regular Lindelöf space is normal.

In fact, a stronger result holds: every regular Lindelöf space is paracompact (), and every paracompact space is normal (). But we give a straightforward proof of XIII.7.6.12. which is simpler than the proofs of these two stronger results.

Proof: Let X be a T_3 Lindelöf space, and E and F disjoint closed sets in X. For each $p \in E$, there is an open neighborhood W_p of p such that $\bar{W}_p \cap F = \emptyset$ (XIII.7.5.1.). Then $\{W_p : p \in E\} \cup \{E^c\}$ is an open cover of X, so has a countable subcover $\{E^c, W_1, W_2, \ldots\}$. Similarly, there is a countable cover $\{F^c, Z_1, Z_2, \ldots\}$ of X with $\bar{Z}_n \cap E = \emptyset$ for all n. We have $E \subseteq \cup_n W_n$ and $F \subseteq \cup_n Z_n$. Inductively define $U_1 = W_1$, $V_1 = Z_1 \setminus \bar{U}_1$, $U_2 = W_2 \setminus \bar{V}_1$, $V_2 = Z_2 \setminus (\bar{U}_1 \cup \bar{U}_2)$, $U_3 = W_3 \setminus (\bar{V}_1 \cup \bar{V}_2)$, etc. Each U_n and V_n is open, and $U_n \cap V_m = \emptyset$ for all n and m. If $p \in E$, then $p \in W_n$ for some n, hence $p \in U_n$ since $p \notin \bar{V}_m \subseteq \bar{Z}_m$ for any m. Similarly, if $q \in F$, then $q \in V_m$ for some m. Thus $U = \cup_n U_n$ and $V = \cup_n V_n$ are disjoint neighborhoods of E and F. 👍

The second theorem is a key result showing that normal spaces can be completely studied by analytic methods (specifically, real-valued continuous functions):

XIII.7.6.13. THEOREM. [URYSOHN'S LEMMA] Let X be a normal topological space. If E_0 and E_1 are disjoint closed sets in X, then there is a continuous function $f : X \to [0,1]$ with $f(x) = 0$ for all $x \in E_0$ and $f(x) = 1$ for all $x \in E_1$.

This result is a special case of the Tietze Extension Theorem, but we will use it in the proof of the Tietze Theorem.

PROOF: We will make repeated use of XIII.7.6.2.. Let $U_0 = E_0^c$. Then U_0 is an open neighborhood of E_1. Let $U_{1/2}$ be an open neighborhood of E_1 with $\bar{U}_{1/2} \subseteq U_0$. Let $U_{3/4}$ be an open neighborhood of E_1 with $\bar{U}_{3/4} \subseteq U_{1/2}$. U_0 is an open neighborhood of $\bar{U}_{1/2}$; let $U_{1/4}$ be an open neighborhood of $\bar{U}_{1/2}$ with $\bar{U}_{1/4} \subseteq U_0$. Continuing in this way, for each dyadic rational t with $0 \leq t < 1$ choose an open neighborhood U_t of E_1 such that $\bar{U}_t \subseteq U_s$ if $s < t$.

For $x \in X$ define $f(x) = \sup\{t : x \in U_t\}$ if $x \in U_0$ and $f(x) = 0$ if $x \in E_0$. Then $0 \leq f(x) \leq 1$ for all $x \in X$, and $f(x) = 1$ if $x \in E_1$. We show f is continuous. If (x_i) is a net in X with $x_i \to x$, we show that $f(x_i) \to f(x)$. Let $t = f(x)$. If $t > 0$, then for any dyadic rational s, $0 \leq s < t$, we have $x \in U_s$; since U_s is open, $x_i \in U_s$ for sufficiently large i, i.e. $f(x_i) \geq s$ for sufficiently large i. This shows that $f(x_i) \to f(x)$ if $t = 1$. Now suppose $t < 1$. If s is any dyadic rational with $t < s < 1$, choose a dyadic rational r with $t < r < s$. Then $x \notin U_r$. Since $\bar{U}_s \subseteq U_r$, x is in the open set $(\bar{U}_s)^c$, so $x_i \in (\bar{U}_s)^c$ for sufficiently large i, i.e. $f(x_i) \leq s$ for sufficiently large i. Thus $f(x_i) \to f(x)$. 👍

The Axiom of Dependent Choice is used in this proof. Some Choice is necessary for the result (XIII.11.14.20.). No Choice is necessary for metrizable spaces (XIII.7.10.25.).

XIII.7.6.14. Normality is a nice separation condition to have, but it is somewhat more delicate than the other conditions: for example, unlike all the other separation axioms it does not pass to subspaces or products in general (see XIII.11.14.7. and XIII.7.10.14. for counterexamples; cf. XIII.10.1.2.).

XIII.7.7. Fully Normal Spaces

An important tightening of normality is full normality. This notion apparently first explicitly appeared in the literature in [Tuk40]; TUKEY said the concept goes back at least to URYSOHN.

