(iii) There is a strongest completely regular topology $\mathcal{S}$ on X which is weaker than $\mathcal{T}$.

[For (i) ⇒ (iii), mimic the argument of XIII.11.9.12. to embed X in a product Y of copies of $[0,1]$. Note that without AC, Y is not necessarily compact, but it is completely regular by XIII.7.10.10.(iiis).]

XIII.7.10.23. **Double Origin Topology** (Aleksandrov and Urysohn, cf. [SS95, Example 74]). Let $X = \mathbb{R}^2 \cup \{\mathbf{0}'\}$. Give X a topology $\mathcal{T}$ consisting of all unions of the following types of sets: any subset of $X \setminus \{\mathbf{0}, \mathbf{0}'\}$ which is open in $\mathbb{R}^2 \setminus \{\mathbf{0}\}$ in the usual topology; the union of $\{\mathbf{0}\}$ and an open half-disk in the upper half plane centered at $\mathbf{0}$; the union of $\{\mathbf{0}'\}$ and an open half-disk in the lower half plane centered at $\mathbf{0}$.

(a) Show that $\mathcal{T}$ is a topology on X.

(b) Show that $(X, \mathcal{T})$ is Hausdorff.

(c) Show that $\mathbf{0}$ and $\mathbf{0}'$ do not have disjoint closed neighborhoods. Thus $(X, \mathcal{T})$ is not completely Hausdorff.

(d) Show that $(X, \mathcal{T})$ is path-connected.

XIII.7.10.24. Using AC, prove the following generalization of XIII.7.6.8.:

Theorem. Let X be a topological space. The following are equivalent:

(i) X is T_4.

(ii) Every point-finite open cover of X has a shrinking.

(iii) Every finite open cover of X has a shrinking.

(iv) Every finite open cover of X has a locally finite closed refinement.

(Note that (i) ⟺ (iii) is XIII.7.6.8..)

(a) For (i) ⇒ (ii), well-order the index set and use the proof of XIII.7.6.8. by transfinite induction. (This is where the AC is used, so the AC is not needed to prove that (i), (iii), and (iv) are equivalent.)

(b) For (iv) ⇒ (i), let A and B be disjoint closed subsets of X. Take a locally finite closed refinement $\mathcal{V}$ of $\{X \setminus A, X \setminus B\}$, and let E [resp. F] be the union of the sets in $\mathcal{V}$ disjoint from A [resp. B]. Show that E and F are closed, and take $U = X \setminus E$, $V = X \setminus F$. Show that U and V are disjoint neighborhoods of A and B.

(c) Deduce the following corollary:

Corollary. Let X and Y be topological spaces, and $f : X \to Y$ a continuous closed surjection. If X is T_4, then Y is also T_4. If X is normal, Y is also normal.

(d) Show that the result of (c) is not necessarily true if f is not closed. [Let Y be any topological space, and let X be the set Y with the discrete topology.]

XIII.7.10.25. (a) Let (X, ρ) be a metric space, and A, B disjoint closed subsets of X. Show that

$$f(x) = \frac{\rho(x, A)}{\rho(x, A) + \rho(x, B)}$$

is a well-defined continuous function from X to $[0,1]$ with $A = f^{-1}(0)$ and $B = f^{-1}(1)$.

(b) Show that Urysohn's Lemma for metrizable spaces can be proved without any Choice, and that a metrizable space is normal.

XIII.7.10.26. Say a topological space $(X, \mathcal{T})$ is $T_{1/2}$ (nonstandard definition) if every singleton subset of X is a Borel set (). A T_1 space is trivially $T_{1/2}$.

(a) If p and q are distinct points of X with the same open neighborhoods, show that any Borel set containing one of them contains the other [show the collection of such sets is a σ-algebra]. Conclude that a $T_{1/2}$ space is T_0.

(b) If X is T_0 and p and q are distinct points of X, show that there is a Borel set (either open or closed) containing p but not q. Conclude that every countable T_0 space is $T_{1/2}$. In particular, the Sierpiński space () is $T_{1/2}$ but not T_1.

(c) Show that every second countable T_0 space X is $T_{1/2}$. [If (U_n) is a countable base of open sets, and $p \in X$, for each n either $p \in U_n$ or $p \in U_n^c$. Let E_n be the one containing p. Then $\cap_n E_n = \{p\}$.]

(d) Put a topology on $\mathbb{R}$ as follows. Let $Y = \mathbb{R} \setminus \{0\}$. Let $\mathcal{T}$ consist of $\emptyset$ and all subsets of $\mathbb{R}$ containing 0 and all but finitely many points of Y. Then $\mathcal{T}$ is a T_0 topology on $\mathbb{R}$. The Borel sets in $(\mathbb{R}, \mathcal{T})$ are all countable subsets of Y and all sets containing 0 and all but countably many points of Y; thus $\{0\}$ is not a Borel set and $(\mathbb{R}, \mathcal{T})$ is not $T_{1/2}$.

(e) Is there a simple characterization of $T_{1/2}$ not using Borel sets or σ-algebras? Is a first countable T_0 space necessarily $T_{1/2}$, or conversely?

XIII.8. Quotient Spaces and the Quotient Topology

In this section, we will examine what happens when we take a topological space X and "collapse" various subsets of X to points.

Recall (II.3.3.9.) that there are three equivalent points of view for identifying subsets of a set X:

(i) Equivalence relations on X.

(ii) Partitions of X.

(iii) Functions from X onto another set Y.

We suppose the set X has a given topology, and want to topologize the set of equivalence classes, or the set Y, in an appropriate way. This topological space will be called the *quotient space* of X by the relation.

Many constructions in topology amount to forming a quotient space.

XIII.8.1. The Quotient Topology

We first take the point of view of having a function f from our set X onto another set Y. If X has a specified topology $\mathcal{T}$, we want to put a topology $\mathcal{T}_f$ on Y which makes f continuous, and which is "universal", i.e. the strongest possible. There is an obvious way to do this, since for f to be continuous $f^{-1}(V)$ must be in $\mathcal{T}$ for every $V \in \mathcal{T}_f$ (cf. XIII.5.1.14.).

XIII.8.1.1. DEFINITION. Let $(X, \mathcal{T})$ be a topological space, and $f : X \to Y$ a surjective function. The *quotient topology* on Y from f is the topology

$$\mathcal{T}_f = \{V \subseteq Y : f^{-1}(V) \in \mathcal{T}\} .$$

In other words, a subset of Y is open in the quotient topology if and only if its preimage in X is open. Equivalently, a subset of Y is closed in the quotient topology if and only if its preimage in X is closed.

It is easily checked () that the quotient topology is indeed a topology. The quotient topology on Y has a universal property. If g is a function from X to a set Z, and $g(x_1) = g(x_2)$ whenever $x_1, x_2 \in X$ and $f(x_1) = f(x_2)$, then there is an induced function $\bar{g} : Y \to Z$ with $g = \bar{g} \circ f$. The next result is obvious from the definition of the quotient topology.

XIII.8.1.2. PROPOSITION. Let X be a topological space, and f a surjective function from X to Y. Give Y the quotient topology. If Z is a topological space and $g : X \to Z$ factors through f, i.e. $g = \bar{g} \circ f$, then g is continuous if and only if $\bar{g}$ is continuous.

XIII.8.1.3. EXAMPLES. (i) Let π_1 be the projection of $\mathbb{R}^2$ onto the x-axis, regarded as $\mathbb{R}$, i.e. $\pi_1(x, y) = x$. It is easily seen that the quotient topology on $\mathbb{R}$ is the ordinary topology (preimages of sets in $\mathbb{R}$ are unions of vertical lines through points of the set). More generally, if X and Y are topological spaces, the projection from $X \times Y$ onto X (or onto Y) is a quotient map, i.e. the quotient topology on X is the given topology.

(ii) Let $X = [0, 1]$, Y the unit circle in $\mathbb{R}^2$, and $f(t) = (\cos 2\pi t, \sin 2\pi t)$. Then f is surjective, and one-to-one except at the endpoints. It is easy to check that the quotient topology on Y is the usual topology (relative topology from $\mathbb{R}^2$). Thus we can regard a circle as the quotient of a closed interval with the endpoints identified.

Not all quotient spaces are this nice (cf. XIII.8.1.11.).

XIII.8.1.4. The quotient topology is not the only topology on Y making f continuous in general; any weaker topology (e.g. the indiscrete topology) also will. But by XIII.8.1.2. (taking $Z = Y$ and $g = f$), the quotient topology is the *strongest* topology on Y making f continuous. For example, if $f : X \to X$ is the identity function, the quotient topology on X from f is precisely the original topology on X.

Quotients by Equivalence Relations

XIII.8.1.5. Now switch to the equivalent point of view of an equivalence relation $\sim$ on X. The set Y can be identified with the set of equivalence classes, and the function $f : X \to Y$ is the function $f(x) = [x]$. We will write $X/\sim$ for Y from this point of view, and call f the *projection*, *quotient map*, or *identification map*, of X onto $X/\sim$, which is called the *quotient space* or *identification space* of X by $\sim$. We give $X/\sim$ the quotient topology.

XIII.8.1.6. DEFINITION. Let $\sim$ be an equivalence relation on a set X.

(i) A subset A of X is *saturated* if it is closed under $\sim$, i.e. if $x \in A$ and $y \sim x$, then $y \in A$.

(ii) If $A \subseteq X$, the *saturation* of A is the set of all elements of X equivalent to an element of A.

XIII.8.1.7. It is obvious that the saturation of a subset of X is saturated, and is the smallest saturated set containing A. If $f : X \to X/\sim$ is the projection from X to $X/\sim$, the saturation of A is precisely $f^{-1}(f(A))$. More generally, a subset A of X is saturated if and only if $A = f^{-1}(B)$ for some subset B of $X/\sim$. In fact, $A = f^{-1}(f(A))$ if A is saturated.

A saturated set is just a union of equivalence classes. An arbitrary union, intersection, or complement of saturated sets is saturated.

XIII.8.1.8. The quotient map $f : X \to X/\sim$, besides being continuous, has the additional property that if U is a saturated open set in X, then $f(U)$ is open in $X/\sim$, or equivalently (since the complement of a saturated open set is a saturated closed set, and vice versa) if E is a saturated closed set in X, then $f(E)$ is closed in $X/\sim$. A surjective continuous map from a topological space X to Y with the quotient topology has this property for the equivalence relation defined by $x_1 \sim x_2$ if $f(x_1) = f(x_2)$.

It would be natural to give this type of function a name. Three names have been proposed and used in various references: (1) *strongly continuous*, first used in [AH74]; (2) *bicontinuous*, first used in [Kur66];

(3) *quasi-compact*, first used in [Why50]. None of the names have become generally established, and none is satisfactory since, among other reasons, they are all also sometimes used to mean other things. The term *quasi-compact* is the most unsatisfactory, since this term is sometimes used for spaces which are compact but not necessarily Hausdorff, and a mapping of the above type has nothing to do with quasi-compactness, and anyway the term *quasi-compact mapping* is commonly used to mean something else in algebraic geometry (more appropriately related to quasi-compactness). The term *strongly continuous* is also not appropriate, since it is too easily confused with the common use of "strongly continuous" in functional analysis (), and anyway it does not have the right intuitive connotation: a better term (which we do not seriously advocate) would be *barely continuous*, since the topology on Y is "just barely" weak enough to make the function continuous. The term *bicontinuous* is the least objectionable and we will use it, although it is also used to refer to simultaneous continuity with respect to two pairs of topologies (cf. [Kel63]). The term "bicontinuous" is especially appropriate in our context in the case where f is also injective: f is then bicontinuous if and only if both f and f^{-1} are continuous (i.e. f is a homeomorphism).

It is easily seen that, conversely, if X and Y are topological spaces and f is a surjective continuous map which is bicontinuous in the above sense, then the topology on Y is necessarily the quotient topology. Thus we obtain:

XIII.8.1.9. Proposition. Let X and Y be topological spaces and f a surjective function from X to Y. Then the topology on Y is the quotient topology from f (i.e. f is a quotient map) if and only if f is bicontinuous.

XIII.8.1.10. This proposition characterizes when a surjective continuous function is a quotient map. Since it is obvious that a surjective continuous function which is either open or closed is bicontinuous, it follows that any such map is a quotient map. But a bicontinuous map need not be either open or closed (XIII.8.1.11.).

A quotient space can be badly behaved:

XIII.8.1.11. Example. Let $\sim$ be the equivalence relation on $\mathbb{R}$ defined by $x \sim y$ if $x - y \in \mathbb{Q}$ (). Then each equivalence class is dense in $\mathbb{R}$. Let $f : \mathbb{R} \to \mathbb{R}/\sim$ be the projection. If E is a nonempty closed set in $\mathbb{R}/\sim$, then $f^{-1}(E)$ is a saturated closed subset of $\mathbb{R}$. Since each equivalence class is dense, $f^{-1}(E)$ is dense in $\mathbb{R}$, hence $f^{-1}(E) = \mathbb{R}$, $E = \mathbb{R}/\sim$. Thus the quotient topology on $\mathbb{R}/\sim$ is the indiscrete topology.

The same argument works for any X and $\sim$ if all equivalence classes are dense in X.

XIII.8.2. Semicontinuous Decompositions

We want some conditions on $\sim$ which will give that the quotient map f is closed or open. These are easily describable:

XIII.8.2.1. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space, $\sim$ an equivalence relation on X, and $f : X \to X/\sim$ the quotient map. The following are equivalent:

(i) The saturation of every closed set in X is closed.

(ii) If p is any point of X, and U is an open neighborhood of $[p]$, then there is a saturated open set $V \subseteq X$ with $[p] \subseteq V \subseteq U$.

(iii) If A is any saturated subset of X, and U is an open neighborhood of A, then there is a saturated open set $V \subseteq X$ with $A \subseteq V \subseteq U$.

(iv) If U is an open set in X, the union of all saturated subsets of U is also open.

(v) f is a closed mapping.

An equivalence relation or partition of X satisfying these conditions is called an *upper semicontinuous (usc) decomposition* of X.

PROOF: (iii) $\Rightarrow$ (ii) is trivial, and for the converse, suppose A is saturated and U is an open neighborhood of A. For each $p \in A$ let V_p be a saturated open neighborhood of $[p]$ contained in U. Then $V = \cup_p V_p$ is a saturated open neighborhood of A contained in U.

(i) $\Rightarrow$ (ii): Let $p \in X$ and U an open neighborhood of $[p]$. Then U^c is closed, so the saturation B of U^c is closed. If $p \in B$, then there is a $q \in X$, $q \sim p$, with $q \in U^c$, contradicting that $[p] \subseteq U$. Thus $V = B^c$ is a saturated open set containing $[p]$ and contained in U.

(iii) $\Rightarrow$ (i): Let E be a closed subset of X, and B its saturation. Then $U = E^c$ is an open neighborhood of the saturated set $A = B^c$, so there is a saturated open neighborhood V of A contained in U. The saturated closed set V^c contains $U^c = E$ and is contained in $A^c = B$; since B is the saturation of E, we have $V^c = B$ and B is closed.

(i) $\Longleftrightarrow$ (iv): Let U be open. Then the saturation of U^c is precisely the complement of the union of all saturated subsets of U.

(i) $\Longleftrightarrow$ (v): If E is a closed set in X, and B is the saturation of E, then B is closed if and only if $f(B) = f(E)$ is closed. ☝

There is a similar characterization of when a quotient map is open, although there does not appear to be a clean analog of conditions (ii)–(iv).

XIII.8.2.2. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space, $\sim$ an equivalence relation on X, and $f : X \to X/\sim$ the quotient map. Then f is an open mapping if and only if the saturation of every open set in X is open.

An equivalence relation or partition of X satisfying these conditions is called a *lower semicontinuous (lsc) decomposition* of X.

XIII.8.2.3. More generally, if X and Y are topological spaces and 2^X is given the topology of (), a similar definition can be made for a function from Y to 2^X to be upper or lower semicontinuous. There is a connection with upper and lower semicontinuous functions from $\mathbb{R}$ to $\mathbb{R}$ (XIII.8.5.16.), which probably motivated the terminology for decompositions. See [Kur66, p. 174] or [Kel75, 3F].

A decomposition which is both upper and lower semicontinuous is called *continuous*. A decomposition is continuous if and only if the quotient map is both open and closed.

Combining these characterizations with XIII.8.1.10., we obtain:

XIII.8.2.4. Proposition. Let X and Y be topological spaces, and $f : X \to Y$ a continuous surjection. If f is closed [open], then f is a quotient map and the corresponding decomposition of X is usc [lsc].

XIII.8.2.5. Examples. (i) The decomposition of XIII.8.1.3.(i) is lower semicontinuous but not upper semicontinuous: if E is the closed set $\{(x, y) : xy = 1\}$ of $\mathbb{R}^2$, the saturation of E is $\mathbb{R}^2$ with the y-axis removed, and $\pi_1(E) = \mathbb{R} \setminus \{0\}$, which are not closed. The projection π_1 is open ().

(ii) The decomposition of XIII.8.1.3.(ii) is upper semicontinuous but not lower semicontinuous. Upper semicontinuity is obvious since only one equivalence class has more than one point. But the saturation and image of the open set $\left[0, \frac{1}{2}\right)$ is not open.

(iii) Let π_1 be projection of $[0, 1]^2$ onto the first coordinate. Then the corresponding decomposition of $[0, 1]^2$ into vertical line segments is continuous (), ().

(iv) The decomposition of XIII.8.1.11. is neither upper nor lower semicontinuous.

XIII.8.3. Separation Axioms for Quotient Spaces

Since a primary use of quotient spaces is to construct new topological spaces, it is important to know how properties of X, especially separation properties, pass to $X/\sim$. Example XIII.8.1.11. shows that nothing is preserved in general; however, under reasonable and verifiable conditions separation properties do pass to quotients.

We begin with a simple observation:

XIII.8.3.1. Proposition. Let $\sim$ be an equivalence relation on a topological space X. Then $X/\sim$ is a T_1 space if and only if each equivalence class is closed.

XIII.8.3.2. Corollary. Let $\sim$ be an equivalence relation on a T_1 topological space X, and $f : X \to X/\sim$ the quotient map. If f is closed (i.e. if the decomposition is usc), then $X/\sim$ is T_1.

Proof: If $p \in X$, then $\{p\}$ is closed in X, and hence its saturation $[p]$ is also closed. 👍

An important variation is that the equivalence relation is closed:

XIII.8.3.3. Definition. Let X be a topological space. A relation R on X is *closed* if it is a closed subset of $X \times X$ with the product topology.

More generally, we can define closed relations from one topological space to another.

XIII.8.3.4. If $\sim$ is an equivalence relation, the condition that $\sim$ is closed implies that each equivalence class is closed. But the conditions are not equivalent: for example, if X is a T_1 space which is not Hausdorff, the equality relation on X has closed equivalence classes (singletons) but is not a closed relation (i.e. the diagonal is not closed in $X \times X$, cf. ()).

This example shows that for an equivalence relation, being closed is not closely related to being upper or lower semicontinuous: the equality relation on a topological space is always both upper and lower semicontinuous, but only closed if the space is Hausdorff. Conversely, the equivalence relations of XIII.8.2.5.(i)-(ii) are closed, but the decompositions fail to be lsc and usc respectively.

XIII.8.3.5. Proposition. Let $\sim$ be an equivalence relation on a topological space X. If $X/\sim$ is Hausdorff, then $\sim$ is closed.

Proof: Suppose $\sim$ is not closed. Then there is a net $((x_i, y_i))$ in $X \times X$ converging to an $(x, y) \in X \times X$ with $x_i \sim y_i$ for all i but $x \not\sim y$. If $f : X \to X/\sim$ is the quotient map, then the net $(f(x_i)) = (f(y_i))$ in $X/\sim$ in $X/\sim$ converges to both $f(x)$ and $f(y)$, so $X/\sim$ is not Hausdorff.

The converse of XIII.8.3.5. is not true in general. But we have:

XIII.8.3.6. Proposition. Let $\sim$ be an equivalence relation on a topological space X, and $f : X \to X/\sim$ the quotient map. If f is open (i.e. the decomposition is lsc) and $\sim$ is closed, then $X/\sim$ is Hausdorff.

Proof: Let $y_1, y_2 \in X/\sim$ and $x_1, x_2 \in X$ with $f(x_1) = y_1$, $f(x_2) = y_2$. Then $x_1 \not\sim x_2$, so, since $\sim$ is closed, there are open neighborhoods V and W of x_1 and x_2 such that $V \times W$ is disjoint from the relation $\sim$. Then $f(V)$ and $f(W)$ are disjoint open neighborhoods of y_1 and y_2.

XIII.8.3.7. The converse of XIII.8.3.6. is also false in general: in XIII.8.2.5.(ii), the quotient space is Hausdorff but the decomposition is not lsc. We also have:

XIII.8.3.8. Proposition. Let $\sim$ be an equivalence relation on a T_4 topological space X, and $f : X \to X/\sim$ the quotient map. If f is closed (i.e. if the decomposition is usc), then $X/\sim$ is T_4.

Proof: Let E_1 and E_2 be disjoint closed subsets of $X/\sim$. Then $f^{-1}(E_1)$ and $f^{-1}(E_2)$ are disjoint closed subsets of X, so they have disjoint open neighborhoods V and W. We have that V^c and W^c are closed and $V^c \cup W^c = X$, so $f(V^c)$ and $f(W^c)$ are closed in $X/\sim$ and $f(V^c) \cup f(W^c) = X/\sim$. Thus $U_1 = [f(V^c)]^c$ and $U_2 = [f(W^c)]^c$ are disjoint open sets. Since $f^{-1}(E_1) \subseteq V$, $f(V^c)$ is disjoint from E_1 and $E_1 \subseteq U_1$. Similarly, $E_2 \subseteq U_2$.

XIII.8.3.9. Corollary. Let $\sim$ be an equivalence relation on a normal topological space X, and $f : X \to X/\sim$ the quotient map. If f is closed (i.e. if the decomposition is usc), then $X/\sim$ is normal and $\sim$ is closed.

Proof: Combine XIII.8.3.8. and XIII.8.3.2. to conclude that $X/\sim$ is normal. Since $X/\sim$ is Hausdorff, $\sim$ is closed by XIII.8.3.5.. 👍

The Maximal T_0 Quotient

We have so far skipped the T_0 condition. There is an important result here:

XIII.8.3.10. Theorem. Let X be a topological space. Then there is a maximal T_0 quotient $\bar{X}$, a quotient space of X, such that:

(i) $\bar{X}$ is T_0.

(ii) If Y is any T_0 space and $f : X \to Y$ a continuous function, then there is a unique continuous function $\bar{f} : \bar{X} \to Y$ such that $f = \bar{f} \circ \pi_0$, where $\pi_0 : X \to \bar{X}$ is the quotient map.

(iii) The quotient map π_0 is open and closed, i.e. the partition of X is continuous.

(iv) If A is any subset of X and $B = \pi_0^{-1}(\pi_0(A))$ is the saturation of A, then

$$\bar{A} = \bar{B} = \pi_0^{-1}(\overline{\pi_0(A)}) = \pi_0^{-1}(\pi_0(\bar{A}))$$

and $\overline{\pi_0(A)} = \pi_0(\bar{A})$. Every closed set and every open set in X is saturated.

The quotient space $\bar{X}$ is uniquely determined up to bijective equivalence by conditions (i) and (ii). The space $\bar{X}$ is $X/\sim$, where $\sim$ is the equivalence relation on X defined by $x \sim y$ if $\overline{\{x\}} = \overline{\{y\}}$.

Proof: We verify that the quotient by the given equivalence relation has properties (i)–(iv). Let $A \subseteq X$, and $B = \pi_0^{-1}(\pi_0(A))$. Let $p \in \bar{B}$. If U is any open neighborhood of p, then there is a $y \in U \cap B$. Then $y \sim x$ for some $x \in A$, so $y \in \overline{\{x\}}$. Thus any neighborhood of y contains x, and in particular $x \in U$. Thus every neighborhood of p contains a point of A, so $p \in \bar{A}$, i.e. $\bar{B} \subseteq \bar{A}$, and the opposite inclusion is trivial. Thus $\bar{A} = \bar{B}$.

If A is closed, then we have $A = \bar{A} = \bar{B}$, so $B \subseteq A$, and the opposite inclusion is trivial, so A is saturated. Since the complement of a saturated set is saturated, every open set is saturated. Thus (iii) is an immediate consequence.

If A is again a general subset of X, then $\pi_0(\bar{A})$ is a closed set containing $\pi_0(A)$, so $\overline{\pi_0(A)} \subseteq \pi_0(\bar{A})$, and the opposite inclusion holds by continuity. Since $\bar{A}$ is saturated, $\bar{A} = \pi_0^{-1}(\pi_0(\bar{A}))$. Thus (iv) is proved.

We then easily obtain (i): if $x, y \in X$ and $\overline{\{\pi_0(x)\}} = \overline{\{\pi_0(y)\}}$, we have

$$\overline{\{x\}} = \pi_0^{-1}(\overline{\{\pi_0(x)\}}) = \pi_0^{-1}(\overline{\{\pi_0(y)\}}) = \overline{\{y\}}$$

so $x \sim y$ and $\pi_0(x) = \pi_0(y)$. Apply XIII.7.2.1..

To show (ii), suppose f is a continuous function from X to a T_0 space Y. It suffices to show that if $x_1, x_2 \in X$ and $x_1 \sim x_2$, then $f(x_1) = f(x_2)$. Suppose $f(x_1) \neq f(x_2)$. Since Y is T_0, we may assume without

loss of generality that $f(x_1)$ has an open neighborhood V not containing $f(x_2)$. But then $f^{-1}(V)$ is an open neighborhood of x_1 not containing x_2, so $x_1 \not\sim x_2$.

Finally, we verify uniqueness; in fact, we show slightly more. We use the standard uniqueness argument for universal properties (). Let $\tilde{X}$ be a T_0 space, and $\tilde{\pi} : X \to \tilde{X}$ a continuous function with the universal property of (ii). Then there is a (unique) $f : \bar{X} \to \tilde{X}$ such that $\tilde{\pi} = f \circ \pi_0$, and a (unique) $g : \tilde{X} \to \bar{X}$ such that $\pi_0 = g \circ \tilde{\pi}$. But then $(g \circ f) \circ \pi_0 = \pi_0$, so $g \circ f$ is the unique $h : \bar{X} \to \bar{X}$ such that $\pi_0 = h \circ \pi_0$. But the identity map $\iota_{\bar{X}}$ also has this property, so $g \circ f = \iota_{\bar{X}}$. Similarly, $f \circ g = \iota_{\tilde{X}}$, so $g = f^{-1}$ is a homeomorphism. 👍

This result is due to KOLMOGOROV, and the maximal T_0 quotient is sometimes called the *Kolmogorov quotient*. There is also a maximal Hausdorff quotient (XIII.8.5.6.).

Other Properties Preserved in Quotients

We now discuss some properties other than separation properties.

XIII.8.3.11. Any property preserved under all surjective continuous maps, e.g. separability and compactness, is of course preserved under arbitrary quotient maps.

For first and second countability, we need the decomposition to be lsc, i.e. the quotient map is open:

XIII.8.3.12. PROPOSITION. Let $\sim$ be an equivalence relation on a topological space X, and $f : X \to X/\sim$ the quotient map. If f is open (i.e. the decomposition is lsc) and X is first countable [second countable], then $X/\sim$ is also first countable [second countable].

PROOF: Let $p \in X$, and $\{U_n : n \in \mathbb{N}\}$ a countable base at p. Then $\{f(U_n)\}$ is a collection of open neighborhoods of $f(p)$. If V is an open neighborhood of $f(p)$, then $f^{-1}(V)$ is an open neighborhood of p, so there is an n such that $U_n \subseteq f^{-1}(V)$. Then $f(U_n) \subseteq V$ and $\{f(U_n) : n \in \mathbb{N}\}$ is a countable base at $f(p)$.

If $\{U_n : n \in \mathbb{N}\}$ is a countable base for the topology of X, then by a nearly identical argument $\{f(U_n) : n \in \mathbb{N}\}$ is a countable base for the topology of $X/\sim$. 👍

Compactness and Local Compactness

XIII.8.3.13. If X is compact and Y is Hausdorff, and $f : X \to Y$ is continuous, then f is automatically a closed mapping (XIII.11.5.1.); so if f is surjective it is a usc quotient map (XIII.8.2.4.) and Y is also compact. But f need not be lsc (i.e. an open map); see XIII.11.14.30.. Conversely, if X is compact Hausdorff and $X \to Y$ is a usc quotient map, then Y is compact Hausdorff (XIII.8.3.8.); see XIII.9.1.2. for an application.

XIII.8.4. Quotient Metrics

A construction related to, but not in general identical to, the quotient space construction is the construction of a quotient (pseudo)metric.

XIII.8.4.1. Let (X, ρ) be a metric space and $\sim$ an equivalence relation on X, and let $Y = X/\sim$ be the set-theoretic quotient. We want to put a "quotient metric" $\bar{\rho}$ on Y. As a first try, we could consider setting

$$\bar{\rho}([x],[y]) = \inf\{\rho(x', y') : x' \in [x], y' \in [y]\} .$$

This function is well-defined, nonnegative, and symmetric, but easy examples (e.g. ()) show that $\bar{\rho}$ defined this way usually does not satisfy the triangle inequality (and it is not definite in general, i.e. could only be a pseudometric).

There is a way to modify this definition to give a pseudometric (Exercise XIII.8.5.15.), but there is a very slick way to define what is obviously the right candidate for the quotient metric:

XIII.8.4.2. Definition. Let (X, ρ) be a metric space, and $\sim$ an equivalence relation on X. Define $\beta : X \times X \to [0, +\infty)$ by

$$\beta(x, y) = \begin{cases} \rho(x, y) & \text{if} \quad x \not\sim y \\ 0 & \text{if} \quad x \sim y \end{cases} .$$

Let ρ_β be the maximum pseudometric of β (VI.2.5.7.), and set $\bar{\rho}([x],[y]) = \rho_\beta(x, y)$. Then $\bar{\rho}$ is the *quotient pseudometric* on $X/\sim$.

It is not hard to see that $\bar{\rho}$ is well defined (Exercise XIII.8.5.16.), and it is then obviously a pseudometric.

XIII.8.4.3. Examples. (i) Let $X = [0, 1]$ with the usual metric, and $\sim$ the equivalence relation obtained by identifying 0 and 1 (i.e. $0 \sim 1$ and the other equivalence classes are singletons). Then $X/\sim$ is a circle of circumference 1, and the quotient pseudometric is the arc length metric.

(ii) Let $X = [0, +\infty)$ with the usual metric ρ, and $\sim$ the equivalence relation obtained by identifying $\mathbb{N} \cup \{0\}$ to a point, i.e. the equivalence classes are $\mathbb{N} \cup \{0\}$ and singletons. $(X/\sim, \bar{\rho})$ is homeomorphic to the space of XIII.19.5.9..

(iii) Let $X = (0, 1]$ with the usual metric ρ, and $\sim$ the equivalence relation obtained by identifying $N = \left\{\frac{1}{n} : n \in \mathbb{N}\right\}$ to a point, i.e. the equivalence classes are N and singletons. $(X/\sim, \bar{\rho})$ is homeomorphic to the Hawaiian earring (XIII.19.5.8.).

(iv) Let $X = \mathbb{R}$ with the usual metric ρ, and $\sim$ the equivalence relation whose classes are the cosets of $\mathbb{Q}$. Every equivalence class is dense, so $\bar{\rho}$ is the zero pseudometric.

(v) Let $X = (0, 1)$ with the usual metric ρ. Let $\sim$ be the equivalence relation obtained by identifying x with $\frac{x}{2}$ for each $x \in (0, 1)$. Then each equivalence class is closed, but we still have that $\bar{\rho}$ is the zero pseudometric.

XIII.8.4.4. Examples (iv) and (v) show that $\bar{\rho}$ is not always a metric if ρ is, even if all equivalence classes are closed. Since $\bar{\rho}([x],[y]) \leq \rho(x, y)$ for all $x, y \in X$, the quotient map from (X, ρ) to $(X/\sim, \bar{\rho})$ is continuous, i.e. the $\bar{\rho}$ topology on $X/\sim$ is weaker than the quotient topology. It is the quotient topology in good cases (e.g. (i), (iv)), but strictly weaker in general (e.g. in (ii), (iii), (v)). The $\bar{\rho}$ topology can depend on the exact metric and not just on the topology: examples (ii) and (iii) are homeomorphic respecting the equivalence relation, but the quotient metric topologies are not the same.

XIII.8.4.5. But if X is metrizable and $X/\sim$ is also metrizable in the quotient topology (cf. ()), there is a metric on X giving its topology such that the quotient metric gives the quotient topology. For if σ is a metric on X giving its topology and τ a metric on $X/\sim$ giving its topology, and $\pi : X \to X/\sim$ is the quotient map, then $\rho = \sigma + (\tau \circ \pi)$ is a metric on X which is equivalent to σ, and the $\bar{\rho}$-topology on $X/\sim$ is stronger than than the τ-topology and weaker than the quotient topology, hence they all coincide, i.e. $\bar{\rho}$ is equivalent to τ.

XIII.8.5. Exercises

XIII.8.5.1. Let X, Y, Z be topological spaces, and $f : X \to Y$ and $g : Y \to Z$ surjective continuous functions. Set $h = g \circ f : X \to Z$.

(a) Show that if f and g are quotient maps, then h is also a quotient map.

(b) Show that if h is a quotient map, then g is also a quotient map. Is f necessarily a quotient map?

XIII.8.5.2. (a) Let X and Y be topological spaces, and let π_1 be projection of $X \times Y$ onto X. Show that π_1 is a quotient map and that the corresponding decomposition of $X \times Y$ is lsc.

(a) Let $\{X_i : i \in I\}$ be a family of topological spaces, and let $X = \prod_{i\in I} X_i$. For $j \in I$, let π_j be projection of X onto X_j. Show that π_j is a quotient map and that the corresponding decomposition of X is lsc.

XIII.8.5.3. Let $\sim$ be an equivalence relation on a topological space X, and $f : X \to X/\sim$ the quotient map. If $Z \subseteq X$, let $\sim_Z$ be the restriction of $\sim$ to Z. Is $Z/\sim_Z$ homeomorphic to $f(Z)$ in general? What if Z is open or closed in X? What if the decomposition is usc or lsc?

XIII.8.5.4. Let X_1, X_2, Y_1, Y_2 be topological spaces, and $f : X_1 \to Y_1$ and $g : X_2 \to Y_2$ be quotient maps. Define $h : X_1 \times X_2 \to Y_1 \times Y_2$ by $h(x_1, x_2) = (f(x_1), g(x_2))$. Is h necessarily a quotient map? What if f and g are open or closed? (cf. [Mun75, p. 141-143].)

XIII.8.5.5. Show that the maximal T_0 quotient of a topological space X can be described alternately as follows.

(a) Define an equivalence relation $\approx$ on X by $x_1 \approx x_2$ if $f(x_1) = f(x_2)$ for every continuous function f from X to a T_0 space Y_f (which can depend on f). Show that $X/\approx$ is T_0. Conclude that $\approx = \sim$.

(b) Describe $\bar{X}$ explicitly by considering the map π from X to $\prod_f Y_f$ by $(\pi(x))_f = f(x)$ (show that this can be done without set-theoretic difficulties by choosing a suitable representative set of functions). Set $Y = \pi(X)$. Show that $Y \cong \bar{X}$ and that π_0 can be identified with π, regarded as a map from X to Y.

XIII.8.5.6. **The Maximal Hausdorff Quotient**. Let X be a topological space. Prove the following theorem:

THEOREM. Let X be a topological space. Then there is a maximal Hausdorff quotient $\tilde{X}$, a quotient space of X, such that:

(i) $\tilde{X}$ is Hausdorff.

(ii) If Y is any Hausdorff space and $f : X \to Y$ a continuous function, then there is a unique continuous function $\tilde{f} : \tilde{X} \to Y$ such that $f = \tilde{f} \circ \pi_2$, where $\pi_2 : X \to \tilde{X}$ is the quotient map.

The quotient space $\tilde{X}$ is uniquely determined up to bijective equivalence by conditions (i) and (ii).

(a) Define an equivalence relation $\approx$ on X by $x_1 \approx x_2$ if $f(x_1) = f(x_2)$ for every continuous function f from X to a Hausdorff space Y_f (which can depend on f). Show that $\tilde{X} = X/\approx$ is Hausdorff. Describe $\tilde{X}$ as in XIII.8.5.5.(b). Give the standard proof of uniqueness.

(b) It is not easy to explicitly describe the equivalence relation $\approx$. As a first approximation, define $\sim$ on X by $x \sim y$ if x and y do not have disjoint neighborhoods. Is $\sim$ an equivalence relation?

(c) Extend $\sim$ to an equivalence relation by taking its transitive closure. Is $X/\sim$ necessarily Hausdorff? If it is, it must be (up to bijective equivalence) the $\tilde{X}$ of (a).

(d) If $X/\sim$ is not Hausdorff, iterate the construction. Let $\sim'$ be the relation on $\mathcal{X}/\sim$ defined in the same way as $\sim$. Write $\sim_1 = \sim$ on X, and let $\sim_2$ be the equivalence relation on X corresponding to the relation $\sim'$ on $X/\sim$. Describe $\sim_2$ explicitly.

(e) Transfinitely define an increasing collection $\sim_\alpha$ of equivalence relations on X in this way. Show that this collection stabilizes at some β, and that $X/\sim_\beta$ is Hausdorff and is bijectively equivalent to $\tilde{X}$.

The smallest such β is called the *Hausdorff height* of X and is an ordinal invariant of X.

The maximal Hausdorff quotient of X is sometimes called the *Hausdorffization* or *Hausdorffification* of X. See () for details.

XIII.8.5.7. (a) Is there a maximal T_1 quotient of a topological space X along the same lines as the maximal T_0 quotient and the maximal Hausdorff quotient?

(b) Show there is no maximal regular, completely regular, normal, or completely normal quotient in general. [There are nonregular topologies on $\mathbb{R}$ which are stronger than the usual topology (e.g. XIII.7.10.17.).]

XIII.8.5.8. There are $2^{\aleph_0}$ pairwise disjoint dense subsets of $\mathbb{R}$ [this can be proved without any form of choice, e.g. by taking rational translates of the von Neumann numbers (III.8.4.13.). See also XIII.8.5.9..] Let $\{A_t : t \in \mathbb{R}\}$ be such a collection. We may assume $\cup_t A_t = \mathbb{R}$ by expanding one of the sets if necessary. Set

$$X = \{(t, y) \in \mathbb{R}^2 : y \in A_t\} \subseteq \mathbb{R}^2 \ .$$

Then projection π_2 of X onto the second coordinate is a bijection from X onto $\mathbb{R}$. The projection π_1 is a surjective but not injective function from X to $\mathbb{R}$. Let $\mathcal{E}$ denote the usual topology on $\mathbb{R}$.

(a) Let $\mathcal{T}$ be any topology on $\mathbb{R}$. Let $\mathcal{T}_X$ be the relative topology on X of the product topology $\mathcal{T} \otimes \mathcal{E}$ on $\mathbb{R} \times \mathbb{R}$. Show that $\mathcal{T}_X$ is a Hausdorff topology on X. [Distinct points of X have distinct second coordinates.]

(b) If $\mathcal{T}$ is any topology on $\mathbb{R}$, let $\mathcal{H}(\mathcal{T})$ be the topology on $\mathbb{R}$ obtained by transferring $\mathcal{T}_X$ to $\mathbb{R}$ via the bijection π_2. Then $\mathcal{H}(\mathcal{T})$ is a Hausdorff topology on $\mathbb{R}$ which is stronger than $\mathcal{E}$. If $\mathcal{T}_1$ and $\mathcal{T}_2$ are different topologies on $\mathbb{R}$, then $\mathcal{H}(\mathcal{T}_1)$ and $\mathcal{H}(\mathcal{T}_2)$ are different topologies on $\mathbb{R}$. Thus there are enormously many distinct (Hausdorff) topologies on $\mathbb{R}$ stronger than $\mathcal{E}$.

(c) The surjective map $\pi_1 \circ \pi_2^{-1}$ is continuous and open from $(\mathbb{R}, \mathcal{H}(\mathcal{T}))$ to $(\mathbb{R}, \mathcal{T})$.

(d) Show that $(\mathbb{R}, \mathcal{T})$ has the quotient topology from $(\mathbb{R}, \mathcal{H}(\mathcal{T}))$ under this map.

(e) If Y is any topological space of cardinality $\leq 2^{\aleph_0}$, then Y can be identified as a subset of $\mathbb{R}$ with some relative topology. Thus Y is a continuous open image of a Hausdorff space.

This can be extended to topological spaces of arbitrary cardinality (XIII.8.5.9.).

XIII.8.5.9. (a) Let κ be a cardinal. Then there is a compact Hausdorff space Z which has a collection of κ pairwise disjoint dense subsets. [Let $Z = \{0,1\}^\kappa$, and consider the equivalence relation on Z where two points are equivalent if they differ in only finitely many coordinates. Use II.9.9.14.]

(b) If Y is any topological space of cardinality κ, let Z be as in (a) with a collection $\{A_y : y \in Y\}$ of pairwise disjoint dense subsets with $\cup_y A_y = Z$. Set

$$X = \{(y,z) : z \in A_y\} \subseteq Y \times Z \ .$$

Repeat problem XIII.8.5.8. with this X to show that Y is a continuous open image (quotient) of a Hausdorff space.

XIII.8.5.10. Let Y be the Sierpiński space. Define $f : [0,1] \to Y$ by $f(t) = a$ if $t < 1$ and $f(1) = b$. Show that f is a quotient map. However, f is neither open nor closed. Use XIII.8.5.8. to write Y as a quotient of a Hausdorff space by an open map; see XIII.7.10.17.(d). (It cannot be done by a closed map since the quotient of a T_1 space by a closed map is T_1.)

XIII.8.5.11. Let X and Y be topological spaces, and $f : X \to Y$ a surjective continuous map. Say f is *semiclosed* if the image of the closure of every saturated set in X is closed in Y.

(a) Show that f is semiclosed if and only if, for every subset B of Y, we have

$$\bar{B} = f(\overline{f^{-1}(B)}) \ .$$

(b) Show that every semiclosed map is a quotient map. In fact, f is semiclosed if and only if, for every subset B of Y, $f|_{f^{-1}(B)}$ is a quotient map from $f^{-1}(B)$ onto B. Thus a semiclosed map is also called a *hereditary quotient map*.

(c) Show that every (surjective) closed map is semiclosed.

(d) Show that all the examples of quotient maps in this section (except XIII.8.5.12.) are semiclosed. In particular, a semiclosed map need not be closed.

(e) If $f : X \to Y$ is a quotient map and Y is Hausdorff and first countable, then f is semiclosed.

(f) Not every quotient map is semiclosed (XIII.8.5.12.).

(g) Show that if X and Y are first countable and Y is T_1, $f : X \to Y$ is semiclosed, (y_n) is a sequence in Y, and $y \in Y$, then $y_n \to y$ if and only if for every subsequence of (y_n) there is a subsubsequence (y_{k_n}) for which there is a sequence (x_{k_n}) in X and an $x \in X$ with $x_{k_n} \to x$, $f(x_{k_n}) = y_{k_n}$ for all n, and $f(x) = y$. In other words, convergent sequences in Y have subsequences which can be lifted to convergent sequences in X.

This result is quite useful in identifying and describing quotient topologies. The restriction that Y be T_1, or something like it, is necessary (XIII.8.5.13.). And even if X and Y are compact metrizable spaces (where the result in (g) is almost trivial), and f is closed, passage to subsequences is necessary in general (XIII.8.5.14.).

XIII.8.5.12. Let $X = \{a_1, a_2, b_1, b_2, c_1, c_2, x_1, x_2\}$, $Y = \{a, b, c, y\}$, and $f : X \to Y$ with $f(a_j) = a$, $f(b_j) = b$, $f(c_j) = c$, $f(x_j) = y$ for $j = 1, 2$. Give X the topology generated by $\{b_1, x_1\}$ and $\{c_2, x_2\}$.

(a) Show that the quotient topology on Y is the indiscrete topology.

(b) Show that y is in the closure of $\{a\}$ in Y, but neither x_1 nor x_2 is in the closure in X of $f^{-1}(\{a\}) = \{a_1, a_2\}$. Thus f is not semiclosed.

XIII.8.5.13. Let $X = \{x_n, z_n : n \in \mathbb{N}\}$, $Y = \{y\} \cup \{y_n : n \in \mathbb{N}\}$, $f : X \to Y$ with $f(x_n) = y_n$ and $f(z_n) = y$ for all n. Give X the topology generated by $\{\{x_n\}, \{x_n, z_n\} : n \in \mathbb{N}\}$, and give Y the quotient topology.

(a) Show that X and Y are first countable but not T_1, and that the quotient map f is semiclosed.

(b) Show that $y_n \to y$ in Y, but no subsequence of (y_n) lifts to a convergent sequence in X.

XIII.8.5.14. Let X be the compact subset

$$\left\{\left(\frac{1}{n}, 1\right) : n \in \mathbb{N} \text{ odd}\right\} \cup \left\{\left(\frac{1}{n}, 0\right) : n \in \mathbb{N} \text{ even}\right\} \cup \{(0,0), (0,1)\}$$

of $\mathbb{R}^2$, and $Y = \{0\} \cup \left\{\frac{1}{n} : n \in \mathbb{N}\right\} \subseteq \mathbb{R}$. Define $f : X \to Y$ by $f(x, y) = x$.

(a) Show that f is a quotient map which is closed, hence semiclosed.

(b) Show that the convergent sequence $y_n = \frac{1}{n}$ in Y does not lift to a convergent sequence in X.

XIII.8.5.15. Let (X, ρ) be a metric space, and $\sim$ an equivalence relation on X. Show that the quotient metric $\bar{\rho}$ can be explicitly described as

$$\bar{\rho}(a, b) = \inf \sum_{k=1}^{n} \rho(x_k, y_k)$$

where the infimum is over all finite sets $\{x_1, \ldots, x_{n+1}, y_1, \ldots, y_n\}$, where $x_1 = a$, $x_{n+1} = b$, and $y_k \sim x_{k+1}$ for $1 \leq k \leq n$ (n may vary). The definition does not change if we only require that $x_1 \sim a$, along with the other conditions.

XIII.8.5.16. Let $X, \rho, \sim, \beta$ be as in XIII.8.4.2.. Use the triangle inequality to show that if σ is a pseudometric on X with $\sigma \leq \rho_\beta$, then σ drops to a well-defined pseudometric on $X/\sim$. In particular, $\bar{\rho}$ is well defined.

XIII.8.5.17. Let $f : \mathbb{R} \to \mathbb{R}$ be a function, and $X = \{(x, y) \in \mathbb{R}^2 : y \leq f(x)\}$ be the subgraph. Give X the relative topology from $\mathbb{R}^2$. Let $\sim$ be the equivalence relation on X from projection onto the X-axis (i.e. the decomposition partitions X into vertical rays). Show that the decomposition is usc [resp. lsc] if and only if f is upper semicontinuous [resp. lower semicontinuous] in the sense of (). [XIII.11.14.19. is helpful.]

XIII.9. Identification Spaces

Perhaps the most important method of construction of topological spaces is by identification or "gluing." There are a few variations, which all fall under the quotient space construction.

XIII.9.1. Collapsing a Subset to a Point

XIII.9.1.1. Let X be a topological space, and A a subset. We can "collapse A to a point" by taking the equivalence relation $\sim$ for which A is one equivalence class and all other equivalence classes are single points. Then the space $X/\sim$ with the quotient topology is usually denoted X/A and is called the *identification space* of X by A, or with A collapsed to a point. (This notation X/A is common, but sometimes conflicts with other common notation. For example, if X is a topological group and A a subgroup, then X/A usually denotes the quotient group (), which is not the same thing. See also XIII.9.3.6..) We may identify X/A with $(X \setminus A) \cup \{a\}$, where $a = \{A\}$.

In order to obtain a T_1 quotient, A must be closed in X, and the collapsing construction is almost exclusively used in this situation.

More generally, we may take a finite or infinite collection of pairwise disjoint subsets of X and collapse each one to a point. If A and B are disjoint subsets of X (usually closed), write $X/(A,B)$ for the space obtained from X by collapsing A and B to (separate) points. The collapsing can be done consecutively, i.e. by forming $(X/A)/B$ or $(X/B)/A$, or simultaneously. Note that $X/(A,B) \ncong X/(A \cup B)$.

XIII.9.1.2. Proposition. Let X be a topological space and A a closed subset of X, and $f : X \to X/A$ the quotient map. Then f is closed, i.e. the decomposition is usc, and the restriction of f to $X \setminus A$ is a homeomorphism onto the open set $(X/A) \setminus \{a\}$.

Proof: $X \setminus A$ is open in X, $W = (X/A) \setminus \{a\}$ is open in X/A, and f is a bijection of $X \setminus A$ to W. Identifying W with $X \setminus A$, a subset V of W is open in X/A if and only if the corresponding subset of $X \setminus A$ is open in X, i.e. V is relatively open in W if and only if $f^{-1}(V)$ is relatively open in $X \setminus A$. Thus $f|_{X \setminus A}$ is a homeomorphism.

If E is a subset of X, then $f^{-1}(f(E)) = E$ if $E \cap A = \emptyset$, and $f^{-1}(f(E)) = E \cup A$ if $E \cap A \neq \emptyset$. In any case, if E is closed, $f^{-1}(f(E))$ is closed, so f is closed.

All the results can fail if A is not closed (Exercise XIII.9.5.1.).

XIII.9.1.3. Conversely, if $f : X \to Y$ is a quotient map and every point of Y but one has a singleton preimage, then $Y = X/f^{-1}(\{q\})$, where q is the exceptional point. If $\{q\}$ is closed in Y (e.g. if Y is T_1), then f is closed and $f|_{X \setminus f^{-1}(\{q\})}$ is a homeomorphism onto $Y \setminus \{q\}$.

XIII.9.1.4. Examples. (i) Let f be the map from $[0,1]$ to $\mathbb{T} \cong S^1$ from XIII.8.1.3.(ii). We have $S^1 \cong [0,1]/\{0,1\}$, i.e. a circle is a closed interval with endpoints identified.

(ii) More generally, let B^n be the closed unit ball in $\mathbb{R}^n$. The boundary is the $(n-1)$-sphere S^{n-1}. We have that $B^n/S^{n-1} \cong S^n$, as is easily checked (e.g. via XIII.9.1.8.). For another construction of S^n by collapsing, see XIII.9.1.12.(iii).

XIII.9.1.5. Proposition. Let X be a Hausdorff topological space, and $A \subseteq X$. Then X/A is Hausdorff if and only if, for each $p \in X \setminus A$, A and p have disjoint neighborhoods. (This entails that A must be a closed subset of X.) In particular, if X is regular and A is closed, then X/A is Hausdorff.

XIII.9.1.6. An identification space from a regular space need not be regular. For example, if X is regular but not normal, and A and B are disjoint closed sets in X which do not have disjoint neighborhoods, then X/A is not regular. However, we have the following special case of XIII.8.3.9.:

XIII.9.1.7. Proposition. Let X be a normal space and A a closed subset of X. Then X/A is normal.

A particularly important special case is:

XIII.9.1.8. Proposition. Let X be a compact Hausdorff space, and A a closed subset of X. Then X/A is homeomorphic to the one-point compactification (XIII.11.8.3.) of $X \setminus A$.

Proof: Combine XIII.9.1.3. and XIII.11.8.5.. 👍

Cones and Suspensions

We can define a cone over any topological space X by forming a cylinder with base X and collapsing the top edge to a point:

XIII.9.1.9. Definition. Let X be a topological space. The space $CX = ([0,1] \times X)/(\{1\} \times X)$ is called the *cone* over X.