Star Refinements

XIII.7.7.1. DEFINITION. Let X be a topological space and $\mathcal{U}$ an open cover of X. For each $x \in X$, the *star* of $\mathcal{U}$ at x is

$$St(x,\mathcal{U}) = \bigcup\{U \in \mathcal{U} : x \in U\}$$

and if $A \subseteq X$, the *star* of $\mathcal{U}$ at A is

$$St(A,\mathcal{U}) = \bigcup\{U \in \mathcal{U} : A \cap U \neq \emptyset\} = \bigcup_{x \in A} St(x,\mathcal{U}) \ .$$

Note that $\{St(x,\mathcal{U}) : x \in X\}$ is an open cover of X, and that $St(A,\mathcal{U})$ is open for any $A \subseteq X$.

XIII.7.7.2. DEFINITION. Let X be a topological space and $\mathcal{U}, \mathcal{V}$ open covers of X.

(i) The cover $\mathcal{V}$ *barycenter-refines* or Δ-*refines* $\mathcal{U}$, or is a *barycenter refinement* or Δ-*refinement* of $\mathcal{U}$, if the open cover $\{St(x, \mathcal{V}) : x \in X\}$ refines $\mathcal{U}$, i.e. for every $x \in X$ there is a $U \in \mathcal{U}$ with $St(x, \mathcal{V}) \subseteq U$.

(ii) The cover $\mathcal{V}$ *star-refines* $\mathcal{U}$, or is a *star refinement* of $\mathcal{U}$, written $\mathcal{V} <^* \mathcal{U}$, if for every $V \in \mathcal{V}$ there is a $U \in \mathcal{U}$ with $St(V, \mathcal{V}) \subseteq U$.

XIII.7.7.3. A star refinement of $\mathcal{U}$ is a barycentric refinement of $\mathcal{U}$, and a barycentric refinement of $\mathcal{U}$ is a refinement of $\mathcal{U}$, but the converses are far from true in general. But it is easily checked that a barycentric refinement of a barycentric refinement of $\mathcal{U}$ is a star refinement of $\mathcal{U}$.

XIII.7.7.4. EXAMPLE. Let (X, ρ) be a metric space, and for $\epsilon > 0$ let $\mathcal{U}_\epsilon$ be the open cover of X consisting of all open balls of radius ϵ. Then $\mathcal{U}_{\epsilon/2}$ is a star-refinement of $\mathcal{U}_\epsilon$ for any $\epsilon > 0$.

XIII.7.7.5. DEFINITION. A Hausdorff topological space X is *fully normal* every open cover of X has a star refinement.

Because of XIII.7.7.3., a Hausdorff space is fully normal if and only if every open cover has a barycentric refinement.

XIII.7.7.6. PROPOSITION. A fully normal topological space is normal.

PROOF: Let X be fully normal. Then X is Hausdorff. Let A and B be disjoint closed sets in X, and set $\mathcal{U} = \{X \setminus A, X \setminus B\}$. Then $\mathcal{U}$ is an open cover of X. Let $\mathcal{V}$ be a star refinement of $\mathcal{U}$. Then $St(A, \mathcal{V})$ and $St(B, \mathcal{V})$ are disjoint neighborhoods of A and B respectively. 👍

XIII.7.7.7. There are many normal spaces which are not fully normal. In fact, a space is fully normal if and only if it is paracompact (XIII.11.10.6.). We give the essential part of the easier direction here:

XIII.7.7.8. THEOREM. Let X be a topological space, and $\mathcal{U} = \{U_i : i \in I\}$ a locally finite open cover of X which has a shrinking $\mathcal{V} = \{V_i : i \in I\}$. Then $\mathcal{U}$ has a barycentric refinement.

PROOF: The open cover $\mathcal{V}$ is also locally finite. For $x \in X$, set $A_x = \bigcap\{U_i : x \in \bar{V}_i\}$ and $B_x = \bigcup\{\bar{V}_i : x \notin \bar{V}_i\}$. Since $\mathcal{V}$ is locally finite, these are really finite unions and intersections, so A_x is open and B_x is closed; and $x \in A_x$, $x \notin B_x$. Let $W_x = A_x \setminus B_x$. Then W_x is an open neighborhood of x, so $\mathcal{W} = \{W_x : x \in X\}$ is an open cover of X.

We claim $\mathcal{W}$ is a barycentric refinement of $\mathcal{U}$. Let $y \in X$, and fix i with $y \in \bar{V}_i$. For any $x \in X$ with $y \in W_x$, we have $x \in \bar{V}_i$ since otherwise $\bar{V}_i \subseteq B_x$ contradicting that $y \in W_x$. Thus $W_x \subseteq A_x \subseteq U_i$. This is true for every x such that $y \in W_x$, so $St(y, \mathcal{W}) \subseteq U_i$. 👍

XIII.7.7.9. This theorem does not require any Choice. If the AC is assumed and X is normal, the hypothesis of the shrinking is automatic (XIII.7.6.9.). But there is an important consequence which does not require any Choice (XIII.11.4.5.).

XIII.7.8. Completely Regular Spaces

Another separation axiom is commonly added to the hierarchy:

XIII.7.8.1. DEFINITION. Let X be a topological space. Then X is *completely regular* if it is T_0 and, whenever E is a closed set in X and p a point of X not in E, there is a continuous function $f : X \to [0,1]$ such that $f(p) = 1$ and $f(x) = 0$ for all $x \in E$.

XIII.7.8.2. PROPOSITION. A completely regular space is regular (and in particular Hausdorff).

PROOF: Suppose X is completely regular. If E is a closed set in X and p a point of X not in E, and f is a continuous function from X to $[0,1]$ as in XIII.7.8.1., then $f^{-1}((1/2,1])$ and $f^{-1}([0,1/2))$ are disjoint open neighborhoods of p and E, so X is T_3. Since X is T_0, it is regular (). 👍

XIII.7.8.3. A normal space is completely regular by Urysohn's Lemma. Thus the completely regular condition is a separation axiom between T_3 and T_4, and is sometimes called $T_{3\frac{1}{2}}$ (with the usual ambiguity about whether the space is required to be Hausdorff). A completely regular space is also sometimes called a *Tikhonov space*.

There are regular spaces which are not completely regular (see [SS95]), and completely regular spaces which are not normal, e.g. XIII.20.5.8..

XIII.7.8.4. THEOREM. Let X be a topological space. Then X is homeomorphic to a subset of a compact Hausdorff space if and only if X is completely regular.

PROOF: Since compact Hausdorff spaces are normal (XIII.11.4.3.) and hence completely regular, and complete regularity obviously passes to subspaces, the complete regularity condition is necessary. Conversely, let X be completely regular. Let $\mathcal{C}$ be a set of continuous functions from X to $[0,1]$ such that for every closed set E in X and $p \in X \setminus E$, there is an $f \in \mathcal{C}$ with $f(p) = 1$ and $f = 0$ on E, and form the space $Y = [0,1]^{\mathcal{C}}$ with the product topology. Y is Hausdorff, and compact by Tikhonov's theorem (). Define a function $\phi : X \to Y$ by letting $\phi(x)$ be the point whose f'th coordinate is $f(x)$, for each $f \in \mathcal{C}$. ϕ is continuous since its composition with each coordinate projection is continuous. We need only show that it is a homeomorphism, e.g. if (x_i) is a net in X, and $x \in X$ with $\phi(x_i) \to \phi(x)$, then $x_i \to x$. We have $\phi(x_i) \to \phi(x)$ if and only if $f(x_i) \to f(x)$ for every $f \in \mathcal{C}$. If $x_i \not\to x$, there is a neighborhood U of x and a subnet (x_j) such that $x_j \notin U$ for all j. There is an $f \in \mathcal{C}$ such that $f(x) = 1$ and $f(y) = 0$ for all $y \in U^c$; for this f, $f(x_j) = 0$ for all j, so $f(x_i) \not\to f(x)$, a contradiction. 👍

XIII.7.8.5. A good case can be made that complete regularity is the most natural restriction for topological spaces, and that completely regular spaces form the proper class of spaces to consider, especially for applications in analysis. This is the general thesis of [GJ76], for example. Completely regular spaces are precisely the spaces characterized by each of the following conditions (under some mild Choice assumptions):

(i) Spaces which can be embedded in compact Hausdorff spaces.

(ii) Spaces with a topology arising from a uniform structure.

(iii) Spaces whose topology is defined by a (separating) family of pseudometrics.

(iv) Spaces whose structure can be completely analyzed by study of real-valued continuous functions (i.e. analytic methods).

XIII.7.9. The Tietze Extension Theorem

The Tietze Extension Theorem is an important extension of Urysohn's Lemma.

XIII.7.9.1. THEOREM. [TIETZE EXTENSION THEOREM] Let X be a normal topological space, and E a closed subspace. If I is any interval in $\mathbb{R}$, and f is a continuous function from E to I, then f extends to a continuous function from X to I. Conversely, if X is a T_1 topological space and every real-valued continuous function on a closed subspace of X extends to X, then X is normal.

PROOF: ($\Rightarrow$) Since every interval in $\mathbb{R}$ is homeomorphic to $[-1,1]$, $(-1,1)$, or $(-1,1]$, it suffices to prove the statement for these intervals.

First suppose $I = [-1,1]$. If $f : E \to I$ is continuous, let $A_1 = f^{-1}\left(\left[\frac{1}{3},1\right]\right)$ and $B_1 = f^{-1}\left(\left[-1,-\frac{1}{3}\right]\right)$. Then A_1 and B_1 are disjoint closed subsets of E, hence of X, so by Urysohn's Lemma there is a continuous function $g_1 : X \to \left[-\frac{1}{3},\frac{1}{3}\right]$ with $g_1(x) = \frac{1}{3}$ for $x \in A_1$ and $g_1(x) = -\frac{1}{3}$ for $x \in B_1$. Then, for all $x \in E$,

$$|f(x) - g_1(x)| \leq \frac{2}{3}$$

for all $x \in E$. Thus $f - g_1 : E \to \left[-\frac{2}{3},\frac{2}{3}\right]$. Repeat the process with $f - g_1$ in place of f and $\frac{2}{9}$ in place of $\frac{1}{3}$ to get $g_2 : X \to \left[-\frac{2}{9},\frac{2}{9}\right]$ with

$$|(f(x) - g_1(x)) - g_2(x)| \leq \frac{4}{9}$$

for all $x \in E$. Continuing inductively, for each n there is a continuous function $g_n : X \to \left[-\frac{2^{n-1}}{3^n},\frac{2^{n-1}}{3^n}\right]$ with

$$\left| f(x) - \sum_{k=1}^{n} g_k(x) \right| \leq \left[\frac{2}{3}\right]^n$$

for all $x \in E$.