This construction is primarily used when X is a compact Hausdorff space. In this case, CX is homeomorphic to the one-point compactification of $[0,1) \times X$ (XIII.9.1.8.).

XIII.9.1.10. Examples. (i) The cone over $[0,1]$ is (homeomorphic to) a solid triangle.

(ii) The cone over S^1 is an ordinary cone, which is homeomorphic to a closed disk.

(iii) More generally, for any n the cone over S^n is homeomorphic to B^{n+1} (note that $B^{n+1} \setminus \{\mathbf{0}\}$ is homeomorphic to $[0,1) \times S^n$).

(iv) The cone CK over the Cantor set K can be identified with the union of all line segments in $\mathbb{R}^2$ between $\left(\frac{1}{2}, 1\right)$ and points of K, regarded as a subset of the x-axis. The point $\left(\frac{1}{2}, 1\right)$ can be replaced by any point of $\mathbb{R}^2$ not on the x-axis. This is a good example of a space which is path-connected but not locally path connected. (CX is path-connected for any topological space X.)

We can similarly form the "suspension" of X by collapsing each end of the cylinder over X to (separate) points:

XIII.9.1.11. DEFINITION. Let X be a topological space. The *suspension* of X is

$$SX = ([0,1] \times X)/(\{0\} \times X, \{1\} \times X) \ .$$

This is also primarily used in the case where X is a compact Hausdorff space, and gives a "two-point compactification" of $(0,1) \times X \cong \mathbb{R} \times X$ in this case. In general, the suspension of X is formed by collapsing the base of CX to a point.

The suspension of X can be thought of as two copies of CX joined base-to-base ().

XIII.9.1.12. EXAMPLES. (i) The suspension of $[0,1]$ can be pictured as a (solid) diamond in $\mathbb{R}^2$.

(ii) The suspension of S^1 can be pictured as the union of two cones joined along their base circles (). This space is homeomorphic to S^2.

(iii) More generally, the suspension of S^n is homeomorphic to S^{n+1}. This can be seen by first forming $CS^n \cong B^{n+1}$, and then collapsing the base, which is the boundary S^n, to a point (cf. XIII.9.1.4.(ii)).

Wedge Sums

XIII.9.1.13. Let $\{X_i : i \in I\}$ be a collection of topological spaces, and for each i let $*_i$ be a designated point of X_i. The *wedge sum* of $\{(X_i, *_i) : i \in I\}$ is the space X obtained from the separated union of the X_i with all the $*_i$ identified together to one point $*$. (The homeomorphism class of X depends in general on the choice of the $*_i$.) If each X_i is a circle, the space X is called a *wedge of circles* or *bouquet of circles*.

If I is a finite set with n elements and each X_i is a circle, the space X is the bouquet of n circles, resembling a flower with n petals. A bouquet of two circles is homeomorphic to a figure 8.

A wedge sum of infinitely many nontrivial spaces is rarely metrizable. For example, a wedge or bouquet of infinitely many circles is not first countable (XIII.9.5.7., XIII.9.5.8.).

XIII.9.2. Gluing and Attaching

Gluing and attaching are perhaps the most extensively used constructions in topology.

XIII.9.2.1. Let X be a topological space, and A and B disjoint subsets of X (with care, the disjointness can be relaxed). Let $f : A \to B$ be a homeomorphism, or more generally a quotient map. We take the quotient of X obtained by identifying x with $f(x)$ for all $x \in A$. More precisely, we define an equivalence relation $\sim$ on X by taking

$$[x] = \{y \in A : f(y) = f(x)\} \cup \{f(x)\}$$

if $x \in A$, $[x] = \{x\} \cup f^{-1}(\{x\})$ if $x \in B$, and $[x] = \{x\}$ if $x \notin A \cup B$. The space $X/\sim$ is called the *identification space* of X with A identified with B via f, or with A *glued* (or *sewed*) to B via f. Note that if f is a homeomorphism, the equivalence classes just consist of $\{x, f(x)\}$ for $x \in A$ and $\{x\}$ for $x \notin A \cup B$.

We may more generally do more than one gluing, gluing A_1 to B_1 and A_2 to B_2, etc. We need that A_j and B_j are disjoint for each j, but A_j and A_k, B_j and B_k, and A_j and B_k need not be disjoint for $j \neq k$, but the gluings have to be consistent on the overlaps. The gluing can be done consecutively or simultaneously. See e.g. XIII.9.2.3.(v).

XIII.9.2.2. In the gluing construction, to obtain a nice quotient space it is not necessary that A and B be closed (XIII.9.2.3.(ii)); however, the case where they are not closed is rather delicate. The construction is more robust if they are closed.

XIII.9.2.3. EXAMPLES. (i) Let $X = [0,1]$, $A = \{0\}$, $B = \{1\}$, f the obvious homeomorphism. Then the identification space with A glued to B is S^1, as in XIII.8.1.3.(ii) or XIII.9.1.4..

(ii) Let $X = (0,1)$, $A = \left(0, \frac{1}{3}\right)$, $B = \left(\frac{2}{3}, 1\right)$, $f(x) = x + \frac{2}{3}$ for $x \in A$. Then the identification space is homeomorphic to S^1.

The identification space depends crucially on the choice of homeomorphism. If instead we take $f(x) = 1 - x$ for $x \in A$, the identification space is not Hausdorff.

(iii) Let $X = [0,1]^2$, $A = [0,1] \times \{0\}$, $B = [0,1] \times \{1\}$. Define $f : A \to B$ by $f(t,0) = (t,1)$. Then the identification space is a cylinder (Figure XIII.2). Informally, we take a rectangle and glue the ends together with no twist.

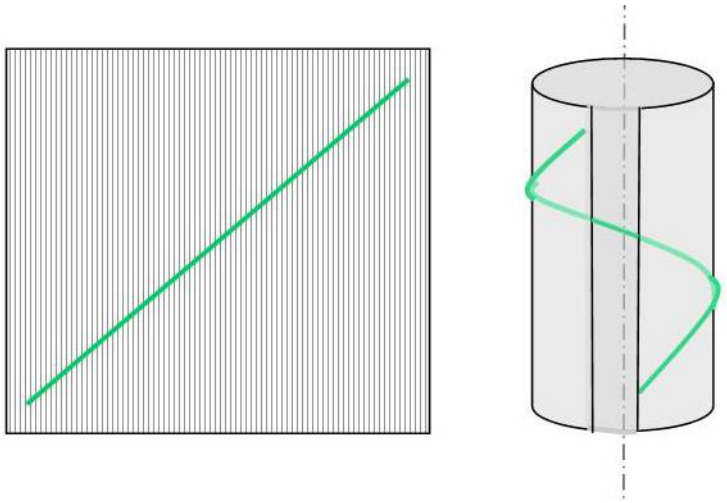

Figure XIII.2: A cylinder.

(iv) Let $X = [0,1]^2$, $A = [0,1] \times \{0\}$, $B = [0,1] \times \{1\}$. Define $f : A \to B$ by $f(t,0) = (1-t,1)$. Then the identification space is a Möbius strip (Figure XIII.3, from https://upload.wikimedia.org/wikipedia/commons/d/d9/M bius_strip.jpg). Informally, we take a rectangle and glue the ends together with a twist.

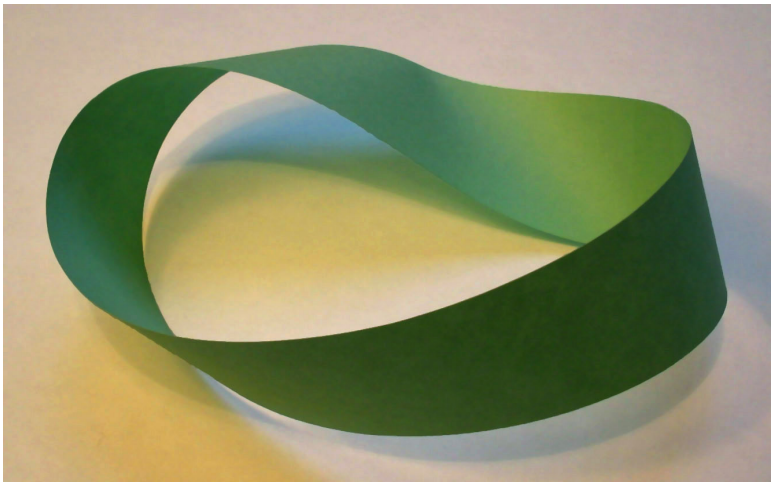

Figure XIII.3: A Möbius strip.

(v) Let $X = [0,1]^2$, $A_1 = [0,1] \times \{0\}$, $B_1 = [0,1] \times \{1\}$, $A_2 = \{0\} \times [0,1]$, $B_2 = \{1\} \times [0,1]$. Define $f_1 : A_1 \to B_1$ by $f(t,0) = (t,1)$ and $f_2 : A_2 \to B_2$ by $f_2(0,t) = (1,t)$. The identification space is homeomorphic to a 2-torus $T^2 \cong S^1 \times S^1$. It can be made from a rectangle by first gluing the top and bottom edges to form a cylinder, and then gluing the end circles (with no twist); see Figure XIII.4, from http://bakingandmath.com/tag/torus/. (See this website, or https://en.wikipedia.org/wiki/Homotopy, for an animation of the topological equivalence of a torus and a coffee cup; the old joke is that a topologist is a mathematician who cannot tell the difference between a doughnut and a coffee cup.)

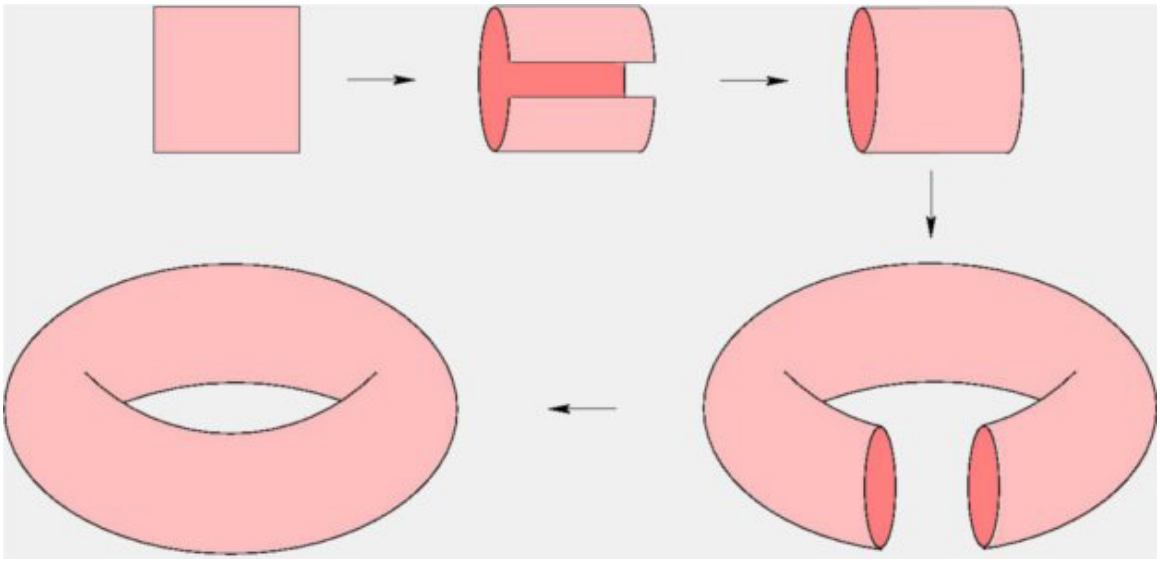

Figure XIII.4: Construction of a torus.

(vi) Let $X = [0,1]^2$, $A_1 = [0,1]\times\{0\}$, $B_1 = [0,1]\times\{1\}$, $A_2 = \{0\}\times[0,1]$, $B_2 = \{1\}\times[0,1]$. Define $f_1 : A_1 \to B_1$ by $f(t,0) = (t,1)$ and $f_2 : A_2 \to B_2$ by $f_2(0,t) = (1,1-t)$. The identification space is called a *Klein bottle* (actually in German it is *Kleinsche Fläche*, "Klein surface," not *Kleinsche Flasche*; the English name may be a mistranslation, although the standard picture indicates that the "bottle" name is not inappropriate). It can be made from a rectangle by first gluing the top and bottom edges to form a cylinder, and then gluing the end circles with an orientation-reversing map; see Figure XIII.5 (from https://en.wikipedia.org/wiki/Klein_bottle) or, for an animated version, https://www.youtube.com/watch?v=E8rifKlq5hc; note that the apparent self-intersection is only an artifact of trying to depict the Klein bottle as a subset of $\mathbb{R}^3$ – the picture is really a higher-dimensional version of a knot diagram in $\mathbb{R}^2$. A Klein bottle cannot be topologically embedded in $\mathbb{R}^3$, but it can be embedded in $\mathbb{R}^4$. A Klein bottle can also be constructed from a Möbius strip by suitably identifying points on the boundary circle (Figure XIII.6, from http://squareone-learning.com/blog/2014/09/around-and-round-and-never-off-the-surface/), or by gluing two Möbius strips together along their boundary circle. There are many nice pictures and videos of the Klein bottle on the internet, e.g. https://www.youtube.com/watch?v=sRTKSzAOBr4.

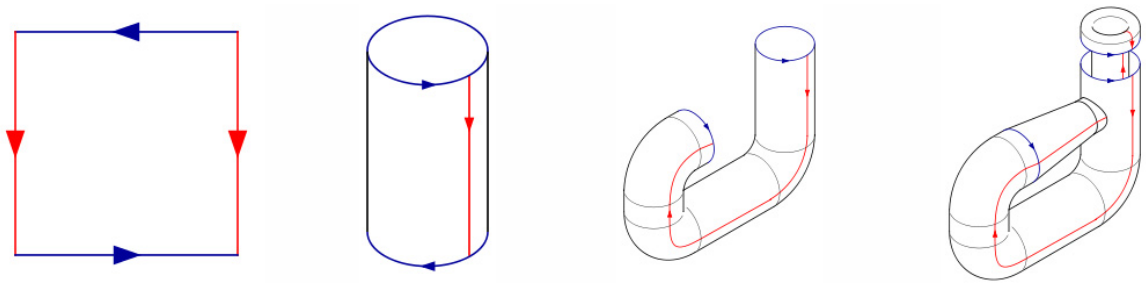

Figure XIII.5: Construction of a Klein bottle.

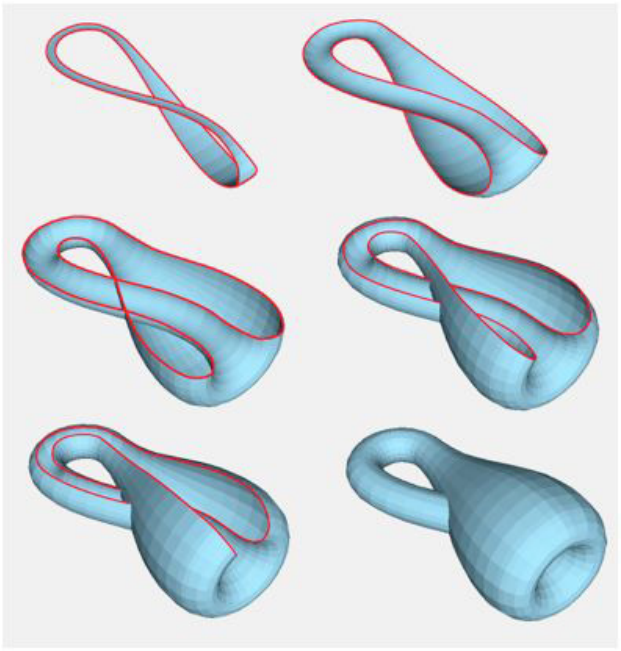

Figure XIII.6: Construction of a Klein bottle from a Möbius strip.

(vii) Let $X = [0,1]^2$, $A_1 = [0,1] \times \{0\}$, $B_1 = [0,1] \times \{1\}$, $A_2 = \{0\} \times [0,1]$, $B_2 = \{1\} \times [0,1]$. Define $f_1 : A_1 \to B_1$ by $f(t,0) = (1-t,1)$ and $f_2 : A_2 \to B_2$ by $f_2(0,t) = (1,1-t)$. The identification space is called the *projective plane*. It can be made from a rectangle by first gluing the top and bottom edges with a twist to form a Möbius strip, and then suitably identifying points on the boundary circle (not in the same way as for a Klein bottle). A better way is to take A as the union of the top and left edges, and B the union of the right and bottom edges (these sets are not quite disjoint), and then gluing A to B. This amounts to gluing the top semicircle of the closed unit disk in $\mathbb{R}^2$ to the bottom semicircle by a 180° rotation, or identifying $\boldsymbol{x}$ with $-\boldsymbol{x}$ for each $\boldsymbol{x}$ of norm 1. See Figure XIII.7, from http://www.math.cornell.edu/~mec/Winter2009/Victor/part3.htm.

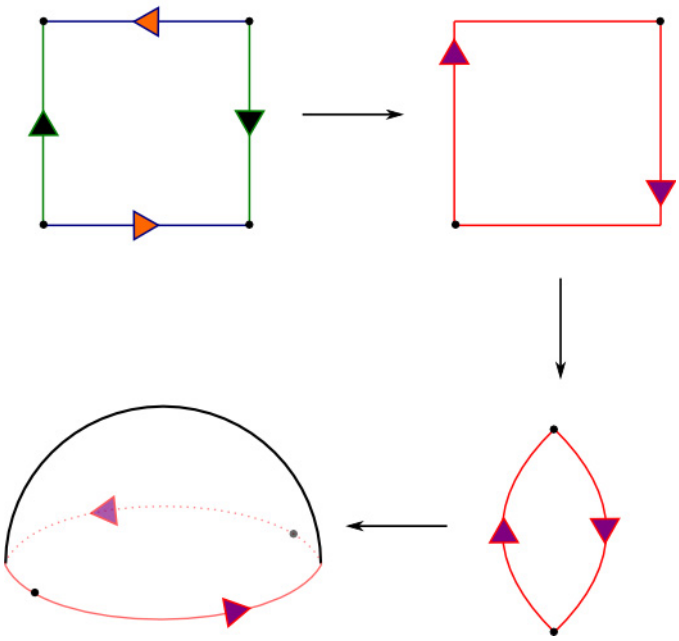

Figure XIII.7: Construction of the projective plane.

A projective plane is harder to picture than a Klein bottle, but there are many ways to do it; see Figure XIII.8, from http://xahlee.info/math/riemann_sphere__real_projective_plane.html for one way. Unlike this picture which has a pinch point, there is a (nonobvious – HILBERT thought it was impossible!) way to immerse the projective plane in $\mathbb{R}^3$ called *Boy's surface* [Boy03]; see https://www.youtube.com/watch?v=9gRx66xKXek for a nice animation. Note again that the apparent self-intersection is only an artifact of trying to depict the projective plane as a subset of $\mathbb{R}^3$. A projective plane cannot be topologically embedded in $\mathbb{R}^3$, but it can be embedded in $\mathbb{R}^4$. There are several other standard ways to construct the projective plane (XIII.9.3.7.); another nice way to visualize it is as *Steiner's Roman surface* (see https://en.wikipedia.org/wiki/Roman_surface#/media/File:Steiner's_Roman_Surface.gif for an animation). The projective plane is denoted $\mathbb{R}P^2$; there are generalizations (real projective spaces) $\mathbb{R}P^n$ for each n (XIII.9.3.7.(iii)), as well as complex projective spaces $\mathbb{C}P^n$ (XIII.9.3.7.(iv)).

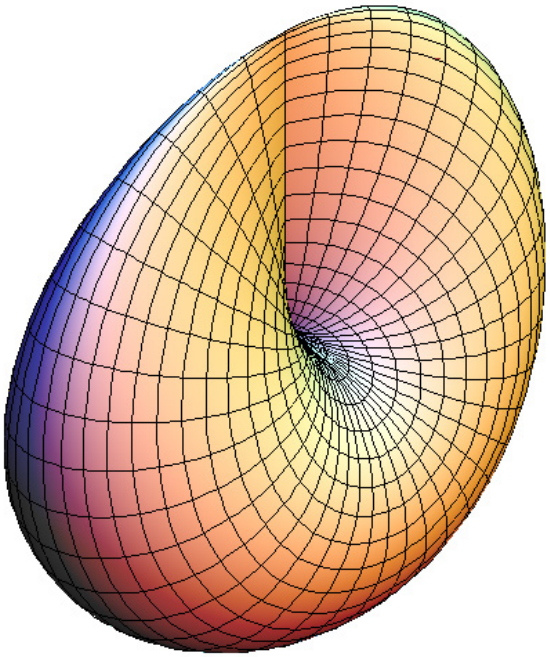

Figure XIII.8: Projective plane as disk with cross-cap.

(viii) Every closed surface (closed 2-manifold) (including S^2!) can be obtained by starting with a regular $(2n)$-gon for some n and identifying pairs of edges in an appropriate way (XIII.9.5.4.).

(ix) A more complicated identification construction important in the theory of dynamical systems is the "flow under a constant function." Let X be a topological space (typically a compact metrizable space), and $\phi : X \to X$ a homeomorphism (typically a *minimal homeomorphism*, i.e. all orbits are dense). From $[0,1] \times X$, form the identification space by identifying $\{0\} \times X$ with $\{1\} \times X$ by identifying $(0,x)$ with $(1,\phi(x))$ for $x \in X$. The identification space is often called the *mapping torus of* ϕ. If ϕ is the identity map, one just obtains $S^1 \times X$, but if ϕ is minimal a (typically complicated) connected space is obtained. The construction in XIII.19.5.18. is a prime example. Another simple example is to take $X = S^1$ and ϕ the antipodal map (this homeomorphism is not minimal!); the construction then yields the Klein bottle. Even a minimal homeomorphism does not necessarily give something exotic: if $X = S^1$ and ϕ is an irrational rotation, the construction just gives a torus. However, in general more than just the identification space is obtained from the construction: there is an obvious canonical action of $\mathbb{R}$ on the identification space ("flow"), and the orbits of this action (if X is infinite and the homeomorphism is minimal) are densely embedded continuous images of $\mathbb{R}$. In the last case of an irrational rotation, one gets copies of $\mathbb{R}$ wrapped around the torus at irrational angle. See XIII.9.5.10.(c) for more about mapping tori.

Attaching

XIII.9.2.4. A variation of gluing is to have two spaces X and Y, subsets A of X and B of Y, and a homeomorphism (or quotient map) $f : A \to B$. This can be put into the previous setting by considering the disjoint union of X and Y. The glued identification space is usually denoted $X \cup_f Y$; we say X is *attached* to Y via f.

XIII.9.2.5. There are two especially important examples of attaching: CW complexes () and surgery. See XIII.26.2.25. for some interesting examples where f is not injective; actually collapsing a subset to a point is an example (where $B = Y$ is a single point).

Handles and Surgery

Surgery is a method of creating new manifolds from known ones. The general setup of surgery in topology is based on the following important fact:

XIII.9.2.6. PROPOSITION. Let M and N be n-manifolds with boundary, and let $f : \partial M \to \partial N$ be a homeomorphism. Then $M \cup_f N$ is an n-manifold without boundary.

XIII.9.2.7. The general idea of surgery is to remove from a (usually closed) n-manifold M an open submanifold and glue in another n-manifold N whose boundary is homeomorphic to the boundary of the removed piece to obtain a new closed n-manifold. The simplest interesting example is:

XIII.9.2.8. Let M be a closed surface, e.g. S^2. Cut two disjoint open disks out of a larger disk in M. What is left is a compact 2-manifold with boundary M_0 whose boundary consists of a disjoint union of two circles, which may be given a consistent orientation. The cylinder $N = [0, 1] \times S^1$ is also a closed manifold with boundary, whose boundary consists of two circles. Glue N to M_0 along the boundary circles, giving them the same orientation. The result is called M *with a handle attached*. See Figure XIII.9, from http://www.uff.br/cdme/pdp/pdp-html/pdp-en.html. It is easy to see that S^2 with a handle attached is homeomorphic to T^2, and T^2 with a handle attached is a two-holed torus. An n-holed torus is obtained by adding n handles to S^1 (Figure XIII.10, from https://upload.wikimedia.org/wikipedia/commons/a/ac/Sphere_with_three_handles.png). It turns out that every closed surface is homeomorphic to either S^2 (if orientable) or $\mathbb{R}P^2$ or a Klein bottle (if nonorientable) with some finite number of handles attached. In the orientable case, the number of handles is called the *genus* and is a topological invariant (). Genus can also be defined in the nonorientable case (XIII.9.2.12.).

If N is attached to S^2 with the end circles given opposite orientations, the surface obtained is the Klein bottle, not the torus.

XIII.9.2.9. A variation is to take closed surfaces M and N, cut out small disks from both of them, and glue the remainders together along the boundary circles (see Figure XIII.11, from https://upload.wikimedia.org/wikipedia/commons/thumb/5/52/Connected_sum.svg/1280px-Connected_sum.svg). The resulting surface is called the *connected sum* of M and N, denoted $M\#N$. The connected sum of an m-holed torus and an n-holed torus is an $(m + n)$-holed torus. Connected sum with a torus is topologically the same thing as adding a handle.

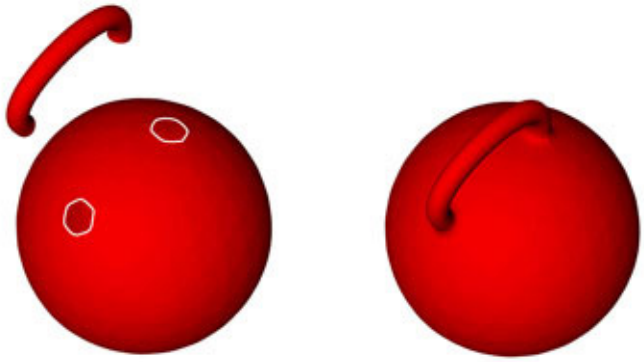

Figure XIII.9: Attaching a handle to a sphere.

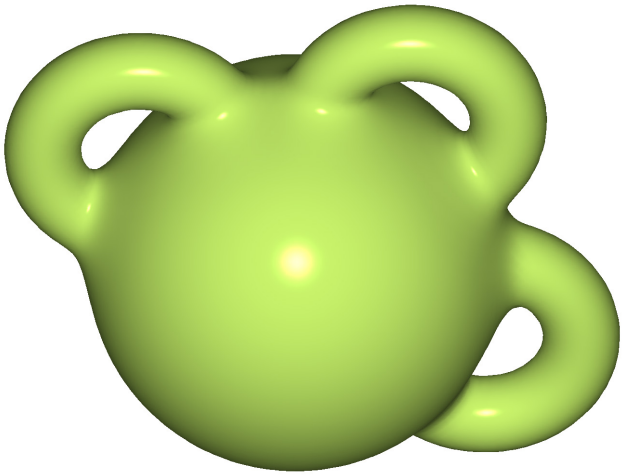

Figure XIII.10: Sphere with three handles.

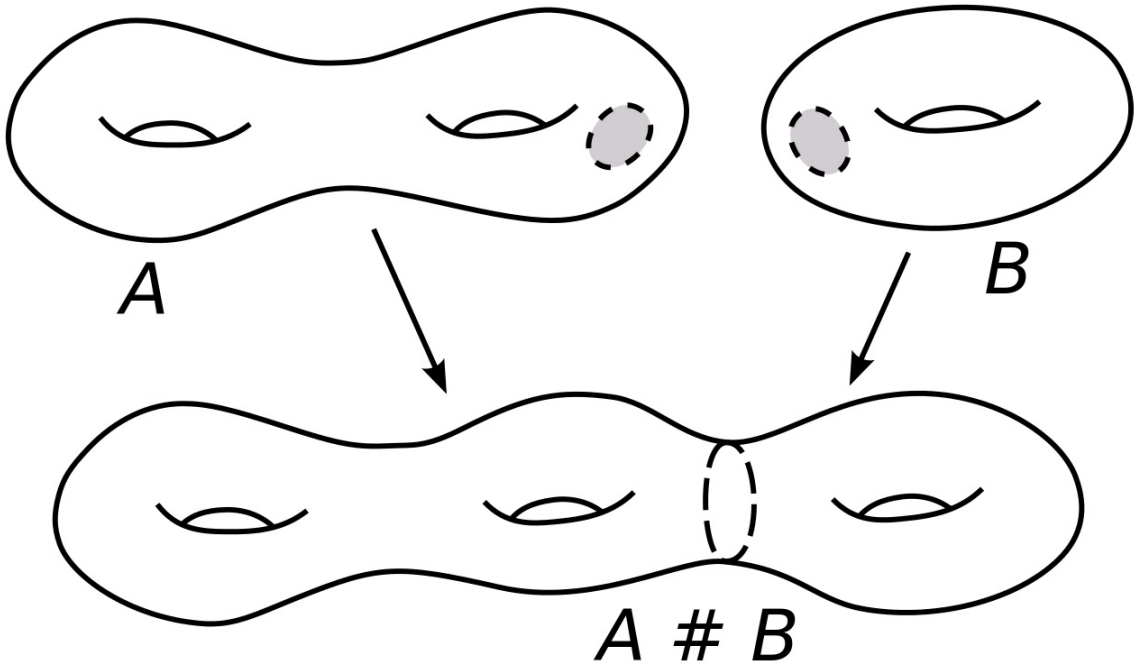

Figure XIII.11: Connected sum.

Connected sum can be done for n-manifolds by cutting out a small ball B^n from both and gluing the remainders along the boundary S^{n-1}'s. In general, the orientation chosen for the identification of the boundaries affects the homeomorphism class of the connected sum ().

XIII.9.2.10. In higher dimensions, there is more flexibility in surgery. A key observation is that for any p and q, the boundary of $S^p \times B^q$ is homeomorphic to $S^p \times S^{q-1}$, as is the boundary of $B^{p+1} \times S^{q-1}$. (We used this for handles with $p = 0$ and $q = 2$). Thus, if M is an n-manifold, we can take any p and q with $p + q = n$, cut out an open submanifold whose closure is homeomorphic to $S^p \times B^q$, and glue in a copy of $B^{p+1} \times S^{q-1}$.

If $n = 3$, the only possibility of this type is to add a "three-dimensional handle," cutting out two 3-balls (a copy of $S^0 \times B^3$) and replacing it by a copy of $B^1 \times S^2 \cong [0, 1] \times S^2$. But if $n = 4$, there is another interesting possibility: cutting out a copy of $S^1 \times B^3$ and replacing it with a copy of $B^2 \times S^2$. See ().

XIII.9.2.11. Actually, even in three dimensions, there is another interesting possibility: the removed manifold with boundary can be glued back in, but with a different homeomorphism on the boundary. (It may be hard to believe this could make a different manifold, but such a self-homeomorphism of the boundary does not generally extend to a self-homeomorphism of the removed manifold.) This can be done also in two dimensions by removing a handle and gluing it back on reversing the orientation of one of the boundary circles, but the three-dimensional case is more interesting since if the removed piece is a solid torus, there are many essentially different ways of gluing it back in (), none of which affect orientability. The removed solid torus may be knotted or unknotted, and this type of surgery is called *surgery on a knot*. More generally, we can do surgery on a link. It is known (Lickorish-Wallace Theorem) that every closed orientable 3-manifold can be obtained from S^3 by surgery on a link ([Wal60], [Lic62]).

XIII.9.2.12. Other types of surgery are possible. For example, the boundary of a Möbius strip is a circle, so if M is a 2-manifold, we may cut a disk out of M and glue in a Möbius strip (called a *cross-cap*). A 2-sphere with a cross-cap added is a projective plane (Figure XIII.8). Adding a cross-cap is the same thing as taking connected sum with a projective plane. Every nonorientable closed surface is obtained by adding a number of cross-caps to a sphere; this number is the genus (). Similar things can be done in higher dimensions.

XIII.9.3. Group Actions on Spaces

XIII.9.3.1. Another important source of quotients arises from group actions. A *group of homeomorphisms* of a topological space X is a set G of homeomorphisms of X such that

(i) G is closed under composition: if $g, h \in G$, then $g \circ h$ (usually written gh) is also in G.

(ii) G is closed under inversion: if $g \in G$, then $g^{-1} \in G$.

(recall that compositions and inverses of homeomorphisms are homeomorphisms). It follows that the identity map on X is in G.

It turns out to be convenient to change point of view slightly:

XIII.9.3.2. DEFINITION. Let G be a group and X a topological space. An *action* of G on X is a homomorphism $\sigma : G \to \text{Homeo}(X)$ from G to the homeomorphism group of X.

We usually write σ_g in place of $\sigma(g)$, and often just write $g \cdot x$ for $\sigma_g(x)$. The homomorphism property of σ is that $\sigma_{gh} = \sigma_g \circ \sigma_h$ (written $\sigma_g\sigma_h$), or $(gh) \cdot x = g \cdot (h \cdot x)$, for $g, h \in G$, $x \in X$; we have $\sigma_{g^{-1}} = \sigma_g^{-1}$ for $g \in G$, and σ_e is the identity homeomorphism if e is the identity of g.

XIII.9.3.3. The group action picture includes the group of homeomorphisms picture: if G is a group of homeomorphisms of X, the inclusion map of G into $\text{Homeo}(X)$ is an action of G on X. Conversely, if σ is an injective homeomorphism from G to $\text{Homeo}(X)$ (we say σ is a *faithful* action of G on X), then G can be identified with the group $\sigma(G)$ of homeomorphisms of X. The group action picture is slightly more general since group actions need not be faithful (in the theory of group representations () it turns out to be important to allow nonfaithful representations). The conceptual importance of the group action picture is that the group G can be considered abstractly and is not *a priori* tied to homeomorphisms of a particular space, and it is useful to let the same abstract group act on many different spaces.

Group actions of groups on sets can be similarly defined with no relation to topology: just consider homomorphisms from a group to the group of bijections (permutations) of the set. This can be regarded as a special case of group actions of groups on topological spaces where the space has the discrete topology.

Actions of topological groups on topological spaces are also considered (). In this section, we will not consider the case of topological groups (or, alternatively, we will give all groups the discrete topology).

Orbits

XIII.9.3.4. DEFINITION. Let σ be an action of a group G on a topological space X, and $x \in X$. The *orbit* of x under G (or σ) is the set

$$[x] = \{g \cdot x : g \in G\} = \{\sigma_g(x) : g \in G\} \ .$$

Of course, $x \in [x]$ since $x = e \cdot x$. The crucial fact about orbits is that they form a partition of the space:

XIII.9.3.5. PROPOSITION. Let σ be an action of a group G on a topological space X. If $x, y \in X$, then either $[x] = [y]$ or $[x]$ and $[y]$ are disjoint. Equivalently, the relation $x \sim y$ if $[x] = [y]$ is an equivalence relation on X.

PROOF: Suppose $z \in [x] \cap [y]$. Then there are $g, h \in G$ with $z = g \cdot x$ and $z = h \cdot y$. Then $y = h^{-1} \cdot z = (h^{-1}g) \cdot x$, and similarly $x = (g^{-1}h) \cdot y$, so $[x] = [y]$.

XIII.9.3.6. Thus, if σ is an action of a group G on a topological space X, we may form the quotient space X/σ of orbits, called the *orbit space* of the action, and give it the quotient topology. The orbit space is also often written X/G, especially if G is given concretely as a group of homeomorphisms of X, although this notation conflicts with the notation for identification spaces (XIII.9.1.1.). 

Many interesting topological spaces can be constructed as orbit spaces of group actions:

XIII.9.3.7. EXAMPLES. (i) Let X be the unit circle in $\mathbb{R}^2$. The set consisting of the identity and reflection across the x-axis is a group of homeomorphisms of X. Each orbit consists of two points except for $[(1,0)]$ and $[(-1,0)]$, which are singletons. The orbit space is homeomorphic to the closed interval $[-1,1]$, and the quotient map can be identified with projection onto the x-axis.

(ii) Let $\mathbb{Z}$ act on $\mathbb{R}$ by translation: $n \cdot x = x + n$. Each orbit contains a unique point in the interval $(0,1]$. But the quotient topology is not the subspace topology on $(0,1]$: for example, we have $\left[\frac{1}{n}\right] \to [0] = [1]$. In fact, the quotient space $\mathbb{R}/\mathbb{Z}$ is homeomorphic to the circle obtained from $[0,1]$ by identifying 0 and 1.

(iii) Let X be the unit sphere S^{n-1} in $\mathbb{R}^n$. The set consisting of the identity and the antipodal map $\boldsymbol{x} \mapsto -\boldsymbol{x}$ is a group of homeomorphisms of S^{n-1}. Every orbit has two points. The quotient space consists of S^{n-1} with antipodal points identified, and is called *real projective* $(n-1)$*-space*, denoted $\mathbb{R}P^{n-1}$. If $n = 3$, we obtain the (real) projective plane (XIII.9.2.3.). If $n = 2$, we obtain the quotient of the circle by the antipodal map, which is a (smaller) circle. Note that this action of $\mathbb{Z}_2$ on the circle is very different from the action in (i).

(iv) We may also define complex projective space. Let $\mathbb{T}$ be the multiplicative group of complex numbers of absolute value 1. Regard S^{2n-1} as the unit sphere in $\mathbb{C}^n$. Then $\mathbb{T}$ acts on S^{2n-1} by $\lambda \cdot \boldsymbol{x} = \lambda \boldsymbol{x}$. The quotient $S^{2n-1}/\mathbb{T}$ is called *complex projective* n*-space*, denoted $\mathbb{C}P^{n-1}$. It is a $(2n-2)$-dimensional manifold.

Projective spaces can also be described in other ways. $\mathbb{R}P^n$ can be described as the set of lines through the origin in $\mathbb{R}^{n+1}$, the quotient of $\mathbb{R}^{n+1} \setminus \{\mathbf{0}\}$ by identifying two points if they lie on the same line through $\mathbf{0}$. Each such line contains exactly two points on the unit sphere, which are identified; this leads to the picture of $\mathbb{R}P^n$ as the closed upper hemisphere of S^n with antipodal points on the "equator" identified, the higher-dimension analog of the picture in XIII.9.2.3.(vii). Similarly, $\mathbb{C}P^n$ is the set of complex "lines" through the origin (one-dimensional complex subspaces) in $\mathbb{C}^{n+1}$.

$\mathbb{R}P^n$ can also be described as $\mathbb{R}^n$ with certain points at infinity added: identify $\boldsymbol{x} \in \mathbb{R}^n$ with the line through the origin and the point $(\boldsymbol{x}, 1) \in \mathbb{R}^{n+1}$ (or, equivalently, the equivalent point of norm 1 on the upper hemisphere of S^n). The points at infinity added to make $\mathbb{R}P^n$ can be regarded as "lines at infinity," which form a copy of $\mathbb{R}P^{n-1}$. There is a similar description for $\mathbb{C}P^n$ as $\mathbb{C}^n$ with "complex lines at infinity" added (a copy of $\mathbb{C}P^{n-1}$). These pictures are the origin of the name "projective space."

(v) The 3-sphere S^3 can be regarded as the unit sphere in $\mathbb{C}^2$:

$$S^3 = \{(z,w) \in \mathbb{C}^2 : |z|^2 + |w|^2 = 1\} .$$

Fix $p > 1$ and let $\lambda = e^{2\pi i/p}$. Then λ is a complex number of absolute value 1, and $\lambda^p = 1$. Define a faithful action of $\mathbb{Z}_p$ (or a nonfaithful action of $\mathbb{Z}$) on S^3 by

$$k \cdot (z,w) = (\lambda^k z, \lambda^k w) .$$

The quotient space $S^3/\mathbb{Z}_p$ is called a *lens space*. If $p = 2$, we obtain $\mathbb{R}P^3$. More generally, if q is an integer relatively prime to p (we may restrict to $0 < q < p$), we can define the action by

$$k \cdot (z,w) = (\lambda^k z, \lambda^{qk} w) .$$

The lens spaces obtained, denoted $L(p,q)$, $L(p;q)$, or $L_{q/p}$, depend rather subtly on p and q: they can be homotopy equivalent without being homeomorphic, and, although orientable, can fail to have orientation-reversing homeomorphisms (). Lens spaces can also be constructed by gluing two solid tori along their boundary (); see [Mun84] for another construction of lens spaces by identifying points on the boundary of B^3, or [Thu97] for more constructions and an explanation of why these are called "lens spaces."

Homogeneous Spaces

XIII.9.3.8. A simple but particularly important example of a group action is when the space X is a topological group and G is a subgroup of X. A topological group acts on itself by (right) translation (), and so does any subgroup, i.e. $g \cdot x = xg^{-1}$ for $g \in G$, $x \in X$ (this formula with the inverse is needed to make $(gh) \cdot x = g \cdot (h \cdot x)$ for $g, h \in G$, $x \in X$). The orbit space X/G, which is the space of left cosets () of G in X, with the quotient topology is called a *homogeneous space*. (There is additional structure here: the group X acts on X/G by left translation. If G is a normal subgroup of X, then X/G is also a topological group.) The quotient space has reasonable properties, e.g. is Hausdorff, only when G is a closed subgroup of X (cf. Exercise XIII.9.5.1.). The simplest case is when G is a closed discrete subgroup.

Example XIII.9.3.7.(ii) is a basic example of this construction. A closely related example is to take $X = \mathbb{R}^n$ and $G = \mathbb{Z}^n$ the additive subgroup of integer points; the quotient is the n-torus $\mathbb{T}^n$, which is a product of n circles. In the case $n = 2$ we obtain the ordinary torus (XIII.9.2.3.(v)); higher-dimensional tori can be similarly constructed by identifying opposite faces of an n-cube.

XIII.9.3.9. The lens spaces $L(p, 1)$ (XIII.9.3.7.(v)) are another example. The topological group $SU(2)$ (also isomorphic to $Sp(1)$ and to the multiplicative group of unit quaternions) is homeomorphic to S^3, and we can take the quotient by the cyclic subgroup generated by $diag(\lambda, \bar{\lambda})$. Other lens spaces do not arise as homogeneous spaces of $SU(2)$.

$SU(2)$ has other interesting finite subgroups, perhaps the most interesting of which is the *binary icosahedral group*, which covers the group of rigid motions of a regular icosahedron centered at the origin (a subgroup of $SO(3)$, which is a quotient of $SU(2)$); the quotient of $SU(2) \cong S^3$ by this group is called the *Poincaré homology sphere*, a closed 3-manifold with the same homology as S^3 but not homeomorphic to S^3 (it is not simply connected; its fundamental group is the binary icosahedral group, a group of order 120 with no nontrivial abelian quotients). The Poincaré homology sphere can also be constructed from a regular dodecahedron by identifying opposite faces with an appropriate twist (). See [Thu97] and [Wee02] for a nice description and for many other examples of 3-manifolds obtained from polyhedra by gluing faces (cf. XIII.9.5.6.).

Stabilizers and Freeness

XIII.9.4. Local Homeomorphisms and Covering Maps

XIII.9.5. Exercises

XIII.9.5.1. (a) Let $X = \mathbb{R}$ and $A = \mathbb{Q}$, and consider the identification space X/A. Show that all the conclusions of XIII.9.1.2. fail, and X/A is not T_1. Is X/A T_0?

(b) Let $\mathbb{R}/\mathbb{Q}$ be the homogeneous space (XIII.9.3.8.) considering $\mathbb{Q}$ as an additive subgroup of $\mathbb{R}$. Show that $\mathbb{R}/\mathbb{Q}$ is the space of XIII.8.1.11., and thus has the indiscrete topology.

Note that, although the notation $\mathbb{R}/\mathbb{Q}$ is used in both (a) and (b), the spaces are quite different.

XIII.9.5.2. Figures XIII.12 and XIII.13 show orientable closed surfaces. By the classification, each is homeomorphic to S^2 with some number of handles. Find the number of handles (genus), and describe a homeomorphism. (There are not only homeomorphisms, but even isotopies; cf. https://www.youtube.com/watch?v=k8Rxep2Mkp8.)

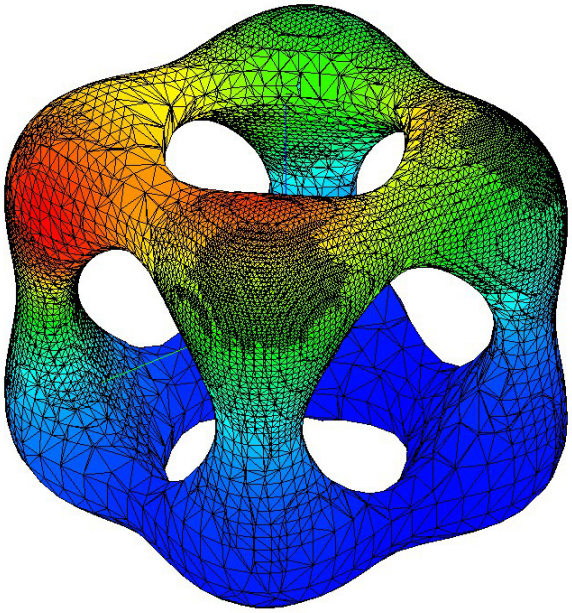

Figure XIII.12: An orientable closed surface.

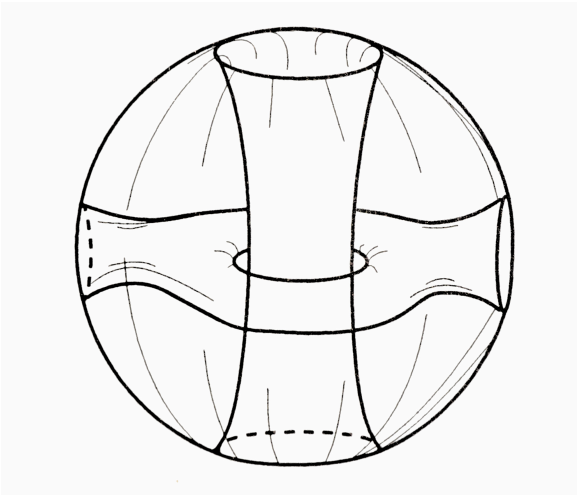

Figure XIII.13: Another orientable closed surface.

XIII.9.5.3. (a) Show that $\mathbb{R}P^2\#\mathbb{R}P^2$ is homeomorphic to the Klein bottle K.

(b) Show that $\mathbb{R}P^2\#K$ is homeomorphic to $\mathbb{R}P^2\#T^2$, and hence $\mathbb{R}P^2\#T^2$ is homeomorphic to $\mathbb{R}P^2\#\mathbb{R}P^2\#\mathbb{R}P^2$.

(c) Show that $\mathbb{R}P^2$ with n handles attached is homeomorphic to the connected sum of $2n+1$ copies of $\mathbb{R}P^2$, and that K with n handles attached is homeomorphic to the connected sum of $2n+2$ copies of $\mathbb{R}P^2$.

XIII.9.5.4. Let P be a polygon with $2n$ sides, which we may take to be a regular polygon. A *gluing scheme* on P consists of a choice of an orientation and a labeling of each edge of P, such that each label names exactly two edges. A gluing scheme defines a gluing of P by gluing each pair of edges with the same label according to the designated orientation. For example, the gluing scheme of Figure XIII.5 gives a Klein bottle when glued.

(a) Show that the gluing scheme of Figure XIII.14 gives a two-holed torus.

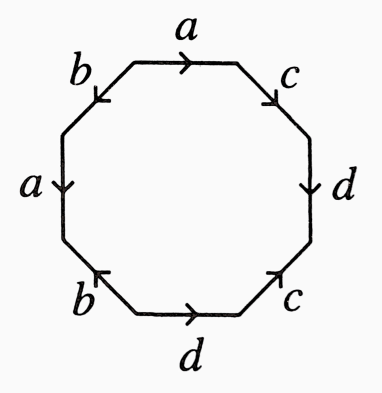

Figure XIII.14: Gluing scheme for a two-holed torus.

(b) Show that the gluing schemes of Figure XIII.15 both give S^2 when glued.

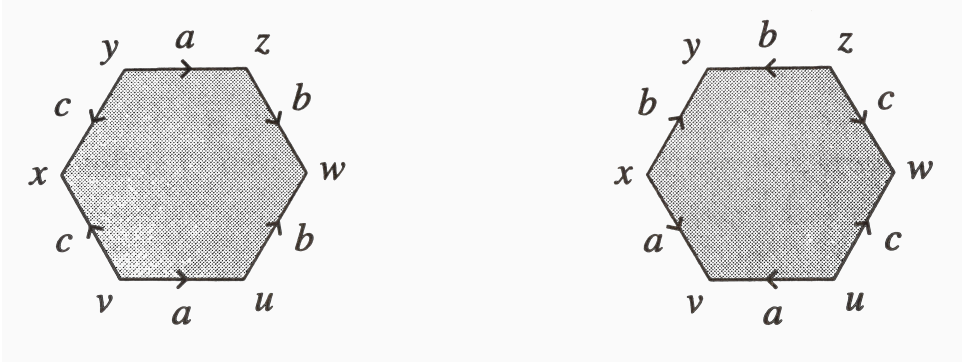

Figure XIII.15: Gluing schemes for a sphere.

(c) Show that in any gluing scheme, two consecutive edges with the same label and opposite orientations can be eliminated. [Fold them into the interior of the polygon.]

(d) Show that if a gluing scheme contains a labeled pair of edges with the same orientation (with respect to the boundary circle), then the glued space contains a Möbius strip. [See Figure XIII.16.] Thus the glued space is not orientable.

(e) Show that if all pairs of glued edges have opposite orientations, a sphere with some number of handles (perhaps none) is obtained from the gluing.

(f) In the situation of (d), show that the glued space consists of adding a cross-cap to a glued space from a polygon with fewer sides. Conclude by induction that the glued space is a connected sum of projective planes, or, equivalently, a sphere with a number of cross-caps added (cf. Exercise XIII.9.5.3.).

(g) Conclude from (e) and (f) that the glued space is always a closed surface which is either a sphere with handles attached if orientable, or a sphere with cross-caps attached (a connected sum of projective planes) if nonorientable. Show that every such surface can be obtained this way (although the polygon and gluing scheme are not unique).

(h) Show that if a connected closed surface can be triangulated (), it can be represented as the gluing of a polygon by a gluing scheme. Since every 2-manifold can be triangulated, every connected closed surface (2-manifold) is of the form of (g).

(i) Show that no two of the surfaces of (g) with different numbers of handles or projective planes are homeomorphic (). Thus (g) gives a complete classification of closed 2-manifolds.

See [Mas77] (or [Mas91]), or [Blo97] (from which the above pictures are taken), for a nice almost complete discussion of the classification of closed 2-manifolds. See [Tho92] for a different approach, and [FW99] or [Wee02] for a modern proof due to J. Conway. (Note that these proofs are all incomplete since they use the nontrivial fact that every surface can be triangulated, first proved by T. Radó in 1925 [**?**], cf. [AS60]. For a short proof of triangulability see [DM68] or [Tho92], and `http://arxiv.org/pdf/1312.3518.pdf` for a different argument not using the Jordan-Schönflies Theorem. See [Ber03, p. 139] for a simple approach to triangulating a compact surface using Riemannian geometry.) For a complete classification of connected noncompact (triangulable) surfaces, see [Ric63].

XIII.9.5.5. (a) Let $X = [0,1]$, $n \in \mathbb{N}$, $A_n = \left\{\frac{k}{n} : 0 \le k \le n\right\}$. Show that X/A_n is a bouquet of n circles. In particular, X/A_2 is a figure 8. Show that X/A_n is the one-point compactification of the disjoint union of n open intervals (copies of $\mathbb{R}$).

(b) Let $X = [0,1]$, $A_\omega = \{0\} \cup \left\{\frac{1}{n} : n \in \mathbb{N}\right\}$. Show that X/A_ω is homeomorphic to the Hawaiian earring (XIII.19.5.8.). Show that X/A_ω is the one-point compactification of the disjoint union of $\aleph_0$ open intervals (copies of $\mathbb{R}$).