Since $|g_k(x)| \leq \frac{2^{k-1}}{3^k}$ for all k and $x \in X$, the series $\sum_{k=1}^{\infty} g_k(x)$ converges uniformly on X to a function $g : X \to \mathbb{R}$ by the Weierstrass M-test (), and g is continuous by (). The function g takes values in $[-r,r]$, where

$$r = \sum_{k=1}^{\infty} \frac{2^{k-1}}{3^k} = \frac{1}{2} \cdot \frac{\frac{2}{3}}{1-\frac{2}{3}} = 1 \ .$$

We clearly have $g(x) = f(x)$ for $x \in E$.

Now suppose $I = (1,1)$ and $f : E \to I$. There is an extension of f to a continuous function $g : X \to [-1,1]$. If $B = g^{-1}(\{-1,1\})$, then B is a closed set in X disjoint from E, so there is a continuous function $\phi : X \to [0,1]$ with $\phi(x) = 1$ for $x \in E$ and $\phi(x) = 0$ for $x \in B$. Set $h = \phi \cdot g$. Then $h : X \to (-1,1)$ and $h = f$ on E. The proof if $I = (-1,1]$ is almost identical.

Conversely, suppose X has the Tietze extension property and A, B are disjoint closed subsets of X. Then $A \cup B$ is closed. Let $f : A \cup B \to [0,1]$ with $f = 0$ on A and $f = 1$ on B. Extend f to a continuous $g : X \to [0,1]$, and set $U = g^{-1}\left(\left[0, \frac{1}{2}\right)\right)$ and $V = g^{-1}\left(\left(\frac{1}{2}, 1\right]\right)$. Then U and V are disjoint open neighborhoods of A and B. So X is normal. 👍

XIII.7.9.2. This theorem requires Dependent Choice, both for this argument and Urysohn's Lemma itself. However, if X is metrizable, there is a canonical choice of Urysohn function for any pair of disjoint closed subspaces (XIII.7.10.25.), so the construction of the extension is recursive and no Choice is needed.

XIII.7.10. Exercises

XIII.7.10.1. Let $(X, \mathcal{T})$ be a topological space, and $Y \subseteq X$. Give Y the relative topology $\mathcal{T}_Y$.

(a) If $(X, \mathcal{T})$ is T_0, then $(Y, \mathcal{T}_Y)$ is T_0.

(b) If $(X, \mathcal{T})$ is T_1, then $(Y, \mathcal{T}_Y)$ is T_1.

(c) If $(X, \mathcal{T})$ is Hausdorff, then $(Y, \mathcal{T}_Y)$ is Hausdorff.

(d) If $(X, \mathcal{T})$ is regular, then $(Y, \mathcal{T}_Y)$ is regular.

(e) If $(X, \mathcal{T})$ is completely regular, then $(Y, \mathcal{T}_Y)$ is completely regular.

The corresponding statement for normal spaces is false (XIII.11.14.7.).

XIII.7.10.2. Let X be a topological space. Show that the following are equivalent:

(i) Every singleton subset of X is an intersection of open sets.

(ii) Every subset of X is an intersection of open sets.

(iii) X is T_1.

XIII.7.10.3. Let $X = \{a, b\}$, and let $\mathcal{T} = \{\emptyset, \{a\}, X\}$.

(a) Show that $\mathcal{T}$ is a topology on X.

(b) $\{b\}$ is closed, but $\{a\}$ is not closed; $\{a\}$ is open, and the closure of $\{a\}$ is X (i.e. $\{a\}$ is dense in X).

(c) $(X, \mathcal{T})$ satisfies T_0 and T_4, but not T_1, T_2, or T_3.

(d) If $x_n = a$ for all n, then $x_n \to a$ and $x_n \to b$.

(e) X is compact () and connected (). In fact, X is path-connected ().

$(X, \mathcal{T})$ is called the *Sierpiński space*.

XIII.7.10.4. (a) Let X be a T_0 space, and U a finite nonempty open subset of X. Show that U contains an open singleton subset of X. [Consider a minimal nonempty open subset of U.]

(b) Let X be a T_1 space, and U a finite nonempty open subset of X. Show that every point of U is an isolated point of X. In particular, a finite T_1 space has the discrete topology.

A T_0 space containing a nonempty finite open set need not have any isolated points, and not every singleton subset of a finite open set is open in general. The Sierpiński space is a counterexample to both.

XIII.7.10.5. Let X be a topological space.

(a) If each point of X has a closed neighborhood which is Hausdorff in the relative topology, show that X is Hausdorff.

(b) If each point of X has a closed neighborhood which is T_3 in the relative topology, show that X is T_3.

(c) (cf. [Eng89, 3.3.1]) If each point of X has a closed neighborhood which is $T_{3\frac{1}{2}}$ in the relative topology, show that X is $T_{3\frac{1}{2}}$.

(d) If each point of X has a closed neighborhood which is [completely] regular in the relative topology, show that X is [completely] regular.

Example XIII.20.1.3.(v) shows that the word "closed" cannot be removed from any of the statements. Since there are locally compact Hausdorff spaces which are not normal (XIII.11.14.7.), the corresponding statements with "T_4" or "normal" do not hold.

XIII.7.10.6. (a) Let X be a Hausdorff space. Suppose X has a dense subspace D of cardinality κ. Show that $card(X) \leq 2^{2^\kappa}$. Thus $card(X) \leq 2^{2^{d(X)}}$ (XIII.2.3.16.). [For each $p \in X$, let

$$\mathcal{A}_p = \{U \cap D : U \text{ an open neighborhood of } p\} \in \mathcal{P}(\mathcal{P}(D)) \ .$$

Show that $\mathcal{A}_p \neq \mathcal{A}_q$ if $p \neq q$.] In particular, a separable Hausdorff space has cardinality $\leq 2^{2^{\aleph_0}}$.

There are separable Hausdorff spaces of cardinality $2^{2^{\aleph_0}}$, even compact ones, e.g. $\beta\mathbb{N}$ () and $[0,1]^{\mathfrak{c}}$ (). In fact, if Y is a discrete space of infinite cardinality κ, then the Stone-Čech compactification βY is a compact Hausdorff space of cardinality 2^{2^κ}.

(b) Show that if X is any set with the finite complement topology (), then any infinite subset of X is dense, and hence X is separable if $card(X) \geq \aleph_0$. Thus the conclusion of (a) fails in general for compact T_1 spaces, and there is no bound at all on the cardinality of such spaces.

(c) If X is a separable, first countable Hausdorff space, show that X has cardinality $\leq 2^{\aleph_0}$. [If D is a countable dense set in X, for each $x \in X$ choose a sequence in D converging to x.] In general, if X is Hausdorff, we have $card(X) \leq d(X)^{\chi(X)}$ (XIII.1.2.11., XIII.2.3.16.).

Note that unlike for (a), the Axiom of Choice is needed for (c) [the AC is needed for the examples at the end of (a)].

XIII.7.10.7. (a) Let X be a regular space. Suppose X has a dense subspace D of cardinality κ. Show there is a base for the topology of cardinality $\leq 2^\kappa$. Thus $w(X) \leq 2^{d(X)}$ (XIII.1.2.11., XIII.2.3.16.). [If $\{U_i : i \in I\}$ is a base, for each i set $V_i = [(U_i \cap D)^-]^o$. Note that $U_i \subseteq V_i \subseteq \bar{U}_i$. Show that $\{V_i : i \in I\}$ is a base of cardinality $\leq 2^\kappa$.]

(b) If X is a T_0-space, and there is a base for the topology of cardinality κ, then $card(X) \leq 2^\kappa$. Thus $card(X) \leq 2^{w(X)}$ (XIII.1.2.11.). [If $\mathcal{U}$ is the base, associate to each p the collection $\mathcal{U}_p$ of all elements of $\mathcal{U}$ containing p.]

(c) Combine (a) and (b) to give an alternate proof of XIII.7.10.6.(a) for regular spaces.

XIII.7.10.8. (a) Let X be a T_1 topological space. Show that X is normal if and only if, whenever E is a closed set in X and U an open set in X containing E, there is a sequence (V_n) of open sets in X with

$\bar{V}_n \subseteq U$ for all n and $E \subseteq \cup_{n=1}^{\infty} V_n$. [If A and B are disjoint closed subsets of X, choose such sequences (V_n) for A in $X \setminus B$ and (W_n) for B in $X \setminus A$. Then

$$\bigcup_{n=1}^{\infty} \left(V_n \setminus \left[\bigcup_{k \leq n} \bar{W}_k \right] \right) \text{ and } \bigcup_{n=1}^{\infty} \left(W_n \setminus \left[\bigcup_{k \leq n} \bar{V}_k \right] \right)$$

are disjoint neighborhoods of A and B.]

(b) Use (a) to show that every F_σ in a normal space is normal.

XIII.7.10.9. Let X be a normal space.

(a) Use Urysohn's Lemma to prove that if E is a closed set in X and U is an open neighborhood of E, then there is an open F_σ V with $E \subseteq V \subseteq U$.

(b) Give an alternate proof of (a) not using Urysohn's Lemma by repeatedly applying XIII.7.6.2. to obtain a sequence (V_n) of open sets with $E \subseteq V_n \subseteq \bar{V}_n \subseteq V_{n+1} \subseteq U$.

(c) Extend the argument of (b) to show that if F is an F_σ in X and U an open neighborhood of F, there is an open F_σ V with $F \subseteq V \subseteq U$. [Write $F = \cup_n F_n$ with F_n closed, and successively apply XIII.7.6.2. to $F_n \cup \bar{V}_n$.]

(d) Extend the argument of (b) to show that if E is a closed set in X and U a neighborhood of E, there is an open F_σ V with $E \subseteq V \subseteq \bar{V} \subseteq U$. [First find an open set W with $E \subseteq W \subseteq \bar{W} \subseteq U$ and do the construction within W.] Does (c) similarly extend? [Consider the case where F is an open F_σ and $U = F$.]

Compare with XIII.22.8.2..

XIII.7.10.10. Let $\{X_i : i \in I\}$ be an indexed collection of (nonempty) sets with $X = \prod_{i \in I} X_i \neq \emptyset$. Prove the following without using the AC:

(o) X is T_0 if and only if each X_i is T_0.