(c) Let K be the Cantor set. Show that the quotient $[0,1]/K$ is also homeomorphic to the Hawaiian earring. [The complement is a countable disjoint union of open intervals.] What about the quotient by identifying other compact subsets of $[0,1]$?

XIII.9.5.6. [Thu97] Identify the faces of two solid tetrahedra as in Figure XIII.16 (there is a unique identification consistent with the picture). Note that the six thick edges are all identified together, as are the six thin edges and all eight vertices.

(a) Show that every point of the identification space X has a neighborhood homeomorphic to $\mathbb{R}^3$ except the point v coming from the vertices. Thus, if $Y = X \setminus \{v\}$, then Y is a (noncompact) 3-manifold. If Z is X

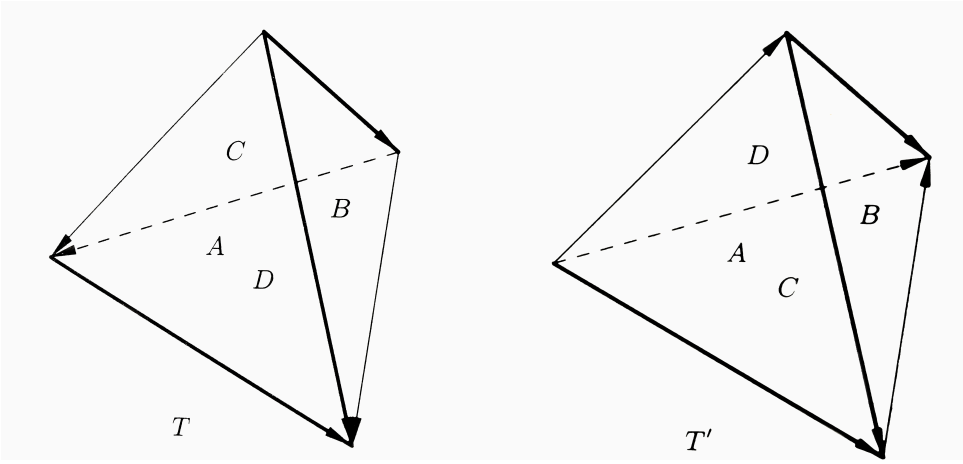

Figure XIII.16: Gluing scheme for two tetrahedra.

with a suitable small open neighborhood of v removed, then $Z \subseteq Y$ is a compact 3-manifold with boundary homeomorphic to a 2-torus, and there is a deformation retraction of Y onto Z.

(b) Show that Y is homeomorphic to the complement in S^3 of a figure 8 knot (), and Z is the complement of a tubular neighborhood of the knot.

(c) [Thu97, p. 129-132] Show similarly that there are two gluing schemes on a pair of octahedra with vertices removed, which respectively give the complement in S^3 of the Whitehead link (XIII.19.6.8.) and the Borromean rings (XIII.19.6.4.). Generalize.

XIII.9.5.7. [Eng89, 1.6.18] Consider the quotient space X obtained from $\mathbb{R}$ by collapsing $\mathbb{Z}$ to a point z (in the notation of XIII.9.1.1., this is $\mathbb{R}/\mathbb{Z}$, but this notation is generally reserved for the quotient group $\mathbb{T}$ as in XIII.9.3.8., quite a different space.)

(a) Show that X is perfectly normal (XIII.10.6.11.). In particular, $\{z\}$ is a G_δ.

(b) Show that z does not have a countable local base. Thus X is not first countable.

(c) Show that X is a Fréchet-Urysohn space (XIII.3.5.2.).

(d) Describe the topological differences, if any, between this space, the Hawaiian earring (XIII.19.5.8.), the space of XIII.19.5.9., an infinite wedge of circles (), and the one-point compactification of a countable separated union of copies of $\mathbb{R}$ (cf. XIII.9.5.8.).

XIII.9.5.8. (a) As a special case of XIII.8.5.1.(a), show that collapsing subsets of a space can be done in two or more steps: if (A_j) and (B_k) respectively are families of pairwise disjoint subsets of a topological space X and each A_j is a union of B_k's, the quotient space of X obtained by collapsing each A_j to a (separate) point can be obtained by first collapsing the B_k to (separate) points and then collapsing the set of points corresponding to each A_j to a point.

(b) As a special case, let X be a countable separated union of copies of $[0, 1]$, indexed by $\mathbb{Z}$. First identify the endpoints of the n'th interval to a single point $*_n$ to obtain a separated union of circles with distinguished

point. Then identify all the $*_n$ to a single point. Show that an infinite wedge of circles is obtained.

(c) On the other hand, first identify the right endpoint of the n'th interval with the left endpoint of the $(n+1)$'st interval for each n. Show that the quotient space is homeomorphic to $\mathbb{R}$ with the identified points corresponding to $\mathbb{Z}$. Then identify these points together to obtain the space from XIII.9.5.7..

(c) Conclude that both the space of XIII.9.5.7. and a (countably) infinite wedge of circles are homeomorphic to the quotient of X obtained by identifying all endpoints of all the intervals together to one point, and, in particular, the first two spaces are homeomorphic.

XIII.9.5.9. Let X and Y be compact Hausdorff spaces, A a closed subset of X, and f a continuous function from A onto a (necessarily closed) subset B of Y.

(a) Use XIII.8.3.13. to show that f is a quotient map from A to B.

(b) Show that the quotient map π from the separated union of X and Y to $X \cup_f Y$ is usc. [Adapt the proof of XIII.9.1.8..]

(c) Conclude that $X \cup_f Y$ is compact and Hausdorff. [Use XIII.8.3.8..]

XIII.9.5.10. Let X and Y be topological spaces, and $f : X \to Y$ a continuous function. Let A be the (closed) subspace $X \times \{1\}$ of $X \times [0,1]$, and define $g : A \to Y$ by $g((x,1)) = f(x)$. The identification space $(X \times [0,1]) \cup_g Y$ is called the *mapping cylinder* of f.

(a) Show that if X and Y are normal and f is a quotient map from X to $f(X)$, then the mapping cylinder of f is also normal.

(b) Show that if X and Y are compact Hausdorff spaces, so is the mapping cylinder of any map from X to Y. [Use XIII.8.3.13..]

(c) The *mapping torus* of $f : X \to Y$ is the space obtained from the mapping cylinder by identifying $(x,0)$ with $(f(x),1)$ for every $x \in X$. Show that the conclusions of (a) and (b) hold also for the mapping torus under the hypotheses there. The flow under a constant function (XIII.9.2.3.(ix)) is the mapping torus of the homeomorphism.

XIII.9.5.11. Let X be a metrizable space, and A a closed subspace of X. Show that the identification space X/A embeds in the cone CX over X. [Let ρ be a metric for X with $diam(X) = 1$ (), and identify $x \in X$ with $(x, 1 - \rho(x, A))$.]

XIII.10. Metrizable Spaces

Although the notion of topological space was designed to abstract the concept of a metric space in order to take specific reference to a metric out of the picture, metrizable spaces (topological spaces whose topology comes from a metric) have some nice properties not shared by more general topological spaces, and it is useful to know which topological spaces are metrizable. In this section we give (partial) answers to this question and pursue some of the special properties of metrizable spaces. Completely metrizable spaces (ones whose topology comes from a complete metric) are especially important and also have intrinsic characterizations.

Note that a metrizable space is *not* the same thing as a metric space: a metrizable space is a topological space for which there *exists* a metric (which is highly non-unique) giving the topology. A metric space can be regarded as a (metrizable) topological space with a specified metric giving its topology.

XIII.10.1. Metrizability

It is a nontrivial problem to determine exactly when a topology comes from a metric, i.e. when a topological space is metrizable. Necessary conditions are that the space be first countable and completely normal (XIII.10.1.2.), but these are not sufficient (). (Note that any subspace of a metrizable space is metrizable).

The first observation is that a metric space (X, ρ) is Hausdorff: if $x, y \in X$ $x \neq y$, and $\epsilon = \frac{\rho(x,y)}{3}$, then $B_\epsilon(x)$ and $B_\epsilon(y)$ are disjoint neighborhoods of x and y. We also have the following strengthening of T_4:

XIII.10.1.1. Proposition. Let X be a metrizable space, $A, B \subseteq X$ with $\bar{A} \cap B = A \cap \bar{B} = \emptyset$ (such A and B are said to be *separated*). Then A and B have disjoint open neighborhoods in X.

Proof: Let ρ be a metric on X defining the given topology. The conditions on A and B are equivalent to: $\rho(x, B) > 0$ for all $x \in A$ and $\rho(x, A) > 0$ for all $x \in B$. Set

$$U = \{x \in X : \rho(x, A) < \rho(x, B)\}$$

$$V = \{x \in X : \rho(x, B) < \rho(x, A)\}$$

and note that $A \subseteq U$, $B \subseteq V$. An easy application of the triangle inequality shows that U and V are open, and they are obviously disjoint.

XIII.10.1.2. A T_1 topological space satisfying the conclusion of this proposition is called *completely normal*. A completely normal space is obviously normal. A topological space X is completely normal if and only if every subspace of X is normal (XIII.10.6.11.), and thus a completely normal space is sometimes called *hereditarily normal*. This property is also sometimes called T_5.

The first metrization theorem, and still probably the most useful, was due to Urysohn in [Ury25b]:

XIII.10.1.3. Theorem. [Urysohn Metrization Theorem] Every second countable regular topological space is metrizable.

Proof: A second countable regular space is Lindelöf (XIII.1.3.5.), hence normal (XIII.7.6.12.).

Let X be a second countable regular (hence normal) space, and let $\mathcal{U}$ be a countable base for the topology of X. For each pair (U, V) of sets in $\mathcal{U}$ with $\bar{V} \subseteq U$, let f_{UV} be a continuous function from X to $[0, 1]$ which is 1 on $\bar{V}$ and 0 on U^c; such a function exists by Urysohn's Lemma (XIII.7.6.13.). Let $\mathcal{C}$ be the set of all the f_{UV}. Then $\mathcal{C}$ is countable. If E is a closed set in X and $x \in X \setminus E$, then E^c is an open neighborhood of x, so there is a $U \in \mathcal{U}$ with $x \in U \subseteq E^c$. There is an open neighborhood W of x with $\bar{W} \subseteq U$ (XIII.7.5.1.), and there is a $V \in \mathcal{U}$ with $x \in V \subseteq W$. Then $\bar{V} \subseteq U$, and f_{UV} satisfies $f_{UV}(x) = 1$ and $f_{UV} = 0$ on E. Thus by the proof of XIII.7.8.4., X embeds into the cube $[0, 1]^{\mathcal{C}}$. Since $\mathcal{C}$ is countable, this cube is metrizable (). 👍

Note that the proof shows slightly more than the statement of the theorem: any second countable regular space embeds in the Hilbert cube ().

XIII.10.1.4. There are many other metrization theorems, some of which are quite recent, and there are now various known necessary and sufficient conditions for metrizability. We will state only one of these results here since too many additional definitions are required for the others, and the results are of limited use in analysis. See [SS95] or [Pea75] for a survey.

XIII.10.1.5. Theorem. [Nagata-Smirnov Theorem] [] A topological space $(X, \mathcal{T})$ is metrizable if and only if it is regular and has a sequence $(\mathcal{U}_n)$ of locally finite open covers (XIII.11.10.1.) whose union forms a base for $\mathcal{T}$ (such an X is *σ-locally finite*).

XIII.10.1.6. Corollary. [Dug78, p. 207] Let $(X, \mathcal{T})$ be a topological space. Then X is metrizable if and only if it is regular and has a sequence $(\mathcal{U}_n)$ of open covers such that if $\mathcal{V}$ is any finite open cover of X, $\mathcal{U}_n$ refines $\mathcal{V}$ for some n.

Metrization of Products and Separated Unions

It is fairly obvious that a finite product of metrizable spaces is metrizable (). It is not true that an arbitrary product of metrizable spaces is metrizable; an uncountable product of nontrivial Hausdorff spaces is not even first countable (XIII.6.3.2.). But a *countable* product of metrizable spaces is metrizable. And an arbitrary separated union of metrizable spaces is metrizable.

The technical device giving a simple proof of both facts is:

XIII.10.1.7. Proposition. Let ρ be a metric on a set X. Then there is a uniformly equivalent metric $\tilde{\rho}$ on X with $\tilde{\rho}(x, y) \leq 1$ for all $x, y \in X$. If ρ is complete, then $\tilde{\rho}$ is complete.

Proof: There are two standard ways to construct such a metric. One way to do it is to set

$$\tilde{\rho}(x, y) = \frac{\rho(x, y)}{1 + \rho(x, y)} \ .$$

The triangle inequality needs proof for this metric, which is nontrivial but not difficult (see below). There is, however, a different low-tech way to define $\tilde{\rho}$ which is perhaps less elegant but does the trick more simply: let

$$\tilde{\rho}(x,y) = \min(\rho(x,y), 1) \ .$$

Proving the triangle inequality for this version of $\tilde{\rho}$ is just a trivial case-by-case verification. For either definition, we have $\tilde{\rho}(x,y) \leq \rho(x,y)$ for all $x, y \in X$ and $\rho(x,y) \leq 2\tilde{\rho}(x,y)$ if $\rho(x,y) \leq 1$, from which it follows easily that ρ and $\tilde{\rho}$ are uniformly equivalent. Since uniformly equivalent metrics have the same Cauchy sequences, the completeness statement follows.

For the reader's edification, we give a proof of the triangle inequality for the metric

$$\tilde{\rho}(x,y) = \frac{\rho(x,y)}{1+\rho(x,y)} \ .$$

The proof is not difficult, but requires a little trick. Let $x, y, z \in X$. We may assume $x \neq z$. Then

$$\tilde{\rho}(x,z) = \frac{\rho(x,z)}{1+\rho(x,z)} = \frac{1}{\frac{1}{\rho(x,z)}+1} \leq \frac{1}{\frac{1}{\rho(x,y)+\rho(y,z)}+1}$$

$$= \frac{\rho(x,y)+\rho(y,z)}{1+\rho(x,y)+\rho(y,z)} = \frac{\rho(x,y)}{1+\rho(x,y)+\rho(y,z)} + \frac{\rho(y,z)}{1+\rho(x,y)+\rho(y,z)}$$

$$\leq \frac{\rho(x,y)}{1+\rho(x,y)} + \frac{\rho(y,z)}{1+\rho(y,z)} = \tilde{\rho}(x,y) + \tilde{\rho}(y,z) \ .$$

XIII.10.1.8. THEOREM. A countable product of metrizable spaces is metrizable in the product topology. A countable product of completely metrizable spaces is completely metrizable.

PROOF: Let (X_k) be a sequence of metrizable spaces, and for each k let ρ_k be a metric on X_k giving the topology on X_k, with the property that $\rho_k(x,y) \leq 1$ for all $x, y \in X_k$, with ρ_k complete if X_k is completely metrizable (XIII.10.1.7.).

On $X = \prod_{k\in\mathbb{N}} X_k$, define

$$\rho(x,y) = \sum_{k=1}^{\infty} 2^{-k}\rho_k(x_k, y_k)$$

for $x = (x_1, x_2, \dots)$ and $y = (y_1, y_2, \dots)$ in X. Note that the infinite series converges absolutely for any x, y. It is simple and routine to verify that ρ is a metric on X. So we need to show that ρ defines the product topology. It suffices to show that, for fixed $x = (x_1, x_2, \dots) \in X$, every ρ-ball around x contains an open rectangle around x, and conversely.

Let $\epsilon > 0$. Fix n with $2^{-n+1} < \epsilon$. Then

$$B^{\rho_1}_{\epsilon/2}(x_1) \times B^{\rho_2}_{\epsilon/2}(x_2) \times \cdots \times B^{\rho_n}_{\epsilon/2}(x_n) \times \prod_{k=n+1}^{\infty} X_k$$

is an open rectangle in X containing x and contained in $B^\rho_\epsilon(x)$: if $y = (y_1, y_2, \dots) \in X$ with $\rho_k(x_k, y_k) < \frac{\epsilon}{2}$ for $1 \le k \le n$, then

$$\sum_{k=1}^{\infty} 2^{-k}\rho_k(x_k, y_k) = \sum_{k=1}^{n} 2^{-k}\rho_k(x_k, y_k) + \sum_{k=n+1}^{\infty} 2^{-k}\rho_k(x_k, y_k) < \frac{\epsilon}{2}\sum_{k=1}^{n} 2^{-k} + \sum_{k=n+1}^{\infty} 2^{-k} < \frac{\epsilon}{2} + 2^{-n} < \epsilon \ .$$

Conversely, if

$$V = U_1 \times U_2 \times \cdots U_m \times \prod_{k=n+1}^{\infty} X_k$$

is an open rectangle containing x, for $1 \le k \le m$ there is an ϵ_k such that $B^{\rho_k}_{\epsilon_k}(x_k) \subseteq U_k$. Set

$$\epsilon = \min(\epsilon_1/2, \epsilon_2/4, \dots, 2^{-m}\epsilon_m) \ .$$

If $y = (y_1, y_2, \dots) \in X$ with $\rho(x, y) < \epsilon$, then, for $1 \le k \le m$

$$\rho_k(x_k, y_k) < 2^k\rho(x, y) < 2^k\epsilon \le \epsilon_k$$

so $y \in V$, i.e. $B^\rho_\epsilon(x) \subseteq V$.

If $(x^{(n)}) = ((x^{(n)}_k))$ is a Cauchy sequence in (X, ρ), the last inequality shows that $(x^{(n)}_k)$ is a Cauchy sequence in (X_k, ρ_k) for each k. If each ρ_k is complete, then these sequences all converge, and hence $(x^{(n)})$ also converges, so ρ is complete. 👍

This proof requires the Countable AC (but only to choose the ρ_k).

XIII.10.1.9. Proposition. An arbitrary separated union () of metrizable spaces is metrizable. An arbitrary separated union of completely metrizable spaces is completely metrizable.

Proof: Let $\{X_i : i \in I\}$ be a collection of metrizable spaces. Fix a metric ρ_i on X_i for each i giving the topology on X_i, with the property that $\rho_i(x, y) \le 1$ for all $x, y \in X_i$, with ρ_i complete if X_i is completely metrizable (XIII.10.1.7.). Let X be the separated union of the X_i. For $x, y \in X$, set $\rho(x, y) = \rho_i(x, y)$ if x and y are both in the same X_i, and $\rho(x, y) = 1$ otherwise. It is easily checked that ρ is a metric giving the topology of X, and that ρ is complete if each ρ_i is. 👍

This proof uses the AC; the case of I countable requires the Countable AC.

Metrizability of Compact Hausdorff Spaces

XIII.10.1.10. Theorem. Let X be a compact Hausdorff space. The following are equivalent:

(i) X is metrizable.

(ii) X is second countable.

(iii) X embeds in the Hilbert cube.

(iv) $C_{\mathbb{R}}(X)$ is separable (for the uniform norm).

PROOF: (i) ⇒ (ii): Let d be a metric on X. (X, d) is totally bounded, hence separable, and a separable metric space is second countable.

(ii) ⇒ (iii): Let $\{U_n : n \in \mathbb{N}\}$ be a countable base for the topology. For each n, m with $\bar{U}_n \subseteq U_m$, let $f_{n,m}$ be a continuous function from X to $[0, 1]$ with $f = 1$ on $\bar{U}_n$ and $f = 0$ on U_m^c (there is such an $f_{n,m}$ by Urysohn's Lemma since X is normal). Set $I = \{(n, m) : \bar{U}_n \subseteq U_m\} \subset \mathbb{N}^2$ and $Y = [0, 1]^I$ with the product topology. Then Y is homeomorphic to the Hilbert cube (unless I is finite). Define $\phi : X \to Y$ by $\phi(x)_{(n,m)} = f_{n,m}(x)$. Then ϕ is continuous by the coordinatewise criterion since each $f_{n,m}$ is continuous. If $x_1, x_2 \in X$, $x_1 \neq x_2$, let V be a neighborhood of x_1 not containing x_2, U_m a basic neighborhood of x_1 contained in V, and U_n a basic neighborhood of x_1 with $\bar{U}_n \subseteq U_m$ (there is such a U_n since X is regular). Then $f_{n,m}(x_1) = 1$ and $f_{n,m}(x_2) = 0$, so $\phi(x_1) \neq \phi(x_2)$ and thus ϕ is one-to-one. To show ϕ is a homeomorphism onto its image, suppose (x_i) is a net in X and $\phi(x_i) \to \phi(x)$ for some $x \in X$. If $x_i \not\to x$, then there is a neighborhood V of x which does not contain any x_i for a cofinal set of i. As in the previous part of the proof, there are n, m such that $x \in U_n \subseteq \bar{U}_n \subseteq U_m \subseteq V$; then $f_{n,m}(x) = 1$ but $f_{n,m}(x_i) = 0$ for i in a cofinal set, contradicting that $\phi(x_i) \to \phi(x)$. Thus $x_i \to x$.

(iii) ⇒ (i) since the Hilbert cube is metrizable.

(iii) ⇒ (iv): note first that $C_{\mathbb{R}}(\mathbb{H})$ is separable: polynomials in the coordinates with rational coefficients are dense by the Stone-Weierstrass Theorem. $C_{\mathbb{R}}(X)$ is a quotient of $C_{\mathbb{R}}(\mathbb{H})$ by restriction of functions (this map is surjective by the Tietze Extension Theorem), so $C_{\mathbb{R}}(X)$ is also separable.

(iv) ⇒ (iii): if $C_{\mathbb{R}}(X)$ is separable, the set $\mathcal{G}$ of continuous functions from X to $[0, 1]$ is also separable in the topology of uniform convergence. Let $\mathcal{F}$ be a countable dense subset of $\mathcal{G}$, and let $Y = [0, 1]^{\mathcal{F}}$. Then Y is homeomorphic to the Hilbert cube. Define $\phi : X \to Y$ by $\phi(x)_f = f(x)$. If $x \in X$ and V is any neighborhood of x, there is a $g \in \mathcal{G}$ with $g(x) = 1$ and $g = 0$ on V^c since X is completely regular, and g can be uniformly approximated arbitrarily closely by an $f \in \mathcal{F}$. The proof that ϕ is a homeomorphism onto its image is then almost identical to the proof of (ii) ⇒ (iii). 👍

XIII.10.1.11. COROLLARY. Let X and Y be compact Hausdorff spaces. If X is metrizable and there is a continuous function from X onto Y, then Y is also metrizable.

PROOF: Let $\phi : X \to Y$ be surjective. Then $f \mapsto f \circ \phi$ embeds $C_{\mathbb{R}}(Y)$ as a subspace of $C_{\mathbb{R}}(X)$. Since $C_{\mathbb{R}}(X)$ is separable and metrizable, so is $C_{\mathbb{R}}(Y)$. 👍

XIII.10.1.12. Note that the normed algebra $C(X)$ of complex-valued continuous functions on X is separable if and only if $C_{\mathbb{R}}(X)$ is separable. Thus, if X is a compact Hausdorff space, $C(X)$ is separable if and only if X is metrizable.

XIII.10.1.13. Compactness is essential in this result: it fails in general even if X is locally compact and second countable, and Y is perfectly normal. There is a countable perfectly normal space Y which is not first countable (), hence not metrizable, and Y is a continuous image of $\mathbb{N}$ with the discrete topology. There is even a counterexample if f is a closed map (XIII.9.5.7.). The problem seems to be that a single point can be a G_δ even if the point does not have a countable neighborhood base, which cannot happen in a compact space (XIII.11.4.6.).

XIII.10.2. Continuity and Oscillation

We can generalize the notion of oscillation discussed in ().

XIII.10.2.1. DEFINITION. Let X be a set, (Y, σ) a metric space, and $f : X \to Y$ a function.
(i) If $\emptyset \neq A \subseteq X$, define the *oscillation of f on A* to be

$$\omega(f, A) = \sup sigma(f(x_1), f(x_2)| : x_1, x_2 \in A\} \in [0, +\infty] \ .$$

(ii) If X is a topological space and $x \in X$, define the *oscillation of f at x* to be

$$\omega(f, x) = \inf\{\omega(f, U) : U \text{ a neighborhood of } x\} \in [0, +\infty] \ .$$

The next characterization is obvious.

XIII.10.2.2. PROPOSITION. Let X be a topological space, (Y, σ) a metric space, and $f : X \to Y$. Then f is continuous at $x \in X$ if and only if $\omega(f, x) = 0$.

XIII.10.2.3. The oscillation of a function depends on the metric on Y. However, if the metric is replaced by an equivalent metric, whether the oscillation of a function on a set or at a point is zero or not does not change. Thus in XIII.10.2.2., the requirement that Y be a metric space can be relaxed to just the requirement that Y be metrizable. This makes sense since continuity of f depends only on the topology of Y, not on the specific metric.

The next observation has important consequences:

XIII.10.2.4. COROLLARY. Let X be a topological space, (Y, σ) a metric space, and $f : X \to Y$. Then the set of points of X at which f is continuous is a G_δ.

PROOF: It is easy to check that $\{x \in X : \omega(f, x) < \epsilon\}$ is open in X for any $\epsilon > 0$. 👍

If (in the case where X is a topological space) the function f is only defined on a subset A of X, we can extend the definition of oscillation at a point as follows:

XIII.10.2.5. DEFINITION. Let X be a topological space, (Y, σ) a metric space, $A \subseteq X$, and $f : A \to Y$ a function. Let $x \in \bar{A}$. Then the *oscillation* of f at x is

$$\omega(f, x) = \inf\{\omega(f, U \cap A) : U \text{ a neighborhood of } x\} \in [0, +\infty] \ .$$

Note that this definition only makes sense if $x \in \bar{A}$, since otherwise there will be a neighborhood U of x with $U \cap A = \emptyset$.

Corollary XIII.10.2.4. extends to this situation:

XIII.10.2.6. COROLLARY. Let X be a topological space, (Y, σ) a metric space, $A \subseteq X$, and $f : A \to Y$. Then the set of points x of $\bar{A}$ at which $\omega(f, x) = 0$ is a G_δ in $\bar{A}$ for the relative topology..

XIII.10.3. Completely Metrizable Spaces

Once metrizable spaces are characterized, there is a clean characterization of topological spaces which are homeomorphic to complete metric spaces (such spaces are called *completely metrizable*).

XIII.10.3.1. THEOREM. Let X be a topological space. The following are equivalent:

(i) X is completely metrizable.

(ii) X is metrizable, and whenever X is embedded in a completely metrizable space, it is a G_δ.

(iii) X is metrizable, and whenever X is embedded in a metrizable space, it is a G_δ.

XIII.10.3.2. It is trivial that (iii) $\Rightarrow$ (ii), and the converse is nearly trivial too: if X is embedded in a metrizable space Y, it is naturally embedded in the completion $\bar{Y}$. If (ii) holds, X is a G_δ in $\bar{Y}$, i.e. $X = \cap_n U_n$ for open sets U_n in $\bar{Y}$; but then $X = \cap_n (Y \cap U_n)$, so X is a G_δ in Y in the relative topology.

A topological space satisfying (ii) (hence (iii)) is called an *absolute* G_δ.

To prove the equivalence of (i) with (ii)–(iii), it is convenient to separate the two directions. Begin with (ii) $\Rightarrow$ (i):

XIII.10.3.3. PROPOSITION. Let X be a completely metrizable space, and E a G_δ in X. Then the relative topology on E is completely metrizable.

PROOF: Fix a complete metric ρ on X. Suppose E is a G_δ in X. We could simply write down an explicit formula for a complete metric on E giving the relative topology, but the formula is somewhat complicated and deserves some motivation.

Let U be an open subset of X, and for $x \in U$ define $g(x) = \frac{1}{\rho(x, U^c)}$. Then g is a continuous function from U to $\mathbb{R}$, and the graph

$$\Gamma = \{(x, g(x)) : x \in U\} \subseteq X \times \mathbb{R}$$

is a closed subset of $X \times \mathbb{R}$ which is homeomorphic to U via projection onto the first coordinate. $X \times \mathbb{R}$ is a complete metric space under the metric

$$\sigma((x, s), (y, t)) = \rho(x, y) + \min(|s - t|, 1) \ .$$

Hence the restriction of σ to Γ transfers to a complete metric on U, also denoted σ:

$$\sigma(x, y) = \rho(x, y) + \min(|g(x) - g(y)|, 1) \ .$$

Now write $E = \cap_n U_n$ with U_n open, and let g_n and σ_n be the corresponding function and metric for U_n. For $x, y \in E$, set

$$\tau(x,y) = \sum_{n=1}^{\infty} 2^{-n}\sigma_n(x,y) = \rho(x,y) + \sum_{n=1}^{\infty} 2^{-n}\min(|g_n(x) - g_n(y)|, 1) \ .$$

Then τ is a metric on E, and it is easily shown (Exercise ()) that τ induces the relative topology on E. If (x_k) is a τ-Cauchy sequence, then (x_k) is a ρ-Cauchy sequence, hence ρ-converges to some $x \in X$. Since (x_k) is also a σ_n-Cauchy sequence for each n, it σ_n-converges to some $x^{(n)} \in U_n$. But the σ_n-topology on U_n is the relative topology, so $x_k \to x^{(n)}$ in X and hence $x^{(n)} = x$, i.e. $x \in U_n$ for all n, so $x \in E$ and x_k τ-converges to x; thus (E, τ) is complete. 👍

For the converse (i) ⇒ (ii), we need a result of independent interest:

XIII.10.3.4. Proposition. Let X be a topological space and Y a completely metrizable space, and A a dense subspace of X. If $f : A \to Y$ is continuous, then f extends to a continuous function f^* from a G_δ subset A^* of X containing A to Y. If X is metrizable, the requirement that A be dense in X can be eliminated.

Proof: We first reduce the last statement to the first. If X is metrizable, then the closed subset $\bar{A}$ is a G_δ in X, and thus any G_δ in $\bar{A}$ (in the relative topology) is a G_δ in X. Replacing X by $\bar{A}$, we may thus assume A is dense in X.
Set $A^* = \{x \in X : \omega(f, x) = 0\}$; then A^* is a G_δ in X containing A. If $x \in A^*$, choose a sequence $(V_x^{(n)})$ of neighborhoods of x with $diam(f(A \cap V_x^{(n)})) < \frac{1}{n}$, and $x_n \in A \cap V_x^{(n)}$. Then $(f(x_n))$ is a τ-Cauchy sequence in Y, hence converges to an element of Y we call $f^*(x)$. The element $f^*(x)$ is independent of the choice of the x_n and even the $V_x^{(n)}$ (any neighborhood of x has nonempty intersection with A since A is dense in X). Then $f : A^* \to Y$ is continuous, and if $x \in A$, we have $f^*(x) = f(x)$. 👍

We now prove (i) ⇒ (ii) in XIII.10.3.1..
Proof: Suppose X is a completely metrizable subspace of a completely metrizable space Y (the metrics may be different!). Then $\bar{X}$ is a closed subspace of Y, hence a G_δ, so any G_δ in $\bar{X}$ is a G_δ in Y, i.e. it suffices to show that X is a G_δ in $\bar{X}$, so we may assume X is dense in Y. If g is the inclusion map from X to Y, let f be the "inverse" which is the identity map from the subspace X of Y to the completely metrizable space X. Then f extends to a continuous function f^* from a G_δ X^* in Y to X. We have that $g \circ f^*(x) = x$ for all x in the dense subspace X of X^*, hence $g \circ f^*(x) = x$ for all $x \in X^*$. But the range of g is X, so $X^* = X$. This completes the proof of XIII.10.3.1.. 👍

Note that the AC is used in the proof of XIII.10.3.4. and hence in XIII.10.3.1.. However, if (Y, τ) is σ-complete (), a simple modification of the proof along the lines of () removes any dependence on Choice.

XIII.10.3.5. Corollary. Let X and Y be metrizable spaces, with X completely metrizable, and $A \subseteq X$, $B \subseteq Y$. If A and B are homeomorphic and A is a G_δ in X, then B is a G_δ in Y.

Proof: A, hence B, is completely metrizable. 👍

Extension of Homeomorphisms

Here is another interesting consequence of XIII.10.3.4.:

XIII.10.3.6. THEOREM. Let A be a subset of a completely metrizable space X, and let f be a homeomorphism from A onto a subset B of a completely metrizable space Y. Then f extends to a homeomorphism from a G_δ subset of X containing A onto a G_δ subset of Y containing B.

PROOF: Replacing Y by $\bar{B}$, which is completely metrizable and a G_δ in Y, we may assume B is dense in Y. By XIII.10.3.4., f extends to a continuous function f^* from a G_δ A^* in X containing A to Y. By XIII.10.3.3., A^* is itself a completely metrizable space, and any G_δ in A^* is a G_δ in X. So, replacing X by A^*, we may assume that f extends to a continuous function f^* from X to Y. The continuous function $g = f^{-1}$ from B to A extends to a continuous function g^* from a G_δ B^* in Y to X. We have that $(f^* \circ g^*)(y) = y$ for all $y \in B$, hence for all $y \in B^*$ since B is dense in B^*. Thus f^* is a homeomorphism from $D = g^*(B^*)$ onto $f^*(D) = B^*$. Since D is homeomorphic to B^*, it is a G_δ in X by XIII.10.3.5.. 👍

We have the following remarkable and far-reaching analog (not exactly an extension) of XIII.10.3.5.:

XIII.10.3.7. COROLLARY. Let X and Y be completely metrizable spaces, and $A \subseteq X$, $B \subseteq Y$. If A and B are homeomorphic and A is a Borel set in X, then B is a Borel set in Y.

PROOF: Let $f : A \to B$ be a homeomorphism. Then f extends to a homeomorphism f^* from a G_δ A^* in X onto a G_δ B^* in Y. Since A^* is a Borel set in X, the (relative) Borel subsets of A^* are precisely the Borel sets in X contained in A^* (XVI.2.1.8.), and similarly for B^*. Since a homeomorphism sends Borel sets to Borel sets, the result follows. 👍

The following special case was proved by LUZIN using a different argument ():

XIII.10.3.8. COROLLARY. Let A be a Borel subset of $\mathbb{R}$. If B is a subset of $\mathbb{R}$ homeomorphic to A, then B is also a Borel set.

XIII.10.4. A Universal Space

We describe a "universal" separable complete metric space:

XIII.10.4.1. DEFINITION. Let $\mathcal{N} = \mathbb{N}^{\mathbb{N}}$ with the product topology, taking the discrete topology on $\mathbb{N}$.

$\mathcal{N}$ consists of all sequences of natural numbers. If (a_n) is a sequence in $\mathcal{N}$, say $a_n = (a_{n1}, a_{n2}, \cdots)$, then $a_n \to b = (b_1, b_2, \cdots)$ if and only if, for each k, there is an n_k such that $a_{nk} = b_k$ for all $n \geq n_k$.

Recall that set theorists typically write ω for $\mathbb{N}$ (actually $\mathbb{N} \cup \{0\}$), and in set theory $\mathcal{N}$ is often denoted ${}^{\omega}\omega$.

A notation we will use repeatedly: if $s = (s_1, s_2, \dots) \in \mathcal{N}$, write $s|n = (s_1, \dots, s_n) \in \mathbb{N}^n$. These are called *initial segments* of s. Take $s|0$ to be the "empty string."

XIII.10.4.2. PROPOSITION. $\mathcal{N}$ is separable.

PROOF: The set of sequences which are eventually 1 is countable and dense in $\mathcal{N}$. 👍

$\mathbb{N}$ is a complete metric space under the discrete metric $\delta(a,b) = 1$ if $a \neq b$ (). The topology on $\mathcal{N}$ also comes from a complete metric:

XIII.10.4.3. PROPOSITION. The function $\rho(a,b) = \sum_{k=1}^{\infty} 2^{-k}\delta(a_k,b_k)$ for $a = (a_k)$ and $b = (b_k)$ in $\mathcal{N}$ is a complete metric on $\mathcal{N}$ giving the product topology.

This is a special case of ().

XIII.10.4.4. PROPOSITION. (i) $\mathcal{N}$ is homeomorphic to $\mathbb{N} \times \mathcal{N}$, and to $\{1,\dots,n\} \times \mathcal{N}$ for any $n \in \mathbb{N}$. $\mathcal{N}$ is a disjoint union of a finite or countable sequence of closed subsets, each homeomorphic to $\mathcal{N}$.
(ii) $\mathcal{N}$ is homeomorphic to $\mathcal{N}^n$ for any $n \in \mathbb{N}$, and to $\mathcal{N}^{\mathbb{N}}$.

PROOF: (i): The map $(n,(a_1,a_2,\dots)) \mapsto (n,a_1,a_2,\dots)$ is a homeomorphism from $\mathbb{N} \times \mathcal{N}$ onto $\mathcal{N}$. If $n \in \mathbb{N}$, we have

$$\{1,\dots,n\} \times \mathcal{N} \cong \{1,\dots,n\} \times \mathbb{N} \times \mathcal{N} \cong \mathbb{N} \times \mathcal{N} \cong \mathcal{N}$$

taking a one-one correspondence between $\{1,\dots,n\} \times \mathbb{N}$ and $\mathbb{N}$. To obtain an explicit sequence of disjoint closed subsets homeomorphic to $\mathcal{N}$ partitioning $\mathcal{N}$, for each $n \in \mathbb{N}$ let $\mathcal{N}_n = \{a = (a_k) : a_1 = n\}$.
(ii): If $n \in \mathbb{N}$, then $\mathcal{N}^n \cong \mathbb{N}^{\mathbb{N}\times\{1,\dots,n\}}$, and similarly $\mathcal{N}^{\mathbb{N}} \cong \mathbb{N}^{\mathbb{N}\times\mathbb{N}}$. Fix one-one correspondences between $\mathbb{N} \times \{1,\dots,n\}$ and $\mathbb{N}$, and between $\mathbb{N} \times \mathbb{N}$ and $\mathbb{N}$. 👍

XIII.10.4.5. REMARK. Note that this proposition does not depend on any form of the Axiom of Choice, since explicit one-one correspondences can be specified (cf. ().)

It follows from XIII.10.4.2. and XIII.10.4.3. that $\mathcal{N}$ is second countable. An explicit countable base for the topology for $\mathcal{N}$ can be given:

XIII.10.4.6. PROPOSITION. For each $m \in \mathbb{N}$ and each $(k_1,\dots,k_m,n_1,\dots,n_m) \in \mathbb{N}^{2m}$ with $k_1 < k_2 < \cdots k_m$, set

$$U_{(k_1,\dots,k_m,n_1,\dots,n_m)} = \{a = (a_k) : a_{k_j} = n_j \text{ for } 1 \leq j \leq m\} .$$

Then the $U_{(k_1,\dots,k_m,n_1,\dots,n_m)}$ form a base for the topology of $\mathcal{N}$.

The sets $U_{(k_1,\dots,k_m,n_1,\dots,n_m)}$ can be explicitly arranged in a sequence without using any form of the Axiom of Choice (Exercise ()).

The space $\mathcal{N}$ is universal among separable complete metric spaces in the following sense:

XIII.10.4.7. THEOREM. Let (X, σ) be a nonempty separable complete metric space. Then there is a locally contractive (hence continuous) map from $\mathcal{N}$ onto X.

PROOF: By induction on n, choose nonempty closed sets $F_{s_1,\dots,s_n}$ for each finite sequence $(s_1, \dots, s_n)$ in $\mathbb{N}$ by choosing a sequence F_k of nonempty closed sets (not necessarily distinct) of diameter ≤ 1 with $\cup_k F_k = X$, and if sets for sequences of length n have been chosen, choose nonempty closed sets $F_{s_1,\dots,s_n,k}$ for each $(s_1, \dots, s_n, k)$ of diameter $\leq 2^{-n}$ such that $\cup_k F_{s_1,\dots,s_n,k} = F_{s_1,\dots,s_n}$ for each $(s_1, \dots, s_n)$. (Such a collection of subsets is called a *Luzin scheme* in X.)

The $F_{s_1,\dots,s_n}$ can be chosen without any form of choice: fix a dense sequence (x_k) in X, let F_k be the closed ball of radius 2^{-1} around x_k, and at the $n+1$'st stage let $F_{s_1,\dots,s_n,k}$ be the intersection of $F_{s_1,\dots,s_n}$ with the closed ball of radius 2^{-n-1} around x_k if this intersection has nonempty interior, and otherwise the intersection of $F_{s_1,\dots,s_n}$ with the closed ball of radius 2^{-n-1} around x_j for the first j for which the intersection has nonempty interior. It is easily checked that these sets have the desired properties.

If $s = (s_1, s_2, \dots) \in \mathcal{N}$, there is a unique point in $\cap_n F_{s_1,\dots,s_n}$ by completeness; call this point $f(s)$. Then f is a map from $\mathcal{N}$ onto X. If $s, t \in \mathcal{N}$ with $\rho(s,t) < 1$, choose n so that $2^{-n} \leq \rho(s,t) < 2^{-n+1}$; then $s_j = t_j$ for $1 \leq j \leq n$, so $f(s), f(t) \in F_{s_1,\dots,s_n}$, $\sigma(f(s), f(t)) \leq 2^{-n}$, and f is locally contractive. 👍

Such a map can be explicitly described in some cases:

XIII.10.4.8. EXAMPLES. (i) Define $\phi : \mathbb{N} \to \{0,1\}$ by $\phi(1) = 1$ and $\phi(n) = 0$ for $n > 1$. Applying ϕ coordinatewise, we obtain a map from $\mathcal{N}$ onto $\{0,1\}^{\mathbb{N}}$ which is a contraction. Since there is a uniform homeomorphism between $\{0,1\}^{\mathbb{N}}$ and the Cantor set K, we obtain a Lipschitz function from $\mathcal{N}$ onto K. Also, there is a contractive mapping from $\{0,1\}^{\mathbb{N}}$ onto $[0,1]$ (), hence a contractive mapping from $\mathcal{N}$ onto $[0,1]$. Writing $\mathcal{N}$ as a disjoint union of closed sets $\mathcal{N}_n$ as in (), and taking the corresponding Lipschitz map from $\mathcal{N}_n$ onto $[n, n+1]$, we obtain a locally Lipschitz map from $\mathcal{N}$ onto $[0, +\infty)$. By taking a one-one correspondence between $\mathbb{N}$ and $\mathbb{Z}$, we obtain a similar map from $\mathcal{N}$ onto $\mathbb{R}$.

(ii) There is a homeomorphism from $\mathcal{N}$ onto the set $\mathbb{J}$ of irrational numbers given by continued fractions (): the sequence $(n_1, n_2, \dots)$ corresponds to the number with continued fraction $(n_1, n_2, \dots)$, i.e.

$$(n_1, n_2, \dots) \mapsto n_1 + \frac{1}{n_2 + \frac{1}{n_3 + \cdots}}$$

(this actually maps to the irrational numbers greater than 1; use a homeomorphism between $\mathcal{N}$ and $\mathcal{N} \times \{0,1\}$ to get a map onto all of $\mathbb{J}$).

XIII.10.4.9. There is an important extension of this result. Recall that if X is a topological space and $Y \subseteq X$, a *retraction* of X onto Y is a continuous function $f : X \to Y$ such that $f(y) = y$ for all $y \in Y$. Y is called a *retract* of X if there is a retraction from X onto Y. If X is Hausdorff, then a retract of X is necessarily a closed subset of X. It is relatively rare to have a retraction onto a general closed subset of a topological space; however, $\mathcal{N}$ has the following remarkable property:

XIII.10.4.10. THEOREM. Let Y be a nonempty closed subset of $\mathcal{N}$. Then there is a contractive retraction from $\mathcal{N}$ onto Y.

The proof is a slight refinement of the proof of XIII.10.4.7., and is left to the reader (Exercise ().) Alternatively, an easy proof can be given using the language of trees.

Trees

Trees can be described in various ways. For our purposes, we will take the following definition:

XIII.10.4.11. DEFINITION. A *tree* is a directed graph T for which:

(i) Every vertex (node) has a rank in $\mathbb{N} \cup \{0\}$.

(ii) Every edge goes from a node of rank n to a node of rank $n+1$ for some n.

(iii) There is a unique node of rank 0, called the *root*.

(iv) For every node x, there is a unique path (necessarily of length equal to the rank of x) from the root to x. In particular, every node of rank $n \geq 1$ has a unique predecessor of rank $n-1$.

A tree T is *pruned* if every node has at least one successor.

A *subtree* of a tree T is a subgraph which is itself a tree. A subtree is a *pruned subtree* if it is itself a pruned tree. (We also regard the empty subgraph as a subtree, which is a pruned subtree.)

XIII.10.4.12. EXAMPLE. Take the nodes of rank n to be $\{s|n : s \in \mathcal{N}\}$, and take an edge from $s|n$ to $s|(n+1)$ for each $s \in \mathcal{N}$ and $n \in \mathbb{N} \cup \{0\}$. This is a pruned tree, called the *tree over* $\mathbb{N}$, denoted $T_{\mathbb{N}}$. The root is the empty string, and $\mathcal{N}$ can be naturally identified with the infinite paths in $T_{\mathbb{N}}$.

The proof of the next proposition is a simple exercise which is left to the reader.

XIII.10.4.13. PROPOSITION. When $\mathcal{N}$ is identified with the set of infinite paths in $T_{\mathbb{N}}$, there is a natural one-one correspondence between the closed subsets of $\mathcal{N}$ and the pruned subtrees of $T_{\mathbb{N}}$, where the subset of $\mathcal{N}$ corresponding to a pruned subtree S is the set of infinite paths in S.

XIII.10.4.14. *Proof of Theorem XIII.10.4.10.:* In light of XIII.10.4.13., we need only show that if S is a nonempty pruned subtree of $T_{\mathbb{N}}$, there is a retraction ϕ of $T_{\mathbb{N}}$ onto S which preserves rank and edges. Define ϕ by induction on rank as follows. Let $\phi(s|0) = s|0$. Suppose $\phi(s|n)$ has been defined for each $s \in \mathcal{N}$. For each node $s|(n+1)$ (there are countably many distinct nodes of this type), if $s|(n+1) \in S$, set $\phi(s|(n+1)) = s|(n+1)$, and otherwise let $\phi(s|(n+1))$ be any successor of $\phi(s|n)$ in S (to make it definite and avoid using AC, let it be the successor node in S with smallest possible $(n+1)$'st coordinate). It is easily checked that this ϕ has the desired properties. □

XIII.10.5. Polish Spaces

XIII.10.5.1. Definition. A topological space is a *Polish space* if it is homeomorphic to a separable complete metric space.

Note that a Polish space is a topological space, not a metric space: it does not come with a specified metric, and even if it is given as a metric space, the given metric may not be complete – there need only be an equivalent complete metric (cf. XIII.10.5.3.). Any topological space homeomorphic to a Polish space is a Polish space.

XIII.10.5.2. Examples. (i) $\mathbb{R}^n$, or more generally any separable Banach space regarded as a topological space. An open ball in $\mathbb{R}^n$ is homeomorphic to $\mathbb{R}^n$, hence a Polish space.

(ii) Any (nonempty) closed subset of a Polish space; in particular, any closed subset of $\mathbb{R}^n$. (See XIII.10.5.3. for a generalization.)

(iii) Any second countable compact Hausdorff space ().

(iv) The space $\mathcal{N}$ (XIII.10.4.1.). More generally, a finite or countable Cartesian product of Polish spaces is Polish with the product topology (XIII.10.1.8.).

(v) A countable separated union of Polish spaces is a Polish space (XIII.10.1.9.).

A Polish space is second countable, Hausdorff, and normal, and is a Baire space (satisfies the conclusion of the Baire Category Theorem).

XIII.10.5.3. Theorem. A subset of a Polish space is a Polish space if and only if it is a G_δ. Thus a topological space is a Polish space if and only if it is a separable absolute G_δ.

Proof: This is a special case of XIII.10.3.1., with the observation that every subset of a separable metrizable space is separable.

Various Polish Topologies on a Set

We begin with an interesting fact which has a nice application when we discuss Borel sets (XVI.2.9.3.).

XIII.10.5.4. Theorem. Let X be a set. Let $(\mathcal{T}_n)$ be a sequence of Polish topologies on X. Suppose there is a Hausdorff topology $\mathcal{T}$ on X which is weaker than all the $\mathcal{T}_n$. If $\mathcal{T}_\infty$ is the weakest topology on X stronger than all the $\mathcal{T}_n$, then $\mathcal{T}_\infty$ is a Polish topology.

Proof: Let $Y = \prod_n (X_n, \mathcal{T}_n)$, where each $X_n = X$. Then Y is a Polish space with the product topology. For $x \in X$, set $\phi(x) = (x, x, x, \dots)$. If $y = (x_1, x_2, \dots) \in Y \setminus \phi(X)$, then there are m, n with $x_m \neq x_n$. Let U and V be disjoint $\mathcal{T}$-neighborhoods of x_m and x_n respectively. Set $W_m = U$, $W_n = V$, and $W_k = X$ for $k \neq m, n$, and $W = \prod W_k$. Then W is an open neighborhood of y in Y disjoint from $\phi(X)$. Thus $\phi(X)$ is closed in Y, and so is Polish in the relative topology, which when transfered back to X by ϕ^{-1} is easily seen to be $\mathcal{T}_\infty$.

We also have the following result of Kuratowski [**?**], which is a sharpening of XIII.10.4.7.. The proof is rather involved, although fairly elementary, and we omit it; see, for example, [**?**, 2.4.1].

XIII.10.5.5. THEOREM. Let X be an uncountable Polish space which is dense in itself. Then there is an injective continuous function from $\mathcal{N}$ onto X such that the image of every open set is an F_σ.

This theorem says that if $(X, \mathcal{T})$ is a perfect Polish space, there is a Polish topology $\mathcal{S}$ on X stronger than $\mathcal{T}$ such that $(X, \mathcal{S})$ is homeomorphic to $\mathcal{N}$ and every open set in the $\mathcal{S}$-topology is an F_σ in the $\mathcal{T}$-topology.

Since by the Cantor-Bendixson Theorem (XIII.2.5.4.) every Polish space is a disjoint union of a countable open subset and a closed subset which is dense-in-itself, we obtain:

XIII.10.5.6. COROLLARY. Every uncountable Polish space has cardinality $2^{\aleph_0}$.

How Many Polish Spaces Are There?

XIII.10.5.7. THEOREM. There are exactly $2^{\aleph_0}$ Polish spaces up to homeomorphism.

PROOF: Let $\mathcal{P}$ be the set of homeomorphism classes of infinite Polish spaces (there are countably many finite Polish spaces, which are just finite discrete spaces). There are $2^{\aleph_0}$ pairwise nonhomeomorphic compact subsets of $\mathbb{R}^2$ (XIII.19.5.1.), each of which is a Polish space, so $card(\mathcal{P}) \geq 2^{\aleph_0}$. On the other hand, if X is an infinite Polish space, ρ is a complete metric on X, and D is a countable dense set in X, then (X, ρ) is the completion of $(D, \rho|_D)$. If D is identified with $\mathbb{N}$, the metric $\rho|_D$ can be transferred to $\mathbb{N}$; thus X is homeomorphic to the completion of $\mathbb{N}$ with respect to some metric. So if $\mathcal{M}$ is the set of all metrics on $\mathbb{N}$, $card(\mathcal{M}) = 2^{\aleph_0}$ and there is a function from $\mathcal{M}$ onto $\mathcal{P}$. Therefore $card(\mathcal{P}) \leq 2^{\aleph_0}$. 👍

XIII.10.5.8. The above proof uses the AC (how?). The full AC is not needed: it suffices to assume that $\mathbb{R}$ can be well ordered, i.e. that $2^{\aleph_0}$ is an aleph. For the best that can be proved in ZF, see Exercise XIII.10.6.10..

XIII.10.6. Exercises

XIII.10.6.1. Arrange the tuples occurring as indexes in () into an explicit sequence, as follows:

(a) The set of pairs $((n_1, \dots, n_m), (k_1, \dots, k_m))$ ($m = 0$ is allowed, giving the "empty pair"), with the n_j strictly increasing in $\mathbb{N}$ and the $k_j \in \mathbb{N}$, is in natural one-one correspondence with the set $\mathcal{C}$ of sequences in $\mathbb{N} \cup \{0\}$ which are eventually 0: the pair $((n_1, \dots, n_m), (k_1, \dots, k_m))$ corresponds to the sequence with k_j in the n_j'th place and zeroes elsewhere.

(b) The set $\mathcal{C}$ is in one-one correspondence with $\mathbb{N}$:

$$(t_1, t_2, \dots) \longleftrightarrow \prod_j p_j^{t_j}$$

where p_j is the j'th prime.

XIII.10.6.2. In the proof of XIII.10.5.3., show that τ gives the relative topology on E. [Hint: Suppose $(x_m) \subseteq E$ ρ-converges to $x \in E$. Given $\epsilon > 0$, fix n so that $2^{-n} < \epsilon/3$, and find M so that $\rho(x_m, x) < \epsilon/3$ and $|g_k(x_m) - g_k(x)| < \epsilon/3$ for all $m \geq M$ and $1 \leq k \leq n$.]

XIII.10.6.3. (a) Show that if K is a compact subset of $\mathcal{N}$, then for each $n \in \mathbb{N}$ there is a $k_n \in \mathbb{N}$ such that $s_n \leq k_n$ whenever $s = (s_1, s_2, \dots) \in K$. [Consider the image of K under the n'th coordinate map $\pi_n : \mathcal{N} \to \mathbb{N}$.]

(b) Show that if $K \subseteq \mathcal{N}$ is compact, then $\mathcal{N} \setminus K$ is dense in $\mathcal{N}$.

(c) Conclude from the Baire Category Theorem that $\mathcal{N}$ is not σ-compact.

XIII.10.6.4. If (X, ρ) is a separable metric space, show that X is homeomorphic to a subspace of the Hilbert cube $[0,1]^{\mathbb{N}}$, as follows.

(a) Let $\sigma = min(\rho, 1)$ be a $[0,1]$-valued metric equivalent to ρ, and let (y_n) be a dense sequence in X. Define $f_n : X \to [0,1]$ by $f_n(x) = \sigma(x, y_n)$. Define $f : X \to [0,1]^{\mathbb{N}}$ by $f(x) = (f_1(x), f_2(x), \dots)$. Show that f is continuous.

(b) Show that f is a homeomorphism from X onto $f(X)$. [If $f(x_n) \to f(x)$, for $\epsilon > 0$ choose m so that $\sigma(x, y_m) < \epsilon/2$. Since $f_m(x_n) = \sigma(x_n, y_m) \to f_m(x) = \sigma(x, y_m) < \epsilon/2$, there is an N such that $f_m(x_n) < \epsilon/2$ for $n \geq N$, so $\sigma(x_n, x) < \epsilon$ for $n \geq N$.]

XIII.10.6.5. Show that every metrizable space is homeomorphic to a closed subspace of a product (uncountable in general) of completely metrizable spaces. [If X is metrizable with metric ρ, let $\bar{X}$ be the completion of X with respect to ρ, and consider

$$\prod_{y \in \bar{X} \setminus X} (\bar{X} \setminus \{y\}) \ .]$$

XIII.10.6.6. [Wil04, 23.2] Give a direct proof of XIII.10.1.11. as follows. Let X and Y be compact Hausdorff spaces, and $f : X \to Y$ a surjective continuous function. Suppose X is second countable. Let $\mathcal{B}$ be a countable base for the topology of X which is closed under finite unions. Set

$$\mathcal{D} = \{Y \setminus f(X \setminus B) : B \in \mathcal{B}\} \ .$$

Show that $\mathcal{D}$ is a countable base for the topology of Y.

XIII.10.6.7. **The Hausdorff Metric.** Let (X, ρ) be a metric space, and let $\mathcal{K}(X)$ be the set of nonempty compact subsets of X. For $x \in X$ and $F \in \mathcal{K}(X)$, set

$$\rho(x, F) = \inf_{y \in F} \rho(x, y) = \min_{y \in F} \rho(x, y) \ .$$

For $E, F \in \mathcal{K}(X)$, set

$$\rho_1(E, F) = \sup_{x \in E} \rho(x, F) = \max_{x \in E} \rho(x, F)$$

and

$$\rho_h(E, F) = \max(\rho_1(E, F), \rho_1(F, E)) \ .$$

This ρ_h is called the *Hausdorff metric* (or *Hausdorff distance*) on $\mathcal{K}(X)$. (It can be defined more generally on the space of closed bounded subsets of X, but not all of the same properties hold in this space. Such spaces of subsets are often called *hyperspaces*.)

(a) Show that ρ_h is a metric on $\mathcal{K}(X)$.

(b) Show that if ρ is complete, then ρ_h is also complete. [It suffices to show that every ρ_h-Cauchy sequence has a convergent subsequence. Let (E_n) be a sequence in $\mathcal{K}(X)$ with $\rho_h(E_n, E_{n+1}) < 2^{-n}$. If

$$D = \{x \in X : \exists x_n \in E_n \text{ with } x_n \to x \text{ and } \rho(x_n, x_{n+1}) < 2^{-n}\}$$

then $E = \bar{D}$ is nonempty and compact (totally bounded), and $E_n \to E$.]

(c) Show that if (X, ρ) is separable, then $(\mathcal{K}(X), \rho_h)$ is also separable. [Consider finite subsets of a countable dense set in X.]

(d) Show that if (X, ρ) is totally bounded, so is $(\mathcal{K}(X), \rho_h)$. [If $\mathcal{D}$ is a δ-cover of X, then $\mathcal{P}(\mathcal{D})$ is a δ-cover of $\mathcal{K}(X)$.] Conclude from (b) and () that if (X, ρ) is compact, so is $(\mathcal{K}(X), \rho_h)$.

(e) The map $x \mapsto \{x\}$ is an isometry from (X, ρ) onto a closed subset of $(\mathcal{K}(X), \rho_h)$. Deduce the converses of the statements in (b), (c), and (d).

(f) If $E, E_1, E_2, \cdots \in \mathcal{K}(X)$ and $E_n \to E$, then $\cap_n E_n \subseteq E \subseteq \overline{\cup_n E_n}$. If Y is a closed subset of X, then $\mathcal{K}(Y)$ is a closed subset of $\mathcal{K}(X)$. If Y is compact and $\mathcal{K}(X)_Y = \{E \in \mathcal{K}(X) : Y \subseteq E\}$, then $\mathcal{K}(X)_Y$ is also a closed subset of $\mathcal{K}(X)$. In particular, if $p \in X$, then

$$\mathcal{K}(X)_p = \mathcal{K}(X)_{\{p\}} = \{E \in \mathcal{K}(X) : p \in E\}$$

is a closed subset of $\mathcal{K}(X)$.

(g) Let $X = \{\frac{1}{n} : n \in \mathbb{N}\} \cup \{0\} \subseteq [0, 1]$ with the metric $\rho(x, y) = |x - y|$. Show that $\mathcal{K}(X)_0$ is homeomorphic to the Cantor set. [A compact subset of X containing 0 is of the form $E_S = \{\frac{1}{n} : n \in S\} \cup \{0\}$ for a subset S of $\mathbb{N}$. Send E_S to the usual sequence in $\{0, 1\}^{\mathbb{N}}$ associated to S as in ().] The complement of $\mathcal{K}(X)_0$ in $\mathcal{K}(X)$ is countable. Describe the topological space $\mathcal{K}(X)$.

(h) $\mathcal{K}([0, 1])$ is topologically infinite-dimensional. [If $n \in \mathbb{N}$ and $x_1, \ldots, x_n$ are distinct numbers in $(0, 1)$, then there is a neighborhood U of $(x_1, \ldots, x_n)$ in $\mathbb{R}^n$ such that $(y_1, \ldots, y_n) \mapsto \{y_1, \ldots, y_n\}$ is a homeomorphism from U into $\mathcal{K}([0, 1])$.] In fact, $\mathcal{K}([0, 1])$ is homeomorphic to the Hilbert cube [?], as is $\mathcal{K}(X)$ for any compact, connected, locally connected metric space X [CS78].

(i) Show that $(\mathcal{K}(X), \rho_h)$ is connected [*resp.* totally disconnected] if and only if (X, ρ) is connected [*resp.* totally disconnected].

XIII.10.6.8. The Hausdorff Metric Continued. [Mic51] Use the notation of Exercise XIII.10.6.7.. Let (X, ρ) be a metric space.

(a) Show that if $E, E_1, E_2, \cdots \in \mathcal{K}(X)$, then $E_n \to E$ if and only if, for every finite set $\{U_1, \ldots, U_n\}$ of open subsets of X with $E \subseteq \cup_k U_k$ and $E \cap U_k \neq \emptyset$ for all k, we have, for all sufficiently large n, $E_n \subseteq \cup_k U_k$ and $E_n \cap U_k \neq \emptyset$ for all k. (A topology can be defined on $\mathcal{K}(X)$ in this way for any topological space X; this topology is called the *finite topology* or *Vietoris topology* on $\mathcal{K}(X)$.)

(b) Let (Y, σ) be another metric space, and $f : X \to Y$ a continuous function. Define $f_* : \mathcal{K}(X) \to \mathcal{K}(Y)$ by setting $f_*(E) = f(E)$ for $E \in \mathcal{K}(X)$ (recall () that $f(E)$ is compact). Show that $f_* : (\mathcal{K}(X), \rho_h) \to (\mathcal{K}(Y), \sigma_h)$ is continuous.

(c) Show that if σ is another metric on X which is equivalent to ρ, then σ_h is equivalent to ρ_h. So the topology on $\mathcal{K}(X)$ depends only on the topology of X, not on the choice of metric.

(d) Show that if $E_n \to E$ in $\mathcal{K}(X)$, then $F = E \cup [\cup_{n=1}^{\infty} E_n]$ is compact in X. [If $\mathcal{U}$ is an open cover of F, let $\{U_1, \ldots, U_m\}$ be a finite subcover of E. Then $E_n \subseteq \cup_{k=1}^{m} U_k$ for all but finitely many n.] More generally, if $\mathcal{E}$ is a compact subset of $\mathcal{K}(X)$, then $\cup_{E \in \mathcal{E}} E$ is a compact subset of X [Mic51, 2.5.1].

XIII.10.6.9. (a) Show that there is a subset of $\mathcal{N}$ homeomorphic to the Cantor set. [Consider all sequences of 1's and 2's.]

(b) Since $\mathcal{N}$ is homeomorphic to $\mathbb{J}$ (XIII.10.4.8.(ii)), there is a subset of $\mathbb{J}$ homeomorphic to the Cantor set. Since this set is compact, it is closed and bounded in $\mathbb{R}$.

(c) If $(X, \mathcal{T})$ is a perfect Polish space, use the function $f : \mathcal{N} \to X$ of XIII.10.5.5. to show that X contains a subset homeomorphic to the Cantor set. [The image of a Cantor set in $\mathcal{N}$ is compact in the relative topology from $\mathcal{N}$ and Hausdorff in the relative $\mathcal{T}$-topology, so these topologies coincide.]

(d) Give a direct constructive proof that every perfect completely metrizable space contains a copy of the Cantor set ().

XIII.10.6.10. Let $\mathcal{P}$ be the set of homeomorphism classes of Polish spaces, and $\kappa = card(\mathcal{P})$. Show that the following weak version of XIII.10.5.7. is the best which can be proved in ZF [recall (II.9.9.9.) that it cannot be proved in ZF that $\aleph_1$ and $2^{\aleph_0}$ are comparable.]

THEOREM.

(i) $\kappa \geq \aleph_1 + 2^{\aleph_0}$.

(ii) $\kappa \precsim 2^{\aleph_0}$ (II.9.4.2.).

(iii) $\kappa < 2^{2^{\aleph_0}}$.

The arguments are the ones from the proof of XIII.10.5.7.. For (i), note that by XIII.19.5.4. there are also $\aleph_1$ pairwise nonhomeomorphic compact subsets of $\mathbb{R}$, none of which are homeomorphic to the ones of XIII.19.5.1.. For (iii), use II.9.9.7. and II.5.3.3..

XIII.10.6.11. Prove the following theorem:

THEOREM. Let X be a (necessarily T_1) topological space. The following are equivalent:

(i) X is completely normal (XIII.10.1.2.).

(ii) Every open subspace of X is normal.

(iii) Every subspace of X is normal.

(iv) Every subspace of X is completely normal.

(a) Show that (i) $\Rightarrow$ (iv).

(b) For (ii) $\Rightarrow$ (i), suppose $A, B \subseteq X$ with $A \cap \bar{B} = \bar{A} \cap B = \emptyset$ and $W = X \setminus (\bar{A} \cap \bar{B})$ normal. Show A and B have disjoint neighborhoods in W, hence in X.

(c) A topological space X is *perfectly normal* if it is normal and every closed set in X is a G_δ (equivalently, every closed set in X is a zero set (), or that every open set in X is an F_σ). Use the theorem and XIII.7.10.8.(b) to show that every perfectly normal space is completely normal. Show that every metrizable space is perfectly normal. There are completely normal spaces which are not perfectly normal, e.g. the one-point compactification of an uncountable discrete space. A space which is perfectly normal is sometimes called T_6.

(d) Since there are completely regular spaces, even locally compact Hausdorff spaces, which are not normal (), not every compact Hausdorff space is completely normal.

XIII.10.6.12. Show that a T_1 topological space X is completely normal if and only if, whenever Y_1 and Y_2 are closed subspaces and $Y = Y_1 \cup Y_2$, there are closed subspaces X_1 and X_2 of X with $X_1 \cup X_2 = X$ and $X_j \cap Y = Y_j$ for $j = 1, 2$. [Set $A = Y_1 \setminus Y_2$ and $B = Y_2 \setminus Y_1$; then A and B are separated. If U and V are disjoint open neighborhoods, set $X_1 = V^c$ and $X_2 = U^c$. Conversely, if A and B are separated, set $Y_1 = \bar{A}$ and $Y_2 = \bar{B}$.]

Note that this condition for Y_1 and Y_2 disjoint is exactly normality.

XIII.10.6.13. **Another Universal Polish Space.** The space $\mathcal{N}$ of XIII.10.4.1. is a universal Polish space in the sense of XIII.10.4.7.. There is a "dual" universal Polish space, the product of a countable number of copies of $\mathbb{R}$ with the product topology from the usual topology, denoted $\mathbb{R}^{\mathbb{N}}$.

(a) Show that $\mathbb{R}^{\mathbb{N}}$ is a Polish space (cf. XIII.10.5.2.(iv)).

(b) Every Polish space is homeomorphic to a closed subset of $\mathbb{R}^{\mathbb{N}}$ ().

(c) $\mathbb{R}^{\mathbb{N}}$ is a topological vector space under coordinatewise operations (), and in fact a Fréchet space.

(d) Every separable infinite-dimensional Banach space (or, more generally, Fréchet space) is [nonlinearly!] homeomorphic to $\mathbb{R}^{\mathbb{N}}$ ([Kad66], [And66], [AB68]; cf. [BP75]). As a result, topologists often call $\mathbb{R}^{\mathbb{N}}$ "Hilbert space" and denote it ℓ^2.

(e) Show that $\mathbb{R}^{\mathbb{N}}$ is not σ-compact (cf. XIII.10.6.3.). Conclude that no infinite-dimensional Banach space is σ-compact.

(f) If A is a σ-compact subset of $\mathbb{R}^{\mathbb{N}}$, then $\mathbb{R}^{\mathbb{N}} \setminus A$ is homeomorphic to $\mathbb{R}^{\mathbb{N}}$ (cf. e.g. [vM89, 6.5.9]). In particular, if B is a separable infinite-dimensional Banach space and p is a point of B, then $B \setminus \{p\}$ is homeomorphic to B.

(g) Let (I_n) be a sequence of nondegenerate intervals in $\mathbb{R}$. If infinitely many I_n are noncompact, then $\prod_n I_n$ is homeomorphic to $\mathbb{R}^{\mathbb{N}}$ [vM89, 6.5.10]. In particular, $[0,1)^{\mathbb{N}}$, $[0,1) \times \mathbb{R}^{\mathbb{N}}$, $[0,1] \times \mathbb{R}^{\mathbb{N}}$, and $\mathbb{H} \times \mathbb{R}^{\mathbb{N}}$ (where $\mathbb{H}$ is the Hilbert cube) are all homeomorphic to $\mathbb{R}^{\mathbb{N}}$.

XIII.11. Compactness

"Something like half of all mathematics consists of showing that some space is compact."

J. & B. Hubbard[1]

Compactness is one of the most important notions in topology, and especially for its applications in analysis. Compact sets behave roughly like finite sets. Compactness is used in applications to insure boundedness, the existence of limits, and the achievement of extrema, among other things.

Use of the Axiom of Choice is pervasive in the theory of compactness, and we will freely employ it; we will usually point out which results depend on it and which do not. Use of the Axiom of Choice can be almost entirely avoided if one sticks only to second countable topological spaces.

XIII.11.1. Basic Definitions

XIII.11.1.1. DEFINITION. Let $(X, \mathcal{T})$ be a topological space. An *open cover* (*$\mathcal{T}$-open cover*) is a set $\mathcal{U} = \{U_i : i \in I\}$ of $\mathcal{T}$-open sets with $\cup_{i\in I} U_i = X$. The open cover $\mathcal{U}$ is *finite* if I is finite. A subset $\mathcal{V}$ of an open cover $\mathcal{U}$ is a *subcover* if it is itself an open cover.
If $Y \subseteq X$ and $\mathcal{U} = \{U_i : i \in I\} \subseteq \mathcal{T}$, then $\mathcal{U}$ is an open cover of Y in X if $Y \subseteq \cup_{i\in I} U_i$. Subcovers of Y in X are defined similarly.

XIII.11.1.2. DEFINITION. Let $(X, \mathcal{T})$ be a topological space. $(X, \mathcal{T})$ is *compact* if every open cover of X has a finite subcover.
If $Y \subseteq X$, then Y is a *compact subspace* of X if every open cover of Y in X has a finite subcover in X.

XIII.11.1.3. **Caution:** In some older references, particularly from Eastern Europe, "compact" is used to mean "countably compact" (XIII.11.7.1.). A space which is compact according to the modern definition XIII.11.1.2. is called "bicompact" in these references. Also, in some references, especially French ones and [Eng89], the term "compact" is reserved for Hausdorff spaces; a space which is compact in the sense of XIII.11.1.2. but not necessarily Hausdorff is called "quasi-compact." In some references like [Pea75], "bicompact" means "compact and Hausdorff." Check the definitions in any reference. For brevity, we will call a compact Hausdorff space a *compactum*, plural *compacta* (some authors require a compactum to be metrizable, but we will not).

The first observation is that compactness of a subspace depends only on the relative topology of the subspace, not on the way it is embedded:

XIII.11.1.4. PROPOSITION. If Y is a subspace of a topological space $(X, \mathcal{T})$, then Y is a compact subspace of X if and only if $(Y, \mathcal{T}_Y)$ is compact.

PROOF: This is obvious from the fact that every relatively open subset of Y is of the form $U \cap Y$, where $U \in \mathcal{T}$. (The AC can be avoided in this argument as in ().)

The next result, an immediate corollary of XIII.11.2.2. and the Bolzano-Weierstrass theorem, gives the most important basic examples of compact spaces, and begins to give a picture of the meaning of compactness.

[1] [HH99, p. 89]. The comment is an intentional exaggeration, but not far wrong in spirit.

XIII.11.1.5. THEOREM. A subset of $\mathbb{R}^n$ is compact if and only if it is closed and bounded.

Here is a far-reaching version (not quite a generalization) of XIII.11.1.5.. Because of this, compact sets are often thought of as sets which are "absolutely closed" (although this is only really accurate in Hausdorff spaces). See XIII.11.4.1. and XIII.11.4.2. for generalizations of the second statement.

XIII.11.1.6. PROPOSITION. A closed subspace of a compact space is compact. A compact subspace of a Hausdorff space is closed.

PROOF: Let $(X, \mathcal{T})$ be a compact space, and Y a closed subset of X. Let $\mathcal{U}$ be an open cover of Y in X. Then $\mathcal{V} = \mathcal{U} \cup \{X \setminus Y\}$ is an open cover of X. Let $\{U_{i_1}, \ldots, U_{i_n}, X \setminus Y\}$ be a finite subcover of $\mathcal{V}$; then $\{U_{i_1}, \ldots, U_{i_n}\}$ is a finite subcover of the cover $\mathcal{U}$ of Y.

If $(X, \mathcal{T})$ is a Hausdorff space and Y is a compact subspace of X, and $x \in X \setminus Y$, for each $y \in Y$ let U_y and V_y be disjoint open neighborhoods (in X) of x and y respectively. Then $\{V_y : y \in Y\}$ is an open cover of Y in X. Let $\{V_{y_1}, \ldots, V_{y_n}\}$ be a finite subcover. Then $U = U_{y_1} \cap \cdots \cap U_{y_n}$ is an open neighborhood of x disjoint from Y. Thus $X \setminus Y$ is open. 👍

Note that the Axiom of Choice is used in the second half of the proof. The result is true, however, without any Choice assumption (Exercise XIII.11.14.2.).

A compact subspace of a general topological space, even a T_1-space, is not necessarily closed (Exercise XIII.11.14.1..)

A continuous image of a closed set is not necessarily closed. But one of the important properties of compactness is that it is preserved under continuous images:

XIII.11.1.7. PROPOSITION. Let $(X, \mathcal{T})$ and $(Z, \mathcal{S})$ be topological spaces, and $f : X \to Z$ a continuous function. If Y is a compact subset of X, then $f(Y)$ is a compact subset of Z.

PROOF: Let $\mathcal{V} = \{V_i : i \in I\}$ be an open cover of $f(Y)$ in Z. For each i, let $U_i = f^{-1}(V_i)$. Then $\mathcal{U} = \{U_i : i \in I\}$ is an open cover of Y in X. If $\{U_{i_1}, \ldots, U_{i_n}\}$ is a finite subcover of Y, then $\{V_{i_1}, \ldots, V_{i_n}\}$ is a finite subcover of $f(Y)$. 👍

An important corollary generalizes the Extreme Value Theorem of calculus:

XIII.11.1.8. COROLLARY. Let X be a topological space, $f : X \to \mathbb{R}$ a continuous function, and E a compact subset of X. Then f is bounded on E, and attains its maximum and minimum values on E.

PROOF: By XIII.11.1.7., $f(E)$ is compact in $\mathbb{R}$, and therefore closed and bounded by XIII.11.1.5.. 👍

There is a useful rephrasing of the definition of compactness, using the Finite Intersection Property. This characterization of compactness is strongly reminiscent of the Nested Intervals Property of $\mathbb{R}$.

XIII.11.1.9. DEFINITION. Let $(X, \mathcal{T})$ be a topological space. A (nonempty) collection $\mathcal{F} = \{F_i : i \in I\}$ of closed subsets of X has the *Finite Intersection Property* if, whenever $F_{i_1}, \ldots, F_{i_n}$ is a finite collection of sets in $\mathcal{F}$, we have $F_{i_1} \cap \cdots \cap F_{i_n} \neq \emptyset$.

XIII.11.1.10. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space. Then $(X, \mathcal{T})$ is compact if and only if, whenever $\mathcal{F} = \{F_i : i \in I\}$ is a nonempty collection of closed sets in X with the Finite Intersection Property, we have $\cap_{i \in I} F_i \neq \emptyset$.

PROOF: Suppose $(X, \mathcal{T})$ is compact, and let $\mathcal{F} = \{F_i : i \in I\}$ be a collection of closed sets in X with $\cap_{i \in I} F_i = \emptyset$. Let $U_i = X \setminus F_i$ for each i. Then $\mathcal{U} = \{U_i : i \in I\}$ is an open cover of X. Let $\{U_{i_1}, \ldots, U_{i_n}\}$ be a finite subcover. Then $F_{i_1} \cap \cdots \cap F_{i_n} = \emptyset$, so $\mathcal{F}$ does not have the Finite Intersection Property.

Conversely, suppose every collection of closed sets in X with the Finite Intersection Property has a nonempty intersection, and let $\mathcal{U} = \{U_i : i \in I\}$ be an open cover of X. Set $F_i = X \setminus U_i$ for each i. Then $\mathcal{F} = \{F_i : i \in I\}$ is a collection of closed subsets of X with $\cap_{i \in I} F_i = \emptyset$, so $\mathcal{F}$ does not have the Finite Intersection Property, i.e. there is a finite set $\{F_{i_1}, \ldots, F_{i_n}\}$ with $F_{i_1} \cap \cdots \cap F_{i_n} = \emptyset$. But then $\{U_{i_1}, \ldots, U_{i_n}\}$ is a finite subcover of $\mathcal{U}$. 👍

Here is a useful variation:

XIII.11.1.11. PROPOSITION. Let X be a topological space, $\{E_i : i \in I\}$ a collection of closed subsets of X, with at least one compact. If U is an open subset of X containing $\cap_{i \in I} E_i$, then there is a finite subset F of I such that $\cap_{i \in F} E_i \subseteq U$.

PROOF: Fix an i_0 with E_{i_0} compact. For each i, let $K_i = E_i \cap E_{i_0} \cap U^c$. Then the K_i are closed subsets of E_{i_0}, and they have empty intersection, so they do not have the Finite Intersection Property, i.e. there are $i_1, \ldots, i_n$ such that $K_{i_1} \cap \cdots \cap K_{i_n} = \emptyset$. Then $E_{i_0} \cap E_{i_1} \cap \cdots \cap E_{i_n} \subseteq U$. 👍

XIII.11.1.12. COROLLARY. Let X be a topological space. Let (F_n) be a decreasing sequence of closed compact subsets of X ("closed" is redundant if X is Hausdorff) with $F = \cap_n F_n$. If U is any open set in X with $F \subseteq U$, then $F_n \subseteq U$ for all sufficiently large n.

Here is an interesting and important special case:

XIII.11.1.13. COROLLARY. Let X be a topological space, $p \in X$. Let (V_n) be a decreasing sequence of closed compact neighborhoods of p ("closed" is redundant if X is Hausdorff) with $\cap_n V_n = \{p\}$. Then the V_n form a local neighborhood base at p for the topology.

XIII.11.2. Compactness and Convergence

The next theorem gives the main equivalent ways compactness is characterized:

XIII.11.2.1. THEOREM. Let $(X, \mathcal{T})$ be a topological space. The following are equivalent:

(i) $(X, \mathcal{T})$ is compact.

(ii) Every nonempty collection of closed subsets of X with the Finite Intersection Property has nonempty intersection.

(iii) Every net in X has a cluster point.

(iv) Every net in X has a convergent subnet.

(v) Every filter on X has a cluster point.

PROOF: (i) $\iff$ (ii) is XIII.11.1.10., (iii) $\iff$ (iv) is (), and (iii) $\iff$ (v) is ().
(ii) $\Rightarrow$ (iii): Let $(x_i)_{i\in I}$ be a net in x. For each i, let F_i be the closure of $\{x_j : j \geq i\}$, and let $\mathcal{F} = \{F_i : i \in I\}$. If $i_1, \ldots, i_n \in I$, then since I is directed there is an $i_0 \geq i_k$ for $1 \leq k \leq n$. Thus $x_{i_0} \in F_{i_1} \cap \cdots \cap F_{i_n}$, and hence $F_{i_1} \cap \cdots \cap F_{i_n} \neq \emptyset$ and so $\mathcal{F}$ has the Finite Intersection Property. By (ii), there is an $x \in \cap_{i\in I} F_i$, and x is a cluster point of the net (x_i).
(iii) $\Rightarrow$ (ii): Let $\mathcal{F}$ be a nonempty collection of closed sets with the Finite Intersection Property. We may assume that $\mathcal{F}$ is closed under finite intersections. Set

$$I = \{(x, F) \in X \times \mathcal{F} : x \in F\} .$$

Put a preorder on I by setting $(x_1, F_1) \leq (x_2, F_2)$ if $F_2 \subseteq F_1$. Then I is directed: for any $(x_1, F_1), (x_2, F_2)$ we have

$$(x_1, F_1), (x_2, F_2) \leq (x_3, F_1 \cap F_2)$$

where x_3 is any element of $F_1 \cap F_2$. Now, for $i = (x, F) \in I$, define $x_i = x$. Then (x_i) is a net in X. By (iii) this net has a cluster point y. If U is any neighborhood of y, and $F_0 \in \mathcal{F}$, and $x_0 \in F_0$, then there is an $i = (x, F)$ with $(x_0, F_0) \leq i$ (i.e. $F \subseteq F_0$) and $x_i = x \in U$. Since $x \in F \subseteq F_0$, we have that $U \cap F_0 \neq \emptyset$. Fixing F_0 and letting U vary, we conclude that y is a limit point of F_0, hence $y \in F_0$ since F_0 is closed. This is true for all $F_0 \in \mathcal{F}$, so $y \in \cap_{F\in\mathcal{F}} F$ and $\mathcal{F}$ has nonempty intersection. 👍

Note that no form of Choice is needed for this result.

XIII.11.2.2. COROLLARY. Let X be a second countable topological space. Then X is compact if and only if every sequence in X has a convergent subsequence (a topological space with this property is called *sequentially compact*).

This result is false in general for spaces which are just first countable, even for normal spaces: the space ω_1 of ordinals less than the first uncountable ordinal, with the order topology (), is a normal Hausdorff space which is first countable and sequentially compact, but not compact. A first countable topological space which is compact is sequentially compact, but $\beta\mathbb{N}$ (XIII.11.9.16.), which is not first countable, is compact but not sequentially compact. See XIII.11.7.3..

There is a variation of XIII.11.2.1.(v) which is useful. One direction of this result uses the Ultrafilter Property (), which is equivalent to the Boolean Prime Ideal Theorem ().

XIII.11.2.3. PROPOSITION. (BPI) Let $(X, \mathcal{T})$ be a topological space. Then $(X, \mathcal{T})$ is compact if and only if every ultrafilter on X converges.

PROOF: If X is compact, then by XIII.11.2.1. every ultrafilter on X has a cluster point, hence converges (). Conversely, suppose every ultrafilter on X converges. Let $\mathcal{F}$ be a filter on X. Then by the Ultrafilter Property () there is an ultrafilter $\mathcal{G}$ on X containing $\mathcal{F}$, which converges by assumption. The limit of $\mathcal{G}$ is a cluster point for $\mathcal{F}$, so X is compact by XIII.11.2.1.. 👍

XIII.11.3. Compact Metrizable Spaces

There is a very clean characterization of compact metric spaces, using the idea of total boundedness:

XIII.11.3.1. DEFINITION. Let ρ be a metric on a set X. Then ρ is *totally bounded* if for every $\epsilon > 0$, a finite number of open ρ-balls of radius ϵ cover X.

In other words, ρ is totally bounded if for every $\epsilon > 0$, there is a finite set of points $\{x_1, \ldots, x_n\}$ such that every point of X is within ϵ of at least one of the x_k.

A totally bounded metric is bounded: taking $\epsilon = 1$, if $\{x_1, \ldots, x_n\}$ are the centers of balls of radius 1 covering X, and M is the maximum of the distances between the x_k's, then any two points of X are distance less than $M + 2$ apart. But a bounded metric is not necessarily totally bounded: for example, the discrete metric () on an infinite set is bounded but not totally bounded.

XIII.11.3.2. PROPOSITION. A totally bounded metric space is separable (and hence second countable by ()).

PROOF: For each $m \in \mathbb{N}$ let $S_m = \{x_{m,1}, \ldots, x_{m,n_m}\}$ be a finite set of points of X such that the open balls of radius $\frac{1}{m}$ centered at the $x_{m,k}$ cover X. If $S = \cup_m S_m$, then S is a countable dense subset of X. 👍

XIII.11.3.3. PROPOSITION. Let (X, ρ) be a totally bounded metric space. Then every sequence in X has a Cauchy subsequence.

PROOF: For each m, choose a finite set $\{y_{k,m}\}$ in X such that every element of X is within $\frac{1}{2m}$ of one of the y_{km}.

Let (x_n) be a sequence in X. Since there are only finitely many $y_{k,1}$, there are infinitely many x_k within $\frac{1}{2}$ of some single $y_{k,1}$. Thus there is a subsequence $(x_{n,1})$ of (x_n) all of whose terms lie within $\frac{1}{2}$ of this y_{k1}, hence within 1 of each other. Successively let $(x_{n,m+1})$ be a subsequence of $(x_{n,m})$, all of whose terms lie within $\frac{1}{2(m+1)}$ of some $y_{k,m+1}$ and hence within $\frac{1}{m}$ of each other. Then the diagonal sequence $(x_{n,n})$ is a subsequence of (x_n) which is a Cauchy sequence. 👍

The Countable AC () is needed in this proof to choose the $y_{k,m}$, and DC () is needed to choose the subsequences.

The main characterization theorem is:

XIII.11.3.4. THEOREM. Let (X, ρ) be a metric space. Then X is compact (in the metric topology) if and only if ρ is complete and totally bounded.

PROOF: Suppose X is compact. Since X is first countable, every sequence in X has a convergent subsequence. In particular, if (x_n) is a Cauchy sequence, it must have a convergent subsequence, hence must converge (). Thus (X, ρ) is complete. If ρ is not totally bounded, there is an $\epsilon > 0$ such that no finite set of open balls of radius ϵ covers X, so a sequence (x_n) can be chosen so that $\rho(x_n, x_m) \geq \epsilon$ for all n and m. But such a sequence can have no convergent subsequence, a contradiction. Thus ρ is totally bounded.

Conversely, suppose ρ is complete and totally bounded. Suppose $\mathcal{U} = \{U_i : i \in I\}$ is an open cover of X. Since X is second countable (XIII.11.3.2.), it is Lindelöf (), so $\mathcal{U}$ has a countable subcover $\{U_1, U_2, \dots\}$. Suppose this cover does not have a finite subcover. For each n, let $x_n \in X \setminus \cup_{k=1}^{n} U_k$. By XIII.11.3.3., (x_n) has a Cauchy subsequence, which must converge to some x since (X, ρ) is complete. We have $x \in U_n$ for some n, but U_n is open and $x_k \notin U_n$ for all $k > n$, so no subsequence of (x_n) can converge to x, a contradiction. Thus there is a finite subcover, which is a subcover of $\mathcal{U}$. So X is compact. 👍

This result requires some Choice (DC suffices), cf. XIII.15.12.9..

Combining the previous results, we get:

XIII.11.3.5. COROLLARY. Let X be a compactum. Then X is metrizable if and only if it is second countable.

PROOF: If X is metrizable, it is second countable by XIII.11.3.4. and XIII.11.3.2.. Conversely, since a compactum is regular, if it is second countable it is metrizable by the Urysohn Metrization Theorem (). 👍

XIII.11.3.6. There are compacta which are both separable and first countable, but not second countable and hence not metrizable (e.g. XIII.11.14.4.).

Lebesgue Numbers of an Open Cover

The Lebesgue Property and Lebesgue numbers of an open cover are particularly relevant for compact metric spaces, but can be defined in general:

XIII.11.3.7. DEFINITION. Let $\mathcal{U}$ be an open cover of a metric space (X, ρ). $\mathcal{U}$ has the *Lebesgue Property* if there is a $\delta > 0$ such that, for every $x \in X$, there is a $U \in \mathcal{U}$ with $B_\delta(x) \subseteq U$. Such a δ is a *Lebesgue number* of the open cover $\mathcal{U}$.

Any positive number smaller than a Lebesgue number for $\mathcal{U}$ is a Lebesgue number for $\mathcal{U}$. The supremum of all Lebesgue numbers for $\mathcal{U}$ can be ∞, and if finite may or may not be a Lebesgue number for $\mathcal{U}$; thus $\mathcal{U}$ need not have a largest Lebesgue number. If $\mathcal{V}$ is a refinement of $\mathcal{U}$ (in particular, if it is a subcover of $\mathcal{U}$), any Lebesgue number of $\mathcal{V}$ is a Lebesgue number of $\mathcal{U}$. The Lebesgue Property and Lebesgue numbers depend on the metric and are not topological properties.

XIII.11.3.8. EXAMPLES. (i) In $\mathbb{R}$ with the usual metric, the open cover $\mathcal{U} = \{(-n, n) : n \in \mathbb{N}\}$ has the Lebesgue Property, and any positive number is a Lebesgue number for $\mathcal{U}$.

(ii) In $\mathbb{R}$ with the usual metric, the open cover $\mathcal{U}$ consisting of all open intervals of length less than 2 has the Lebesgue Property, and any positive number less than 1 is a Lebesgue number for $\mathcal{U}$. The supremum of the Lebesgue numbers is 1, but 1 is not a Lebesgue number for $\mathcal{U}$.

(iii) In $(0, 1)$ with the usual metric, the open cover $\left\{\left(\frac{1}{n}, 1\right) : n \in \mathbb{N}\right\}$ does not have the Lebesgue Property.

(iv) Even a finite open cover need not have the Lebesgue Property. Let $X = (0, 1)$ with the usual metric. Fix two disjoint decreasing sequences (x_n) and (y_n) in $(0, 1)$ converging to 0, and set $U = (0, 1) \setminus \{x_n : n \in \mathbb{N}\}$ and $V = (0, 1) \setminus \{y_n : n \in \mathbb{N}\}$. Then the open cover $\{U, V\}$ does not have the Lebesgue Property.

XIII.11.3.9. PROPOSITION. Let (X, ρ) be a metric space of bounded diameter d. If $\mathcal{U}$ is an open cover of X by proper subsets, and $\mathcal{U}$ has the Lebesgue property, then any Lebesgue number for $\mathcal{U}$ is $\leq d$. If $\mathcal{U}$ is a finite open cover of X by proper subsets, and $\mathcal{U}$ has the Lebesgue Property, then the supremum of all Lebesgue numbers for $\mathcal{U}$ is a Lebesgue number for $\mathcal{U}$, i.e. $\mathcal{U}$ has a largest Lebesgue number.

PROOF: For any $x \in X$ and $U \in \mathcal{U}$, there is a $y \in X$ with $y \notin U$. Since $\rho(x, y) \leq d$, any Lebesgue number of $\mathcal{U}$ must be $\leq d$. If $\mathcal{U} = \{U_1, \ldots, U_n\}$ is a finite open cover by proper subsets, and δ is the supremum of the Lebesgue numbers of $\mathcal{U}$ ($\delta < \infty$ by the first part of the proof), fix $x \in X$. Then there must be a k such that $B_{\delta - 1/m}(x) \subseteq U_k$ for infinitely many m; hence $B_\delta(x) \subseteq U_k$. So δ is a Lebesgue number for $\mathcal{U}$. 👍

The main result is:

XIII.11.3.10. PROPOSITION. Let (X, ρ) be a compact metric space. Then any open cover of X has the Lebesgue Property.

PROOF: Let $\mathcal{U}$ be an open cover of X. Suppose $\mathcal{U}$ does not have the Lebesgue property. Then for each n there are points $x_n, y_n \in X$ with $\rho(x_n, y_n) < \frac{1}{n}$, but for which there is no $U \in \mathcal{U}$ containing both x_n and y_n. Passing to a subsequence if necessary, we may assume (x_n) converges to a point $x \in X$. Then also $y_n \to x$. There is a $U \in \mathcal{U}$ with $x \in U$. Then x_n and y_n are both in U if n is sufficiently large, a contradiction. 👍

See XIII.11.14.3. for an alternate proof which gives an explicit Lebesgue number.

Here is a sample application:

XIII.11.3.11. COROLLARY. Let (X, ρ) and (Y, σ) be metric spaces, with X compact, and $F : X \to Y$ a continuous function. Then f is uniformly continuous.

PROOF: Let $\epsilon > 0$. For each $y \in Y$, let $U_y = f^{-1}(B_{\epsilon/2}(y))$. Then $\{U_y : y \in Y\}$ is an open cover of X. If $\delta > 0$ is the Lebesgue number of this open cover, and $x_1, x_2 \in X$ with $\rho(x_1, x_2) < \delta$, there is a y with $B_\delta(x_1) \subseteq U_y$; thus $f(x_1)$ and $f(x_2)$ are both in $B_{\epsilon/2}(y)$ and $\sigma(f(x_1), f(x_2)) < \epsilon$. 👍

XIII.11.4. Separation Properties

The results of this subsection give important senses in which compact sets behave like finite sets (see XIII.11.10.19. for another example). The first result is a strengthening of the second half of XIII.11.1.6., with essentially the same proof:

XIII.11.4.1. PROPOSITION. Let X be a Hausdorff space, E a compact subset of X, and y a point of $X \setminus E$. Then E and y have disjoint open neighborhoods.

PROOF: This is another example of an elementary result in topology whose standard proof uses an unnecessary application of the AC (cf. XIII.1.4.2.). We give a proof due to A. KARAGILA which avoids the AC, and is no more difficult than the standard one.

Let $\mathcal{U}$ be the collection of all open sets U in X which have the property that there is an open neighborhood of y disjoint from U. Then $\mathcal{U}$ covers E since X is Hausdorff. Let $\{U_1, \ldots, U_n\}$ be a finite subcover of E. For each k, let V_k be an open neighborhood of y disjoint from U_k. Then $U = \cup_{k=1}^n U_k$ and $V = \cap_{k=1}^n V_k$ are disjoint neighborhoods of E and y. 👍

There is a nice generalization:

XIII.11.4.2. PROPOSITION. Let X be a Hausdorff space, and E and F disjoint compact subsets of X. Then E and F have disjoint open neighborhoods.

PROOF: Let $\mathcal{U}$ be the collection of all open sets U in X such that there is an open neighborhood of F disjoint from U. Then $\mathcal{U}$ covers E by XIII.11.4.1.. Let $\{U_1, \ldots, U_n\}$ be a finite subcover of E. For each k, let V_k be an open neighborhood of F disjoint from U_k. Then $U = \cup_{k=1}^n U_k$ and $V = \cap_{k=1}^n V_k$ are disjoint neighborhoods of E and F. 👍

XIII.11.4.3. COROLLARY. A compactum is normal.

In an almost identical manner (Exercise ()), we can show:

XIII.11.4.4. PROPOSITION. Let X be a regular space, and E and F disjoint subsets of X, with E compact and F closed. Then E and F have disjoint open neighborhoods.

In fact, we have (no Choice needed):

XIII.11.4.5. THEOREM. A compactum is fully normal (XIII.7.7.5.).

PROOF: Let X be a compactum, and $\mathcal{U}$ an open cover of X. Then $\mathcal{U}$ has a finite subcover $\mathcal{U}_0$. The finite cover $\mathcal{U}_0$ has a closed shrinking since X is normal (XIII.11.4.3., XIII.7.6.8.). Thus XIII.7.7.8. applies to give a barycentric refinement of $\mathcal{U}_0$ and hence of $\mathcal{U}$. 👍

Note the following consequence of XIII.11.1.12.:

XIII.11.4.6. PROPOSITION. Let X be a compactum, and p a point of X. The following are equivalent:

(i) $\{p\}$ is a G_δ, and whenever (F_n) is a decreasing sequence of closed neighborhoods of p with $\cap_n F_n = \{p\}$, then $\{F_n : n \in \mathbb{N}\}$ is a local base at p for the topology of X.

(ii) There is a countable local base at p for the topology of X.

(iii) $\{p\}$ is a G_δ.

PROOF: (i) $\Rightarrow$ (ii): Let (U_n) be a sequence of open sets in X with $\cap_n U_n = \{p\}$. Set $V_0 = X$ and inductively let V_n be an open neighborhood of p with $\bar{V}_n \subseteq U_n \cap V_{n-1}$ (using regularity of X). Then $(\bar{V}_n)$ is a decreasing sequence of closed neighborhoods of p with intersection $\{p\}$, so they form a local base at p (XIII.11.1.13.). (ii) $\Rightarrow$ (iii) is trivial (since X is Hausdorff, the intersection of any local base at p is $\{p\}$), and (iii) $\Rightarrow$ (i) is a special case of XIII.11.1.12.. 👍

XIII.11.5. Automatic Continuity and Comparison of Topologies

Propositions XIII.11.1.6. and XIII.11.1.7. combine in a useful consequence:

XIII.11.5.1. PROPOSITION. Let X and Y be topological spaces, with X compact and Y Hausdorff. If $f : X \to Y$ is continuous, then f is a closed mapping.

PROOF: Let E be a closed subset of X. Then E is compact by XIII.11.1.6., so $f(E)$ is compact by XIII.11.1.7. and hence closed by XIII.11.1.6.. 👍

XIII.11.5.2. COROLLARY. Let X and Y be topological spaces, with X compact and Y Hausdorff. If $f : X \to Y$ is continuous and injective, then $f(X)$ is closed in Y and f is a homeomorphism from X onto $f(X)$. In particular, X must also be Hausdorff.

PROOF: A bijective continuous closed mapping is automatically a homeomorphism (i.e. the inverse map is continuous). 👍

XIII.11.5.3. Let X be a set. Any topology on X weaker than a compact topology is compact, and any topology stronger than a Hausdorff topology is Hausdorff. Thus if $\mathcal{T}$ is a compact Hausdorff topology on X, then $\mathcal{T}$ is delicately balanced: no strictly stronger topology is compact, and no strictly weaker topology is Hausdorff [consider the identity map and apply XIII.11.5.2.].

XIII.11.6. Products of Compact Spaces and Tikhonov's Theorem

Perhaps the most important theorem of general topology is Tikhonov's Theorem (see XIII.11.9.21. for some historical comments):

XIII.11.6.1. THEOREM. [TIKHONOV'S THEOREM] Let $\{(X_i, \mathcal{T}_i) : i \in I\}$ be a collection of topological spaces, $X = \prod_{i \in I} X_i$, and $\mathcal{T}$ the product topology on X. If each $(X_i, \mathcal{T}_i)$ is compact, then $(X, \mathcal{T})$ is compact.

This theorem is one of the two theorems of topology, along with the Baire Category Theorem, which are used most extensively in analysis.

Tikhonov's Theorem can, among other things, be interpreted as giving compelling evidence that the product topology is the "right" topology on the Cartesian product.

XIII.11.6.2. Tikhonov's Theorem depends on the Axiom of Choice; in fact, it is equivalent to the Axiom of Choice (cf. Exercise XIII.11.14.6.). Important and frequently-used special cases, however, need only weaker versions of AC or no choice at all. We will prove some important versions under weaker choice assumptions.

There are several known proofs of Tikhonov's Theorem; they are for the most part variations of the arguments we use in the various special cases. For a more complete discussion of these proofs and their history, see [Kel75], [Mun75], ...

Finite Products

The simplest case is that of finite products, where no version of AC is needed:

XIII.11.6.3. THEOREM. Let $(X_1, \mathcal{T}_1), \ldots, (X_n, \mathcal{T}_n)$ be a finite number of topological spaces, and $\mathcal{T}$ the product topology on $X = X_1 \times \cdots \times X_n$. If each $(X_k, \mathcal{T}_k)$ is compact, then $(X, \mathcal{T})$ is compact.

PROOF: The argument is a slight generalization of the one in (). We prove the theorem in the case $n = 2$; this case can be applied successively, or the arguments in the proof repeated finitely many times, to give the general result for finite products. We will also change notation slightly for clarity: we begin with two compact spaces $(X, \mathcal{T})$ and $(Y, \mathcal{S})$, and show that $X \times Y$ is compact in the product topology.

Suppose $(z_i)_{i \in I}$ is a net in $X \times Y$, with $z_i = (x_i, y_i)$. Then (x_i) is a net in X, and since X is compact there is a convergent subnet $(x_{\alpha(j)})_{j \in J}$, where $\alpha : J \to I$, with limit $x \in X$. The net $(y_{\alpha(j)})$ is a net in Y, and Y is compact, so has a convergent subnet $(y_{\alpha(\beta(k))})_{k \in K}$, where $\beta : K \to J$, with limit $y \in Y$. The subnet $(x_{\alpha(\beta(k))})_{k \in K}$ of $(x_{\alpha(j)})$ also converges to x, and hence the subnet $(z_{\alpha(\beta(k))})$ of (z_i) converges to $z = (x, y)$ by ().

XIII.11.6.4. This proof can be modified to show that a countable product of compact spaces is compact, but there is a logical complication and one additional step needed. The additional step is to construct a "diagonal" subnet after a sequence of subnets has been chosen; see Exercise () for details. The logical complication is that an infinite sequence of subnets must be chosen, each depending on the previous one; for this, the Axiom of Dependent Choice is needed. Using another argument (), one can get away with the weaker Countable Axiom of Choice for this result (in fact it is equivalent to Countable AC).

The General Tikhonov Theorem

Next we prove the full Tikhonov Theorem (XIII.11.6.1.). This proof is due to P. CHERNOFF [Che92]; cf. [Fol99,]. At one point we use an argument similar to the one in the proof of XIII.11.6.3.. This proof uses the full Axiom of Choice (in the form of Zorn's Lemma), as it must.

XIII.11.6.5. PROOF: Let $(x_\alpha)_{\alpha\in A}$ be a net in $X = \prod_{i\in I} X_i$. We need to show that (x_α) has a cluster point. If $J_1 \subseteq J_2 \subseteq I$, write π_{J_1} for the projection from $\prod_{i\in J_2} X_i$ onto $\prod_{i\in J_1} X_i$ (the notation avoids mention of J_2 to avoid unnecessary complication). Consider the set of all pairs (J, y), where J is a nonempty subset of I and $y \in \prod_{i\in J} X_i$ is a cluster point for the net $(\pi_J(x_\alpha))_{\alpha\in A}$. The collection $\mathcal{S}$ of such pairs is nonempty since there is such a y whenever J is a singleton by the assumption that each X_i is compact. Put a partial ordering on $\mathcal{S}$ by setting $(J_1, y_1) \leq (J_2, y_2)$ if $J_1 \subseteq J_2$ and $y_1 = \pi_{J_1}(y_2)$.

Suppose $\mathcal{C} = \{(J_k, y_k)\}$ is a chain in $\mathcal{S}$, and set $J_0 = \cup_k J_k$. For each $i \in J_0$, choose k with $i \in J_k$ and let $z_i = \pi_{\{i\}}(y_k)$. If $i \in J_{k_1} \cap J_{k_2}$, then either $J_{k_1} \subseteq J_{k_2}$ or vice versa, and if $J_{k_1} \subseteq J_{k_2}$ we have $\pi_{\{i\}}(y_1) = \pi_{\{i\}}(\pi_{J_1}(y_2)) = \pi_{\{i\}}(y_2)$, so z_i is well defined independent of the choice of k. Set $y = (z_i) \in \prod_{i\in J_0} X_i$. For each $i \in J_0$ we have that z_i is a cluster point of the net $(\pi_{\{i\}}(x_\alpha))_{\alpha\in A}$. If U is a neighborhood of y_0 in $\prod_{i\in J_0} X_i$, then there are indices $i_1, \ldots, i_n \in J_0$ and neighborhoods U_r of z_{i_r} in X_{i_r} such that

$$\prod_{r=1}^{n} U_r \quad \times \prod_{i\in J\setminus\{i_1,\ldots,i_n\}} X_i \quad \subseteq U \ .$$

Since $\mathcal{C}$ is totally ordered, there is a k such that $i_1, \ldots, i_n \in J_k$; for any α_0 there is an $\alpha \geq \alpha_0$ with

$$\pi_{J_k}(x_\alpha) \in \prod_{r=1}^{n} U_r \quad \times \prod_{i\in J_k\setminus\{i_1,\ldots,i_n\}} X_i$$

and hence $\pi_{J_0}(x_\alpha) \in U$. So we have that y_0 is a cluster point of the net $(\pi_{J_0}(x_\alpha))_{\alpha\in A}$ by (). Thus (J_0, y_0) is an upper bound for $\mathcal{C}$.