(i) X is T_1 if and only if each X_i is T_1.

(ii) X is Hausdorff if and only if each X_i is Hausdorff.

(iii) X is regular if and only if each X_i is regular. [Use XIII.7.5.1..]

(iiis) X is completely regular if and only if each X_i is completely regular.

The corresponding statement for normal spaces is false (XIII.7.10.14.(h)).

XIII.7.10.11. Let X be a T_3 space, Y a dense subspace of X, and $p \in Y$. Suppose $\{V_i : i \in I\}$ is a local base for the relative topology of Y consisting of relatively open sets, and for each i U_i is an open set in X with $U_i \cap Y = V_i$ (to avoid use of the AC we may choose the U_i as in ()). Show that $\{U_i : i \in I\}$ is a local base for p in X, as follows.

(a) If U is an open set in X, then $U \cap Y$ is dense in U, so $U \subseteq Cl_X(U \cap Y)$. In particular, $U_i \subseteq Cl_X(V_i)$ for all i.

(b) Let W be an open neighborhood of p in X. Then there is an open neighborhood Z of p in X with $Cl_X(Z) \subseteq W$ (XIII.7.5.1.). There is an i such that $V_i \subseteq Z \cap Y$.

(c) For this i we have $U_i \subseteq Cl_X(V_i) \subseteq Cl_X(Z \cap Y) = Cl_X(Z) \subseteq W$.

(d) In particular, if p has a countable local base in Y, then it has a countable local base in X.

(e) Result (d) can fail if X is not T_3, even if it is T_1. [Let X be an uncountable set with the finite complement topology, and Y a countably infinite subset; cf. XIII.1.2.8.(iv).]

XIII.7.10.12. [Pea75] Make the following definitions:

DEFINITION. Let X be a topological space.

A subset Y of X is a *generalized* F_σ in X if, whenever U is an open neighborhood of Y in X, there is an F which is an F_σ in X with $Y \subseteq F \subseteq U$.

A subset Y of X is *normally situated* in X if, whenever U is an open neighborhood of Y in X, there is a locally finite cover $\{V_i : i \in I\}$ of Y with each V_i an open F_σ in X contained in U.

X is *totally normal* if X is normal and every subset of X is normally situated in X.

(a) Show that if X is normal, then every generalized F_σ in X is normally situated in X. [Use ().]

(b) Show that if X is normal and Y is normally situated in X, then Y is normal.

(c) Show that every subspace of a totally normal space is totally normal.

(d) Show that every totally normal space is completely normal (XIII.10.1.2.).

(e) Show that the space of ordinals less than or equal to the first uncountable ordinal (which is completely normal by XIII.16.1.1.) is not totally normal (cf. XIII.11.14.12.).

(f) Show that every perfectly normal space (XIII.10.6.11.) is totally normal. Give an example of a totally normal space which is not perfectly normal.

***(g) What is the relationship between total normality and (hereditary) paracompactness (XIII.11.10.3.)?

XIII.7.10.13. Show that a separable normal space cannot have a closed discrete subspace of cardinality $2^{\aleph_0}$. [Count the number of real-valued continuous functions and apply Urysohn's Lemma.] More generally, if X is normal and has a dense set of cardinality κ, and a closed discrete subspace of cardinality λ, then $2^\lambda \leq 2^\kappa$; in particular, X cannot have a closed discrete subspace of cardinality 2^κ (Jones's Lemma).

XIII.7.10.14. The Sorgenfrey Line. Put a topology $\mathcal{S}$ on $\mathbb{R}$ by taking $\{(a, b] : a, b \in \mathbb{R}, a < b\}$ as a base. (Many references use base sets of the form $[a, b)$, which gives a different but homeomorphic topology.) $(\mathbb{R}, \mathcal{S})$ is called the *Sorgenfrey line*, denoted S.

(a) Show that $\mathcal{S}$ is stronger than the usual topology on $\mathbb{R}$, and thus is Hausdorff.

(b) Show that S is zero-dimensional, hence normal. [Show that $(a, b]$ is clopen for all $a < b$.]

(c) Show that any bounded nondecreasing sequence in $\mathbb{R}$ converges in S to its limit in $\mathbb{R}$, but that no strictly decreasing sequence converges in S.

(d) Show that S is first countable and separable.

(e) Show that every subset A of S is separable and Lindelöf. [Show that

$$\{x \in A : (x - \epsilon, x) \cap A = \emptyset \text{ for some } \epsilon > 0\}$$

is countable. Then show that if $\mathcal{U}$ is an open cover of A, and V is the union of all intervals (a, b) for which $(a, b]$ is contained in some element of $\mathcal{U}$, then $A \setminus V$ is countable.] In particular, S is (hereditarily) paracompact.

(f) Show that every closed subset of S is a G_δ. Thus S is perfectly normal (XIII.10.6.11.), hence completely normal.

(g) Show that a subset of S is compact if and only if it is closed in the usual topology of $\mathbb{R}$, bounded above, and has no strictly decreasing sequences (i.e. is well ordered in the usual ordering). Conclude that every compact subset of S is countable (cf. ()). In particular, S is not locally compact or σ-compact.