By Zorn's Lemma, $\mathcal{S}$ has a maximal element (J, y). We need to show that $J = I$, for then y will be the desired cluster point of (x_α). Suppose $J \neq I$, and let $i \in I\setminus J$, $J' = J\cup\{i\}$. There is a subnet $(\pi_J(x_{\alpha(\beta)}))_{\beta\in B}$ of $(\pi_J(x_\alpha))_{\alpha\in A}$ which converges to y by (). The net $\pi_{\{i\}}(x_{\alpha(\beta)}))_{\beta\in B}$ has a subnet $(\pi_{\{i\}}(x_{\alpha(\beta(\gamma))}))_{\gamma\in C}$ which converges to some $z \in X_i$ since X_i is compact. The subnet $\pi_J(x_{\alpha(\beta(\gamma))}))_{\gamma\in C}$ of $(\pi_J(x_{\alpha(\beta)}))_{\beta\in B}$ converges to y, so the subnet $(\pi_{J'}(x_{\alpha(\beta(\gamma))}))_{\gamma\in C}$ of $(\pi_{J'}(x_\alpha))_{\alpha\in A}$ converges to (y, z), and thus $(J', (y, z))$ is an element of $\mathcal{S}$ strictly larger than (J, y), contradicting maximality. Thus $J = I$ and the theorem is proved. 👍

Tikhonov's Theorem for Hausdorff Spaces

Tikhonov's Theorem for Hausdorff spaces does not require the full Axiom of Choice, only the Ultrafilter Property, which is equivalent to the Boolean Prime Ideal Theorem (II.6.3.11.).

The proof we give was developed by H. CARTAN for BOURBAKI. CARTAN'S proof had an additional step (using the full Axiom of Choice) and gave a proof of the full Tikhonov Theorem, but it simplifies nicely to give an efficient proof in the Hausdorff case. The proof is deceptively quick to write, but it depends on earlier results about convergence and projection of ultrafilters.

XIII.11.6.6. THEOREM. [TIKHONOV'S THEOREM FOR HAUSDORFF SPACES] Let $\{(X_i, \mathcal{T}_i) : i \in I\}$ be a collection of Hausdorff topological spaces, $X = \prod_{i\in I} X_i$, and $\mathcal{T}$ the product topology on X. If each $(X_i, \mathcal{T}_i)$ is compact, then $(X, \mathcal{T})$ is compact.

PROOF: By XIII.11.2.3. (which depends on BPI), it suffices to show that if $\mathcal{F}$ is an ultrafilter on X, then $\mathcal{F}$ converges. For each $i \in I$, the ultrafilter $\mathcal{F}_i = \pi_{\{i\}}(\mathcal{F})$ () converges to a unique point $x_i \in X_i$ since X_i is compact and Hausdorff. Then $\mathcal{F}$ converges to $x = (x_i) \in X$ by (). 👍

XIII.11.6.7. If the X_i are not Hausdorff, the same proof works except that the limit point x_i is not necessarily unique. Thus an application of the Axiom of Choice is necessary to choose an x_i for each i. (If I is countable, the Countable AC plus the BPI suffices; cf. XIII.11.6.4..)

XIII.11.6.8. Under a fairly drastic set-theoretic assumption, there is an explicit metrizable product of compact Hausdorff spaces (two-point discrete spaces) which is not compact (XIII.15.12.9.).

Tikhonov's Theorem for the Hilbert Cube

It turns out that it can be proved that the Hilbert cube $[0,1]^{\mathbb{N}}$ is compact without any form of choice. We give an argument here from [Wag93].

XIII.11.6.9. THEOREM. The Hilbert cube $[0,1]^{\mathbb{N}}$ is compact.

PROOF: Suppose $\mathcal{U}$ is an open cover of $[0,1]^{\mathbb{N}}$ with no finite subcover. We will obtain a contradiction by repeatedly subdividing coordinatewise. By passing to a refinement, we may assume that the sets in $\mathcal{U}$ are rectangular open sets of the form $U_1 \times \cdots \times U_n \times [0,1] \times [0,1] \times \cdots$, where the U_k are open sets in $[0,1]$ (this can be done without using any form of choice by simply replacing each $U \in \mathcal{U}$ with the collection of all rectangular open sets contained in U).

Divide the space into $[0,1/2] \times [0,1] \times [0,1] \times \cdots$ and $[1/2,1] \times [0,1] \times [0,1] \times \cdots$. At least one of these sets does not have a finite subcover of $\mathcal{U}$; choose the first one which does not, and call it F_1. Further subdivide into eight pieces, ordered lexicographically:

$$[0,1/4] \times [0,1/2] \times [0,1] \times \cdots, [0,1/4] \times [1/2,1] \times [0,1] \times \cdots, [1/4,1/2] \times [0,1/2] \times [0,1] \times \cdots, \text{ etc.}$$

Let F_2 be the first of these sets in this order for which there is no finite subcover of $\mathcal{U}$. Continue inductively to generate a decreasing sequence of closed sets (F_k) which are products of subintervals. For each n the n'th coordinate intervals $I_{k,n}$ of the F_k have an intersection consisting of a single point x_n, and the point $x = (x_n) \in [0,1]^{\mathbb{N}}$ is in the intersection of all the F_k (in fact, this intersection is a singleton). There is a $U \in \mathcal{U}$ with $x \in U$. Since U is a rectangular open set determined by finitely many coordinates, we have that $F_k \subseteq U$ for some sufficiently large k, contradicting the choice of F_k as a set with no finite subcover from $\mathcal{U}$. 👍

XIII.11.6.10. It is shown more generally in [**?**] by a somewhat similar argument that compactness of a product $\prod_{i \in I} X_i$ of compact spaces can be proved without any form of choice if the index set can be well ordered and there is a choice function for the family of all, or sufficiently many, closed sets in the X_i. (Of course, if the AC is assumed, this proof then gives the full Tikhonov Theorem.)

XIII.11.6.11. If, for each n, X_n is a closed subset of the Hilbert cube, then without any form of choice it follows that $X = \prod_{n=1}^{\infty} X_n$ also embeds as a closed subset of the Hilbert cube, and thus from XIII.11.6.9. it follows that X and each X_n is compact. But it does not seem to be possible to prove that a countable product of compact metrizable spaces is compact without some form of choice, even though such a space embeds in the Hilbert cube (by making some choices): a specific such embedding must be chosen for each n before one can conclude by the above argument that the product embeds, requiring the Countable AC. If one tries to prove directly that the product space is totally bounded with respect to the product metric () (proving

completeness is no problem), choices have to be made also using the Countable AC. Thus this form of the theorem seems to require Countable AC; if so, it is logically no easier than the version for countable products of arbitrary compact spaces (XIII.11.6.4.). It would also be in contrast with the corresponding results for arbitrary products: no more choice is needed to prove that arbitrary products of compact metrizable spaces (indeed, arbitrary products of compact Hausdorff spaces) are compact than to prove that arbitrary powers of $[0,1]$ are compact (each is equivalent to BPI; cf. ()).

XIII.11.7. Variations on Compactness

Countable compactness, sequential compactness, quasicompactness, bicompactness, σ-compactness, local compactness paracompactness, pseudocompactness, metacompactness, Lindelof spaces, precompactness (relative compactness), ...

XIII.11.7.1. DEFINITION. A topological space X is *countably compact* if every countable open cover of X has a finite subcover.

Some useful alternate characterizations of countably compact spaces are given by the next result:

XIII.11.7.2. THEOREM. Let X be a topological space. The following are equivalent:

(i) X is countably compact.

(ii) If (F_n) is a sequence of closed sets in X with the Finite Intersection Property, then $\cap_{n=1}^{\infty} F_n$ is nonempty.

(iii) Every sequence in X has a cluster point.

PROOF: (i) $\iff$ (ii) is proved by taking complements exactly as in the proof of XIII.11.1.10. with the word "countable" added in appropriate places.

(iii) $\Rightarrow$ (i): Suppose $\{U_1, U_2, \dots\}$ is a countable open cover of X with no finite subcover. For each n, let $x_n \in X \setminus \cup_{k=1}^{n} U_k$. If $x \in X$, then $x \in U_m$ for some m; but $x_n \notin U_m$ for $n \geq m$, so x is not a cluster point of (x_n). Thus (x_n) is a sequence in X with no cluster point.

(i) $\Rightarrow$ (iii): Suppose (x_n) is a sequence in X with no cluster point. For each n, let F_n be the closure of $\{x_k : k > n\}$, and let $U_n = F_n^c$. Then $\mathcal{U} = \{U_n : n \in \mathbb{N}\}$ is an open cover of X since any point of X has a neighborhood containing only finitely many of the x_n. Since the F_n are decreasing, the U_n are increasing. If there is a finite subcover of $\mathcal{U}$, then $U_n = X$ for some n. This is a contradiction since F_n is nonempty. Thus $\mathcal{U}$ has no finite subcover. 👍

XIII.11.7.3. COROLLARY. A sequentially compact topological space (XIII.11.2.2.) is countably compact. A first countable topological space is countably compact if and only if it is sequentially compact.

A countably compact space, even a compactum, which is not first countable need not be sequentially compact (XIII.11.9.16.(v)).

XIII.11.7.4. PROPOSITION. A countably compact Lindelöf space is compact. A countably compact metrizable space is compact.

PROOF: Let X be countably compact. If X is Lindelöf, then any open cover of X has a countable subcover, which has a finite subcover. If X is metrizable, fix a metric ρ on X. Any Cauchy sequence in X has a cluster point, hence converges by (); thus (X, ρ) is complete. If X is not totally bounded, then for some $\epsilon > 0$ a sequence (x_n) exists in X with $\rho(x_n, x_m) \geq \epsilon$ for $n \neq m$; this sequence cannot have a cluster point, a contradiction.

XIII.11.7.5. EXAMPLE. Let ω_1 be the first uncountable ordinal, with the order topology. Every sequence in ω_1 has an upper bound, hence is contained in a compact initial segment. Thus ω_1 is sequentially compact, hence countably compact (it is also first countable). But ω_1 is not compact: the "identity net" in ω_1 has no cluster point.

As a variation, the "long line" (XIII.20.5.5.) is sequentially compact but not compact.

σ-Compact Spaces

XIII.11.7.6. DEFINITION. A topological space X is *σ-compact* if X is a countable union of compact subsets of X. More generally, a subset E of X is σ-compact if E is a union of a countable number of compact subsets of X.

Some authors require a σ-compact space to be locally compact, but we will not.

XIII.11.7.7. EXAMPLES. (i) Any compact space is σ-compact.

(ii) $\mathbb{R}^n$ is σ-compact [the closed ball around 0 of radius k is compact for any k].

(iii) A manifold (XIII.20.1.7.) is σ-compact if and only if it has only countably many connected components, i.e. satisfies the equivalent conditions of XIII.20.1.4..

(iv) Any countable topological space is σ-compact. A space with the discrete topology is σ-compact if and only if it is countable.

The next result is an immediate corollary of XIII.11.1.7.:

XIII.11.7.8. PROPOSITION. Let X and Y be topological spaces, and $f : X \to Y$ a continuous function. If E is a σ-compact subset of X, then $f(E)$ is a σ-compact subset of Y.

Recall () that an F_σ in a topological space is a countable union of closed subsets.

XIII.11.7.9. PROPOSITION. Let X and Y be topological spaces, with X σ-compact and Y Hausdorff. Then

(i) Every F_σ in X is σ-compact.

(ii) Every σ-compact subset of Y is an F_σ.

PROOF: (i): Suppose $X = \cup_n K_n$, where K_n is compact. If F is a closed subset of X, then $F = \cup_n (F \cap K_n)$, and by XIII.11.1.6. $F \cap K_n$ is compact. Thus every closed set in X is σ-compact, and hence so is every F_σ. (ii): If $E = \cup_n E_n \subset Y$ with E_n compact, then E_n is closed by XIII.11.1.6., so E is an F_σ. 👍

XIII.11.7.10. COROLLARY. Let X be a σ-compact Hausdorff space. Then a subset of X is σ-compact if and only if it is an F_σ.

It follows that the set of irrational numbers in $\mathbb{R}$ is not σ-compact since it is not an F_σ ().

Combining these results, we get an interesting consequence. Although a continuous image of a closed set is not closed in general, we have:

XIII.11.7.11. PROPOSITION. Let X and Y be topological spaces, with X σ-compact and Y Hausdorff, and let $f : X \to Y$ be a continuous function. If E is an F_σ in X, then $f(E)$ is an F_σ in Y.

PROOF: E is σ-compact by XIII.11.7.9.(i), so $f(E)$ is also σ-compact by XIII.11.7.8., and hence by XIII.11.7.9.(ii) we conclude that $f(E)$ is an F_σ in Y. 👍

In particular, under the hypotheses, the image of any closed subset of X is an F_σ in Y. The hypotheses hold if X and Y are Euclidean spaces, or manifolds with X separable. The corresponding statements for G_δ's are false in general (XIII.11.14.18.). The result fails in general if X is not σ-compact: the image of a closed set need not even be a Borel set, even if X is locally compact and Y is compact [for a simple example, let $X = Y = [0, 1]$ with Y having the ordinary topology and X the discrete topology, and $f = id$]. Even if X and Y are Polish spaces, the image of a closed set in X need not be a Borel set in Y ().

XIII.11.7.12. PROPOSITION. A σ-compact topological space is Lindelöf. Thus a σ-compact regular space is normal.

PROOF: Let $X = \cup_n K_n$, with K_n compact. If $\mathcal{U}$ is an open cover of X, for each n let $\mathcal{V}_n$ be a finite subset of $\mathcal{U}$ which covers K_n. Then $\mathcal{V} = \cup_n \mathcal{V}_n$ is a countable subset of $\mathcal{U}$ which covers X. (This argument uses the Countable AC.) The last statement follows from (). 👍

XIII.11.8. Locally Compact Spaces

Many important spaces such as Euclidean spaces are not compact, but are "locally compact":

XIII.11.8.1. DEFINITION. A Hausdorff space X is *locally compact* if every point of X has a neighborhood (not necessarily open) which is compact.

We will deal with the non-Hausdorff case in XIII.11.8.20..

XIII.11.8.2. EXAMPLES. (i) Any compactum is locally compact. (The whole space is a compact neighborhood of any point.)

(ii) $\mathbb{R}^n$ is locally compact since every closed ball is compact. More generally, any open set in $\mathbb{R}^n$ is locally compact in the relative topology for the same reason.

(iii) Any space with the discrete topology is locally compact.

(iv) Any closed subspace of a locally compact Hausdorff space is locally compact in the relative topology: if Y is a closed subset of a locally compact Hausdorff space X, $p \in Y$, and K is a compact neighborhood of p in X, then $K \cap Y$ is a compact neighborhood of p in Y in the relative topology. In particular, any closed subset of $\mathbb{R}^n$ is locally compact in the relative topology.

(v) Any open subset of a compactum is locally compact (in the relative topology): if U is an open subset of a compactum X, and $p \in U$, then by XIII.11.4.2. p and $X \setminus U$ have disjoint neighborhoods V and W in X. $\bar{V}$ is a compact neighborhood of p in X which is contained in U, i.e. a compact neighborhood of p in U.

Actually, any open subset of a locally compact Hausdorff space is locally compact (XIII.11.8.8.); in fact, any locally compact Hausdorff space is homeomorphic to an open set in a compactum (XIII.11.8.4.).

(vi) Spaces such as $\mathbb{Q}$, $\mathcal{N} = \mathbb{N}^{\mathbb{N}}$ (), and $\mathbb{R}^{\mathbb{N}}$ () are not locally compact; in fact, no point in any of these spaces has a compact neighborhood.

The One-Point Compactification

XIII.11.8.3. If X is a locally compact Hausdorff space, a single point can be added to X to make a compactum, called the *one-point compactification* of X and denoted $X^\dagger$. Specifically, take a point not in X which we call ∞, and let $X^\dagger = X \cup \{\infty\}$. Put a topology on $X^\dagger$ by taking all open subsets of X to be open in $X^\dagger$, along with all subsets consisting of ∞ along with the complement of a compact subset of X (including the complement of $\emptyset$, giving the whole space $X^\dagger$). It is simple and routine to verify that this is a topology (Exercise XIII.11.14.14.), and that X is an open subset of $X^\dagger$. See XIII.11.14.14. for a generalization of the one-point compactification construction.

XIII.11.8.4. PROPOSITION. $X^\dagger$ is a compactum with this topology.

PROOF: It is easy to see that $X^\dagger$ is compact. If $\{U_i\}$ is an open cover, there is a set U_{i_0} containing ∞. The complement of U_{i_0} is a compact subset of X, so the open cover of $X^\dagger \setminus U_{i_0}$ by the remaining U_i has a finite subcover $\{U_{i_1}, \ldots, U_{i_n}\}$. Then $\{U_{i_0}, U_{i_1}, \ldots, U_{i_n}\}$ is a finite subcover of $X^\dagger$.

To see that $X^\dagger$ is Hausdorff, it suffices to show that if $p \in X$, then p and ∞ have disjoint neighborhoods. Since X is locally compact, there is an open neighborhood U of p in X whose closure in X is compact (e.g. the interior of a compact neighborhood). Thus U and $\{\infty\} \cup (X \setminus \bar{U})$ are disjoint neighborhoods of p and ∞. 👍

The one-point compactification of X is essentially unique. Thus it can often be realized or recognized in a different form:

XIII.11.8.5. PROPOSITION. Let X be a locally compact Hausdorff space, Y a compactum, and $\phi : X \to Y$ a homeomorphism from X onto a (necessarily open) subspace $\phi(X)$ of Y with $Y \setminus \phi(X)$ a single point q. Then ϕ extends to a homeomorphism $\bar{\phi}$ from $X^\dagger$ onto Y with $\bar{\phi}(\infty) = q$.

PROOF: The map $\bar{\phi}$ is obviously completely determined; it is only necessary to show it is a homeomorphism. If V is an open set in Y, and V does not contain q, then since ϕ is continuous, $\bar{\phi}^{-1}(V) = \phi^{-1}(V)$ is open in X, hence in $X^\dagger$. And if $q \in V$, then V^c is a compact subset of $\phi(X)$, hence $\phi^{-1}(V^c)$ is compact since ϕ^{-1} is continuous, so $\bar{\phi}^{-1}(V) = X^\dagger \setminus \phi^{-1}(V^c)$ is open in $X^\dagger$. Thus $\bar{\phi}$ is continuous. A continuous bijection from a compact space to a Hausdorff space is a homeomorphism by (), so $\bar{\phi}$ is a homeomorphism. 👍

XIII.11.8.6. EXAMPLES. (i) Let Y be any compactum, and $q \in Y$. Then $X = Y \setminus \{q\}$ is a locally compact Hausdorff space with $X^\dagger$ homeomorphic to Y. By the one-point compactification construction, every locally compact Hausdorff space arises this way.

(ii) An n-sphere with a point removed is homeomorphic to $\mathbb{R}^n$, e.g. by stereographic projection (). Thus $(\mathbb{R}^n)^\dagger$ is homeomorphic to S^n. In particular, $\mathbb{R}^\dagger$ is homeomorphic to a circle.

XIII.11.8.7. If X is already compact, then $\emptyset$ is the complement of a compact subset of X, so $\{\infty\}$ is open in $X^\dagger$, i.e. ∞ is an isolated point in $X^\dagger$, and $X^\dagger$ is the separated union of X and a one-point discrete space. Conversely, if ∞ is isolated in $X^\dagger$, then X is a closed subset of $X^\dagger$, hence compact. Thus X is dense in $X^\dagger$ if and only if X is noncompact.

XIII.11.8.8. It follows that any open subset of a locally compact Hausdorff space is locally compact: if U is an open subset of a locally compact Hausdorff space X, then U is an open subset of the compactum $X^\dagger$ and thus is locally compact in the relative topology by XIII.11.8.2.(v).

We also get the following corollaries of the one-point compactification construction:

XIII.11.8.9. PROPOSITION. A locally compact Hausdorff space is completely regular ().

PROOF: $X^\dagger$ is normal by XIII.11.4.3., hence completely regular, and complete regularity passes to subspaces. 👍

However, a locally compact Hausdorff space need not be normal (XIII.11.14.7., XIII.20.5.8.).

XIII.11.8.10. PROPOSITION. Let X be a locally compact Hausdorff space. If $p \in X$ and V is a neighborhood of p, then there is an open neighborhood U of p such that $\bar{U}$ is compact and contained in V.

PROOF: There is a compact neighborhood K of p in X; the interior W of K is an open neighborhood of p whose closure is compact. Replacing V by $V \cap W$, we may assume $\bar{V}$ is compact. Since X is regular, $\{p\}$ and V^c have disjoint neighborhoods U and Z. Then $\bar{U} \subseteq V$, and $\bar{U}$ is compact since it is a closed subset of $\bar{V}$. 👍

XIII.11.8.11. PROPOSITION. Let X be a locally compact Hausdorff space. The following are equivalent:

(i) The point ∞ has a countable local base in $X^\dagger$.

(ii) $\{\infty\}$ is a G_δ in $X^\dagger$.

(iii) X is σ-compact.

(iv) X is Lindelöf.

PROOF: It is obvious from the construction of $X^\dagger$ that (ii) $\iff$ (iii), and it follows from XIII.11.4.6. that (i) $\iff$ (ii). (iii) $\Rightarrow$ (iv) by XIII.11.7.12.. For (iv) $\Rightarrow$ (iii), each $x \in X$ has an open neighborhood V_x with $\bar{V}_x$ compact. $\{V_x : x \in X\}$ has a countable subcover $\{V_{x_n} : n \in \mathbb{N}\}$, and $X = \cup_n \bar{V}_{x_n}$. 👍

XIII.11.8.12. PROPOSITION. Let X be a locally compact, σ-compact Hausdorff space. Then there is a sequence (U_n) of open sets in X with $\bar{U}_n$ compact and contained in U_{n+1} for each n, and $X = \cup_{n=1}^\infty U_n$.

PROOF: Let (K_n) be a sequence of compact subsets of X with $X = \cup K_n$. Let U_1 and V_1 be disjoint neighborhoods of K_1 and $\{\infty\}$ in $X^\dagger$; then U_1 is open and the closure $\bar{U}_1$ of U_1 in $X^\dagger$ is compact and contained in X. Inductively take U_{n+1} and V_{n+1} to be disjoint open neighborhoods of $\bar{U}_n \cup K_{n+1}$ and $\{\infty\}$ in $X^\dagger$. 👍

XIII.11.8.13. THEOREM. Let X be a locally compact Hausdorff space. The following are equivalent:

(i) X is metrizable and σ-compact.

(ii) There is a countable base for the topology of X consisting of compact sets.

(iii) X is second countable.

(iv) X is a Polish space ().

(v) $X^\dagger$ is metrizable.

There are various other ways to phrase these conditions which are equivalent by general considerations, e.g. "X is separable and metrizable" (). There are metrizable locally compact spaces which do not satisfy the conditions, e.g. an uncountable discrete space.

PROOF: (i) $\Rightarrow$ (v): Let (U_n) be an increasing sequence of open sets in X as in XIII.11.8.12.. Then $\bar{U}_n$ is compact and metrizable for each n, hence second countable (). Thus U_n is second countable. There is also a countable local base at ∞ in $X^\dagger$ by XIII.11.8.11.. Putting together a countable base for the topology of U_n for each n and a countable local base at ∞, we obtain a countable base for the topology of $X^\dagger$; hence $X^\dagger$ is a second countable compactum, so it is metrizable ().

(v) $\Rightarrow$ (iv): A compact metrizable space is a Polish space (); so $X^\dagger$ is Polish. Thus the open subset X of $X^\dagger$ is also a Polish space ().

(iv) ⇒ (iii): A separable metric space is second countable ().

(iii) ⇒ (ii): It suffices to show that if $\{U_n\}$ is a countable base, then the collection

$$\{\bar{U}_n : n \in \mathbb{N},\ \bar{U}_n \text{ compact}\}$$

is also a base. Let $p \in X$ and V a neighborhood of p in X. There is an open set U containing p such that $\bar{U}$ is compact and contained in V (XIII.11.8.10.). Take U_n so that $p \in U_n \subseteq U$. Then $\bar{U}_n \subseteq V$, and $\bar{U}_n$ is compact since it is a closed subset of $\bar{U}$.

(ii) ⇒ (i): X is regular (XIII.11.8.9.), hence metrizable by the Urysohn Metrization Theorem (). (ii) trivially implies that X is σ-compact.

XIII.11.8.14. There is no universally accepted standard notation for the one-point compactification of a space X. I have chosen a notation $X^\dagger$ that is not widely used, and an explanation is in order. The most common notations are X^*, X^+, X_∞; other notations sometimes used are X_*, X_+, X^∞, $\tilde{X}$, and perhaps others.

There are two reasons I have chosen not to use X^*. One is that topologists also often use this notation to mean something else, e.g. the corona space $\beta X \setminus X$ (). The other reason comes from my background in Operator Algebras, where * is normally used to mean something else (); in fact, it is used to mean too many different things in Operator Algebras!) In addition, there is a natural relationship between adding a point at infinity in topology and adding a unit in algebra: a commutative C*-algebra is an algebra of the form $C_0(X)$, the continuous functions vanishing at infinity on a locally compact Hausdorff space X (), and the unitization of this algebra is precisely the continuous functions on the one-point compactification of X. Thus it makes sense to use the same notation for one-point compactification as for adding a unit to a C*-algebra. A common notation in algebra is to write A^+ for the unitization of the algebra A, and thus X^+ would be logical notation for the one-point compactification, giving that $C_0(X)^+ = C(X^+)$. However, a C*-algebra A also has a positive cone which is usually denoted A_+ or sometimes A^+, and the two notations are too easily confused. So in [Bla06] I settled on the notation $A^\dagger$ for the unitization of a C*-algebra, and thus $X^\dagger$ for the one-point compactification of a space (so that $C_0(X)^\dagger = C(X^\dagger)$), as a variation of A^+ which is easily distinguishable but similar enough to be suggestive, and I have kept that notation here. Some readers may not be happy with my choice, but it is my book ...

Urysohn's Lemma for Locally Compact Spaces

Although a locally compact space need not be normal (XIII.20.5.8.), there is a version of Urysohn's Lemma. We first make an observation and a definition:

XIII.11.8.15. Proposition. Let X be a locally compact Hausdorff space, and A a compact subset of X, and V a neighborhood of A in X. Then there is an open neighborhood U of A contained in V with $\bar{U}$ compact.

Proof: This is a routine compactness argument from XIII.11.8.10.. For each $p \in U$, let U_p be an open neighborhood of p contained in V with $\bar{U}_p$ compact. The open cover $\{U_p : p \in A\}$ of A has a finite subcover $\{U_{p_1}, \ldots, U_{p_n}\}$. Set $U = U_{p_1} \cup \cdots \cup U_{p_n}$.

XIII.11.8.16. DEFINITION. Let X be a topological space. A continuous function $f : X \to \mathbb{C}$ has *compact support* if the closure of the support $S_f = \{x \in X : f(x) \neq 0\}$ of f is compact. Denote by $C_c(X)$ the set of all continuous functions of compact support from X to $\mathbb{C}$.

XIII.11.8.17. It is easily verified that $C_c(X)$ is a subalgebra of $C(X)$. But in general it need not contain any nonzero function. However, if X is locally compact, $C_c(X)$ is large enough to separate points and closed sets:

XIII.11.8.18. THEOREM. [URYSOHN'S LEMMA, LOCALLY COMPACT CASE] Let X be a locally compact Hausdorff space. If A and B are disjoint closed subsets of X with A compact, then there is a continuous function $f : X \to [0, 1]$ of compact support with $f(x) = 1$ for all $x \in A$ and $f(x) = 0$ for all $x \in B$.

PROOF: The set $V = B^c$ is a neighborhood of A. Let U be an open neighborhood of A in X contained in V with $\bar{U}$ compact. Regarding X, and hence A, B, U, as subsets of $X^\dagger$, let $C = X^\dagger \setminus U$. Then A and C are disjoint closed subsets of the compact, hence normal, space $X^\dagger$. If $g : X \to [0, 1]$ with $g(x) = 1$ for all $x \in A$ and $g(x) = 0$ for all $x \in C$, then the restriction of g to X is the desired f. 👍

XIII.11.8.19. In particular, if X is a locally compact Hausdorff space, B a closed subset of X, and $p \in X$, $p \notin B$, then (applying the theorem with $A = \{p\}$) there is a continuous function $f : X \to [0, 1]$ of compact support with $f(p) = 1$ and $f(x) = 0$ for all $x \in B$.

The Non-Hausdorff Case

XIII.11.8.20. There is no natural definition of local compactness for non-Hausdorff spaces. Each of the following conditions, which are equivalent for Hausdorff spaces, is a reasonable potential definition for a topological space X:

(i) Every point of X has a neighborhood (not necessarily open) which is compact.

(ii) For any $p \in X$ and any open neighborhood V of X, there is a compact neighborhood U (not necessarily open) of p contained in V.

(iii) Every point of X has an open neighborhood whose closure is compact.

(iii′) For any $p \in X$ and any open neighborhood V of X, there is an open neighborhood U of X contained in V whose closure is compact.

(iv) For any $p \in X$ and any open neighborhood V of X, there is an open neighborhood U of X whose closure is compact and contained in V.

In general, (iv) $\Rightarrow$ (iii) $\Longleftrightarrow$ (iii′) $\Rightarrow$ (i) and (iv) $\Rightarrow$ (ii) $\Rightarrow$ (i). In Hausdorff spaces, (i) $\Rightarrow$ (iv) (XIII.11.8.10.), so all the conditions are equivalent. None of the other implications hold in general [SS95, Examples 9, 18, 35].

XIII.11.9. Compactifications

It is often very convenient to embed a given topological space into a compactum. The first instance of this is to add $\pm\infty$ to the real line to obtain the extended real line, which is topologically and order-theoretically the same as the compact space $[0,1]$. There are some systematic ways to compactify a topological space, which we discuss in this section.

XIII.11.9.1. DEFINITION. Let X be a Hausdorff topological space. A *compactification* of X is a compactum Y and a homeomorphism ϕ of X onto a dense subset of Y.

Some authors consider compactifications where X and/or Y is not Hausdorff (cf. XIII.11.9.20.), but we will only consider the Hausdorff case. By (), a (Hausdorff) space has a compactification if and only if it is completely regular.

XIII.11.9.2. In some references, a pair (Y,ϕ) is called a compactification of X if Y is a compactum and ϕ is simply an injective continuous function from X onto a dense subset of Y. Instances of this are the standard maps of $\mathbb{R}$ to a figure 8, a figure 6, a torus via an irrational angle wraparound (), or a solenoid (). Another instance would be a map from $\mathbb{N}$ with the discrete topology onto a dense subset of $[0,1]$. An important and natural example is the Bohr compactification of $\mathbb{R}$ (XXIII.5.2.2.). We will not consider these to be compactifications, but they are what we call compact representations (XIII.11.9.9.).

XIII.11.9.3. The density of X in a compactification is a natural condition, but is not restrictive: if ϕ is a homeomorphism of X with a subspace of a compactum Z, then the closure of $\phi(X)$ in Z is a compactification of X.

XIII.11.9.4. There are several special instances of compactifications already considered:

(i) If (X,ρ) is a totally bounded metric space, then the completion of (X,ρ) is a compactification of X.

(ii) If X is a totally ordered space with the order topology, then the order-completion of X with endpoints added if necessary, with the order topology, is a compactification of X ().

(iii) If X is a locally compact, noncompact Hausdorff space, then the one-point compactification $X^\dagger$ (XIII.11.8.3.) is a compactification of X. (If X is already compact, then $X^\dagger$ is not a compactification of X since X is not dense in $X^\dagger$; in fact, the only compactification of a compact space X is X itself. The fact that the one-point compactification is not a compactification in this case is an unfortunate inconsistency in standard terminology.)

(iv) There are more complicated compactifications of $\mathbb{R}$ than the extended real line and the one-point compactification (circle). For example, there is a homeomorphism of $\mathbb{R}$ onto the graph of $y=\sin\left(\frac{1}{x}\right)$ for $0<x<\frac{1}{\pi}$, so the topologist's sine curve (XIII.19.5.5.) is a compactification of $\mathbb{R}$.

(v) If X is completely regular, and ϕ is a homeomorphism of X onto a subspace of a cube (XIII.7.8.4.), then the closure of $\phi(X)$ is a compactification of X.

The compactification of (v) is actually universal: every compactification can be done (up to homeomorphism) in this way. For if Y is any compactification of X, then Y can be embedded in a cube as in XIII.7.8.4.. The construction of XIII.11.9.10. using the restrictions to X of the coordinate functions of this embedding yields Y.

XIII.11.9.5. Since a compact metrizable space is second countable, a space with a metrizable compactification is second countable. Conversely, by the construction of XIII.7.8.4. a second countable completely regular space can be embedded in the Hilbert cube, which is metrizable, and hence has a metrizable compactification.

XIII.11.9.6. Although the homeomorphism ϕ is often understood, it is logically cleaner to regard it as a part of the compactification. Two compactifications (Y, ϕ) and (Z, ψ) of a space X are *equivalent* if there is a homeomorphism $\omega : Y \to Z$ with $\psi = \omega \circ \phi$. If there is just a continuous function $\omega : Y \to Z$ with $\psi = \omega \circ \phi$, we say (Y, ϕ) *dominates* (Z, ψ). Such an ω is unique since it is completely determined on the dense subset $\phi(X)$ as $\psi \circ \phi^{-1}$, and it is necessarily surjective since $\omega(Y)$ is a compact subset of Z containing the dense subset $\psi(X)$.

Dominance gives a partial ordering on the equivalence classes of compactifications of X, setting $(Y, \phi) \geq (Z, \psi)$ if (Y, ϕ) dominates (Z, ψ). If X is locally compact and noncompact, then the one-point compactification of X is the smallest compactification of X under this ordering (); conversely, it is not hard to show (cf. ()) that if X has a minimal compactification, it must be a one-point compactification and X must thus be locally compact. There is always a largest compactification of X if X is completely regular, the Stone-Čech compactification βX ().

XIII.11.9.7. More generally, if X_1 and X_2 are (completely regular) spaces with compactifications (Y, ϕ) and (Z, ψ) respectively, and $f : X_1 \to X_2$ is a continuous function, an *extension* of f to (Y, Z) is a continuous function $\tilde{f} : Y \to Z$ with $\tilde{f} \circ \phi = \psi \circ f$. Such an extension, if it exists, is unique.

XIII.11.9.8. A compactification (Y, ϕ) of X naturally defines a uniform structure () on X by restricting the unique uniform structure on Y (). (However, not every uniform structure on X arises in this manner in general.) A continuous function $f : X_1 \to X_2$ extends to compactifications (Y, ϕ) and (Z, ψ) in the sense of XIII.11.9.7. if and only f is uniformly continuous for these uniform structures.

XIII.11.9.9. More generally, we define a *compact representation* of a (completely regular) space X to be a pair (Y, ϕ), where Y is a compactum and ϕ is a continuous function from X onto a dense subspace of Y. Thus a compactification is a special kind of compact representation, as are the "compactifications" of XIII.11.9.2.. Another important example of a compact representation is a bounded continuous function from X to $\mathbb{R}$, e.g. a continuous function from X to $[0, 1]$. Equivalence, domination, and extension can be defined in this more general context. Any compact representation which dominates a compactification is itself a compactification.

The Stone-Čech Compactification

There is a largest (in the sense of XIII.11.9.6.) compactification of any completely regular space X, called the *Stone-Čech compactification* of X and denoted βX. This compactification is attributed to M. Stone and E. Čech (independently), but see XIII.11.9.21..

The Stone-Čech compactification of a space X can be constructed in a number of ways (Stone and Čech used rather different constructions). One construction is via Boolean algebras and/or ultrafilters (cf. XIII.11.9.14.). A very slick construction is as the spectrum of the C*-algebra of bounded complex-valued continuous functions on X (XX.16.2.21.), but this approach is probably not the best for beginning students or topologists. We will give two versions of a purely topological construction.

The first version is based on the next result, which is proved by a pullback construction:

XIII.11.9.10. Proposition. Let X be a completely regular space, and $\{(Y_i, \phi_i) : i \in I\}$ a set of compact representations (XIII.11.9.9.) of X. Then there is a compact representation (Y, ϕ), unique up to equivalence, which is the least upper bound of the (Y_i, ϕ_i).

Proof: It is obvious that the least upper bound, if it exists, is unique up to equivalence. We show existence. Let $Z = \prod_i Y_i$. Then Z is compact by Tikhonov's Theorem (the Hausdorff version XIII.11.6.6. suffices). Define a map $\phi : X \to Z$ by $(\phi(x))_i = \phi_i(x)$ for $x \in X$. Then ϕ is continuous by the universal property of the product topology (). Let Y be the closure of $\phi(X)$ in Z. Then (Y, ϕ) obviously dominates (Y_i, ϕ_i) via coordinate projections. If (Y', ψ) dominates each (Y_i, ϕ_i) via a map $\omega_i : Y' \to Y_i$, define $\omega : Y' \to Y$ by $(\omega(t))_i = \omega_i(t)$ for $t \in Y'$. Then (Y', ψ) dominates (Y, ϕ) via ω. 👍

XIII.11.9.11. One then gets an apparent proof of the existence of a maximal compactification by simply taking the least upper bound of the "set" of all compact representations of X. However, there is a set-theoretic problem: this "set" is not a set. The problem can be circumvented by noting that if X has cardinality κ, then the cardinality of any compact representation is at most 2^{2^κ} (), so we could restrict to only compact representations whose underlying set is a subset of a fixed set of cardinality 2^{2^κ}, and these compact representations form a set. One can also restrict to one compact representation in each equivalence class in the construction. (This appears to require the AC (), but the AC can be avoided by an argument working through XIII.11.9.12.; anyway, use of the AC is not much of a problem here since some form of choice in the guise of Tikhonov's Theorem is necessary to do almost anything with compactifications.)

Call the maximal compact representation βX; it is a compactification since X has at least one compactification, which is dominated by βX. It is customary to identify X with its image in βX.

XIII.11.9.12. A more common and concrete construction of βX is to let $\mathcal{C}$ be the set of all continuous functions from X to $[0, 1]$, and embed X into $[0, 1]^{\mathcal{C}}$ by taking $\phi(x)_f = f(x)$ for $f \in \mathcal{C}$ and taking Y to be the closure of $\phi(X)$. Since each such f gives a compact representation of X, each of these is dominated by the βX constructed previously, hence (Y, ϕ) is dominated by βX. On the other hand, since βX is compact, it embeds into a cube (XIII.7.8.4., XIII.11.4.3.), and the coordinate functions of this embedding, restricted to X, are in $\mathcal{C}$; it follows that (Y, ϕ) dominates βX, and therefore (Y, ϕ) is equivalent to βX.

We summarize in a theorem:

XIII.11.9.13. Theorem. [Stone-Čech Compactification] Let X be a completely regular space. There is a compactum βX containing X as a dense subspace, unique up to homeomorphism which is the identity on X, with the property that if f is a continuous function from X to any compactum Y, then f extends uniquely to a continuous function $\tilde{f} : \beta X \to Y$.

XIII.11.9.14. We describe the ultrafilter version of the construction of βX only for X a set with the discrete topology. For the general version see [GJ76]. If X is a discrete space, βX can be identified with the set σX of all ultrafilters on X, with the hull-kernel topology (): the closure of a set $\mathcal{S}$ of ultrafilters is the set of all ultrafilters containing the filter which is the intersection of the ultrafilters in $\mathcal{S}$. It is easy to show

that this space is a compactum (), and that the set of fixed ultrafilters, which can be naturally identified with X, is dense, so σX is a compactification of X. To show that σX dominates βX,

XIII.11.9.15. If X is locally compact, then the Stone-Čech compactification dominates the one-point compactification $X^\dagger$. Since X is open in $X^\dagger$, its preimage in βX, the image of X in βX, is open. Conversely, if X is open in βX, then X is locally compact by XIII.11.8.2.(v).

The set $\beta X \setminus X$ is called the *corona* or *remainder* of X, especially if X is locally compact; in this case $\beta X \setminus X$ is compact.

XIII.11.9.16. The Stone-Čech compactification of a space is rather huge, and often has pathological properties. We list without proof some key properties of some standard spaces:

(i) If X is second countable and noncompact, then $card(\beta X) = 2^{2^{\aleph_0}}$. In particular, $card(\beta\mathbb{N}) = card(\beta\mathbb{Q}) = card(\beta\mathbb{R}) = 2^{2^{\aleph_0}}$. If X is any space which is locally compact and σ-compact, but not compact, then $card(\beta X \setminus X) \geq 2^{2^{\aleph_0}}$.

(ii) Every infinite closed subset of $\beta\mathbb{N} \setminus \mathbb{N}$ contains a copy of $\beta\mathbb{N}$, and in particular has cardinality $2^{2^{\aleph_0}}$.

(iii) $\beta\mathbb{N}$ is *extremally disconnected*: the closure of every open set is open.

(iv) $\beta\mathbb{R}$ is connected (as is βX for any connected X (XIII.13.1.10.)). $\beta\mathbb{R} \setminus \mathbb{R}$ has two connected components, one at $+\infty$ and the other at $-\infty$ (cf. XIII.13.3.6.). But $\beta\mathbb{R} \setminus \mathbb{R}$ is totally path disconnected, and not locally connected at any point. In fact, if X is locally compact and σ-compact, but not compact, then $\beta X \setminus X$ is an *F-space*: disjoint open F_σ's have disjoint closures. Any F-space is totally path disconnected. In $\beta\mathbb{N} \setminus \mathbb{N}$, $\beta\mathbb{R} \setminus \mathbb{R}$, and many other corona spaces, every nonempty G_δ has nonempty interior.

(v) Although any sequence in $\beta\mathbb{N}$ has a cluster point (in fact, $2^{2^{\aleph_0}}$ cluster points if it has infinite range), the only convergent sequences in $\beta\mathbb{N}$ are ones which are eventually constant. Thus any sequence of distinct points in $\beta\mathbb{N}$ has no convergent subsequence, and $\beta\mathbb{N}$ is compact but not sequentially compact. The same statements are true about $\beta\mathbb{R} \setminus \mathbb{R}$, so $\beta\mathbb{R} \setminus \mathbb{R}$ is also not sequentially compact.

For more detailed structure results about $\beta\mathbb{N}$ and related spaces, see [GJ76] and [vM84].

XIII.11.9.17. There are, however, locally compact noncompact spaces for which the one-point compactification and the Stone-Čech compactification coincide. The simplest example is the space ω_1 of ordinals less than the first uncountable ordinal, with the order topology, since every real-valued continuous function on ω_1 is eventually constant; cf. also XIII.20.5.6.. These spaces are *pseudocompact*: every real-valued continuous function is bounded.

XIII.11.9.18. Note that either Tikhonov's Theorem for Hausdorff spaces or the Ultrafilter Property is needed to prove Theorem XIII.11.9.13.. In fact, this theorem is equivalent to the BPI (II.6.3.11.).

XIII.11.9.19. THEOREM. The following theorems are logically equivalent:

(i) Tikhonov's Theorem for Hausdorff spaces.

(ii) Tikhonov's Theorem for copies of $[0,1]$.

(iii) Existence of Stone-Čech compactification for discrete spaces.

(iv) Existence of Stone-Čech compactification for arbitrary completely regular spaces.

PROOF: (i) ⇒ (ii) and (iv) ⇒ (iii) are trivial. (ii) ⇒ (iv) is the standard construction of the Stone-Čech compactification (XIII.11.9.12.). So we need only prove (iii) ⇒ (i).

Let $\{X_i : i \in I\}$ be an indexed collection of compacta, and let $X = \prod_i X_i$ with the product topology. Let Y be the set X with the discrete topology, and βY its Stone-Čech compactification. For each i, the coordinate map $\pi_i : X \to X_i$, regarded as a map from Y to X_i, extends uniquely to a continuous function f_i from βY to X_i, by the universal property of βY. The f_i define a continuous function from βY to X (), which is surjective since its restriction to Y is the identity map from Y to X. Thus X is a continuous image of the compact space βY, hence compact by ().

Note that (ii) ⇒ (i) is a simple consequence of the fact that every compact Hausdorff space can be embedded in a product of intervals, but we did not need to use this argument. 👍

XIII.11.9.20. There is a compactification of any T_1 space X called the *Wallman compactification*, which is similar to the Stone-Čech compactification but not Hausdorff if X is not normal (it coincides with the Stone-Čech compactification if X is normal). The Wallman compactification shows that every T_1 space can be embedded as a dense subset of a compact T_1 space (for a simpler proof of this, see XIII.11.14.14.).

XIII.11.9.21. According to [Dud02], TIKHONOV was the first to prove existence of the Stone-Čech compactification (in 1930), and ČECH elaborated on TIKHONOV's work; STONE's work appears to have been done independently, but later than TIKHONOV (as GELFAND once observed, TIKHONOV obtained his results "previously but independently.")

On the other hand, according to [Dud02], the general form (XIII.11.6.1.) of Tikhonov's Theorem was first proved by ČECH in 1936; TIKHONOV only proved that an arbitrary product of copies of $[0,1]$ is compact.

XIII.11.10. Paracompactness and Partitions of Unity

For some purposes, it is enough to be able to make an open cover of a space "locally finite" instead of actually (globally) finite, and it suffices to allow making a given open cover "finer" instead of just working with an actual subcover. It turns out that this is possible in the great majority of topological spaces encountered "naturally"; such spaces are called *paracompact*.

Paracompact spaces were only defined and named in 1944 by J. DIEUDONNÉ.

XIII.11.10.1. DEFINITION. Let $\mathcal{U}$ be an open cover of a topological space $(X, \mathcal{T})$. $\mathcal{U}$ is *point finite* if every $x \in X$ is contained in only finitely many $U \in \mathcal{U}$. $\mathcal{U}$ is *locally finite* if each $x \in X$ has an open neighborhood W such that $W \cap U \neq \emptyset$ for only finitely many $U \in \mathcal{U}$.

A locally finite cover is obviously point finite; the converse is false (Exercise ().) A finite cover is obviously locally finite.

XIII.11.10.2. DEFINITION. Let $\mathcal{U}$ and $\mathcal{V}$ be open covers of a topological space $(X, \mathcal{T})$. $\mathcal{V}$ is a *refinement* of $\mathcal{U}$ if every $V \in \mathcal{V}$ is contained in some $U \in \mathcal{U}$.

Note that $\mathcal{U}$ itself, or any subcover of $\mathcal{U}$, is a refinement of $\mathcal{U}$. If X is a metric space, $\epsilon, \delta > 0$, and $\mathcal{U}$ and $\mathcal{V}$ are the collections of all balls of radius ϵ and δ respectively, then $\mathcal{V}$ is a refinement of $\mathcal{U}$ if $\delta \leq \epsilon$. If $\mathcal{V}$ is a refinement of $\mathcal{U}$ and $\mathcal{W}$ is a refinement of $\mathcal{V}$, then $\mathcal{W}$ is a refinement of $\mathcal{U}$.

It can happen that two distinct open covers are each refinements of the other. For example, if $\mathcal{U}$ is the set of (bounded) open intervals in $\mathcal{R}$ of rational length, and $\mathcal{V}$ the set of open intervals of irrational length, then $\mathcal{U}$ and $\mathcal{V}$ are each refinements of the other.

XIII.11.10.3. DEFINITION. Let $(X, \mathcal{T})$ be a topological space. Then $(X, \mathcal{T})$ is *paracompact* if it is Hausdorff and every open cover of $(X, \mathcal{T})$ has a locally finite refinement.

Note that a paracompact space is by definition Hausdorff. It is clear that any compactum is paracompact. But many noncompact spaces are also paracompact, as the next theorem shows (see also XIII.11.10.21.). This result was proved by A. H. STONE [Sto48] (cf. XIII.11.10.5.); the slick proof we give is due to M. E. RUDIN [Rud69].

XIII.11.10.4. THEOREM. Every metrizable space is paracompact.

PROOF: Let X be a metrizable space, and fix a metric ρ on X. Let $\mathcal{U} = \{U_i : i \in I\}$ be an open cover of X. We may well-order the index set I (using AC). Define, inductively on n, a collection of open sets V_{in} for $i \in I$ as follows. Suppose V_{im} has been defined for all i and for all $m < n$. Let V_{in} be the union of all open balls $B_{2^{-n}}(x)$ such that

(1) i is the smallest index such that $x \in U_i$.

(2) $x \notin V_{jm}$ for any j and any $m < n$.

(3) $B_{3 \cdot 2^{-n}}(x) \subseteq U_i$.

If $x \in X$, then there is a smallest i such that $x \in U_i$ and an n large enough that (3) holds. Then, by (2), $x \in V_{im}$ for some $m \leq n$. Thus $\mathcal{V} = \{V_{in} : i \in I, n \in \mathbb{N}\}$ is an open cover of X. Obviously $V_{in} \subseteq U_i$ for each i and n, so $\mathcal{V}$ refines $\mathcal{U}$.

To show that V is locally finite, fix $x \in X$, and let i be the smallest index for which $x \in V_{in}$ for some n. Fix the smallest n for which $x \in V_{in}$. Choose k so that $B_{2^{-k}}(x) \subseteq V_{in}$.

We first claim that if $m \geq n + k$, then $B_{2^{-n-k}}(x)$ intersects no V_{jm} for any $j \in I$. Fix j. Since $m > n$, every ball of radius 2^{-m} used to define V_{jm} has center y outside V_{in}, hence $\rho(x, y) \geq 2^{-k}$ by the choice of k. But $m \geq k + 1$ and $n + k \geq k + 1$, so $2^{-n-k} + 2^{-m} \leq 2^{-k}$, so $B_{2^{-n-k}}(x) \cap B_{2^{-m}}(y) = \emptyset$.

Finally, we claim that if $m < n + k$, then $B_{2^{-n-k}}(x)$ intersects V_{jm} for at most one j; this will complete the proof that $B_{2^{-n-k}}(x)$ intersects at most $n + k$ V_{jm}, and, since $x \in X$ is arbitrary, that $\mathcal{V}$ is locally finite. Suppose $p \in V_{j_1 m}$ and $q \in V_{j_2 m}$ for $j_1 < j_2$; we will show that $\rho(p, q) > 2^{-n-k+1}$, so both cannot be in $B_{2^{-n-k}}(x)$. There are points y and z such that $p \in B_{2^{-m}}(y) \subseteq V_{j_1 m}$ and $q \in B_{2^{-m}}(z) \subseteq V_{j_2 m}$. By (3), $B_{3 \cdot 2^{-m}}(y) \subseteq U_{j_1}$. But $z \notin U_{j_1}$ by (2), so $\rho(y, z) \geq 3 \cdot 2^{-m}$ and $\rho(p, q) > 2^{-m} \geq 2^{-n-k+1}$. 👍

The AC is used in the proof. It is known that this theorem cannot be proved in ZF+(DC).

XIII.11.10.5. Stone's main result from [Sto48] was the following theorem. Combining this with the result from [Tuk40] that metrizable spaces are fully normal, one obtains that all metrizable spaces are paracompact.

XIII.11.10.6. Theorem. A topological space is paracompact if and only if it is fully normal.

See XIII.7.7.8. for the essence of one direction of the proof.

Paracompact spaces share nice separation properties with compact spaces:

XIII.11.10.7. Proposition. Every paracompact space is normal.

Thus there are Hausdorff spaces, even completely regular spaces, which are not paracompact. There are even locally compact completely normal spaces which are not paracompact (Exercise XIII.11.14.12..)

XIII.11.10.8. A subset of a paracompact space is not paracompact in general (e.g. a subset of a compact Hausdorff space need not be normal). Even an open subset of a paracompact space need not be paracompact (Exercise XIII.11.14.12..) But:

XIII.11.10.9. Proposition. A closed subspace of a paracompact space is paracompact.

The proof is essentially identical to the proof of XIII.11.1.6. with "finite subcover" replaced by "locally finite refinement." In fact, an F_σ in a paracompact space is paracompact.

XIII.11.10.10. Proposition. Let X be a (Hausdorff) topological space, and $\{X_i : i \in I\}$ a partition of X into clopen subsets. Then X is paracompact if and only if each X_i is paracompact.

Proof: If X is paracompact, then each X_i is paracompact by XIII.11.10.9.. Conversely, suppose each X_i is paracompact. If $\mathcal{U}$ is an open cover of X, then, for each i, $\mathcal{U}_i = \{U \cap X_i\}$ is an open cover of X_i, which has a locally finite refinement $\mathcal{V}_i$. Then $\cup_{i\in I}\mathcal{V}_i$ is a locally finite open cover of X which refines $\mathcal{U}$. 👍

Paracompact spaces are the natural setting for some constructions of algebraic topology.

Partitions of Unity

For analysis purposes, the most important feature of paracompact spaces is the existence of "partitions of unity." These provide a systematic and controlled way to write a general real- or complex-valued function as a sum of functions of "small" support, and allow "local" phenomena to be stitched together globally.

XIII.11.10.11. DEFINITION. Let $(X, \mathcal{T})$ be a topological space. A *weak partition of unity* on X is a collection of continuous functions $\{f_i : i \in I\}$ from X to $[0, 1]$ such that

(i) For each $x \in X$, $\sum_{i \in I} f_i(x) = 1$.

The collection is a *partition of unity* if in addition

(ii) Each $x \in X$ has a neighborhood U such that $f_i \neq 0$ on U for only finitely many i.

The collection is a *strong partition of unity* if in addition

(iii) For each i, there is an $x \in X$ with $f_i(x) = 1$.

If $\mathcal{U}$ is an open cover of $(X, \mathcal{T})$, and $\{f_i : i \in I\}$ is a partition of unity on $(X, \mathcal{T})$, then $\{f_i\}$ is *subordinate to* $\mathcal{U}$ if for each $i \in I$ there is a $U \in \mathcal{U}$ such that $Z^c_{f_i} \subseteq U$, where for $f : X \to \mathbb{C}$ continuous Z^c_f is the *cozero set* of f, i.e.

$$Z^c_f = \{x : f(x) \neq 0\}$$

(note that Z^c_f is open for any continuous f). The closure of Z^c_f is called the *support* of f.

XIII.11.10.12. If $\{f_i : i \in I\}$ is a partition of unity, set $U_i = Z^c_{f_i} = \{x \in X : f_i(x) > 0\}$. Then $\{U_i : i \in I\}$ is a locally finite open cover of X. If $\mathcal{U}$ is an open cover of X, then the partition of unity is subordinate to $\mathcal{U}$ if and only if this locally finite open cover is a refinement of $\mathcal{U}$. If a partition of unity is subordinate to a refinement of $\mathcal{U}$, it is subordinate to $\mathcal{U}$.

XIII.11.10.13. There is some lack of uniformity in this terminology; what we call "weak partitions of unity" are often called "partitions of unity." Our term "strong partition of unity" is nonstandard, but will be useful; it is a desirable nondegeneracy requirement. It is equivalent to saying that $\{U_i\}$ is a minimal open cover of X, i.e. no proper subcollection covers X.

XIII.11.10.14. EXAMPLE. Let $X = \mathbb{R}$. *****

XIII.11.10.15. THEOREM. Let $(X, \mathcal{T})$ be a paracompact space. If $\mathcal{U}$ is any open cover of $(X, \mathcal{T})$, then there is a strong partition of unity on X subordinate to $\mathcal{U}$.

PROOF: Passing to a refinement if necessary, we may assume that $\mathcal{U}$ is locally finite. We first construct a smaller open cover by transfinite induction. If $\mathcal{U}$ is countable (or has a countable locally finite refinement, e.g. if X is second countable, or locally compact and σ-compact), the transfinite induction can be simplified to an ordinary induction.

Choose a well ordering $\{U_\alpha\}$ of $\mathcal{U}$. We will inductively define an open cover $\{V_\alpha\}$ such that $\overline{V_\alpha} \subseteq U_\alpha$ for each α. Suppose that V_β has been defined for all $\beta < \alpha$ so that $\{V_\beta : \beta < \alpha\} \cup \{U_\beta : \beta \geq \alpha\}$ is an open cover of X (this assumption is vacuous if $\alpha = 0$). Set

$$F_\alpha = X \setminus [(\cup_{\beta<\alpha} V_\beta) \cup (\cup_{\beta>\alpha} U_\beta)] \ .$$

Then F_α is a closed subset of U_α since $U_\alpha \cup F^c_\alpha = X$. Since X is normal (XIII.11.10.7.), there is an open set V_α with $F_\alpha \subseteq V_\alpha$ and $\overline{V_\alpha} \subseteq U_\alpha$. If $F_\alpha = \emptyset$, choose $V_\alpha = \emptyset$. We have $X = (\cup_{\beta<\alpha} V_\beta) \cup (\cup_{\beta>\alpha} U_\beta) \cup V_\alpha$, so the inductive step is finished.

We claim $\mathcal{V} = \{V_\alpha\}$ is an open cover of X. Suppose not; let $x \in X \setminus (\cup_\alpha V_\alpha)$. Then x is in only finitely many U_α, so there is an α such that $x \notin \cup_{\beta \geq \alpha} U_\beta$. For this α, $x \notin (\cup_{\beta<\alpha} V_\beta) \cup (\cup_{\beta \geq \alpha} U_\beta)$. But $\{V_\beta : \beta < \alpha\} \cup \{U_\beta : \beta \geq \alpha\}$ is an open cover of X, a contradiction. Note that since $V_\alpha \subseteq U_\alpha$ for each α, $\{U_\alpha\}$, $\mathcal{V}$ is locally finite. Also note that if $x \in F_\alpha$, then $x \notin V_\beta$ for $\beta < \alpha$ by construction, and $x \notin V_\beta$ for $\beta > \alpha$ since $V_\beta \subseteq U_\beta$ and $x \notin U_\beta$ by construction. Thus $x \notin V_\beta$ for any $\beta \neq \alpha$.

Now repeat the construction using the V_α in place of the U_α to inductively define open sets W_α and

$$E_\alpha = X \setminus [(\cup_{\beta<\alpha} W_\beta) \cup (\cup_{\beta>\alpha} V_\beta)]$$

such that $E_\alpha \subseteq W_\alpha$ and $\overline{W_\alpha} \subseteq V_\alpha$, and $\{W_\alpha\}$ is an open cover of X. Note that $F_\alpha \subseteq E_\alpha$ for each α.

Discard any α for which $V_\alpha = \emptyset$, i.e. $F_\alpha = \emptyset$ (since $F_\alpha \subseteq W_\alpha$, these are also the α for which $W_\alpha = \emptyset$). For each remaining α let g_α be a continuous function from X to $[0,1]$ such that $g_\alpha \equiv 1$ on $\overline{W_\alpha}$ and $g_\alpha \equiv 0$ on $X \setminus V_\alpha$ (XIII.7.6.13.). For $x \in X$, set $g(x) = \sum_\alpha g_\alpha(x)$. Since $\mathcal{V}$ is locally finite, only finitely many g_α are nonzero in a neighborhood of x, so $g(x)$ is finite, and g is continuous at x. Since $g_\alpha(x) = 1$ for at least one α, $g(x) \geq 1$. For each x set $f_\alpha(x) = g_\alpha(x)/g(x)$; then f_α is continuous, $0 \leq f_\alpha(x) \leq 1$ for all α and x, $f_\alpha \equiv 0$ on $X \setminus V_\alpha$, and for each x, only finitely many $f_\alpha(x)$ are nonzero, and $\sum_\alpha f_\alpha(x) = 1$. For any α, if $x \in F_\alpha$, then $x \in W_\alpha$ but $x \notin V_\beta$ for any $\beta \neq \alpha$, so $f_\alpha(x) = 1$, and thus the f_α satisfy (iii). Thus $\{f_\alpha\}$ is a partition of unity subordinate to $\mathcal{U}$. 👍

Note that this proof is a little more complex than the standard proof of existence of partitions of unity, because of condition (iii). What the proof really shows is that if $\mathcal{U}$ is a locally finite cover of a normal space X, then there is a strong partition of unity subordinate to $\mathcal{U}$. Note that this proof requires the Axiom of Choice.

XIII.11.10.16. Conversely, a partition of unity subordinate to an open cover gives a locally finite refinement of the cover, so if every open cover of X supports a partition of unity subordinate to it, X must be paracompact. There is a better result:

XIII.11.10.17. THEOREM. Let X be a T_1 space. If for every open cover $\mathcal{U}$ of X there is a weak partition of unity subordinate to $\mathcal{U}$, then X is paracompact.

PROOF: [Eng89] We first note that X must be completely regular. If E is a closed set in X and $p \notin E$, choose a partition of unity (f_i) subordinate to the open cover $\{X \setminus E, X \setminus \{p\}\}$. There is an i such that $f_i = 0$ on E and $f_i(p) > 0$, and it gives an Urysohn function for (E, p).

Now let $\mathcal{U}$ be an open cover of X, and $\{f_i : i \in I\}$ a partition of unity subordinate to $\mathcal{U}$. If ϕ is a strictly positive real-valued continuous function on X, then for each $x_0 \in X$ there is an open neighborhood U of x_0 and a finite set $I_0 \subseteq I$ such that $f_i(x) < \phi(x)$ for all $x \in U$ and $i \notin I_0$ [Choose I_0 so that $1 - \sum_{i \in I_0} f_i(x_0) < \phi(x_0)$, and $U = \{x \in X : 1 - \sum_{i \in I_0} f_i(x) < \phi(x)\}$.]

For $x \in X$, set $\phi(x) = \sup_{i \in I} f_i(x)$. Then ϕ is strictly positive, and since the supremum is a finite supremum in a neighborhood of each point, ϕ is continuous. For each i set

$$V_i = \left\{ x \in X : f_i(x) > \frac{1}{2}\phi(x) \right\} .$$

Then $\{V_i : i \in I\}$ is a locally finite open cover of X which refines $\mathcal{U}$. 👍

Here is a sample application of XIII.11.10.15.:

XIII.11.10.18. Corollary. Let (X, ρ) be a metric space. Then for any $\epsilon > 0$ there is a strong partition of unity $\{f_i : i \in I\}$ such that the diameter of $Z^c_{f_i}$ is less than ϵ for all i.

Proof: X is paracompact (XIII.11.10.4.), and the balls of radius $< \epsilon/2$ form an open cover of X. 👍

Paracompactness and Local Compactness

XIII.11.10.19. Proposition. Let X be a topological space, K a compact subset of X, and $\{U_i : i \in I\}$ a locally finite open cover of X. Then $K \cap U_i \neq \emptyset$ for only finitely many i.

Proof: For each $x \in K$, there is an open neighborhood V_x of x such that $V_x \cap U_i \neq \emptyset$ only for i in a finite subset F_x of I. Then $\{V_x : x \in K\}$ is an open cover of K, so there is a finite subcover $\{V_{x_1}, \ldots, V_{x_n}\}$. The set U_i can have nonempty intersection with K only if i is in the finite subset $F_{x_1} \cup \cdots \cup F_{x_n}$ of I. 👍

XIII.11.10.20. Proposition. Let X be a (necessarily Hausdorff) topological space which is locally compact, connected, and paracompact. Then X is σ-compact.

Proof: For each $x \in X$, let U_x be an open neighborhood of x with $\bar{U}_x$ compact. Let $\{V_i : i \in I\}$ be a locally finite refinement of $\{U_x : x \in X\}$. Then $\bar{V}_i$ is compact for each i.
Fix $i_1 \in I$ with V_{i_1} nonempty, and set $W_1 = V_{i_1}$, $K_1 = \bar{V}_{i_1}$. There are only finitely many i for which $V_i \cap K_1 \neq \emptyset$ (); let W_2 be their union, and $K_2 = \bar{W}_2$. Then K_2 is also compact, and $K_1 \subseteq W_2$. Repeat the process to get W_n and K_n for each n. Set $W = \cup_n W_n = \cup_n K_n$. Then W is clearly open in X and σ-compact. If $i \in I$ and $V_i \cap W \neq \emptyset$, then $V_i \cap K_n \neq \emptyset$ for some n, so $V_i \subseteq W_{n+1} \subseteq W$. Thus $X \setminus W$ is the union of the V_i which are disjoint from W, hence open; thus W is clopen. Since X is connected and $W \neq \emptyset$, $W = X$. 👍

Conversely:

XIII.11.10.21. Theorem. A locally compact, σ-compact Hausdorff space is paracompact. In fact, any open cover of a locally compact, σ-compact Hausdorff space has a countable locally finite refinement.

XIII.11.11. Compactly Generated Spaces

The great majority of topological spaces encountered naturally, if not compact, at least have their topology completely determined by their compact subsets.

XIII.11.11.1. Definition. Let X be a topological space. X is *compactly generated* if any subset U of X is open (in X) if (and only if) $U \cap K$ is relatively open in K for every compact subset K of X. Equivalently, X is compactly generated if any subset E of X is closed (in X) if (and only if) $E \cap K$ is relatively closed in K for every compact subset K of X.

In other words, X has the weak topology generated by the inclusion maps of its compact subsets. A set $U \subseteq X$ such that $U \cap K$ is relatively open in K for every compact $K \subseteq X$ is called a *k-open* set in X (cf. XIII.11.14.16.), and a compactly generated space is called a *k-space* in some references like [Dug78].

XIII.11.11.2. If X is a Hausdorff space, then X is compactly generated if and only if, for every subset E of X, E is closed if and only if $E \cap K$ is compact for every compact subset K of X.

Any compact space is obviously compactly generated. More generally:

XIII.11.11.3. PROPOSITION. Every locally compact (Hausdorff) space is compactly generated.

PROOF: Let X be locally compact, and $U \subseteq X$ k-open. Let $x \in U$. Then x has an open neighborhood V_x in X such that $\bar{V}_x$ (closure in X) is compact. $U \cap \bar{V}_x$ is relatively open in $\bar{V}_x$, i.e. there is an open set W_x in X such that $U \cap \bar{V}_x = W_x \cap \bar{V}_x$ (in particular, $x \in W_x$). Then $V_x \cap W_x$ is an open neighborhood of x in X which is contained in U. Since $x \in U$ is arbitrary, U is open in X. 👍

Perhaps more significantly, every sequential space (XIII.3.5.2.), and in particular every first countable space, is compactly generated. We need a result of independent interest:

XIII.11.11.4. PROPOSITION. Let X be a topological space and (x_n) a sequence in X. If $x_n \to x$, then $K = \{x\} \cup \{x_n : n \in \mathbb{N}\}$ is a compact subset of X.

PROOF: Let $\mathcal{U}$ be an open cover of K. Then $x \in U$ for some $U \in \mathcal{U}$. Since $x_n \to x$, $x_n \in U$ for all but finitely many n. Finitely many other sets in $\mathcal{U}$ cover the x_n which are not in U. 👍

XIII.11.11.5. **Caution:** This statement is false in general if "sequence" is replaced by "net." ✋

XIII.11.11.6. PROPOSITION. Every sequential space is compactly generated. In particular, every first countable space is compactly generated.

PROOF: Let X be sequential, and $U \subseteq X$ k-open. We show that U^c (complement in X) is closed. Since X is sequential, it suffices to show that if (x_n) is a sequence in U^c and $x_n \to x$, then $x \in U^c$. Let $K = \{x\} \cup \{x_n : n \in \mathbb{N}\}$; then K is compact, so $U \cap K$ is relatively open, i.e. $U^c \cap K$ is relatively closed. Since $x_n \in U^c \cap K$ for all n and $x_n \to x \in K$, $x \in U^c \cap K \subseteq U^c$. 👍

XIII.11.11.7. EXAMPLE. There are topological spaces which are not compactly generated. For example, if X is the space of XIII.11.14.10.(b), and $U = \{\alpha\}$, then $U \cap K$ is relatively open for every compact (i.e. finite) subset K of X. But U is not open in X.

This example is countable, hence σ-compact, and completely normal.

XIII.11.11.8. DEFINITION. Let X and Y be topological spaces, and $f : X \to Y$ a function. Then f is *continuous on compact sets* if, for every compact $K \subseteq X$, $f|_K$ is a continuous function from K to Y.

XIII.11.11.9. Any continuous function is continuous on compact sets. The converse is false in general: if X is the space of XIII.11.14.10.(b) and Y is any topological space, any function from X to Y is continuous on compact (i.e. finite) sets. However:

XIII.11.11.10. PROPOSITION. Let X and Y be topological spaces, with X compactly generated, and $f : X \to Y$ a function. If f is continuous on compact sets, it is continuous.

PROOF: Let V be an open set in Y, and $U = f^{-1}(V)$. If K is any compact subset of X, then $U \cap K = (f|_K)^{-1}(V)$ is relatively open in K since $f|_K$ is continuous. Thus U is open in X since X is compactly generated. 👍

XIII.11.12. Proper Maps

Proper maps can be defined between arbitrary topological spaces, but are particularly important for maps between locally compact spaces, especially manifolds.

XIII.11.12.1. DEFINITION. Let X and Y be topological spaces. A *proper map* from X to Y is a continuous function $f : X \to Y$ such that the preimage of every compact subset of Y is a compact subset of X.

There are variations in this definition in the literature, e.g. some authors require proper maps to be closed; but all the variations are equivalent for reasonable spaces (e.g. compactly generated Hausdorff spaces). ✋

XIII.11.12.2. Since singletons are compact, if $f : X \to Y$ is proper, then $f^{-1}(\{y\})$ is compact for every $y \in Y$.

If X is compact and Y is Hausdorff, then every continuous function from X to Y is proper. If Y is compact and $f : X \to Y$ is proper, then X is also compact.

XIII.11.12.3. EXAMPLE. The following example shows that the continuity condition is not automatic, even for the nicest spaces. Let $Y = \mathbb{N} \cup \{0\}$ with the discrete topology, and $X = \left\{\frac{1}{n} : n \in \mathbb{N}\right\} \cup \{0\} \subseteq \mathbb{R}$. Define $f : X \to Y$ by $f\left(\frac{1}{n}\right) = n$ for each n and $f(0) = 0$. Then f is a bijection, the preimage of every compact subset of Y is compact since every compact subset of Y is finite, but f is not continuous.

Proper maps need not be closed (XIII.11.14.29.), but they are under mild conditions:

XIII.11.12.4. PROPOSITION. Let X be a topological space and Y a compactly generated Hausdorff space, and $f : X \to Y$ a proper map. Then f is a closed mapping.

PROOF: Let E be a closed subset of X. If K is a compact subset of Y, then $f^{-1}(K)$ is compact, so $E \cap f^{-1}(K)$ is compact. Thus $f(E \cap f^{-1}(K))$ is compact since f is continuous. But $f(E \cap f^{-1}(K)) = f(E) \cap K$. Thus $f(E) \cap K$ is compact for every compact $K \subseteq Y$. By XIII.11.11.2., $f(E)$ is closed in Y. 👍

For locally compact spaces, proper maps have an alternate characterization:

XIII.11.12.5. PROPOSITION. Let X and Y be locally compact, and $f : X \to Y$ a continuous function. Let $X^\dagger$ and $Y^\dagger$ be the one-point compactifications, and define $f^\dagger : X^\dagger \to Y^\dagger$ by $f^\dagger(x) = f(x)$ if $x \in X$ and $f(\infty) = \infty$. Then f is proper if and only if $f^\dagger$ is continuous.

XIII.11.12.6. Informally, f is proper if and only if it sends points "close to infinity" to points in Y "close to infinity." If X and Y are locally compact and σ-compact, this has an alternate formulation. Say a sequence (x_n) in a topological space *escapes to infinity* if every compact subset of the space contains only finitely many of the x_n. Then $f : X \to Y$ (continuous) is proper if and only if, whenever (x_n) escapes to infinity in X, $(f(x_n))$ escapes to infinity in Y.

XIII.11.12.7. Proper maps have other equivalent characterizations (cf. XIII.11.14.25.), and closed surjective proper maps preserve much structure. See e.g. [Dug78, IX.5] (cf. XIII.11.14.26.) or [Bou98, I.10].

XIII.11.13. Realcompact Spaces

There is another generalization of compactness, realcompactness. As with paracompactness, the vast majority of reasonable topological spaces are realcompact. There are also a large number of equivalent characterizations, of a varied enough nature that it is a rather natural notion.

Realcompact spaces were first defined in 1948 by E. HEWITT [**?**]. They have been called by a number of names (HEWITT'S was *Q-space*); the term *realcompact* was introduced in [GJ76], which is a prime reference about these spaces. Other useful references are (), (), ()

XIII.11.13.1. Our beginning approach is an algebraic one. In this section, if X is a completely regular topological space (the theory works satisfactorily only in this case), we let $C(X)$ be the ring of real-valued continuous functions on X and $BC(X)$ the subring of bounded real-valued continuous functions on X. In some references $BC(X)$ is denoted $C^*(X)$, but as an operator algebraist I find this notation unsuitable for reasons discussed in (). We could equally well work with complex-valued continuous functions, but there are convenient technical simplifications in the real-valued case (e.g. unital ring-homomorphisms between such $C(X)$ are automatically $\mathbb{R}$-algebra homomorphisms).

XIII.11.13.2. If $p \in X$, then $M_p = \{f \in C(X) : f(p) = 0\}$ is a maximal ideal in $C(X)$, and $C(X)/M_p \cong \mathbb{R}$; the map $f \mapsto f(p)$ is a homomorphism from $C(X)$ to $\mathbb{R}$ with kernel M_p. This homomorphism is called *point evaluation at* p, and M_p is called a *fixed* maximal ideal. Not every maximal ideal in $C(X)$ is fixed in general; indeed, every maximal ideal is fixed if and only if X is compact ().

Similarly, $\tilde{M}_p = M_p \cap BC(X)$ is a maximal ideal in $BC(X)$, the kernel of the evaluation map at p. We again have that every maximal ideal of $BC(X)$ is fixed if and only if X is compact (in this case, $BC(X) = C(X)$).

XIII.11.13.3. If M is a maximal ideal of $C(X)$, then $C(X)/M$ is an ordered field. The image of the constant functions is a subfield isomorphic to $\mathbb{R}$. If this subfield is the whole quotient, the maximal ideal is *real*; otherwise it is *hyperreal* and the quotient is a nonarchimedean ordered field. $C(X)$ will have hyperreal maximal ideals unless $C(X) = BC(X)$ (X is *pseudocompact*).

XIII.11.13.4. DEFINITION. Let X be a completely regular space. Then X is *realcompact* if every real maximal ideal of $C(X)$ is fixed, i.e. every homomorphism from $C(X)$ to $\mathbb{R}$ is a point evaluation at a point of X.

XIII.11.13.5. EXAMPLES. $\mathbb{N}$, $\mathbb{R}$

One of the main characterizations of realcompactness is the following, which we will gradually prove (the proof is ()) obtaining an interesting construction along the way. It is an analog of () for compact spaces.

XIII.11.13.6. THEOREM. Let X be a completely regular space. Then X is realcompact if and only if it is homeomorphic to a closed subspace of a product of copies of $\mathbb{R}$.

XIII.11.14. Exercises

XIII.11.14.1. (a) Show that any set with the indiscrete topology () is compact.

(b) Show that any set with the finite complement topology () is compact and T_1.

(c) Show that every subset of the examples in (a) and (b) is compact. Thus a compact subset of a compact T_1-space need not be closed.

XIII.11.14.2. The aim of this exercise is to show without AC that a compact subset of a Hausdorff space is closed. Let X be a Hausdorff space, and $Y \subseteq X$. Suppose Y is not closed, and let $p \in \bar{Y} \setminus Y$. Fix a net (y_i) in Y converging to p (XIII.3.2.21.). Then the net (y_i) cannot have a cluster point in Y (XIII.7.4.1.), so Y is not compact (XIII.11.2.1.).

XIII.11.14.3. Here is an alternate proof of XIII.11.3.10. which gives an explicit Lebesgue number. Let (X, ρ) be a compact metric space, and $\mathcal{U}$ an open cover of X. Let $\{U_1, \ldots, U_n\}$ be a finite subcover of $\mathcal{U}$. For $x \in X$, define

$$f(x) = \frac{1}{n} \sum_{k=1}^{n} \rho(x, U_k^c) \ .$$

Then f is a continuous function from X to $(0, \infty)$ ().

(a) Let δ be the minimum of f on X. Show that $\delta > 0$.

(b) Show that δ is a Lebesgue number for $\mathcal{U}$.

XIII.11.14.4. Let $X = F([0,1],[0,1]) \cong [0,1]^{\mathfrak{c}}$ be the space of all functions from $[0,1]$ to itself, with the product topology (topology of pointwise convergence) (). Recall (XIII.6.3.2.–XIII.6.3.3.) that X is separable but not first countable. X is compact by Tikhonov's Theorem (XIII.11.6.6. suffices), and Hausdorff.

Let Y be the subset of X consisting of all nondecreasing functions from $[0,1]$ to $[0,1]$, with the relative topology (also the topology of pointwise convergence). Y is called the *Helly space*.

(a) Show that Y is a closed subspace of X, hence compact and Hausdorff.

(b) Show that the set of nondecreasing step functions () with only rational discontinuities, taking only rational values, is dense in Y. Conclude that Y is separable.

(c) Show that Y is first countable. [Use the fact () that a nondecreasing function has only jump discontinuities, and only finitely many jumps of more than ϵ for any fixed $\epsilon > 0$.]

(d) For each $t \in [0,1]$, let f_t be the function with $f_t(x) = 0$ for $x < t$, $f_t(x) = 1$ for $x > t$, and $f_t(t) = 1/2$. Show that $\{f_t : t \in [0,1]\}$ is an uncountable subset of Y which is discrete in the relative topology. Conclude that Y is not second countable, and hence not metrizable.

(e) Although $F([0,1],[0,1])$ has cardinality $2^{2^{\aleph_0}}$, show that Y has cardinality $2^{\aleph_0}$ (cf. XIII.7.10.6.).

XIII.11.14.5. (a) Let X be the unit square $[0,1] \times [0,1]$. Give X the order topology () from the lexicographic ordering (). Show that X is compact, Hausdorff, first countable, but not separable, hence not metrizable.

(b) Do the same as in (a) with the second copy of $[0,1]$ replaced by a three-point set with a total ordering. What if a two-point set is used instead?

XIII.11.14.6. The proof of Tikhonov's theorem (XIII.11.6.1.) uses the Axiom of Choice. Conversely, the Axiom of Choice can be proved from Tikhonov's Theorem for T_1 spaces, showing that the two are equivalent.

(a) Let X be a set. Define the *T_1-compactification of $\mathbb{N}$ by X* to be the disjoint union $\mathbb{N} \cup X$, topologized by taking as the open sets any subset with finite complement, and any subset of $\mathbb{N}$. Show that $\mathbb{N} \cup X$ is compact if X is nonempty, always T_1, but not Hausdorff if X has more than one element.

(b) Let $\{X_i : i \in I\}$ be an indexed collection of nonempty sets, and let $X = \prod_{i \in I} X_i$. Show using Tikhonov's Theorem that X is nonempty, as follows. For each i, let Y_i be the T_1 compactification of $\mathbb{N}$ by X_i, and let $Y = \prod_{i \in I} Y_i$. Then $X \subseteq Y$, and Y is compact by Tikhonov's Theorem.

(c) $Y \neq \emptyset$: for each $n \in \mathbb{N}$ let $y_n \in Y$ be the point with i'th coordinate n for all i. By compactness, the sequence (y_n) has a cluster point p in Y. Show that for each i, the i'th coordinate p_i of p is in X_i, so $p \in X$. (Actually every point of X is a cluster point of this sequence.)

Note that Tikhonov's Theorem for *Hausdorff* spaces is strictly weaker than the Axiom of Choice (it is equivalent to the BPI). See II.6.3.11. for a discussion of this and related matters.

XIII.11.14.7. **The Tikhonov Plank.** Let X be the set of ordinals less than or equal to the first uncountable ordinal ω_1, and Y the set of ordinals less than or equal to ω. Then X and Y are compact Hausdorff spaces in the order topology (). So $X \times Y$ is a compactum, hence normal. Let $Z = (X \times Y) \setminus (\omega_1, \omega)$ (Z is the "plank" $X \times Y$ with the "upper right-hand corner" removed).

(a) Z is an open set in $X \times Y$, hence locally compact; $Z^\dagger \cong X \times Y$. Show that $X \times Y$ is also βZ (cf. XIII.11.9.17.). Z is pseudocompact (XIII.11.9.17.).

(b) Let $T = \{(\alpha, \omega) : \alpha < \omega_1\}$ and $R = \{(\omega_1, \alpha) : \alpha < \omega\}$ be the "top and right edges" of Z. Show that T and R are disjoint closed subsets of Z which do not have disjoint neighborhoods in Z. Thus Z is not normal.

XIII.11.14.8. **Rational Sequence Topology.** [SS95, #65] Put a topology on $\mathbb{R}$ as follows. For each irrational $x \in \mathbb{R}$, fix a sequence $(q_{x,k})$ of rational numbers converging to x. Let $\mathcal{B}$ be the following collection of subsets of $\mathbb{R}$:

(i) $\{q\}$ for each $q \in \mathbb{Q}$.

(ii) $\{x\} \cup \{q_{x,k} : k \geq n\}$ for each $x \in \mathbb{J} = \mathbb{R} \setminus \mathbb{Q}$, $n \in \mathbb{N}$.

(a) Show that if $x, y \in \mathbb{J}$, $x \neq y$, then $\{q_{x,k} : k \in \mathbb{N}\} \cap \{q_{y,k} : k \in \mathbb{N}\}$ is finite.

(b) Show that $\mathcal{B}$ is a base for a topology $\mathcal{Q}$ on $\mathbb{R}$.

(c) Show that $\mathcal{Q}$ is stronger than the ordinary topology on $\mathbb{R}$. Thus $(\mathbb{R}, \mathcal{Q})$ is Hausdorff. Each rational number is an isolated point of $(\mathbb{R}, \mathcal{Q})$.

(d) $(\mathbb{R}, \mathcal{Q})$ is first countable.

(e) $\mathbb{Q}$ is a dense open subset of $(\mathbb{R}, \mathcal{Q})$; thus $(\mathbb{R}, \mathcal{Q})$ is separable.

(f) Each set in $\mathcal{B}$ is compact in $(\mathbb{R}, \mathcal{Q})$ (XIII.11.11.4.). Thus there is a base for $\mathcal{Q}$ consisting of compact open sets, so $(\mathbb{R}, \mathcal{Q})$ is locally compact and $ind(\mathbb{R}, \mathcal{Q}) = 0$ (XIII.22.3.2.). In particular, $(\mathbb{R}, \mathcal{Q})$ is completely regular (XIII.11.8.9.) and totally disconnected (XIII.13.6.1.).

(g) $\mathbb{J}$ is a discrete closed subset of $(\mathbb{R}, \mathcal{Q})$ of cardinality $2^{\aleph_0}$. Thus by XIII.7.10.13., $(\mathbb{R}, \mathcal{Q})$ is not normal.

(h) By XIII.13.6.5., $dim(\mathbb{R}, \mathcal{Q}) > 0$, i.e. $(\mathbb{R}, \mathcal{Q})$ is not zero-dimensional (XIII.13.6.3.). Also, $Ind(\mathbb{R}, \mathcal{Q}) > 0$.

XIII.11.14.9. Compactifications of $\mathbb{N}$. (a) Let X be a separable compactum. Fix a countable dense set (x_k) in X, and let (p_n) be a sequence of points of X with each p_n some x_k, and for each k $p_n = x_k$ for infinitely many n. Set

$$N = \left\{ \left(\frac{1}{n}, p_n \right) : n \in \mathbb{N} \right\} \subseteq [0,1] \times X$$

and $\tilde{X} = N \cup [\{0\} \times X]$. Show that $\tilde{X}$ is compact and Hausdorff, N is a dense open subset of $\tilde{X}$ homeomorphic to $\mathbb{N}$, and $\tilde{X} \setminus N$ is homeomorphic to X. Thus $\tilde{X}$ can be regarded as a compactification of $\mathbb{N}$.

(b) If X and Y are nonhomeomorphic separable compacta, say that the compactifications $\tilde{X}$ and $\tilde{Y}$ are *topologically distinct*. Topologically distinct compactifications of $\mathbb{N}$ are distinct compactifications.

(c) There are at least $2^{2^{\aleph_0}}$ pairwise nonhomeomorphic separable compact Hausdorff spaces (XIII.20.5.11.). Thus there are at least $2^{2^{\aleph_0}}$ topologically distinct compactifications of $\mathbb{N}$.

(d) Not every compactification of $\mathbb{N}$ is of this form: if Z is a compactification of $\mathbb{N}$, then $Z \setminus \mathbb{N}$ is not necessarily separable. [$\beta\mathbb{N} \setminus \mathbb{N}$ is not separable.]

(e) Distinct compactifications of $\mathbb{N}$ need not be topologically distinct. [There are $2^{\aleph_0}$ distinct two-point compactifications of $\mathbb{N}$ since there are $2^{\aleph_0}$ essentially different ways of splitting $\mathbb{N}$ into two infinite sets.]

(f) There are at most $2^{2^{\aleph_0}}$ distinct compactifications of $\mathbb{N}$. [Distinct compactifications define distinct uniformities on $\mathbb{N}$ (), and there are at most $2^{2^{\aleph_0}}$ uniformities on $\mathbb{N}$ (XIII.15.12.3.(a)).]

(g) Conclude that there are exactly $2^{2^{\aleph_0}}$ distinct compactifications of $\mathbb{N}$, and exactly $2^{2^{\aleph_0}}$ distinct separable compacta up to homeomorphism.

XIII.11.14.10. Let α be a point of $\beta\mathbb{N} \setminus \mathbb{N}$, and let $\mathcal{F}$ be the corresponding free ultrafilter on $\mathbb{N}$. Set $X = \mathbb{N} \cup \{\alpha\}$, with the relative topology. Then X is a countable completely regular (hence normal) space.

(a) Show that the open sets in X consist precisely of all subsets of $\mathbb{N}$ and all sets of the form $F \cup \{\alpha\}$, where $F \in \mathcal{F}$. (The space X could have been defined without reference to $\beta\mathbb{N}$ by just taking α to be a point not in $\mathbb{N}$ and defining the open sets this way for the free ultrafilter $\mathcal{F}$.)

(b) Show that α does not have a countable neighborhood base in X. If $x_n = n$, then α is a cluster point of the sequence (x_n), but no subsequence of (x_n) converges to α. [Every infinite subset of $\mathbb{N}$ contains an infinite subset which is not in $\mathcal{F}$.]

(c) Although every singleton subset of X is a G_δ, X is not first countable.

(d) X is not compact; in fact, the only compact subsets of X are the finite subsets. The identity map from $\mathbb{N}$ to X extends to a homeomorphism from $\beta\mathbb{N}$ to βX [GJ76,].

If γ is another point of $\beta\mathbb{N} \setminus \mathbb{N}$, corresponding to another free ultrafilter $\mathcal{G}$ on $\mathbb{N}$, and $Y = \mathbb{N} \cup \{\gamma\}$, then Y is not necessarily homeomorphic to X; in fact, there are $2^{2^{\aleph_0}}$ homeomorphism classes of such spaces since there are $2^{2^{\aleph_0}}$ points in $\beta\mathbb{N} \setminus \mathbb{N}$ and only $2^{\aleph_0}$ permutations of $\mathbb{N}$ [GJ76,].

(e) More generally, consider a topological space X which is countably infinite and in which every point but one is an isolated point. Identify the isolated points with $\mathbb{N}$ and call the nonisolated point α. Show that X is necessarily perfectly normal, and that there is a free filter $\mathcal{F}$ on $\mathbb{N}$ such that the open sets in X consist of all subsets of $\mathbb{N}$ and all sets of the form $F \cup \{\alpha\}$ for $F \in \mathcal{F}$. There is a weakest such topology on $\mathbb{N} \cup \{\alpha\}$, which is the one-point compactification of $\mathbb{N}$; the maximal such topologies are the ones described in (i) (i.e. where $\mathcal{F}$ is an ultrafilter). Every such topology is obtained by taking a compactification Y of $\mathbb{N}$ and letting α be a point of $Y \setminus \mathbb{N}$. [Consider βX.]

See XIII.6.3.4. for a more dramatic example of a countable normal space which is not first countable.

XIII.11.14.11. Let X be a Hausdorff space. Show that X is countably compact if and only if X does not contain a closed subspace homeomorphic to $\mathbb{N}$ (i.e. a countably infinite closed subset whose relative topology is the discrete topology).

XIII.11.14.12. Let X be the space ω_1 of ordinals less than the first uncountable ordinal (), with the order topology (). Let $\mathcal{U}$ be the open cover of X consisting of all sets of the form $[0, \alpha)$ for $\alpha \in X$. Show that $\mathcal{U}$ has no locally finite refinement. [If $\mathcal{V}$ is a refinement of $\mathcal{U}$, show that there is a sequence (V_n) of distinct sets in $\mathcal{V}$ and a strictly increasing sequence (α_n) in X with $\alpha_n \in V_n$, and thus that $\mathcal{V}$ cannot be locally finite at $\alpha = \sup \alpha_n$.] Thus X is locally compact and normal, even completely normal (XIII.16.1.1.), but not paracompact.

XIII.11.14.13. Show that a locally finite open cover of a separable topological space is countable. Conclude that every separable paracompact space is Lindelöf.

XIII.11.14.14. Let X be a topological space. Define a one-point compactification of X as follows. Let $X^\dagger$ be $X \cup \{\infty\}$, where ∞ is something not in X. A subset U of $X^\dagger$ is open if $U \subseteq X$ and U is open in X, or if $\infty \in U$ and $X \setminus U$ is closed and compact in X (regarding $\emptyset$ as a closed compact subset of X).

(a) Show that such open sets form a topology on $X^\dagger$.

(b) Show that the relative topology on X from $X^\dagger$ is the original topology on X.

(c) Show that $X^\dagger$ is compact.

(d) Show that X is dense in $X^\dagger$ if and only if X is not compact.

(e) Show that $\{\infty\}$ is closed in $X^\dagger$; hence $X^\dagger$ is T_1 if and only if X is T_1.

(f) Show that $X^\dagger$ is Hausdorff if and only if X is Hausdorff and locally compact.

XIII.11.14.15. An open cover $\mathcal{U}$ of a topological space X is *minimal* if no proper subset of $\mathcal{U}$ is a cover, i.e. for each $U \in \mathcal{U}$ there is at least one point of U not contained in any other set in $\mathcal{U}$. Note that if $\{f_i : i \in I\}$ is a strong partition of unity for X, then $\mathcal{U} = \{Z_{f_i}^c : i \in I\}$ is a minimal locally finite cover of X, so XIII.11.10.15. shows (under AC) that any open cover of a paracompact space has a minimal locally finite refinement.

Prove the following theorem:

THEOREM. Let $\mathcal{U}$ be a point-finite open cover of a topological space X. Suppose the index set of $\mathcal{U}$ can be well ordered (e.g. is countable). Then $\mathcal{U}$ has a minimal subcover.

(a) Write $\mathcal{U} = \{U_\alpha : \alpha < \sigma\}$ where σ is an ordinal. Transfinitely define subsets $\mathcal{U}_\alpha$ and $\mathcal{V}_\alpha$ of $\mathcal{U}$ as follows. Set $\mathcal{V}_\alpha = \cap_{\beta<\alpha}\mathcal{U}_\beta$ ($\mathcal{V}_0 = \mathcal{U}$) and let $\mathcal{U}_\alpha$ be $\mathcal{V}_\alpha \setminus \{U_\alpha\}$ if this is a cover of X and $\mathcal{U}_\alpha = \mathcal{V}_\alpha$ otherwise. (In other words, remove U_α from the cover if possible, still retaining a cover.)

(b) Using point-finiteness of $\mathcal{U}$, show that $\mathcal{V}_\alpha$ is a cover of X for each α (this is only an issue if α is a limit ordinal).

(c) Show that $\mathcal{V} = \cap_{\alpha<\sigma}\mathcal{V}_\alpha$ is a minimal subcover of $\mathcal{U}$. (Minimality is obvious, and the argument of (b) shows that $\mathcal{V}$ is a cover.)

(d) Show that the conclusion of the theorem is not necessarily true if $\mathcal{U}$ is not point-finite, even if it is countable. [Consider the open cover of $\mathbb{R}$ by open intervals of the form $(-\infty, n)$ for $n \in \mathbb{N}$.]

XIII.11.14.16. Let $(X, \mathcal{T})$ be a topological space, and let $\mathcal{T}^k$ be the set of k-open sets in X. Show that $\mathcal{T}^k$ is a topology on X which is stronger than $\mathcal{T}$; $(X, \mathcal{T})$ is compactly generated if and only if $\mathcal{T}^k = \mathcal{T}$. Is $(X, \mathcal{T}^k)$ always compactly generated? [Show that $\mathcal{T}$ and $\mathcal{T}^k$ have the same compact sets.]

XIII.11.14.17. (D. E. COHEN; cf. [Dug78, XI.9.4]) (a) Show that every compactly generated Hausdorff space is a quotient of a locally compact space. [Consider the separated union of the compact subsets of the space.]

(b) Show that any quotient space of a locally compact space is compactly generated. [If $f : X \to Y$ is a quotient map with X locally compact and U is a k-open set in Y, show that $f^{-1}(U) \cap V$ is open in X for any open set V in X with compact closure.]

(c) ([Dug78, XI.9.5], but note that a Hausdorff hypothesis is omitted there) Conclude that any quotient space of a compactly generated Hausdorff space is compactly generated.

XIII.11.14.18. Define a continuous function $f : \mathbb{R} \to \mathbb{R}$ as follows. Let $\{r_n : n \in \mathbb{Z}\}$ be an enumeration of $\mathbb{Q}$. For each n, set $f(x) = r_n$ if $x \in \left[n - \frac{1}{3}, n + \frac{1}{3}\right]$, and extend f to a continuous function on $\mathbb{R}$ by making it linear on $\left[n + \frac{1}{3}, n + \frac{2}{3}\right]$. If

$$U = \bigcup_{n\in\mathbb{Z}} \left(n - \frac{1}{3}, n + \frac{1}{3}\right)$$

then U is open, but $f(U) = \mathbb{Q}$ is not a G_δ (XIII.12.1.5.). Thus, even if X and Y are locally compact and σ-compact, the image of an open set in X under a continuous function $f : X \to Y$ is not necessarily a G_δ, so the image of a G_δ is *a fortiori* not always a G_δ. Contrast with XIII.11.7.11..

XIII.11.14.19. Let X and Y be topological spaces, A and B compact subsets of X and Y respectively, and W an open set in $X \times Y$ containing $A \times B$. Show that there are open sets U and V in X and Y containing A and B respectively, such that $U \times V \subseteq W$, as follows.

(a) For each $x \in A$ and $y \in B$ there are open neighborhoods $U_{x,y}$ of x and $V_{x,y}$ of y such that $U_{x,y} \times V_{x,y} \subseteq W$. [Open rectangles in $X \times Y$ form a base for the product topology.]

(b) Fix $y \in B$. There are open neighborhoods U_y of A and V_y of y such that $U_y \times V_y \subseteq W$. [The sets $\{U_{x,y} : x \in A\}$ form an open cover of A; let $\{U_{x_1,y}, \ldots, U_{x_n,y}\}$ be a finite subcover, and set $U_y = \cup_{j=1}^n U_{x_j,y}$ and $V_y = \cap_{j=1}^n V_{x_j,y}$.]

(c) The sets $\{V_y : y \in B\}$ form an open cover of B. Let $\{V_{y_1}, \ldots, V_{y_m}\}$ be a finite subcover, and set $U = \cap_{j=1}^m U_{y_j}$ and $V = \cup_{j=1}^m V_{y_j}$.

(d) Modify the argument as in () to avoid any use of the Axiom of Choice.

XIII.11.14.20. **Compacta without AC** ([L63], [Bru83]). (a) If no form of Choice is assumed, there exist infinite compacta on which every real-valued continuous function is constant ([L63]; the space constructed there is only locally compact, but its one-point compactification can be constructed without any Choice and has the same property, or, since the space is orderable, a compactification which is also orderable). Such a space is connected () and is called a *Läuchli continuum.* A Läuchli continuum is normal (XIII.11.4.3.) but not completely regular.

(b) Conclude that Urysohn's Lemma and XIII.7.8.3. require some form of Choice.

XIII.11.14.21. **Minimal Compactifications.** Let X be a completely regular space, and (Y, ϕ) a compactification of X.

(a) If $Y \setminus \phi(X)$ has two distinct points p and q, let Z be the identification space $Y/\{p, q\}$. Show that Z is a compactum [cf. XIII.8.3.6. or XIII.8.3.9..]

(b) If $\omega : Y \to Z$ is the quotient map and $\psi = \omega \circ \phi$, show that (Z, ψ) is a compactification of X which is strictly dominated by (Y, ϕ).

(c) Conclude that X has a minimal compactification if and only if it is locally compact, in which case $X^\dagger$ is the unique minimal compactification (actually the smallest compactification).

XIII.11.14.22. Show without any form of Choice that if X is a compact first countable topological space, then X is sequentially compact. [Use XIII.3.1.9. and XIII.11.2.1..] In particular, since it can be proved without any Choice that $[0, 1]^{\mathbb{N}}$ is compact (), and it is metrizable (), it is sequentially compact.

XIII.11.14.23. Show (in ZF) that the special case of Tikhonov's Theorem where all X_i are the same space is equivalent to the full Tikhonov Theorem, i.e. to prove the Tikhonov Theorem it suffices to show that if X is compact and I is any (nonempty) set, then X^I is compact (and similarly for the Hausdorff version), as follows.

(a) Let $\{X_i : i \in I\}$ be an indexed family of (nonempty) compact spaces. Let X be the one-point compactification () of the separated union of the X_i. Then $\prod_i X_i$ is a closed subset of X^I. Denote by ∞ the point at infinity of X.

(b) Let J be the set of all pairs (F, z), where F is a finite subset of I and $z \in \prod_{i \in F} X_i$. Then J is nonempty, and directed by setting $(F, z) \leq (E, w)$ if $F \subseteq E$. If $z \in \prod_{i \in F} X_i$, denote by $\tilde{z}$ the point of X^I whose

coordinates in F are the same as z and all other coordinates are ∞. Define a net in X^I by $x_{(F,z)} = \tilde{z}$, indexed by J.

(c) Suppose that X^I is compact. Then this net has a cluster point. Show that any cluster point is in $\prod_i X_i$, so $\prod_i X_i$ is nonempty, and compact since it is closed in X^I.

XIII.11.14.24. (a) [GJ76, 9.5] Show that if X is a noncompact completely regular topological space, then no point of $\beta X \setminus X$ is a G_δ. In particular, no point of $\beta X \setminus X$ has a countable local base.

(b) If $p \in X$ has a countable local base in X, then it has a countable local base in βX (XIII.7.10.11.).

(c) If X and Y are completely regular first countable topological spaces (this condition can be relaxed somewhat, cf. [GJ76, 9N]), then any homeomorphism from βX to βY sends X onto Y. In particular, if βX and βY are homeomorphic, then X and Y are homeomorphic.

Result (c) fails in general if X or Y is not first countable (XIII.11.14.10.(d)).

XIII.11.14.25. [Bou98, I.10] A continuous function $f : X \to Y$ is *universally closed* if $f \times id_Z : X \times Z \to Y \times Z$ is closed for every topological space Z. (Such a map is called "proper" in [Bou98].)

(a) Show that if $f : X \to Y$ is universally closed, and $A \subseteq Y$, then $g : f^{-1}(A) \to A$ is universally closed.

(b) Show that if the (unique) function from X to a one-point space is universally closed, then X is compact.

(c) Show that $f : X \to Y$ is universally closed if and only if it is closed and proper. (Thus, by XIII.11.12.4., if Y is compactly generated and Hausdorff, f is universally closed if and only if it is proper.)

XIII.11.14.26. [Dug78, IX.5.3] Let X and Y be topological spaces, and $f : X \to Y$ a continuous function. If f is closed and $f^{-1}(\{y\})$ is compact for every $y \in Y$, show that f is proper.

XIII.11.14.27. Show that if X is Hausdorff and Y is locally compact, and $f : X \to Y$ is proper, then X must also be locally compact. [Cover Y by open sets with compact closure and consider preimages.]

XIII.11.14.28. (AC) Let $\{X_i : i \in I\}$ and $\{Y_i : i \in I\}$ be indexed families of (nonempty) topological spaces, and $f_i : X_i \to Y_i$ a continuous function for each i. Show that $\times_i f_i : \prod_i X_i \to \prod_i Y_i$ is closed and proper if and only if each f_i is closed and proper. Can "closed" be deleted?

XIII.11.14.29. Let $X = \mathbb{N} \cup \{0\}$ with the discrete topology, and $Y = \mathbb{N} \cup \{\alpha\}$ as in XIII.11.14.10.. Let $f : X \to Y$ be the identity on $\mathbb{N}$ and $f(0) = \alpha$. Show that f is proper but not closed. [Every compact subset of Y is finite.]

XIII.11.14.30. A surjective continuous map f from a compact X to a (necessarily compact) Hausdorff Y is a closed mapping (XIII.11.5.1.). Show that f need not be open, even if X is metrizable. [Consider $f : [0,1] \to [0,1]$ defined by $f(t) = \max(0, 2t - 1)$.]

XIII.11.14.31. Prove (using Countable AC) the following slight generalization of a result of ALEKSANDROV:

THEOREM. Let (X, ρ) be a locally compact metric space. If any two points of X are contained in a compact connected subset of X, then X is σ-compact, hence separable and second countable.

Note that the hypotheses are satisfied if X is path-connected (the case considered by ALEKSANDROV). Some such hypothesis is needed, e.g. to rule out an uncountable discrete space.

(a) For $x \in X$, let $r(x)$ be the supremum of the r for which the closed ball of radius r centered at x is compact ($r(x) > 0$ since X is locally compact). Show that either $r(x) = \infty$ for all $x \in X$ or $r(x) < \infty$ for all $x \in X$..

(b) If $r(x) = \infty$ for some (hence every) $x \in X$, then X is the union of the closed balls of radius n around x for all n and is thus σ-compact.

(c) Suppose $r(x) < \infty$ for all $x \in X$. For each x let B_x be the closed ball of radius $r(x)/2$ centered at x. Then B_x is compact. Fix $x_0 \in X$. Set $A_1 = B_{x_0}$ and inductively set

$$A_{n+1} = \bigcup \{B_x : x \in A_n\} .$$

(d) Show inductively that each A_n is compact. [If (x_k) is a sequence in A_{n+1}, for each k there is a $y_k \in A_n$ with $\rho(x_k, y_k) \leq r(y_k)/2$. There is a convergent subsequence of (y_k) converging to some $y \in A_n$. Show that

$$\rho(x_k, y) \leq \frac{3r(y)}{4}$$

for infinitely many k, so infinitely many x_k lie in the compact ball of radius $3r(y)/4$ around y. Hence (x_k) has a convergent subsequence.]

(e) Use the connectedness hypothesis to show that $X = \cup_n A_n$.

XIII.11.14.32. Let (X, ρ) be a metric space.

(a) If $A \subseteq X$ is totally bounded, so is $\bar{A}$. [If $\epsilon > 0$, cover A by finitely many balls of radius $\epsilon/2$, and consider the balls of radius ϵ with the same centers.]

(b) If (X, ρ) is totally bounded, then its completion $(\bar{X}, \bar{\rho})$ is compact.

XIII.11.15. Dini's Theorem

Dini's Theorem is an assertion that certain sequences of functions which converge pointwise actually converge uniformly. Since uniform convergence has all sorts of nice consequences not shared by pointwise convergence, such a result is very useful.