(h) Show that $S \times S$ is not normal. [The set $\{(x, -x) : x \in S\}$ is a closed discrete subset of $S \times S$ of cardinality $2^{\aleph_0}$. Apply Exercise XIII.7.10.13.. Alternatively, show using the Baire Category Theorem that $\{(x, -x) : x \in \mathbb{Q}\}$ and $\{(x, -x) : x \in \mathbb{J}\}$ do not have disjoint neighborhoods.] So $S \times S$ is not paracompact or Lindelöf. Note that $S \times S$ is separable, first countable, and completely regular.

(i) Show that S is not second countable. [If it were, it would be metrizable, so $S \times S$ would also be metrizable. There is also a simple direct proof.]

(j) Show that S is a Baire space ().

(k) Give $\mathbb{R} \times \{0, 1\}$ the lexicographic ordering and the order topology. Show that S is homeomorphic to the subspace $\mathbb{R} \times \{0\}$ with the relative topology. Thus S is a suborderable space (), and hence completely collectionwise normal (XIII.16.1.1.). But S is not an orderable space.

The Sorgenfrey line provides a simple counterexample for many seemingly plausible statements, particularly about product spaces. If T is the subset of S consisting of irrational numbers, with the relative topology, it is plausible that T is homeomorphic to S since S is zero-dimensional; but in fact T is not homeomorphic to S [**?**].

XIII.7.10.15. Let $\mathcal{T}$ be the usual topology on $\mathbb{R}$ and $\mathcal{S}$ the Sorgenfrey topology (XIII.7.10.14.).

(a) Which functions from $\mathbb{R}$ to $\mathbb{R}$ are continuous from $(\mathbb{R}, \mathcal{S})$ to $(\mathbb{R}, \mathcal{T})$?

(b) Which functions from $\mathbb{R}$ to $\mathbb{R}$ are continuous from $(\mathbb{R}, \mathcal{T})$ to $(\mathbb{R}, \mathcal{S})$?

(c) Which functions from $\mathbb{R}$ to $\mathbb{R}$ are continuous from $(\mathbb{R}, \mathcal{S})$ to $(\mathbb{R}, \mathcal{S})$?

XIII.7.10.16. Let X be an uncountable set with the countable complement topology (XIII.1.6.4.).

(a) Show that X is T_1 but not Hausdorff.

(b) Show that a sequence in X converges if and only if it is eventually constant. Thus the convergent sequences in this topology are the same as the convergent sequences in the discrete topology.

(c) Every convergent sequence in X has a unique limit. Contrast with XIII.7.4.1..

XIII.7.10.17. **Smirnov's Deleted Sequence Topology** [SS95, #64]. Let $A = \left\{\frac{1}{n} : n \in \mathbb{N}\right\} \subseteq \mathbb{R}$. Let $\mathcal{T}$ be the usual topology on $\mathbb{R}$. Define a topology $\mathcal{S}$ on $\mathbb{R}$ by

$$\mathcal{S} = \{U \setminus B : U \in \mathcal{T}, B \subseteq A\} .$$

(a) Show that $\mathcal{S}$ is a topology on $\mathbb{R}$ which is stronger than $\mathcal{T}$.

(b) Show that $(\mathbb{R}, \mathcal{S})$ is Hausdorff.

(c) Show that $(\mathbb{R}, \mathcal{S})$ is not regular. [A is a closed set, $0 \notin A$, but 0 and A do not have disjoint neighborhoods.]

(d) Repeat the construction with A replaced by any nonclosed set with dense complement, e.g. $\mathbb{Q}$.

XIII.7.10.18. **The Tangent Disk Space** [SS95, Example 82]. Let X be the closed upper half plane in $\mathbb{R}^2$. Let $\mathcal{T}$ be the collection of all unions of subsets of X of the following types:

(i) Any subset of the open upper half plane which is open in the ordinary topology.

(ii) The union of $\{(a, 0)\}$ and an open disk of radius r $(r > 0)$ centered at (a, r), for some $a \in \mathbb{R}$ (an open disk in the upper half plane tangent to the x-axis at a).

(a) Show that $\mathcal{T}$ is a topology on X which is stronger than the relative Euclidean topology.

(b) Show that $(X, \mathcal{T})$ is separable and first countable.

(c) Show that $(X, \mathcal{T})$ is completely regular.

(d) Show that $(X, \mathcal{T})$ is not normal. [Show that the relative topology on the x-axis is the discrete topology, and apply XIII.7.10.13..]

This example is due to NIEMYTZKI [] and is called the *Niemytzki tangent disk space* or *Niemytzki plane*. Some references call it the *Moore plane* since it was apparently discovered independently by R. L. MOORE, but this name can be confused with the Moore manifold XIII.20.5.8., which is not the same (to make matters worse, the Moore manifold has been occasionally called the Niemytzki plane! But they are closely related: the Niemytzki plane is a quotient of the Moore manifold.)

XIII.7.10.19. Show that every infinite Hausdorff space contains a sequence of pairwise disjoint nonempty open sets. (There is a simple argument using DC. Some form of Choice is needed; cf. **??**.)