XIII.11.15.1. Definition. Let X be a set, and (f_n) a sequence of real-valued functions on X. The sequence (f_n) is *nondecreasing* if, for each $x \in X$, the sequence $(f_n(x))$ of real numbers is nondecreasing. Similarly, (f_n) is *nonincreasing* if $(f_n(x))$ is nonincreasing for all $x \in X$. The sequence (f_n) is *monotone* if it is either a nondecreasing sequence or a nonincreasing sequence.

Note that it is the sequence itself that is nondecreasing (etc.), not the individual functions f_n. (Indeed, if X is a general set, it does not make sense to say an individual function from X to $\mathbb{R}$ is nondecreasing.) This notion of nondecreasing (etc.) is sometimes called *pointwise nondecreasing* (etc.) One can similarly define strictly increasing, strictly decreasing, and strictly monotone sequences of functions.

Here is the general version of Dini's Theorem:

XIII.11.15.2. Theorem. [Dini's Theorem, General Version] Let X be a compact topological space, and (f_n) a nondecreasing sequence of real-valued continuous functions on X converging pointwise to a function f (not assumed to be continuous). If g is a real-valued continuous function on X satisfying $g(x) < f(x)$ for all $x \in X$, then there is an n such that $g(x) < f_n(x)$ for all $x \in X$. The same statement holds with inequalities reversed if (f_n) is nonincreasing.

Proof: For each n, set $K_n = \{x \in X : g(x) \geq f_n(x)\}$. Then K_n is closed since g and f_n are continuous; hence K_n is compact (). Since $f_n(x) \leq f_{n+1}(x)$ for all $x \in X$, we have $K_{n+1} \subseteq K_n$ for all n. Also, $\cap_n K_n = \emptyset$, since if $x \in \cap_n K_n$, we have $g(x) \geq f_n(x)$ for all n, hence $g(x) \geq f(x)$, contrary to hypothesis. Thus (K_n) is a decreasing sequence of compact subsets of X with empty intersection, so $K_n = \emptyset$ for some n by (). The proof of the last statement is analogous. 👍

As a corollary, we get the commonly stated version of Dini's Theorem:

XIII.11.15.3. Corollary. [Dini's Theorem, Common Version] Let X be a compact topological space, and (f_n) a monotone sequence of real-valued continuous functions on X converging pointwise to a continuous function f. Then $f_n \to f$ uniformly.

Proof: Let $\epsilon > 0$. If (f_n) is nondecreasing, set $g(x) = f(x) - \epsilon$ for all x; if (f_n) is nonincreasing, set $g(x) = f(x) + \epsilon$. 👍

Combining this result with (), we obtain:

XIII.11.15.4. Corollary. Let X be a compact topological space, and (f_n) a monotone sequence of real-valued continuous functions on X converging pointwise to a function f. Then $f_n \to f$ uniformly if and only if f is continuous.

XIII.12. Baire Spaces and the Baire Category Theorem

The Baire Category Theorem is one of the two theorems from topology (along with Tikhonov's Theorem) which are most heavily used in advanced analysis. Some of the conclusions are remarkable, and can seem like "magic" or "too good to be true."

It will be most convenient to phrase the theorem by defining the class of topological spaces, the Baire spaces, for which the conclusion holds and then showing that complete metric spaces and locally compact Hausdorff spaces are Baire spaces.

XIII.12.1. Meager Sets and Baire Spaces

XIII.12.1.1. Definition. Let X be a topological space. A subset A of X is *nowhere dense* in X if the complement of $\bar{A}$ is dense in X.

A subset of X is *meager* in X, or *first category* in X, if it is a countable union of nowhere dense subsets of X. A subset is *second category* in X if it is not meager (first category) in X. A subset A is *residual* in X, or *comeager* or *generic* in X, if A^c is meager in X.

The (nonempty) topological space X is a *Baire space* if no nonempty open subset of X is meager in X, i.e. if every residual subset of X is dense in X.

The terms "nowhere dense", "meager", "first category", "second category", "residual", "generic", and "comeager" are relative terms, and the ambient topological space X must be mentioned or at least be understood. The term "Baire space", however, is intrinsic.

The terminology "first category" and "second category" is Baire's, and is still frequently used, but we prefer the more descriptive terminology "meager" and "residual." Note that "second category" and "residual" are not the same; in a Baire space, every residual set is second category, but there are many subsets A for which both A and A^c are second category. (In a non-Baire space, even $\emptyset$ can be residual.)

XIII.12.1.2. Examples. (i) The complement of a nowhere dense set is dense, but a set with dense complement is not nowhere dense in general. For example, $\mathbb{Q}$ is not nowhere dense in $\mathbb{R}$ (in fact, it is dense). A set $A \subseteq X$ is nowhere dense in X if and only if $\bar{A}$ is nowhere dense in X.

(ii) The complement of a dense open set in a topological space X is nowhere dense in X. In particular, the Cantor set is nowhere dense in $\mathbb{R}$.

(iii) $\mathbb{R}$ is not nowhere dense in $\mathbb{R}$ (in fact, no nonempty topological space is nowhere dense in itself). But $\mathbb{R}$ is nowhere dense in $\mathbb{C}$. Thus it is important to specify the ambient space.

(iv) If X is T_1 and $x \in X$ is not an isolated point, then $\{x\}$ is nowhere dense in X. Thus a countable subset of X containing no isolated points is meager. In particular, every countable subset of $\mathbb{R}$ (e.g. $\mathbb{Q}$) is meager.

(v) Any subset of a nowhere dense set is nowhere dense. Any subset of a meager set is meager. So any subset containing a dense G_δ is residual. The converse is true in a Baire space (XIII.12.1.4.).

(vi) Any discrete space is a Baire space, since a nonempty subset of a discrete space cannot be nowhere dense. On the other hand, by (iv), no countable T_1 space without isolated points is a Baire space.

(vii) A countable union of meager sets in X is meager in X (cf. II.5.4.8.).

XIII.12.1.3. PROPOSITION. Let X be a topological space. The following are equivalent:

(i) X is a Baire space.

(ii) The intersection of any sequence of dense open subsets of X is dense.

(iii) The intersection of any finite or countable collection of dense G_δ's is a dense G_δ.

PROOF: (i) $\Rightarrow$ (ii): If X is a Baire space and (A_n) is a sequence of dense open subsets of X, then A_n^c is closed and nowhere dense in X, so $\cup_{n=1}^\infty A_n^c$ is meager and $\cap_{n=1}^\infty A_n$ is residual, hence dense.

(ii) $\Rightarrow$ (i): Suppose the intersection of any sequence of dense open subsets of X is dense, and let A be a residual subset of X. Then $A^c = \cup_{n=1}^\infty B_n$, where B_n is nowhere dense in X. If A_n is the complement of $\bar{B}_n$, then A_n is a dense open set in X, and $\cap_{n=1}^\infty A_n \subseteq A$. By assumption, $\cap_{n=1}^\infty A_n$ is dense in X, so A is also dense in X.

For (iii), the only issue is whether the intersection is dense since in any topological space an intersection of countably many G_δ's is a G_δ. (iii) $\Rightarrow$ (ii) is trivial since an open set is a G_δ, and (ii) $\Rightarrow$ (iii) is nearly trivial since a dense G_δ is an intersection of a sequence of dense open sets. 👍

XIII.12.1.4. COROLLARY. Let X be a Baire space. A subset A of X is residual in X if and only if A contains a dense G_δ.

PROOF: One direction was observed in XIII.12.1.2.(v). Conversely, let A be a residual subset of a Baire space X. Then $A^c = \cup_{n=1}^\infty B_n$, where B_n is nowhere dense in X. If A_n is the complement of $\bar{B}_n$, then A_n is a dense open set in X, and $\cap_{n=1}^\infty A_n$ is a dense G_δ in X which is contained in A. 👍

XIII.12.1.5. If X is a T_1 Baire space and A is a countable dense subset of X containing no isolated points, then A is meager (XIII.12.1.2.), so cannot be a G_δ since if it were A^c would be an F_σ, hence also meager (Exercise XIII.12.5.1.). In particular, $\mathbb{Q}$ is not a G_δ in $\mathbb{R}$.

XIII.12.2. The Baire Category Theorem

It turns out that many standard topological spaces are Baire spaces. The next theorem is the principal result of this section. It is named after R. BAIRE, who proved it in 1899 [] (BAIRE actually only stated it for $\mathbb{R}^n$, but essentially the same proof gives the general result), and is called the "Baire Category Theorem" because of his category terminology (note that it has nothing to do with category theory ()). The case of $\mathbb{R}$ was actually proved earlier (1897) by W. OSGOOD [Osg97], who used different terminology; OSGOOD also independently obtained the result for $\mathbb{R}^n$ [Osg00].

XIII.12.2.1. THEOREM. [BAIRE CATEGORY THEOREM] (i) Every completely metrizable space (topological space whose topology is given by a complete metric) is a Baire space.

(ii) Every locally compact Hausdorff space is a Baire space.

The first sentence is often stated, "Every complete metric space is a Baire space." But note that the property of being a Baire space is a purely topological property, not a metric property. Thus, for example, $(0,1)$ is a Baire space since it is homeomorphic to $\mathbb{R}$, even though the usual metric on $(0,1)$ is not complete. See XIII.10.5. for more detailed results about completely metrizable spaces.

PROOF: The proofs of both parts are nearly identical. In both cases, we must show that if (U_n) is a sequence of dense open subsets of X, then $\cap_{n=1}^{\infty} U_n$ is also dense in X, i.e. if V is a nonempty open set in X, then $V \cap [\cap_{n=1}^{\infty} U_n]$ is nonempty.

First suppose the topology on X is given by a complete metric ρ. Since U_1 is dense in X, $V \cap U_1$ is nonempty. Choose $x_1 \in V \cap U_1$, and let B_1 be an open ball of radius ≤ 1 centered at x_1 whose closure is contained in $V \cap U_1$ (there exists such a ball since $V \cap U_1$ is open in X). Since U_2 is dense in X, there is an $x_2 \in B_1 \cap U_2$. Let B_2 be an open ball centered at x_2 of radius $\leq 1/2$ whose closure is contained in $B_1 \cap U_2$. Inductively define points $x_n \in B_{n-1} \cap U_n$ and balls B_n centered at x_n of radius $\leq 1/n$ whose closure is contained in $B_{n-1} \cap U_n$. By construction, x_m is in the closure of B_n for all $m > n$, and thus $\rho(x_n, x_m) \leq 1/n$ for all $m > n$. Thus (x_n) is a Cauchy sequence in (X, ρ). Since ρ is complete, (x_n) converges to some $x \in X$. We have that x is in the closure of B_n for each n; thus $x \in \cap_{n=1}^{\infty} U_n$. And $x \in \bar{B}_1 \subseteq V$. Thus $V \cap [\cap_{n=1}^{\infty} U_n]$ is nonempty.

The proof of (ii) is similar, but easier. Choose $x_1 \in V \cap U_1$ as before. There is an open neighborhood B_1 of x_1 with compact closure contained in $V \cap U_1$ (). Inductively choose points x_n and open neighborhoods B_n such that the closure of B_n is compact and contained in $B_{n-1} \cap U_n$. Then $(\bar{B}_n)$ is a decreasing sequence of nonempty compact subsets of X and hence there is an $x \in \cap_{n=1}^{\infty} \bar{B}_n$. This x is in U_n for all n, and also in V. 👍

XIII.12.2.2. Note that the proof of this theorem uses the Axiom of Choice to choose the x_n. In fact, only a sequence of choices must be made, each dependent on the previous ones, so the Axiom of Dependent Choice (DC) suffices. Actually, the Baire Category Theorem is logically equivalent to DC (Exercise II.6.4.7.). But if X is separable, no form of choice is necessary to prove the Baire Category Theorem (Exercise ()). (It can be proved without any form of choice that a separable metrizable space is second countable (); however, the Countable Axiom of Choice is needed to prove that a second countable topological space, even a second countable metrizable space, is separable, so Countable AC is needed to prove the Baire Category Theorem for second countable completely metrizable spaces.)

XIII.12.2.3. There are many Baire spaces, even metrizable ones, which do not satisfy the hypotheses of XIII.12.2.1.. In particular, a metrizable Baire space need not be completely metrizable (XIII.12.5.4.).

XIII.12.2.4. One of the important ways the Baire Category Theorem is used in analysis is to prove the existence of objects with a certain (usually pathological) property by showing that the set of objects without the property is a meager subset of some complete metric space. Such proofs are often regarded as "nonconstructive" or "pure existence proofs" which prove existence without exhibiting a specific example. The claim is made in [Oxt71] that this point of view is incorrect (at least in the separable case), and that the proof of the Baire Category Theorem is an explicit construction which in applications gives a

concrete example. This claim is correct, at least in principle: the proof of the theorem does give a recipe for constructing an example. But the actual example is the limit of a Cauchy sequence which may be almost impossible to describe explicitly. Even the terms in the Cauchy sequence can be quite difficult to explicitly describe in many cases. (This point is acknowledged in [Oxt71].)

Here is an interesting sample application of Baire Category. An explicit example of a continuous function which is not differentiable anywhere is given in (). Here is a simpler argument which shows that such functions exist; in fact, in a category sense almost all continuous functions fail to be differentiable anywhere!

XIII.12.2.5. THEOREM. Let $[a, b]$ be a closed bounded interval in $\mathbb{R}$, and $C([a, b])$ the real-valued continuous functions on $[a, b]$, with supremum norm. If D is the set of functions in $C([a, b])$ which have a (finite) derivative at at least one point of $[a, b]$, then D is a meager subset of $C([a, b])$. Hence there is a residual set of functions on $[a, b]$ which are continuous everywhere but differentiable nowhere.

This argument in a sense shows more than the one in (), and in a sense shows less: this argument shows not only that continuous nondifferentiable functions exist, but that such functions are "typical" (despite one's impression from Calculus) and form a set which is uniformly very dense. However, it is hard to identify a specific example of such a function from the Baire Category argument.

There are some rather astounding variations on this result, such as the following theorem of J. MARCINKIEWICZ (1935).

XIII.12.2.6. THEOREM. Let $[a, b]$ be a closed bounded interval, and (h_n) a sequence of nonzero real numbers converging to zero. Then there is a continuous function $f : [a, b] \to \mathbb{R}$ with the following property: if $\phi : [a, b] \to \mathbb{R}$ is any measurable function, then there is a subsequence (h_{k_n}) of (h_n) such that

$$\lim_{n\to\infty} \frac{f(x + h_{k_n}) - f(x)}{h_{k_n}} = \phi(x)$$

for almost all $x \in [a, b]$. (Thus f is differentiable at most on a set of measure zero.) In fact, there is a residual set of such f.

See [Str81, p. 316-317] for an outline of the proof.

XIII.12.3. Meager Sets vs. Null Sets

Meager sets have a close formal resemblance to sets of Lebesgue measure zero. Both notions are reasonable interpretations of what it should mean to be "negligibly small." The relationship is more than just an analogy; the theme of the book [Oxt71] is the close connections between the concepts.

The two notions of smallness are not the same, however, as the next rather dramatic example shows:

XIII.12.3.1. EXAMPLE. There is a dense G_δ in $\mathbb{R}$ of Lebesgue measure 0. Thus $\mathbb{R}$ can be partitioned into a disjoint union of a meager set and a set of measure 0. This follows immediately from () and the fact that $\mathbb{Q}$ is a dense subset of $\mathbb{R}$ of Lebesgue measure 0, but we give an explicit example.

Let (r_n) be an enumeration of $\mathbb{Q}$. Let $I_{n,k}$ be the open interval of length $\frac{1}{2^n k}$ centered at r_n, and for each k let $A_k = \cup_{n=1}^{\infty} I_{n,k}$. Then A_k is open, and dense since $\mathbb{Q} \subseteq A_k$; and

$$\lambda(A_k) \leq \sum_{n=1}^{\infty} \frac{1}{2^n k} = \frac{1}{k} .$$

Thus $A = \cap_{k=1}^{\infty} A_k$ is a dense G_δ in $\mathbb{R}$ of Lebesgue measure 0.

An even more dramatic example is possible: there is a dense G_δ in $\mathbb{R}$ which not only has Lebesgue measure 0, but Hausdorff dimension 0, i.e. s-dimensional Hausdorff measure 0 for all $s > 0$. Such an example can be readily constructed by a refinement of the argument in XIII.12.3.1., but there is a natural and significant example: the Liouville numbers. See ().

XIII.12.4. The Baire Property

XIII.12.4.1. DEFINITION. Let X be a topological space. If $A, B \subseteq X$, write $A =^* B$ if $A \triangle B$ is a meager subset of X (i.e. "A and B differ by a meager set.")

A subset A of X has the *Baire property* if $A =^* U$ for some open set U in X, i.e. "A differs from an open set by a meager set."

XIII.12.4.2. It is easy to check that $=^*$ is an equivalence relation on subsets of X. Note that the Baire property is a relative property of A in X, not an intrinsic property of A. For example, every open set and every meager set in X has the Baire property. In particular, there is no direct connection between having the Baire property and being a Baire space.

XIII.12.4.3. PROPOSITION. Let X be a topological space. Then the collection of all subsets of X with the Baire property is a σ-algebra, and is the σ-algebra generated by the open sets and the meager sets. In particular, every Borel set in X has the Baire property.

PROOF: If U is open, then $U =^* \bar{U}$ since $\bar{U} \setminus U$ is nowhere dense, hence meager. Similarly, if E is closed, $E =^* E^\circ$.

If $A =^* U$ with U open, then $A^c \triangle U^c = A \triangle U$ is meager, so $A^c =^* U^c =^* (U^c)^\circ$, and A^c has the Baire property. And if $A_n =^* U_n$ for all n with each U_n open, then

$$\left(\bigcup_n A_n\right) \triangle \left(\bigcup_n U_n\right) \subseteq \bigcup_n (A_n \triangle U_n)$$

and a countable union of meager sets is meager, hence $\cup_n A_n =^* \cup_n U_n$, so $\cup_n A_n$ has the Baire property. Thus the collection $\mathcal{D}$ of subsets with the Baire property is a σ-algebra.

If $\mathcal{A}$ is the σ-algebra generated by the open sets and the meager sets, then $\mathcal{A} \subseteq \mathcal{D}$. Conversely, if $A \in \mathcal{D}$, then $A \triangle U = M$ is meager for some open set U, and $A = M \triangle U$, so $A \in \mathcal{A}$. Thus $\mathcal{A} = \mathcal{D}$.

XIII.12.4.4. Corollary. Let X be a topological space, and $A \subseteq X$. The following are equivalent:

(i) A has the Baire property.

(ii) $A = E \cup M$ with E a G_δ and M meager.

(iii) $A = F \setminus M$ with F an F_σ and M meager.

Proof: (ii) $\Rightarrow$ (i) and (iii) $\Rightarrow$ (i) by XIII.12.4.3.. For (i) $\Rightarrow$ (ii), suppose $A \triangle U = N$ for a meager set N. Then there is a meager F_σ F with $N \subseteq F$. Then $E = U \setminus F$ is a G_δ, $E \subseteq A$, and $A \setminus E \subseteq N$ is meager. For (i) $\Rightarrow$ (iii), apply (i) $\Rightarrow$ (ii) for A^c. 👍

Baire Measurable Functions

XIII.12.4.5. Definition. Let X and Y be topological spaces, and $f : X \to Y$ a function. Then f is *Baire measurable* if $f^{-1}(U)$ has the Baire property for every open set U in Y.

XIII.12.4.6. It follows from () that if f is Baire measurable, then $f^{-1}(B)$ has the Baire property for any Borel set B in Y. In particular, if f is Borel measurable, it is Baire measurable. (Of course, if f is continuous it is Borel measurable, hence Baire measurable.)

The next result is related to Luzin's Theorem (), at least in spirit. It holds for any topological spaces, but is most interesting if X is a Baire space:

XIII.12.4.7. Theorem. Let X and Y be topological spaces, and $f : X \to Y$ a Baire measurable function. Then there is a residual G_δ E in X such that $f|_E$ is continuous.

XIII.12.4.8. The set E is necessarily dense in X if X is a Baire space. Note that the conclusion is that the *restriction* of f to E is continuous, not that f is continuous at the points of E. In fact, f need not be continuous anywhere, even if X is a Baire space (e.g. $\chi_{\mathbb{Q}} : \mathbb{R} \to \mathbb{R}$; in this case we may take $E = \mathbb{J}$). ✋

In contrast, here is an important result in which actual continuity is obtained on a residual set.

XIII.12.4.9. Theorem. Let X, Y, and Z be metrizable topological spaces, and $f : X \times Y \to Z$ a function. Suppose f is separately continuous, i.e. for each $x \in X$ the function $f_x : Y \to Z$ given by $f_x(y) = f(x, y)$ is continuous, and for each $y \in Y$ the function $f^y : X \to Z$ given by $f^y(x) = f(x, y)$ is continuous. Then there is a residual G_δ E in $X \times Y$, with $E^y = \{x \in X : (x, y) \in E\}$ residual in X for each $y \in Y$, such that f is continuous (i.e. jointly continuous) at all points of E.

XIII.12.4.10. In particular, if $X \times Y$ is a metrizable Baire space, e.g. if X and Y are completely metrizable, then a separately continuous function from $X \times Y$ to any metric space Z is jointly continuous on a dense G_δ.

XIII.12.5. Exercises

XIII.12.5.1. Let X be a complete metric space, or a locally compact Hausdorff space, without isolated points. Show that no countable dense subset of X is a G_δ. (Hence $\mathbb{Q}$ is not a G_δ in $\mathbb{R}$.) In particular, X is uncountable. [The complement of a dense G_δ is meager.]

XIII.12.5.2. (a) Show that a dense G_δ in a Baire space is a Baire space in the relative topology.

(b) Prove that a compact Hausdorff space is a Baire space. [The proof is similar to and not essentially easier than the proof of the second half of XIII.12.2.1..] Conclude from (a) that a G_δ in a compact Hausdorff space is a Baire space.

(c) Deduce both statements in XIII.12.2.1. as corollaries of (b). [Use XIII.7.8.4. and **??** for completely metrizable spaces.]

The word "dense" cannot be eliminated in (a) (XIII.12.5.4.).

XIII.12.5.3. Prove the following strong converse to XIII.12.5.2.(a): If a topological space X contains a dense subspace which is a Baire space in the relative topology, then X is a Baire space. [Use XIII.2.3.9..]

XIII.12.5.4. Let $X = (\mathbb{R} \times [\mathbb{R} \setminus \{0\}]) \cup (\mathbb{Q} \times \{0\})$, with the relative topology from $\mathbb{R}^2$.

(a) Apply XIII.12.5.3. to show that X is a Baire space.

(b) X has a closed subspace, a G_δ, homeomorphic to $\mathbb{Q}$, which is not a Baire space (XIII.12.1.2.(vi)). Thus a closed subspace of a Baire space, even a closed G_δ, is not necessarily a Baire space.

(c) X is metrizable. But a closed subspace of a completely metrizable space is completely metrizable and hence a Baire space, so X is not completely metrizable.

Simpler non-Hausdorff examples of non-Baire closed subspaces of Baire spaces can be given.

XIII.12.5.5. [Boa96, p. 59–61] Use the Baire Category Theorem to show that on any closed bounded interval $[a, b]$, there is a continuous function which is not monotone on any subinterval, and in fact a residual set of such functions in $C([a, b])$. [Use subintervals with rational endpoints.] See XIII.12.5.8. for a closely related result.

XIII.12.5.6. [CSB54] Use the Baire Category Theorem to show that if f is a C^∞-function on an interval $[a, b]$, and for every $x \in [a, b]$ there is an n such that $f^{(n)}(x) = 0$, then f is a polynomial, i.e. there is an n such that $f^{(n)}(x) = 0$ for all $x \in [a, b]$.

XIII.12.5.7. [Wei76] Let $[a, b]$ be a closed bounded interval, and $\mathcal{D}'_b([a, b])$ the set of bounded functions on $[a, b]$ which are derivatives of differentiable functions (i.e. bounded functions on $[a, b]$ which have antiderivatives).

(a) Show that $\mathcal{D}'_b([a, b])$ is a closed subspace of the Banach space of bounded real-valued functions on $[a, b]$ with the supremum norm, hence also a Banach space (cf. V.8.5.7.).

(b) Show that if $f \in \mathcal{D}'_b([a, b])$, then $Z_f = \{x \in [a, b] : f(x) = 0\}$ is a G_δ (cf. V.12.1.8., ()).

(c) Let $\mathcal{D}'_0([a, b])$ be the set of all $f \in \mathcal{D}'_b([a, b])$ for which Z_f is dense in $[a, b]$. Use (b) and the Baire Category Theorem to show that $\mathcal{D}'_0([a, b])$ is a closed subspace of $\mathcal{D}'_b([a, b])$, and thus also a Banach space.

(d) There is a $g \in \mathcal{D}_0'([a,b])$ which is not identically zero (XIII.22.10.3.). By translating and scaling g, show that for any $x \in [a,b]$ and $\epsilon > 0$ there is an $h \in \mathcal{D}_0'([a,b])$ with $\|h\| < \epsilon$ and $h(x) \neq 0$.

(e) If I is a closed (nondegenerate) subinterval of $[a,b]$, let

$$E_I^+ = \{f \in \mathcal{D}_0'([a,b]) : f(x) \geq 0 \text{ for all } x \in I\} .$$

Show that E_I^+ is a closed subset of $\mathcal{D}_0'([a,b])$. Use (d) to show that E_I^+ is nowhere dense in $\mathcal{D}_0'([a,b])$. Do the same for $E_I^- = \{f \in \mathcal{D}_0'([a,b]) : f(x) \leq 0 \text{ for all } x \in I\}$.

(f) Let E be the set of all bounded derivatives of differentiable functions on $[a,b]$ which are monotone on some (nondegenerate) subinterval. Show that E is a meager subset of $\mathcal{D}_0'([a,b])$. [Let (I_n) be an enumeration of the closed subintervals of $[a,b]$ with rational endpoints. Show that $E = \cup_n (E_{I_n}^+ \cup E_{I_n}^-)$.

XIII.12.5.8. This problem is a continuation of XIII.12.5.7., using the same notation.

(a) Let $\mathcal{D}_0([a,b])$ be the set of differentiable functions on $[a,b]$ whose derivative is in $\mathcal{D}_0'([a,b])$. Show that $\mathcal{D}_0([a,b])$ is a subalgebra of $C_{\mathbb{R}}([a,b])$. (The Baire Category Theorem is needed to prove it is closed under multiplication.)

(b) Show that $\mathcal{D}_0([a,b])$ separates points of $[a,b]$. Thus by the Stone-Weierstrass Theorem (XX.10.2.2.) $\mathcal{D}_0([a,b])$ is uniformly dense in $C_{\mathbb{R}}([a,b])$.

(c) Give a direct proof of the result of (b) without using the Stone-Weierstrass Theorem, using:

Lemma. For every $\epsilon > 0$ there is an $f \in \mathcal{D}_0([0,1])$ with the following properties:

(i) $f(0) = 0$, $f(1) = 1$.

(ii) $f'(0) = f'(1) = 0$.

(iii) For every $x \in [0,1]$, $f'(x) < 1 + \epsilon$.

(iv) For every $x \in [0,1]$, $x - \epsilon < f(x) < x + \epsilon$.

(d) To prove the Lemma, let g be an element of $\mathcal{D}_0([a,b])$ for some $[a,b]$ with $1 < \sup g' < 1 + \epsilon$, and let $c, d \in [a,b]$, $c < d$, with $\frac{g(d)-g(c)}{d-c} > 1$. Replace c and d with nearby places where $g' = 0$. Rescale $[c,d]$ to $[0,1]$. Show that (iv) follows from (i), (iii), and the MVT.

(e) By translating and scaling the f of the lemma, show that any piecewise-linear continuous function on any closed bounded interval can be uniformly approximated by functions in $\mathcal{D}_0([a,b])$.

XIII.12.5.9. [HY88] A space X, even $[0,1]$ or $\mathbb{R}$, can have two subsets Y and Z which are homeomorphic in the relative topologies, such that Y is first category in X and Z is second category in X. The Y can even be nowhere dense. In this sense category is "nontopological."

(a) Let Y be the set of points in $[0,1]$ whose ternary expansion contains no 1's and does not end in a string of 0's or a string of 2's. Then Y is the Cantor set K with the endpoints of the complementary intervals removed. Since K is nowhere dense in $[0,1]$ (and in $\mathbb{R}$), Y is also nowhere dense in $[0,1]$ (and in $\mathbb{R}$), and in particular first category.

(b) Let Z be the set of points in $[0,1]$ whose binary expansion does not end in a string of 0's or a string of 1's. The complement of Z in $[0,1]$ is the set of dyadic rationals in $[0,1]$. Since $[0,1] \setminus Z$ is countable and thus first category in $[0,1]$, Z cannot be first category in $[0,1]$ (or in $\mathbb{R}$).

(c) Show that the map that converts 2's to 1's in the expansions is a homeomorphism from Y to Z with their relative topologies. (**Caution:** it is not one-to-one on K!)

(d) Show that if X is a topological space and ϕ is a homeomorphism from X to X, $Y \subseteq X$, and $Z = \phi(Y)$, then Z is first category [resp. nowhere dense, second category, residual] in X if and only if Y is. Thus in this sense all these notions are "topological."

XIII.12.5.10. (a) Show that an open set in a Baire space is a Baire space. [If W is open in X, and (U_n) is a sequence of dense open sets in W, set $V_n = U_n \cup \bar{W}^c$.]

(b) Conversely, if X is a topological space and every point of X has an open neighborhood which is a Baire space (it is enough to check that a dense set of points have this property), then X is a Baire space. ("The property of being a Baire space is a local property.")

XIII.12.5.11. (a) ([Oxt61], [FK78]) A product of two Baire spaces is not necessarily Baire, even if they are metrizable.

(b) [Oxt61] An arbitrary product of Baire spaces with countable pseudo-base (XIII.1.6.7.) is a Baire space.

XIII.12.5.12. Let X be a second countable topological space.

(a) Show that X is a disjoint union of a meager F_σ and a G_δ which is zero-dimensional in the relative topology. [If $\{U_n : n \in \mathbb{N}\}$ is a countable base for the topology, consider $\cup_n \partial U_n$.]

(b) If X is a Baire space, then X has a dense G_δ which is zero-dimensional in the relative topology.

XIII.13. Connectedness

The notion of a connected topological space, or of a connected subset of a topological space, is fundamental in topology and especially in applications in analysis.

The idea is simple. If a topological space can be divided into two disconnected pieces, each piece must be a closed set since no point of one of the sets can be a limit point of the other. Since each set is the complement of the other, the sets must be open as well as closed. Conversely, if a space can be partitioned into two subsets which are each both open and closed, these sets disconnect the space.

A second, more restrictive, notion of connectedness which is perhaps more intuitively appealing is that of *path-connectedness*, that any two points of the space can be connected by a path. Path-connectedness implies connectedness (once we know that intervals are connected), but not conversely. Both types of connectedness are useful in topology and analysis.

XIII.13.1. Connected Spaces

XIII.13.1.1. A subset U of a topological space X is *clopen* if U is both open and closed. ($X \setminus U$ is then also clopen.) In any topological space X, $\emptyset$ and X are clopen; in many interesting topological spaces, these are the only clopen subsets.

Finite unions, finite intersections, and set-theoretic differences of clopen sets are clopen.

The term "clopen" is regarded as a language abomination in some circles and is somewhat unfashionable; but the term is useful and there is no good alternative, so we will use it.

XIII.13.1.2. Definition. Let X be a topological space. A *separation* of X is a decomposition $X = U \cup V$ of X into two nonempty disjoint clopen subsets. X is *connected* if it has no separation, i.e. if the only clopen subsets of X are $\emptyset$ and X.

Connectedness is obviously a topological property of a space, preserved under homeomorphisms.

XIII.13.1.3. Examples. (i) Any space with the indiscrete topology is connected.

(ii) A space with the discrete topology and more than one point is not connected.

(iii) The Sierpiński space () is connected.

(iv) An infinite set with the finite complement topology () is connected.

(v) $\mathbb{Q}$ with the relative topology from $\mathbb{R}$ is not connected: for example, $U = \{x \in \mathbb{Q} : x < \sqrt{2}\}$ and $V = \{x \in \mathbb{Q} : x > \sqrt{2}\}$ form a separation of $\mathbb{Q}$.

Examples (i), (iii), and (iv) show that connectedness can behave strangely in non-Hausdorff spaces. The notion is most interesting for spaces with nice separation properties, although even there some of the behavior can be surprising.

By far the most important example of a connected topological space is:

XIII.13.1.4. THEOREM. $\mathbb{R}$ (with its usual topology) is connected.

PROOF: Let $\mathbb{R} = U \cup V$ be a separation, and let $a \in U$, $b \in V$. We may assume $a < b$. Set

$$Y = \{x \in [a, b] : x \in U\}$$

and set $c = sup(Y)$. We have $c < b$ since $(b - \epsilon, b] \subseteq V$ for some $\epsilon > 0$. Either $c \in U$ or $c \in V$. If $c \in U$, then $[c, c + \epsilon) \subseteq U$ for some $\epsilon > 0$, contradicting that $c = \sup(Y)$. If $c \in V$, then $(c - \epsilon, c] \subset V$ for some $\epsilon > 0$, so $c - \epsilon$ would be an upper bound for Y, another contradiction. So no separation exists. 👍

Connected Subsets of a Space

XIII.13.1.5. If X is a topological space and $E \subset X$, we say E is a connected subset of X if E is a connected space in the relative topology. This can be phrased in several equivalent ways:

XIII.13.1.6. PROPOSITION. Let X be a topological space and $E \subseteq X$. The following are equivalent:

(i) E is not connected.

(ii) There are open sets U and V in X with $U \cap E$ and $V \cap E$ nonempty, such that $E \subseteq U \cup V$ and $U \cap V \cap E = \emptyset$.

(iii) There are nonempty subsets A and B of E such that $E = A \cup B$ and $\bar{A} \cap B = A \cap \bar{B} = \emptyset$.

The proof is an easy exercise, and is left to the reader. A pair $\{U, V\}$ of open sets as in (ii) is called a *separation* of E in X (cf. XIII.10.1.1.).

XIII.13.1.7. COROLLARY. A subset of $\mathbb{R}$ is connected if and only if it is an interval or a singleton.

An interval is connected by (ii) and essentially the same argument as in the proof of XIII.13.1.4.. A subset of $\mathbb{R}$ which is not an interval or singleton can be separated as in XIII.13.1.3.(v).

XIII.13.1.8. An interesting question is whether, if A and B are subsets of a topological space X which are separated as in (iii), then they have disjoint open neighborhoods (essentially, whether the U and V in (ii) can be chosen disjoint). The answer is: not always (Exercise XIII.13.9.4.). It is not even always true if X is a compact Hausdorff space [SS95, Example 86]. But it is true if X is metrizable (XIII.10.1.1.).

Closure of a Connected Set

XIII.13.1.9. PROPOSITION. Let X be a topological space, and E a connected subset of X. Then the closure $\bar{E}$ is also connected.

PROOF: Suppose $\{U, V\}$ is a separation of $\bar{E}$ as in XIII.13.1.6.(ii). Then $U \cap E$ or $V \cap E$ is empty, for otherwise $\{U, V\}$ would be a separation of E. If $V \cap E$ is empty, then $E \subseteq U$. Thus $\bar{E} \subseteq U$, since $\bar{E} \cap U = \bar{E} \cap V^c$ is closed. Thus $\bar{E} \cap V = \emptyset$, a contradiction. 👍

XIII.13.1.10. Corollary. Let X be a topological space. If X has a dense connected subset, then X is connected. In particular, if X is a topological space, E a connected subset of X, and Y a subset of X with $E \subseteq Y \subseteq \bar{E}$, then Y is connected.

Connected Boundary

The next result will be useful in XII.8.3.2..

XIII.13.1.11. Proposition. Let X be a connected topological space and U an open set in X. If ∂U is connected, then $U^c = X \setminus U$ is connected.

Proof: Set $V = (U^c)^\circ = X \setminus \bar{U}$. Then V is open, and X is the disjoint union of U, ∂U, and V. Suppose $U^c = \partial U \cup V$ is not connected, and let E and F be disjoint nonempty relatively clopen subsets of U^c with union U^c. Since U^c is closed, E and F are closed in X. Since ∂U is connected, either $\partial U \subseteq E$ or $\partial U \subseteq F$; suppose without loss of generality $\partial U \subseteq E$. Then $F \subseteq V$, and since F is relatively open in V and V is open in X, F is open in X. Hence F is a nontrivial clopen set in X, contradicting that X is connected. 👍

XIII.13.2. Continuous Images of Connected Sets

One of the most important properties of connected sets is:

XIII.13.2.1. Proposition. Let X and Y be topological spaces and $f : X \to Y$ a continuous function. If E is a connected subset of X, then $f(E)$ is a connected subset of Y.

Informally, a continuous image of a connected space is connected.

Proof: Suppose $\{U, V\}$ is a separation of $f(E)$ as in XIII.13.1.6.(ii). Then $\{f^{-1}(U), f^{-1}(V)\}$ is a separation of E. 👍

XIII.13.2.2. Corollary. Let X be a topological space, and $f : X \to \mathbb{R}$ a continuous function. If E is a connected subset of X, then $f(E)$ is an interval or singleton. In particular, if $f : \mathbb{R} \to \mathbb{R}$ is continuous and I is an interval in $\mathbb{R}$, then $f(I)$ is an interval or singleton.

XIII.13.2.3. Corollary. A connected completely regular space with more than one point has cardinality at least $2^{\aleph_0}$.

Proof: Such a space has a nonconstant real-valued continuous function, whose range has cardinality $2^{\aleph_0}$. 👍

XIII.13.2.4. More generally, a connected Urysohn space (XIII.7.10.21.) has cardinality at least $2^{\aleph_0}$ (same proof). This corollary can fail for spaces which are not completely regular. There are countably infinite connected Hausdorff spaces [SS95, Examples 60, 75], even countable connected completely Hausdorff spaces [SS95, Example 127]. A connected regular space must be uncountable, since a countable topological space is Lindelöf, and a regular Lindelöf space is normal, hence completely regular. There is a connected regular space of cardinality $\aleph_1$ [SS95, Example 92].

The Intermediate Value Theorem

As a corollary, we get one of the most important properties of continuous functions on the real line:

XIII.13.2.5. Corollary. [Intermediate Value Theorem] Let I be an interval in $\mathbb{R}$, and $f : I \to \mathbb{R}$ a continuous function. If $a, b \in I$ and d is any number between $f(a)$ and $f(b)$, then there is at least one $c \in I$ with $f(c) = d$. (See Figure ().)

XIII.13.3. Unions and Intersections

XIII.13.3.1. A union of two or more connected subsets of a topological space X frequently fails to be connected, e.g. the union of two disjoint open sets or of two sets with disjoint closures (e.g. two singletons in a T_1 space). However:

XIII.13.3.2. Proposition. Let X be a topological space, and $\{E_i : i \in I\}$ a collection of connected subsets of X. If $\cap_{i\in I} E_i \neq \emptyset$, then $\cup_{i\in I} E_i$ is connected.

Proof: Let $E = \cup_{i\in I} E_i$, and let $p \in \cap_{i\in I} E_i$. Suppose A and B are subsets of E with $E = A \cup B$ and $\bar{A} \cap B = A \cap \bar{B} = \emptyset$, with $p \in A$. For each i set $A_i = A \cap E_i$ and $B_i = B \cap E_i$. We have $E_i = A_i \cup B_i$ and $\bar{A}_i \cap B_i = A_i \cap \bar{B}_i = \emptyset$, so by XIII.13.1.6.(iii) A_i and B_i cannot both be nonempty. But $p \in A_i$ for all i, so $B_i = \emptyset$ for all i, and hence $B = \cup_i B_i = \emptyset$. Thus E is connected by XIII.13.1.6.(iii). 👍

XIII.13.3.3. Proposition XIII.13.3.2. can be used to "string together" connected subsets: the union of a sequence of connected subsets of a space is connected provided each successive pair has nonempty intersection.

XIII.13.3.4. Corollary. Every topological vector space is connected. In particular, $\mathbb{R}^n$ is connected for any n.

Proof: Any topological vector space is the union of all lines through the origin, each of which is homeomorphic to $\mathbb{R}$ and hence connected. 👍

See XIII.13.8.3.(ii) for another proof.

Intersections

XIII.13.3.5. The intersection of two connected subsets of a topological space is not connected in general. For example, if X is a circle, the closed upper and lower semicircles are connected since they are homeomorphic to intervals (the whole circle is also connected by XIII.13.3.2.), but the intersection consists of two points with the discrete topology.

Decreasing intersections are trickier. It turns out that a decreasing sequence of connected sets, even in $\mathbb{R}^2$, does not have connected intersection in general (Exercise XIII.13.9.5.). However, we have:

XIII.13.3.6. THEOREM. Let X be a Hausdorff space, and $\{E_i : i \in I\}$ be a collection of compact subsets of X. If $\cap_{i\in F} E_i$ is connected for each finite subset F of I, then $\cap_{i\in I} E_i$ is connected. In particular, the intersection of a decreasing sequence of connected compact subsets of X is connected.

"Hausdorff" cannot be weakened to T_1 (Exercise XIII.13.9.6.).

PROOF: Set $E = \cap_{i\in I} E_i$ and $E_F = \cap_{i\in F} E_i$ for $F \subseteq I$ finite. Then $E = \cap_F E_F$ is compact. Suppose E is not connected. Then there are disjoint nonempty relatively clopen subsets A, B of E with $E = A \cup B$. Since A and B are relatively closed in E, they are compact. There are disjoint open neighborhoods U and V of A and B in X (XIII.11.4.2.). By XIII.11.1.11. there is a finite subset F of I such that $E_F \subseteq U \cup V$. Since E_F is connected, either $E_F \cap U$ or $E_F \cap V$ is empty. But $A \subseteq E_F \cap U$ and $B \subseteq E_F \cap V$, a contradiction. Thus E is connected. 👍

XIII.13.4. Components of a Space

XIII.13.4.1. DEFINITION. Let X be a topological space, and $p \in X$. The *connected component* (or just *component*) of p in X is the union of all connected subsets of X containing p. (There is always at least one such set, $\{p\}$.)

XIII.13.4.2. PROPOSITION. Let X be a topological space.

(i) The connected component of any point p of X is closed and connected, and is the largest connected subset of X containing p.

(ii) If p and q are points of X, the connected components of p and q are either identical or disjoint.

PROOF: (i): The union P of all connected subsets of X containing p is nonempty and connected by XIII.13.3.2., and is obviously the largest connected subset of X containing p. By XIII.13.1.9., $\bar{P}$ is a connected set containing p, hence $\bar{P} \subseteq P$, i.e. P is closed.

(ii): If P and Q are the components of p and q in X respectively, and $P \cap Q \neq \emptyset$, then $P \cup Q$ is connected by XIII.13.3.2. and contains p and q, hence $P \cup Q = P = Q$. 👍

XIII.13.4.3. So the connected components of a space X partition X into disjoint closed subsets. Connected components can easily contain more than one point: if X is connected, the connected component of any point of X is all of X. At the other extreme, connected components can be singletons. This obviously happens for isolated points, but can happen for nonisolated points too: the components of the Cantor set K are connected subsets of $\mathbb{R}$, hence points or intervals; since K contains no intervals, the connected components of K are single points. Intermediate possibilities also occur in many spaces.

The connected component of a point p in a space X depends on X; if Y is a subspace of X containing p, the connected component of p in Y can be smaller than the connected component in X (it can even be smaller than the intersection of Y with the connected component in X, as easy examples show).

Quasi-Components

XIII.13.4.4. If X is a topological space, $p \in X$, and U is a clopen subset of X containing p, then any connected subset of X containing p must be contained in U (otherwise $\{U, U^c\}$ would give a separation), and in particular the component P of p in X is contained in U. Thus

$$P \subseteq Q = \bigcap \{U \subseteq X \text{ clopen } : p \in U\} .$$

The set Q is sometimes called the *quasi-component* of p in X. It can be strictly larger than the component of p in X (Exercises XIII.13.9.7. and XIII.13.9.8.). However:

XIII.13.4.5. Proposition. Let X be a compact Hausdorff space. Then the quasi-component of any point is just its component.

"Hausdorff" cannot be weakened to T_1 in this result (Exercise XIII.13.9.7.).

Proof: The argument is similar to the proof of XIII.13.3.6.. Let $p \in X$, and let P and Q be the component and quasi-component of p in X. Since $P \subseteq Q$, it suffices to show that Q is connected. Suppose Q is not connected, and write $Q = A \cup B$ for disjoint nonempty relatively clopen subsets with $p \in A$. Then A and B are compact, so they have disjoint open neighborhoods U and V in X. Since Q is the intersection of all clopen subsets of X containing p and each clopen set in X is compact, by XIII.11.1.11. there are finitely many clopen subsets $W_1, \ldots, W_n$ of X containing p such that $W = W_1 \cap \cdots \cap W_n$ is contained in $U \cup V$. W is clopen, and W is the disjoint union of $W \cap U$ and $W \cap V$. $W \cap U$ is open, and $W \cap U = W \cap V^c$ is also closed, i.e. $W \cap U$ is clopen and contains p, and thus $Q \subseteq W \cap U$, contradicting that B is nonempty. Thus Q is connected. 👍

XIII.13.4.6. Quasi-components, like components, are closed, and two quasi-components are either identical or disjoint. Thus the whole space partitions into quasi-components, each of which partitions into one or more components.

XIII.13.5. Products of Connected Spaces

XIII.13.5.1. Theorem. Let $\{X_i : i \in I\}$ be a collection of topological spaces. Then $\prod_i X_i$ is connected if and only if each X_i is connected.

PROOF: Let $X = \prod_i X_i$. If X is connected, since each coordinate projection is continuous it follows from XIII.13.2.1. that each X_i is connected. Conversely, suppose each X_i is connected. Let $p = (p_i)$ and $q = (q_i)$ be points of X. Let $F = \{i_1, \ldots, i_n\}$ be a finite subset of I. The subset $E_1 = \{(x_i) : x_i = p_i \text{ for } i \neq i_1\}$ is homeomorphic to X_{i_1}, hence connected, and contains the point a_1 with $x_{i_1} = q_{i_1}$ and $x_i = p_i$ for all $i \neq i_1$. Thus a_1 is in the connected component of p. Similarly, if a_2 is the point (x_i) with $x_{i_1} = q_{i_1}$, $x_{i_2} = q_{i_2}$, and $x_i = p_i$ for $i \neq i_1, i_2$, then a_2 is in the connected component of a_1 and hence in the connected component of p. Repeating the argument finitely many times, if q_F is the point (x_i) with $x_i = q_i$ for $i \in F$ and $x_i = p_i$ for $i \notin F$, then q_F is in the connected component of p. This is true for any finite F. Any open neighborhood of q contains q_F for some finite set F, so q is in the closure of the component of p. But components are closed, so q is in the component of p in X. This is true for any p and q, so X consists of only one connected component, i.e. is connected. 👍

XIII.13.6. Totally Disconnected and Zero-Dimensional Spaces

XIII.13.6.1. DEFINITION. Let X be a topological space. X is *totally disconnected* if for every pair $\{p, q\}$ of distinct points of X, there is a clopen set $U \subseteq X$ containing p but not q. (In other words, the quasi-components of X are single points.)

A totally disconnected topological space is Hausdorff: if U is a clopen set containing p but not q, then U and $X \setminus U$ are disjoint open neighborhoods of p and q.

XIII.13.6.2. Some references define a space to be totally disconnected if its connected components are single points (what we have called "totally disconnected" is often then called "totally separated"). This definition is equivalent to the one we have given for compact Hausdorff spaces, but not in general; see Theorem XIII.13.6.7.. Definition XIII.13.6.1. appears to be the usual definition used by topologists.

XIII.13.6.3. DEFINITION. Let X be a topological space. X is *zero-dimensional* if X is T_1 and every finite open cover of X has a refinement consisting of a partition of X into clopen subsets.

More precisely, this is the specification that the covering dimension (XIII.22.3.24.) of X is zero. Some references give a different definition (that there is a base for the topology of X consisting of clopen sets, i.e. that the *small inductive dimension* of X is zero; cf. XIII.22.3.2.). The two definitions are equivalent for T_1 Lindelöf spaces (in particular, for compact Hausdorff spaces and second countable metrizable spaces), but not in general; see Theorem XIII.13.6.7.. The T_1 condition cannot be reasonably weakened to T_0 (Exercise XIII.13.9.1.).

XIII.13.6.4. Actually, if X is zero-dimensional, every finite open cover of X has a refinement consisting of a *finite* partition of X into clopen sets. Even more is true: a finite open cover $\{V_1, \ldots, V_n\}$ has a *shrinking* consisting of a partition, i.e. there is a partition $\{U_1, \ldots, U_n\}$ of X into clopen sets with $U_j \subseteq V_j$ for each j (XIII.22.3.32.).

XIII.13.6.5. PROPOSITION. Let E and F be disjoint closed subsets of a zero-dimensional space X. Then there is a clopen set $U \subseteq X$ with $E \subset U$ and $F \subseteq X \setminus U$. In particular, a zero-dimensional topological space is normal.

PROOF: Let E and F be disjoint closed subsets of a zero-dimensional space X. The open cover $\{X \setminus E, X \setminus F\}$ has a refinement consisting of a partition of the space into clopen subsets. Let U be the union of all the sets in the partition which contain points of E; any such set is disjoint from F since the partition refines $\{X \setminus E, X \setminus F\}$. Then U is an open set containing E, and $F \subseteq X \setminus U$. $X \setminus U$ is the union of the remaining sets in the partition, hence is also open, i.e. U is clopen. 👍

There is a converse: if X is T_1 and any two disjoint closed sets can be separated by a partition, i.e. there is a clopen set containing one but not the other ($Ind(X) = 0$ (XIII.22.3.9.)), then X is zero-dimensional (XIII.22.3.33.).

XIII.13.6.6. PROPOSITION. Let X be a T_0 space for which there is a base for the topology consisting of clopen sets. Then X is completely regular.

PROOF: Let F be a closed set in X, and $p \in V = X \setminus F$. Then V is an open neighborhood of p, so there is a clopen neighborhood U of p contained in V. Define $f : X \to [0, 1]$ by setting $f(x) = 1$ if $x \in U$ and $f(x) = 0$ if $x \in X \setminus U$. Then f is continuous, $f(p) = 1$, and f is identically 0 on F. 👍

XIII.13.6.7. THEOREM. Let X be a compact Hausdorff space. The following are equivalent:

(i) Each component of X is a single point.

(ii) X is totally disconnected.

(iii) There is a base for the topology of X consisting of clopen sets ($ind(X) = 0$).

(iv) X is zero-dimensional ($dim(X) = 0$).

(v) Any two disjoint closed sets in X can be separated by a partition ($Ind(X) = 0$).

If X is metrizable, these are also equivalent to

(vi) X is homeomorphic to a subset of the Cantor set.

XIII.13.6.8. For general topological spaces, we have (vi) $\Rightarrow$ (iv) $\Rightarrow$ (ii) $\Rightarrow$ (i) and (iv) $\Longleftrightarrow$ (v) (XIII.22.3.34.); (iv) $\Rightarrow$ (iii) for T_1 spaces (XIII.22.8.1.), and (iii) $\Rightarrow$ (ii) for T_0 spaces (a space with the indiscrete topology and more than one point satisfies (iii) but not (ii)). (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii) for compact Hausdorff spaces, but not in general: there are G_δ subsets of $\mathbb{R}^2$ satisfying (i) but not (ii), and ones satisfying (ii) but not (iii) ([**?**, §46], [**?**], Exercise XIII.13.9.3.); thus (i) $\Rightarrow$ (ii) and (ii) $\Rightarrow$ (iii) do not hold even in Polish spaces. See also Exercise XIII.13.9.7.. (iii) $\Rightarrow$ (iv) for T_0 Lindelöf spaces, but not for general normal spaces [GJ76, 16M], so (iii), (iv), and (v) are equivalent for T_1 Lindelöf spaces (which are then automatically normal). (iv) does not imply (vi) for compact Hausdorff spaces: an uncountable product of two-point spaces is a counterexample (the space from Exercise () is a more interesting counterexample). (iii) $\Rightarrow$ (vi) for arbitrary second countable T_0 spaces; thus (iii), (iv), (v), and (vi) are equivalent for second countable T_1 spaces (which are then automatically metrizable).