XIII.7.10.20. Let R be a unital ring (III.3.6.3.). Let $\mathrm{Spec}(R)$ be the set of prime ideals (II.6.4.12.) in R. Put a topology on $\mathrm{Spec}(R)$ as follows. If $E \subseteq \mathrm{Spec}(R)$, set

$$\ker(E) = \bigcap_{P \in E} P$$

and define

$$\bar{E} = \{P \in \mathrm{Spec}(R) : \ker(E) \subseteq P\} \ .$$

More generally, if $A \subseteq R$, define

$$\mathrm{hull}(A) = \{P \in \mathrm{Spec}(R) : A \subseteq P\}$$

so that $\bar{E} = \mathrm{hull}(\ker(E))$.

(a) Show that $E \mapsto \bar{E}$ is a Kuratowski closure operator (XIII.2.4.1.), hence defines a topology on $\mathrm{Spec}(R)$, called the *hull-kernel* or *Jacobson topology* on $\mathrm{Spec}(R)$ (if R is commutative, in a slightly different context it is also called the *Zariski topology*).

(b) Show that the hull-kernel topology is always T_0.

(c) Show that the hull-kernel topology on $\mathrm{Spec}(\mathbb{Z})$ is not T_1.

(d) Show that $\mathrm{Spec}(R)$ is compact in the hull-kernel topology.

(e) Let $\mathrm{Maxspec}(R)$ be the subset of $\mathrm{Spec}(R)$ consisting of the maximal ideals (II.6.4.12.) of R, with the hull-kernel topology (which is the relative topology). Show that $\mathrm{Maxspec}(R)$ is closed in $\mathrm{Spec}(R)$, hence also compact, and always T_1. Show that $\mathrm{Maxspec}(\mathbb{Z})$ is not Hausdorff.

(f) Explain why prime ideals must be used, i.e. what goes wrong if we try to take $\mathrm{Spec}(R)$ to be the set of all (proper) ideals in R?

$\mathrm{Spec}(R)$, or certain natural subsets like $\mathrm{Maxspec}(R)$, with the hull-kernel topology, is a fundamental object of study in several parts of mathematics, including Operator Algebras () and Algebraic Geometry ().

XIII.7.10.21. Other Separation Axioms. Several other separation axioms have been considered. Here are two of them.

DEFINITION. Let X be a topological space.

X is *completely Hausdorff*, or $T_{2\frac{1}{2}}$, if distinct points of X have disjoint closed neighborhoods.

X is *Urysohn* if, whenever $p, q \in X$, $p \neq q$, there is a continuous function $f : X \to [0, 1]$ with $f(p) = 0$ and $f(q) = 1$ (equivalently, there is a continuous $g : X \to \mathbb{R}$ with $g(p) \neq g(q)$).

(a) Show that the two conditions in the definition of an Urysohn space are equivalent.

(b) Show that a regular space is completely Hausdorff (use XIII.7.5.1.).

(c) Show that an Urysohn space is completely Hausdorff.

(d) Show that any topology stronger than a completely Hausdorff topology [*resp.* Urysohn topology] is completely Hausdorff [*resp.* Urysohn].

A completely Hausdorff space is obviously Hausdorff, and a completely regular space is Urysohn. There are Hausdorff spaces which are not completely Hausdorff (XIII.7.10.23.), in fact in which no two points have disjoint closed neighborhoods [SS95, Example 75]. There are Urysohn spaces which are not regular, hence not completely regular (XIII.7.10.17.), completely Hausdorff spaces which are neither regular nor Urysohn [SS95, Example 80], regular spaces which are not Urysohn [SS95, Example 90], and regular Urysohn spaces which are not completely regular [SS95, Example 91].

Both properties were introduced (the completely Hausdorff property somewhat more explicitly, but neither property was named) by URYSOHN in [Ury25a], where Urysohn's Lemma was proved and Urysohn's Metrization Theorem (XIII.10.1.3.) first stated.

There has been a bizarre reversal in terminology concerning these two axioms. Our definitions are the ones from [SS95], which were apparently universally used until that time (see e.g. [Bou98]). For unknown reasons, the definitions were reversed in [Wil04]: what we call "completely Hausdorff" is called "Urysohn" there, and vice versa. Since the publication of [Wil04], usage of the terms has been inconsistent but has tended to follow [Wil04]. The earlier definitions make more sense to me since "Urysohn functions" separating points or points and closed sets are standard terminology (although using "completely Hausdorff" in WILLARD'S sense would be in analogy with the term "completely regular," note that the "completely" in "completely normal" means something completely different). My guess is that WILLARD simply made a mistake, which has been perpetuated since; if he had deliberately changed established terminology he probably would have said so and given a reason, and I find it hard to believe he would worry about doing so in such a relatively minor side thread of topology. I have thus reverted to the historical definitions. It would be good if topologists would definitively decide what these definitions should be. There is one additional term sometimes used: spaces which are Urysohn according to our definition are sometimes called *functionally Hausdorff*. (In analogy, completely regular spaces could be called *functionally regular*; "functionally normal" is the same as normal by Urysohn's Lemma.)

XIII.7.10.22. Let $(X, \mathcal{T})$ be a topological space. Show (without using AC) that the following are equivalent:

(i) $(X, \mathcal{T})$ is Urysohn.

(ii) There is a completely regular topology $\mathcal{S}$ on X which is weaker than $\mathcal{T}$.