PROOF: (i) ⇒ (ii) is XIII.13.4.5., and (ii) ⇒ (i) is XIII.13.4.4..

(iii) ⇒ (ii): We use only that X is T_0. Let p and q be points of X, and let V be an open set containing p but not q. Since the clopen sets form a base for the topology, there is a clopen set U with $p \in U \subseteq V$. Then U separates p and q.

(ii) ⇒ (iii): Let $p \in X$ and V an open set containing p. For each $q \notin V$, let U_q be a clopen set containing p but not q. Then $\{U_q^c : q \in V^c\}$ is an open cover for V^c. Since V^c is closed and hence compact, there is a finite subcover $\{U_{q_1}^c, \dots, U_{q_n}^c\}$. Then $U = U_{q_1} \cap \cdots \cap U_{q_n}$ is a clopen set containing p and contained in V. Thus the clopen sets form a base for the topology.

(iv) ⇒ (iii): We use only that X is T_1. Let $p \in X$ and V an open set containing p. Since $\{p\}$ is closed, $\{V, X \setminus p\}$ is an open cover of X, so it has a refinement consisting of a partition into clopen sets. The clopen set containing p must be contained in V. Thus the clopen sets form a base for the topology.

(iii) ⇒ (iv): We will use only that X is T_0 and Lindelöf, and satisfies (iii). Then X is completely regular by XIII.13.6.6., and in particular T_1 (actually X is automatically normal by XIII.7.6.12., but we will not need this; after the fact X will be normal by XIII.13.6.5.). Let $\mathcal{V}$ be an open cover of X (not necessarily finite). Since the clopen sets form a base for the topology, there is a refinement $\mathcal{W}$ of $\mathcal{V}$ consisting of clopen sets. $\mathcal{W}$ has a countable subcover $\{W_1, W_2, \dots\}$. Set $U_1 = W_1$, $U_2 = W_2 \setminus W_1$, $U_3 = W_3 \setminus (W_1 \cup W_2)$, etc. (Any U_n which are empty can be discarded.) Then $\{U_1, U_2, \dots\}$ is a partition of X into clopen sets, refining $\mathcal{W}$ and hence refining $\mathcal{V}$.

Actually, any partition of a compact X into clopen sets is necessarily finite since it forms an open cover of X with no proper subcover.

(iii) ⇒ (vi): We will use only that X is T_0, second countable, and satisfies (iii).
We first show that there is a countable base for the topology of X consisting of clopen sets. Let $\mathcal{V}$ be a countable base for the topology of X. For every pair (V, W) in $\mathcal{V}$ with $\bar{V} \subseteq W$, let $\mathcal{C}(V, W)$ be the set of all clopen sets U with $V \subseteq U \subseteq W$. $\mathcal{C}(V, W)$ might potentially be empty for some (V, W) (after the fact it turns out that it is always nonempty); but if it is nonempty, choose a clopen set $U_{V,W} \in \mathcal{C}(V, W)$. The collection $\mathcal{U}$ of all such $U_{V,W}$ is countable. $\mathcal{U}$ is a base for the topology of X since if p is any point of X and N any open neighborhood of p, there is a $W \in \mathcal{V}$ with $p \in W$ and $W \subseteq N$; since the clopen sets form a base, there is a clopen set U with $p \in U$ and $U \subseteq W$; there is then a $V \in \mathcal{V}$ with $p \in V$ and $V \subseteq U$. Thus $\mathcal{C}(V, W) \neq \emptyset$ and $U_{V,W}$ is defined; then $p \in V \subseteq U_{V,W} \subseteq W \subseteq N$.
Now let $\{U_1, U_2, \dots\}$ be a countable base for the topology of X consisting of clopen sets. Define a function $f : X \to \mathbb{R}$ by letting $f(x)$ be the number with base 3 expansion

$$.d_1 d_2 d_3 \cdots$$

where $d_n = 2$ if $x \in U_n$ and $d_n = 0$ if $x \in U_n^c$. f is one-to-one since X is T_0. The range of f is contained in the Cantor set K. The function f is continuous since if $x_k \to x$, then for each n, if $x \in U_n$ we have $x_k \in U_n$ for all sufficiently large k, and similarly if $x \in U_n^c$, so the n'th decimal term of x_k agrees with the n'th decimal term of x for all sufficiently large k, and hence $f(x_k) \to f(x)$. Conversely, if $(x_k), x \in X$ and $f(x_k) \to f(x)$, then for each n we have that the n'th decimal term of x_k agrees with the n'th term of x for all sufficiently large k, so if $x \in U_n$ we have $x_k \in U_n$ for sufficiently large k. Since the U_n form a base for the topology of X, we have $x_k \to x$. Thus $f^{-1} : f(X) \to X$ is continuous and f is a homeomorphism onto its image.

(vi) ⇒ (iii) since the Cantor set satisfies (iii) and (iii) passes to subspaces. 👍

The Countable AC is needed in several places in this proof.

XIII.13.6.9. There is an extensive theory of dimension for topological spaces, discussed in (), for which the above theory is the dimension zero part; the theory is based on "higher-order connectedness."

XIII.13.7. Locally Connected Spaces

XIII.13.7.1. DEFINITION. Let X be a topological space, $p \in X$. Then X is *locally connected at* p if every open neighborhood of p contains a connected open neighborhood of p, i.e. if there is a local base for the topology at p consisting of connected sets. X is *locally connected* if it is locally connected at every point, i.e. if there is a base for the topology consisting of connected sets.

XIII.13.7.2. Simple examples of locally connected spaces are $\mathbb{R}$ and any discrete space. The latter example shows that a locally connected space need not be connected. Any open set in a locally connected space is locally connected.

The Cantor set is not locally connected at any point. In fact, a nondiscrete totally disconnected space cannot be locally connected.

The topologist's sine curve () is connected, but not locally connected at points on the y-axis. There are more extreme examples: there are compact subsets of Euclidean space, e.g. the pseudo-arc () or a solenoid (), which are connected but not locally connected at any point.

XIII.13.7.3. If X is locally connected, then the components of X are open, hence clopen. The converse is not true since there are connected spaces which are not locally connected. Spaces whose components are open are precisely ones in which each point has at least one connected open neighborhood. If X is locally connected, the connected components of any open subset U of X are also open, since U is also locally connected. Conversely, if every component of every open subset of X is open, then X is locally connected.

XIII.13.8. Path-Connected Spaces

An intuitively appealing variation of connectedness is path-connectedness. A space is path-connected if any two points can be connected by a continuous path; such a space is necessarily connected. Most familiar topological spaces such as (connected) manifolds and polyhedra are path-connected.

XIII.13.8.1. DEFINITION. Let X be a topological space, $p, q \in X$. A *path* in X from p to q is a continuous function $\gamma : [0,1] \to X$ with $\gamma(0) = p$, $\gamma(1) = q$.

The space X is *path-connected* if for any $p, q \in X$, there is a path from p to q.

A path-connected space is also called *arcwise connected*. (Some references make a technical distinction between paths and arcs; cf. XIII.13.8.11..)

Since an interval is connected (XIII.13.1.7.), we obtain:

XIII.13.8.2. PROPOSITION. Let X be a topological space, $p, q \in X$. If there is a path from p to q, then p and q are in the same connected component of X. In particular, a path-connected space is connected.

PROOF: If γ is a path from p to q, then by XIII.13.2.1. the set $\gamma([0,1])$ is a connected subset of X containing both p and q. 👍

XIII.13.8.3. EXAMPLES. (i) Any connected subset of $\mathbb{R}$ (interval or point) is path-connected.

(ii) Any convex set in $\mathbb{R}^n$ (or, more generally, in any topological vector space) is path-connected: the straight line segment between any two points is a path. In particular, any topological vector space, including $\mathbb{R}^n$, is path-connected.

(iii) The topologist's sine curve () is connected but not path-connected. There are more dramatic examples of such spaces (XIII.13.8.6.).

Define a relation $\sim$ on X by $p \sim q$ if there is a path from p to q.

XIII.13.8.4. PROPOSITION. The relation $\sim$ is an equivalence relation.

PROOF: If γ is a path from p to q, set $\bar{\gamma}(t) = \gamma(1-t)$ for $0 \leq t \leq 1$; then $\bar{\gamma}$ is a path from q to p, so $\sim$ is symmetric. The constant function from $[0,1]$ to X with value p is a path from p to p, so $\sim$ is reflexive. Now suppose γ_1 is a path from p to q and γ_2 a path from q to r. Define $\gamma : [0,1] \to X$ by

$$\gamma(t) = \begin{cases} \gamma_1(2t) & \text{if} \quad 0 \leq t \leq \frac{1}{2} \\ \gamma_2(2t-1) & \text{if} \quad \frac{1}{2} \leq t \leq 1 \end{cases} .$$

Then γ is a path from p to r, so $\sim$ is transitive. 👍

XIII.13.8.5. DEFINITION. The equivalence classes of $\sim$ are the *path components* of X.

As with components, the space X partitions into a disjoint union of path components. By XIII.13.8.2., each path component is contained in a connected component of X, i.e. each connected component partitions into one or more path components.

Unlike components, path components need not be closed. For example, the topologist's sine curve () consists of two path components, one closed and the other dense and open. A solenoid () has uncountably many path components, each dense (and not open).

XIII.13.8.6. A space X is *totally path disconnected* if its path components are single points, i.e. if every continuous function from $[0,1]$ into X is constant. There are connected compact metrizable spaces which are totally path disconnected, e.g. the pseudo-arc ().

XIII.13.8.7. DEFINITION. A topological space X is *locally path-connected* at p if there is a local base for the topology at p consisting of path-connected sets, i.e. any open neighborhood of p contains a path-connected open neighborhood of p. X is *locally path-connected* if it is locally path-connected at each point, i.e. if there is a base for the topology consisting of path-connected sets.

A locally path-connected space is locally connected. There are connected and locally connected compact Hausdorff spaces which are not locally path-connected [**?**, Examples 46, 48]; however, a connected compact metrizable space which is locally connected is locally path-connected (Exercise XIII.13.9.11.; in fact, the whole space is a continuous image of $[0,1]$ by the Hahn-Mazurkiewicz Theorem; cf. [HY88, 3.29–3.30], Exercise XIII.13.9.12.). This result is false for noncompact sets (XIII.13.9.14.).

XIII.13.8.8. There are spaces which are path-connected but not locally path-connected: for example, the extended topologist's sine curve () is not locally path-connected (not even locally connected) at points on the y-axis.

XIII.13.8.9. If X is locally path-connected at p, then the path component of p in X is open. If X is locally path-connected, then all its path components are open, hence also closed since the complement of a path component is the union of the other path components. Thus in a locally path-connected space, the path components are the same as the components (and the quasi-components). In particular, if X is connected and locally path-connected, it is path-connected.

XIII.13.8.10. Since $\mathbb{R}^n$ is locally path-connected (open balls form a base for the topology of path-connected sets), any open set in $\mathbb{R}^n$ is locally path-connected. Hence the connected components of any open set in $\mathbb{R}^n$ are the same as the path components, and are open.

The same is true in any locally convex topological vector space (in particular, any normed vector space). In fact, any topological vector space, locally convex or not, is locally path-connected (there is a base for the topology consisting of balanced open sets, which are path-connected).

Path-Connectedness vs. Arcwise Connectedness

XIII.13.8.11. DEFINITION. A topological space X is *arcwise connected* if, for every $p, q \in X$, $p \neq q$, there is a homeomorphism $\gamma : [0,1] \to X$ with $\gamma(0) = p$ and $\gamma(1) = q$.

Arcwise connectedness is more restrictive than path-connectedness, which only requires that there be a continuous γ. A homeomorphic image of $[0,1]$ in X is called an *arc* in X. The Sierpiński space is path-connected but not arcwise connected, as is a set of cardinality $\geq 2^{\aleph_0}$ with the finite complement topology.

The main technical result is that path-connectedness and arcwise connectedness are the same thing for Hausdorff spaces. We give a proof since this result is not discussed in most topology texts, and where it is the proofs given tend to use unnecessarily heavy machinery. Our proof, although somewhat complicated, is quite elementary.

XIII.13.8.12. THEOREM. Let X be a Hausdorff space, $p, q \in X$, $p \neq q$. If there is a path in X from p to q, then there is an arc in X from p to q.

PROOF: Set $p_0 = p$, $p_1 = q$. Let $\gamma : [0,1] \to X$ be a path from p_0 to p_1 (i.e. $\gamma(0) = p_0$, $\gamma(1) = p_1$). We want to find an arc $\tilde{\gamma} : [0,1] \to X$ from p_0 to p_1. In fact, we will find an arc with $\tilde{\gamma}([0,1]) \subseteq \gamma([0,1])$.

(i) Replacing X by $\gamma([0,1])$, we may assume X is compact and metrizable. [The fact that $\gamma([0,1])$ is metrizable is not essential to the rest of the proof, but makes part (vi) of the argument a little cleaner. The slickest proof I know of this fact is to apply XIII.10.1.11..] Fix a metric d on X. Then γ is uniformly continuous, i.e. for every $\epsilon > 0$ there is a $\delta(\epsilon) > 0$ such that $d(\gamma(t), \gamma(s)) < \epsilon$ whenever $t, s \in [0,1]$ and $|t - s| < \delta(\epsilon)$.

(ii) We may assume $\gamma(t) \neq p_0$ and $\gamma(t) \neq p_1$ for all $t \in (0,1)$: since X is Hausdorff, there is a largest $t \in [0,1]$ for which $\gamma(t) = p_0$; call it a_0. We have $0 \leq a_0 < 1$. Then there is a smallest $t \in [a_0, 1]$ with $\gamma(t) = p_1$; call it b_0. We have $a_0 < b_0 \leq 1$. Replace γ by $\gamma|_{[a_0,b_0]}$ (rescaled) if necessary.

(iii) Set $\gamma_1 = \gamma$. Let a_1 be the smallest t such that $\gamma_1(t) = \gamma_1(s)$ for some $s \in \left[\frac{1}{2}, 1\right]$ [there is such a t since $\gamma_1\left(\left[\frac{1}{2}, 1\right]\right)$ is compact and hence closed, so $\gamma_1^{-1}\left(\gamma_1\left(\left[\frac{1}{2}, 1\right]\right)\right)$ is closed]; then $0 < a_1 \leq \frac{1}{2}$. Let b_1 be

the largest t such that $\gamma_1(b_1) = \gamma_1(a_1)$; then $\frac{1}{2} \le b_1 < 1$. Set $p_{1/2} = \gamma_1(a_1) = \gamma_1(b_1)$, and let γ_2 be $\gamma_1|_{[0,a_1]}$ rescaled to $\left[0, \frac{1}{2}\right]$ and $\gamma_1|_{[b_1,1]}$ rescaled to $\left[\frac{1}{2}, 1\right]$. We have $\gamma_2([0,1]) \subseteq \gamma_1([0,1])$. The sets $A_{11} = \gamma_2\left(\left[0, \frac{1}{2}\right]\right)$ and $A_{12} = \gamma_2\left(\left[\frac{1}{2}, 1\right]\right)$ satisfy $A_{11} \cap A_{12} = \{p_{1/2}\}$.

(iv) Repeat the construction of (iii) for the restrictions of γ_2 to $\left[0, \frac{1}{2}\right]$ and $\left[\frac{1}{2}, 1\right]$. We obtain numbers $a_{21} \in \left(0, \frac{1}{4}\right]$, $b_{21} \in \left[\frac{1}{4}, \frac{1}{2}\right)$, $p_{1/4} = \gamma_2(a_{21}) = \gamma_2(b_{21})$ and $\gamma_{31} : \left[0, \frac{1}{2}\right] \to X$ which is rescaled γ_2 on $[0, a_{21}]$ and $[b_{21}, 1/2]$, and similarly $a_{22} \in \left(\frac{1}{2}, \frac{3}{4}\right]$, $b_{22} \in \left[\frac{3}{4}, 1\right)$, $p_{3/4} = \gamma_2(a_{22}) = \gamma_2(b_{22})$ and $\gamma_{32} : \left[\frac{1}{2}, 1\right] \to X$ which is rescaled γ_2 on $[1/2, a_{21}]$ and $[b_{21}, 1]$. Put γ_{31} and γ_{32} together to form $\gamma_3 : [0,1] \to X$, a path from p_0 to p_1 with $\gamma_3(1/2) = \gamma_2(1/2) = p_{1/2}$. We have $\gamma_3\left(\left[0, \frac{1}{2}\right]\right) \subseteq \gamma_2\left(\left[0, \frac{1}{2}\right]\right)$ and $\gamma_3\left(\left[\frac{1}{2}, 1\right]\right) \subseteq \gamma_2\left(\left[\frac{1}{2}, 1\right]\right)$, so $\gamma_3([0,1]) \subseteq \gamma_2([0,1])$.

(v) Continuing inductively in this way, a sequence (γ_n) of paths from p_0 to p_1 is constructed, with $\gamma_n(k/2^m) = p_{k/2^m}$ for $m \le n-1$. We have $\gamma_{n+1}([0,1]) \subseteq \gamma_n([0,1])$, and more generally

$$\gamma_{n+1}\left(\left[\frac{k}{2^m}, \frac{k+1}{2^m}\right]\right) \subseteq \gamma_n\left(\left[\frac{k}{2^m}, \frac{k+1}{2^m}\right]\right)$$

for any $m \le n-1$ and any k. If $A_{n+1,k} = \gamma_{n+1}\left(\left[\frac{k-1}{2^{-n}}, \frac{k}{2^{-n}}\right]\right)$, $A_{n+1,k} \cap A_{n+1,k+1} = \{p_{k/2^n}\}$ and $A_{n+1,k} \cap A_{n+1,k+j} = \emptyset$ for $j > 1$.

(vi) We claim that (γ_n) converges uniformly on $[0,1]$ to a path $\tilde{\gamma}$, i.e. that (γ_n) is a uniform Cauchy sequence. Let $\epsilon > 0$, and fix N with $2^{-N+1} < \delta(\epsilon)$. For any $c \in [0,1]$, there is a k such that $\frac{k}{2^{N-1}} \le c \le \frac{k+1}{2^{N-1}}$. Then $Z = \gamma_N\left(\left[\frac{k}{2^{N-1}}, \frac{k+1}{2^{N-1}}\right]\right)$ is $\gamma([a,b])$ for some interval $[a,b]$ of length $\le 2^{-N+1} < \delta(\epsilon)$, so Z has diameter less than ϵ. If $n, m \ge N$, we have $\gamma_n(c), \gamma_m(c) \in Z$, so $d(\gamma_n(c), \gamma_m(c)) < \epsilon$. Note that N depends only on ϵ and not on c.

We have

$$\tilde{\gamma}\left(\left[\frac{k}{2^m}, \frac{k+1}{2^m}\right]\right) \subseteq \gamma_n\left(\left[\frac{k}{2^m}, \frac{k+1}{2^m}\right]\right)$$

for any n, $m \le n-1$, and k.

(vii) The path $\tilde{\gamma}$ is an arc. To show this, we need only show that $\tilde{\gamma}$ is one-to-one (since X is Hausdorff). So suppose $\tilde{\gamma}(c) = \tilde{\gamma}(d)$ for some c, d, $c < d$. Choose n, k, j with $j \ge 2$ and

$$\frac{k}{2^n} \le c < \frac{k+1}{2^n}, \quad \frac{k+j}{2^n} < d \le \frac{k+j+1}{2^n} .$$

But then

$$\tilde{\gamma}(c) \in \gamma_{n+1}\left(\left[\frac{k}{2^n}, \frac{k+1}{2^n}\right]\right)$$

$$\tilde{\gamma}(d) \in \gamma_{n+1}\left(\left[\frac{k+j}{2^n}, \frac{k+j+1}{2^n}\right]\right)$$

and these sets are disjoint, a contradiction. 👍

XIII.13.8.13. COROLLARY. Let X be a Hausdorff space. If X is path-connected, then X is arcwise connected.

XIII.13.9. Exercises

XIII.13.9.1. Let X be the Sierpiński two-point space (). Every open cover of X has a refinement consisting of clopen sets, namely $\{X\}$, but there is no base for the topology consisting of clopen sets. X is T_0, but not T_1 and hence not zero-dimensional by Definition XIII.13.6.3.; in fact, it is connected, and even path-connected: the function from $[0,1]$ to X sending $[0,1)$ to a and 1 to b is continuous.

XIII.13.9.2. (Erdős) Let X be the set of points in ℓ^2 () with rational coordinates. Show that X is totally disconnected, but there is no base for the topology consisting of clopen sets (in fact, no clopen subset is bounded.)

XIII.13.9.3. [?, §27,VI] Let K be the Cantor set (). Define a function $f : K \to \mathbb{R}$ as follows. If $t \in K$, then t can be uniquely written as a finite or infinite sum

$$t = \sum_k \frac{2}{3^{n_k}}$$

(where $t = 0$ is the "empty sum"), i.e. n_k is the location of the k'th 2 in the base 3 decimal expansion of t. Then set

$$f(t) = \sum_k \frac{(-1)^{n_k}}{2^k}$$

(with $f(0) = 0$). Let X be the graph of f, i.e. $X = \{(t, f(t)) : t \in K\} \subseteq \mathbb{R}^2$.

(a) Show that f is not continuous. Find the points of continuity of f.

(b) Show that X is totally disconnected.

(c) Show that there is no base for the topology of X consisting of clopen sets.

(d) Show that there is a point $p \in \mathbb{R}^2$ such that $X \cup \{p\}$ is not totally disconnected, although its connected components are single points.

(e) Show that X and $X \cup \{p\}$ are G_δ subsets of $\mathbb{R}^2$. [f is a pointwise limit of a sequence of continuous functions.]

XIII.13.9.4. Topologize $X = \{a, b, c\}$ by taking the open sets to be $\{\emptyset, \{a\}, \{a, b\}, \{a, c\}, X\}$. Then X is connected. The relative topology on $E = \{b, c\}$ is the discrete topology and E is not connected. However, there is no separation $\{U, V\}$ of E with U and V disjoint.

XIII.13.9.5. Let X be the subset $G \cup E$ of the plane, where $G = \{(x, y) : 0 < x \leq \frac{1}{\pi}, y = \sin\left(\frac{1}{x}\right)\}$ and $E = \{(0, 1), (0, -1)\}$. Since G is homeomorphic to $(0, 1]$, it is connected. G is dense in X, so X is connected. Let $E_n = E \cup \{(x, y) : 0 < x \leq \frac{1}{n\pi}, y = \sin\left(\frac{1}{x}\right)\}$. Then E_n is connected for all n, and $E = \cap_n E_n$, but E is not connected. Note that E is compact, although the E_n are not compact.

XIII.13.9.6. (a) Give $\mathbb{N}$ the finite complement topology. Then $\mathbb{N}$ is compact and T_1, and every infinite subset of $\mathbb{N}$ is connected. Set $E = \{1, 2\}$, and $E_n = \{1, 2, n + 1, n + 2, \dots\}$. Then E_n is compact and connected for all n, but $E = \cap_n E_n$ is not connected. (E_n is not, however, closed in $\mathbb{N}$.)

(b) Does the conclusion of XIII.13.3.6. hold for arbitrary X if the E_i are assumed to be *closed* compact subsets?

XIII.13.9.7. Let X be $\mathbb{N}$ with two points a, b added. Topologize X by taking the open subsets to be all subsets with finite complement and all subsets of $\mathbb{N}$.

(a) Show that X is a compact T_1 space.

(b) Show that the components of X are single points.

(c) Show that the quasi-component of a and b is $\{a, b\}$, i.e. there is no clopen set containing a but not b.

XIII.13.9.8. Let X be the subset of $\mathbb{R}^2$ consisting of $\left\{\left(\frac{1}{n}, t\right) : n \in \mathbb{N}, 0 \leq t \leq 1\right\}$ along with $(0,0)$ and $(0,1)$.

(a) Show that the components of X are $\{(0,0)\}$, $\{(0,1)\}$, and $\left\{\left(\frac{1}{n}, t\right) : 0 \leq t \leq 1\right\}$ for fixed n.

(b) Show that $(0,0)$ and $(0,1)$ are in the same quasi-component of X.

XIII.13.9.9. Let X be the subset of $\mathbb{R}^2$ obtained by beginning with the line segment between $(0,0)$ and $(1,0)$ and adding the closed line segments between $\left(\frac{1}{n}, 0\right)$ and $\left(\frac{1}{n+1}, \frac{1}{n(n+m)}\right)$ for all $m, n \in \mathbb{N}$. X is called the *infinite broom*. Is X locally connected at $(0,0)$? Note that if our usual convention that neighborhoods be open is relaxed, every neighborhood of $(0,0)$ in X contains a connected neighborhood. (This is false for points $(t,0)$ with $0 < t < 1$). See [HY88, p. 113]. (Note that this X is quite different from the ones in XIII.19.5.1..)

XIII.13.9.10. THEOREM. Let $Y \subseteq \mathbb{R}^n$ $(n > 1)$ be an absolute retract (e.g. Y is homeomorphic to a closed ball of some dimension; cf. ()). Then $\mathbb{R}^n \setminus Y$ is connected.

PROOF: Suppose $\mathbb{R}^n \setminus Y$ is not connected, i.e. it has a nonempty bounded component U. Let $p \in U$, and let $X = Y \cup U$. Then X is compact since $\partial U \subseteq Y$. The identity map on Y extends to a continuous function f from X onto Y (i.e. f is a retraction from X onto Y).

Let B be a closed ball centered at p large enough that X is contained in its interior. Let g be radial retraction from $B \setminus \{p\}$ to $S = \partial B$. Define $r : B \to S$ by

$$r(\boldsymbol{x}) = \begin{cases} g(f(\boldsymbol{x})) & \text{if} \quad \boldsymbol{x} \in X \\ g(\boldsymbol{x}) & \text{if} \quad \boldsymbol{x} \in B \setminus X \end{cases} .$$

Then r is a retraction from B onto S, contradicting the No-Retraction Theorem (). 👍

XIII.13.9.11. [HY88, Theorem 3.17] Show that every locally connected completely metrizable space is locally path-connected. Every open set in a locally connected Polish space is locally path-connected.

XIII.13.9.12. Let X be a compact space, Y a (necessarily compact) Hausdorff space, and f a continuous function from X onto Y. If X is locally connected, show that Y is also locally connected. [If U is an open set in Y, and C is a component of U, show that $f^{-1}(C)$ is a union of components of $f^{-1}(U)$ and hence is open in X (XIII.13.7.3.). Use that $X \setminus f^{-1}(C)$ is compact to conclude that C is open in Y.]

XIII.13.9.13. Let X be a connected locally compact Hausdorff space. Let p be a point of X and U an open neighborhood of p in X. Show that there is a nontrivial subcontinuum of X (i.e. a connected compact subset containing more than one point) containing p and contained in U. In fact, if V is an open neighborhood of p with compact closure, show that the connected component of p in $\bar{V}$ contains a point of ∂V. [Show that the quasi-component of p in $\bar{V}$ contains a point of ∂V, and apply XIII.13.4.5..] This is a weak form of local connectedness.

The statements can fail if X is not locally compact (XIII.13.9.5..)

A point in a connected locally compact metrizable space need not have a connected compact neighborhood: consider the union of the graph of $y = \frac{1}{x} \sin \frac{1}{x}$ $(x > 0)$ and the y-axis in $\mathbb{R}^2$.

XIII.13.9.14. (F. Bernstein [Ber07]; cf. [HY88, p. 110]) (a) Show that there are exactly $2^{\aleph_0}$ nontrivial closed connected subsets of $\mathbb{R}^2$. Note that each has cardinality $2^{\aleph_0}$.

(b) (AC) Well-order these nontrivial closed connected subsets $\{X_\alpha : \alpha < \sigma\}$ according to the first ordinal σ of cardinality $2^{\aleph_0}$. Inductively choose distinct points a_α, b_α in X_α, for each $\alpha < \sigma$ (i.e. a_α, b_α, a_β, b_β are all distinct for $\alpha \neq \beta$).

(c) Let $A = \{a_\alpha : \alpha < \sigma\}$ and $B = \mathbb{R}^2 \setminus A$. Then $b_\alpha \in B$ for all α.

(d) Show that A and B are connected and locally connected.

(e) Show that neither A nor B contains a subcontinuum of more than one point. In particular, they are totally path disconnected.

Thus $\mathbb{R}^2$ is a disjoint union of two connected, locally connected subsets. Compare with XVII.4.10.12..

XIII.13.9.15. Let X be a compact Hausdorff space. Define an equivalence relation $\sim$ on X by $x \sim y$ if x and y are in the same connected component of X. Let $X_c = X/\sim$ with the quotient topology; X_c is called the *component space* of X.

(a) Show that the relation $\sim$ is closed. [Use XIII.13.4.5..]

(b) Show that the decomposition is usc (XIII.8.2.1.). [If E is closed in X and x is not in the saturation of E, show there is a clopen set in X containing x disjoint from E.]

(c) Show that X_c is a compact Hausdorff space. [Use XIII.8.3.9..]

(d) Show that X_c is totally disconnected.

(e) Is the decomposition necessarily lsc?

(f) Extend the results to the case where X is locally compact and normal. [Show that X_c embeds in $(\beta X)_c$.]

(g) To what extent does this construction work if X is not locally compact?

(h) Does a similar construction work for path components?

XIII.13.9.16. **Topological Characterization of $\mathbb{Q}$.** (a) Show that every countable, first countable (hence second countable) regular space is zero-dimensional. [Such a space is normal. Consider continuous functions to $\mathbb{R}$ separating points.]

(b) Show that $\mathbb{Q} \cap [0,1]$ and $\mathbb{Q} \cap (0,1]$ are homeomorphic to $\mathbb{Q}$. [For $\mathbb{Q} \cap (0,1]$, let (c_n) be an increasing sequence of irrational numbers converging to 1, and "reverse" $\mathbb{Q} \cap (c_{2n}, c_{2n+1})$ to the right of 1. Consider the order topology, and use II.5.4.11..]

(c) Show that every countable, first countable regular space X without isolated points is homeomorphic to $\mathbb{Q}$. [Define a dense ordering on X by repeated bisection, using (a), and show the topology on X is homeomorphic to the order topology. Use II.5.4.11..] In particular, $\mathbb{Q}^n$ is homeomorphic to $\mathbb{Q}$ for any $n \in \mathbb{N}$.

(d) Show that every separable, first countable regular space without isolated points contains a dense subspace homeomorphic to $\mathbb{Q}$; in fact, every countable dense subspace with the relative topology is homeomorphic to $\mathbb{Q}$.

(e) A space, even a compact Hausdorff space, containing a dense subspace homeomorphic to $\mathbb{Q}$ is necessarily separable, but need not be first countable. [Consider $\beta\mathbb{Q}$ or $\beta\mathbb{R}$.]

XIII.13.9.17. A space X which is connected and locally path-connected is path-connected. [The path components are clopen sets.]

XIII.14. Direct and Inverse Limits

Direct and, especially, inverse limits are important topological constructions. Actually, they have little to do with topology specifically; they can be defined for systems of sets, or more generally within a category. But they are especially useful in topology.

Caution: The use of the term "limit" in connection with direct and inverse limits has almost nothing to do (at least on the surface) with the usual use of the term "limit" in topology, e.g. "limit of a sequence."

XIII.14.1. Direct Systems and Direct Limits of Sets

XIII.14.1.1. Definition. A *direct system of sets* over $\mathbb{N}$ is a sequence (X_n) of sets and, for each n, a function $\phi_{n,n+1} : X_n \to X_{n+1}$.

Pictorially, we have

$$X_1 \xrightarrow{\phi_{1,2}} X_2 \xrightarrow{\phi_{2,3}} X_3 \xrightarrow{\phi_{3,4}} \cdots$$

Both the sets X_n and the maps $\phi_{n,n+1}$ must be specified. Usually a direct system of sets over $\mathbb{N}$ is denoted $(X_n, \phi_{n,n+1})$.

If $n < m$, then there is an induced map $\phi_{n,m}$ from X_n to X_m defined by composition:

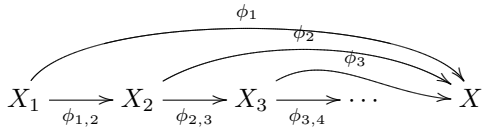
$$\phi_{n,m} = \phi_{m-1,m} \circ \phi_{m-2,m-1} \circ \cdots \circ \phi_{n+1,n+2} \circ \phi_{n,n+1} \ .$$

If $n < m < k$, then $\phi_{n,k} = \phi_{m,k} \circ \phi_{n,m}$.

We can more generally define a direct system over any directed set I ():

XIII.14.1.2. Definition. Let I be a (properly) directed set. A *direct system of sets* over I is an indexed collection $\{X_i : i \in I\}$ of sets and, for each i, j with $i < j$, a function $\phi_{i,j} : X_i \to X_j$ satisfying $\phi_{i,k} = \phi_{j,k} \circ \phi_{i,j}$ whenever $i < j < k$.

We usually write $(X_i, \phi_{i,j})$ or $(X_i, \phi_{i,j})_{i \in I}$ for a direct system of sets over I.



If working in a category such as the category of topological spaces, the sets are objects in the category, e.g. topological spaces in the category of topological spaces, and the functions are required to be morphisms in the category, e.g. continuous functions in the category of topological spaces.

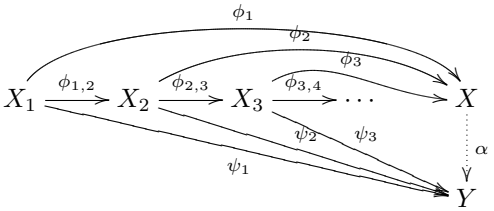
XIII.14.1.3. We want to associate to a direct system a set X which "sits at $+\infty$". To see how this works, first consider the case where $I = \mathbb{N}$ and each $\phi_{n,n+1}$ is injective. Then X_n can be identified with the subset $\phi_{n,n+1}(X_n)$ of X_{n+1} for each n, and the direct limit X is then the "union" of the X_n. (It is not truly a union except in the rare case where each $\phi_{n,n+1}$ is an inclusion map of a subset.)

If the $\phi_{n,n+1}$ are not all injective, things are a little more complicated: X is not the "union" of the X_n since any elements which are identified (i.e. have the same image) in some X_m must be identified in X. Thus in general the direct limit X informally consists of all objects which appear at any stage, with objects identified if they are eventually identified at some stage.

Here is the formal property that the direct limit must have:

XIII.14.1.4. DEFINITION. Let $(X_i, \phi_{i,j})$ be a direct system over a directed set I. A *direct limit* for the direct system is a pair (X, ϕ_i), where X is a set and, for each i, $\phi_i : X_i \to X$ is a function such that $\phi_i = \phi_j \circ \phi_{i,j}$ for any i, j with $i < j$; pictorially, in the case $I = \mathbb{N}$, we have a commutative diagram:

with the following *universal property*:



> If Y is a set and for each i there is a function $\psi_i : X_i \to Y$ such that $\psi_i = \psi_j \circ \phi_{i,j}$ for any i, j with $i < j$, then there is a unique function $\alpha : X \to Y$ such that $\psi_i = \alpha \circ \phi_i$ for all i.

We write

$$(X, \phi_i) = \varinjlim (X_i, \phi_{i,j})$$

for a direct limit. A direct limit is often called an *inductive limit*.

Pictorially, the universal property in the case $I = \mathbb{N}$ is the following commutative diagram:

XIII.14.1.5. THEOREM. Let $(X_i, \phi_{i,j})$ be a direct system of sets over a directed set I. Then

(i) There is a direct limit (X, ϕ_i).

(ii) If (X, ϕ_i) and (Y, ψ_i) are direct limits, there is a unique bijection $\alpha : X \to Y$ such that $\psi_i = \alpha \circ \phi_i$ for all i.

Thus up to natural identification there is a unique direct limit for any direct system.

PROOF: We begin with (ii). This is a simple standard argument that shows that any object with a universal property is unique up to isomorphism.

Since (X, ϕ_i) satisfies the universal property, there is a unique function $\alpha : X \to Y$ such that $\psi_i = \alpha \circ \phi_i$ for all i. Similarly, since (Y, ψ_i) satisfies the universal property, there is a unique function $\beta : Y \to X$ such that $\phi_i = \beta \circ \psi_i$. There is also a unique function $\gamma : X \to X$ such that $\phi_i = \gamma \circ \phi_i$ for all i. Since the identity map ι on X has this property, $\gamma = \iota$. But for each i we have

$$\phi_i = \beta \circ \psi_i = \beta \circ \alpha \circ \phi_i$$

so $\beta \circ \alpha$ has the property of γ and thus equals ι. By a similar argument we have that $\alpha \circ \beta$ is the identity on Y. Thus α and β are mutually inverse bijections.

We now show existence. Let Z be the subset of $[\cup_{i\in I} X_i] \times I$ defined by

$$Z = \{(x,i) : x \in X_i\} \subseteq [\cup_{i\in I} X_i] \times I$$

(Z is sometimes called the *disjoint union* of the X_i). Define a relation $\sim$ on Z by setting $(x,i) \sim (x',j)$ if and only if there is a k, $i < k$ and $j < k$, such that $\phi_{i,k}(x) = \phi_{j,k}(x')$. It is easily checked that $\sim$ is an equivalence relation. Let X be the set of equivalence classes. Write $[(x,i)]$ for the equivalence class of (x,i) in Z.

Fix i. Define a function $\phi_i : X_i \to X$ by $\phi_i(x) = [(x,i)]$ for $x \in X_i$. It is easily checked that $\phi_i = \phi_j \circ \phi_{i,j}$ for $i < j$, since $[(x,i)] = [(\phi_{i,j}(x), j)]$ for $i < j$ and $x \in X_i$.

Now suppose Y is a set and $\psi_i : X_i \to Y$ is a function for each i with $\psi_i = \psi_j \circ \phi_{i,j}$ for $i < j$. Define $\alpha : X \to Y$ by $\alpha([(x,i)]) = \psi_i(x)$ for $x \in X_i$. We need only show that this function is well defined, since then obviously $\psi_i(x) = \alpha([(x,i]]) = \alpha(\phi_i(x))$ for $x \in X_i$. If $[(x,i)] = [(x',j)]$, fix k such that $i < k$, $j < k$, and $\phi_{i,k}(x) = \phi_{j,k}(x')$. Then

$$\psi_i(x) = \psi_k(\phi_{i,k}(x)) = \psi_k(\phi_{j,k}(x')) = \psi_j(x')$$

so α is well defined.

For uniqueness of α, suppose β is another map from X to Y with $\psi_i = \beta \circ \phi_i$ for all i. Let $[(x,i)] \in X$. We have

$$\beta([(x,i)]) = \beta(\phi_i(x)) = \psi_i(x) = \alpha(\phi_i(x)) = \alpha([(x,i)])$$

and so $\beta = \alpha$. 👍

XIII.14.1.6. PROPOSITION. Let $(X, \phi_i) = \varinjlim(X_i, \phi_{i,j})$. Then

(i) For any $x \in X$, there is an i and $x_i \in X_i$ with $x = \phi_i(x_i)$.

(ii) If $x, x' \in X$, $x = \phi_i(x_i)$ and $x' = \phi_j(x'_j)$ for $x_i \in X_i$, $x'_j \in X_j$, then $x = x'$ if and only if there is a $k \in I$, $i < k$, $j < k$, such that $\phi_{i,k}(x_i) = \phi_{j,k}(x'_j)$.

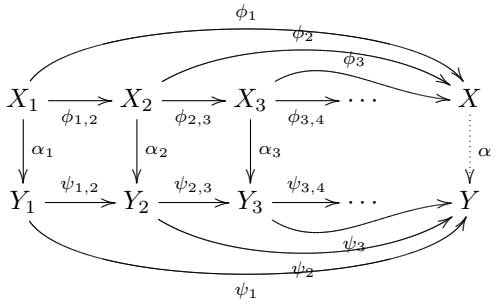
The simple proof is left to the reader.

Passage to Subsystems

XIII.14.1.7. Suppose $(X_n, \phi_{n,n+1})$ is a direct system over $\mathbb{N}$. Let (k_n) be a strictly increasing sequence in $\mathbb{N}$, and let $Y_n = X_{k_n}$, $\psi_{n,n+1} = \phi_{k_n,k_{n+1}}$. If $(X, \phi_n) = \varinjlim(X_n, \phi_{n,n+1})$ and $(Y, \psi_n) = \varinjlim(Y_n, \psi_{n,n+1})$, we will show there is a natural bijection between X and Y. For each n, set $\alpha_n = \psi_n \circ \phi_{n,k_n} : X_n \to Y$; there is then a unique $\alpha : X \to Y$ such that $\alpha_n = \alpha \circ \phi_n$ for all n. If $\beta_n = \phi_{k_n} : Y_n = X_{k_n} \to X$ and $\beta : Y \to X$ is the unique function such that $\beta_n = \beta \circ \psi_n$, we have

$$\beta \circ \alpha \circ \phi_n = \beta \circ \alpha_n = \beta \circ \psi_n \circ \phi_{n,k_n} = \beta_n \circ \phi_{n,k_n} = \phi_{k_n} \circ \phi_{n,k_n} = \phi_n$$

$$\alpha \circ \beta \circ \psi_n = \alpha \circ \beta_n = \alpha \circ \phi_{k_n} = \alpha_{k_n} = \psi_{k_n} \circ \phi_{k_n,k_{k_n}} = \phi_{k_{k_n}} \circ \phi_{k_n,k_{k_n}} = \phi_{k_n} = \psi_n$$

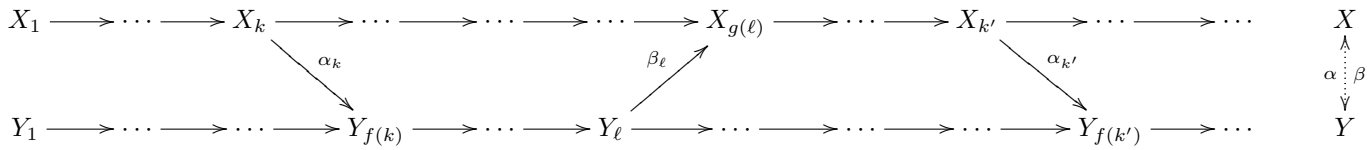


so we have $\beta \circ \alpha = \iota_X$ and $\alpha \circ \beta = \iota_Y$, i.e. α and β are mutually inverse bijections.

Thus the direct limit over a subsystem is the "same" as the direct limit over the whole system. This is an analog (in a quite different setting) of the fact that the limit of a subsequence is the same as the limit of the whole sequence (if it exists).

More generally, the same result holds for direct limits over arbitrary directed sets (XIII.14.1.10.).

Induced Functions



XIII.14.1.8. Let $(X_i, \phi_{i,j})$ and $(Y_i, \psi_{i,j})$ be direct systems over the same index set I. Suppose there is for each i a function $\alpha_i : X_i \to Y_i$ such that $\alpha_j \circ \phi_{i,j} = \psi_{i,j} \circ \alpha_i$ for all $i < j$. Let $(X, \phi_i) = \varinjlim(X_i, \phi_{i,j})$, $(Y, \psi_i) = \varinjlim(Y_i, \psi_{i,j})$. The maps $\psi_i \circ \alpha_i$ are a coherent family of maps from the X_i to Y, so by the universal property there is a unique function $\alpha : X \to Y$ such that $\alpha \circ \phi_i = \psi_i \circ \alpha_i$ for all i. The function α is called the *function induced by the* α_i. For $I = \mathbb{N}$ we have a commutative diagram:

XIII.14.1.9. Here is a general procedure including both XIII.14.1.7. and XIII.14.1.8.. Let I and J be directed sets, and $(X_i, \phi_{i,i'})$ and $(Y_j, \psi_{j,j'})$ be inductive systems over I and J respectively. (Note that we have slightly changed our standard notation.) Let K be a cofinal subset of I, and f a directed function () from K to J, which for simplicity we will take to be order-preserving (this assumption can be eliminated at some technical cost, in the manner of Exercise II.4.5.3.). Suppose we have a compatible set (α_k) of functions $\alpha_k : X_k \to Y_{f(k)}$ (i.e. if $k < k'$ we have $\alpha_{k'} \circ \phi_{k,k'} = \psi_{f(k),f(k')} \circ \alpha_k$). For $i \in I$, define $\theta_i : X_i \to Y$ by $\theta_i = \psi_{f(k)} \circ \alpha_k \circ \phi_{i,k}$ for any $k \in K$, $i < k$ (by compatibility this is well defined independent of the choice of k). The θ_i are a compatible family of functions from the X_i to Y, so there is a unique induced map $\alpha : X \to Y$ such that $\alpha \circ \phi_i = \theta_i$ for all i. This is the function induced by f and the α_k.

XIII.14.1.10. PROPOSITION. Let I and J be directed sets, and $(X_i, \phi_{i,i'})$ and $(Y_j, \psi_{j,j'})$ be direct systems over I and J respectively, with direct limits (X, ϕ_i) and (Y, ψ_j). Let K and L be cofinal subsets of I and J respectively, and $f : K \to J$ and $g : L \to I$ order-preserving directed maps. Let $\alpha_k : X_k \to Y_{f(k)}$ and $\beta_\ell : Y_\ell \to X_{g(\ell)}$ be compatible families of maps, with $\beta_\ell \circ \psi_{f(k),\ell} \circ \alpha_k = \phi_{k,g(\ell)}$ whenever $k \in K$, $\ell \in L$, $f(k) < \ell$ and $k < g(\ell)$, and $\alpha_k \circ \phi_{g(\ell),k} \circ \beta_\ell = \psi_{\ell,f(k)}$ whenever $g(\ell) < k$ and $\ell < f(k)$. Then the induced functions $\alpha : X \to Y$ and $\beta : Y \to X$ are mutually inverse bijections.

The proof is very similar to the proof of XIII.14.1.7., and is left to the reader. Pictorially, if $I = J = \mathbb{N}$, we have a commutative diagram:

XIII.14.1.11. Let $(X_i, \phi_{i,j})$ be a direct system of sets over I, and for each i suppose $Y_i \subseteq X_i$ and $\phi_{i,j}(Y_i) \subseteq Y_j$ whenever $i < j$. Set $\psi_{i,j} = \phi_{i,j}|_{Y_i} : Y_i \to Y_j$ for $i < j$. Then $(Y_i, \psi_{i,j})$ is a direct system of sets over I, and the inclusion maps $\beta_i : Y_i \to X_i$ induce a function $\beta : Y \to X$, where $(X, \phi_i) = \varinjlim(X_i, \phi_{i,j})$ and $(Y, \psi_i) = \varinjlim(Y_i, \psi_{i,j})$.

XIII.14.1.12. Proposition. The map $\beta : Y \to X$ is injective; thus we may write $\varinjlim(Y_i, \psi_{i,j}) \subseteq \varinjlim(X_i, \phi_{i,j})$. (Informally, direct limits of sets commute with taking subsets.)

Proof: Suppose $\beta(y) = \beta(y')$. Let $y = \psi_i(z)$, $y' = \psi_j(z')$ for some $z \in Y_i$, $z' \in Y_j$. Then there is a k with $i < k$, $j < k$, and $\phi_{i,k}(z) = \phi_{j,k}(z')$. But then $\psi_{i,k}(z) = \psi_{j,k}(z')$, so $y = \psi_i(z) = \psi_j(z') = y'$. 👍

XIII.14.2. Inverse Systems and Inverse Limits of Sets

Inverse systems and limits work similarly to direct ones, but the arrows are reversed. The details turn out to be subtly different.

XIII.14.2.1. Definition. An *inverse system of sets* over $\mathbb{N}$ is a sequence (X_n) of sets and, for each n, a function $\phi_{n+1,n} : X_{n+1} \to X_n$.

Pictorially, we have

$$\cdots \xrightarrow{\phi_{4,3}} X_3 \xrightarrow{\phi_{3,2}} X_2 \xrightarrow{\phi_{2,1}} X_1$$

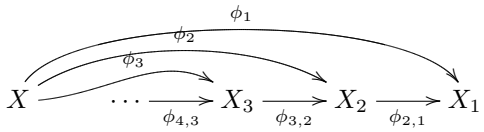
If $n < m$, then there is an induced map $\phi_{m,n}$ from X_m to X_n defined by composition:

$$\phi_{m,n} = \phi_{n+1,n} \circ \phi_{n+2,n+1} \circ \cdots \circ \phi_{m-1,m-2} \circ \phi_{m,m-1} \ .$$

If $n < m < k$, then $\phi_{k,n} = \phi_{m,n} \circ \phi_{k,m}$.

We can again work over any directed set:

XIII.14.2.2. Definition. Let I be a (properly) directed set. An *inverse system of sets* over I is an indexed collection $\{X_i : i \in I\}$ of sets and, for each i, j with $i < j$, a function $\phi_{j,i} : X_j \to X_i$ satisfying $\phi_{k,i} = \phi_{j,i} \circ \phi_{k,j}$ whenever $i < j < k$.



We usually write $(X_i, \phi_{j,i})$ or $(X_i, \phi_{j,i})_{i \in I}$ for an inverse system of sets over I.

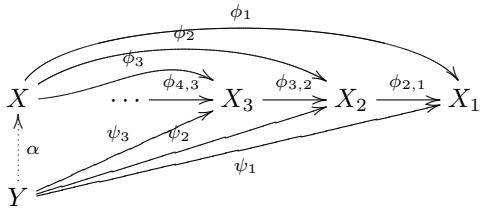
XIII.14.2.3. We want to associate to an inverse system a set X which "sits at $-\infty$"; X will map to each X_i. To see how this works, first consider the case where $I = \mathbb{N}$ and each $\phi_{n+1,n}$ is injective (this is not actually a very interesting case for inverse limits). Then X_{n+1} can be identified with the subset $\phi_{n+1,n}(X_{n+1})$ of X_n for each n, and the inverse limit X is then the "intersection" of the X_n. (It is not truly an intersection except in the rare case where each $\phi_{n+1,n}$ is an inclusion map of a subset.)

If the connecting maps are surjective but not injective (the most interesting case), the inverse limit will be "larger" than the X_i, since the preimage of any element of X_i will be at least as large as the preimage under $\phi_{j,i}$, which increases in size as j increases.

Here is the universal property the inverse limit must have:

XIII.14.2.4. DEFINITION. Let $(X_i, \phi_{j,i})$ be an inverse system over a directed set I. An *inverse limit* for the inverse system is a pair (X, ϕ_i), where X is a set and, for each i, $\phi_i : X \to X_i$ is a function such that $\phi_i = \phi_{j,i} \circ \phi_j$ for any i, j with $i < j$; pictorially, in the case $I = \mathbb{N}$, we have a commutative diagram:

with the following *universal property*:



> If Y is a set and for each i there is a function $\psi_i : Y \to X_i$ such that $\psi_i = \phi_{j,i} \circ \psi_j$ for any i, j with $i < j$, then there is a unique function $\alpha : Y \to X$ such that $\psi_i = \phi_i \circ \alpha$ for all i.

We write

$$(X, \phi_i) = \varprojlim (X_i, \phi_{j,i})$$

for an inverse limit. An inverse limit is often called a *projective limit*.

Pictorially, the universal property in the case $I = \mathbb{N}$ is the following commutative diagram:

XIII.14.2.5. THEOREM. Let $(X_i, \phi_{j,i})$ be an inverse system of sets over a directed set I. Then

(i) There is an inverse limit (X, ϕ_i).

(ii) If (X, ϕ_i) and (Y, ψ_i) are inverse limits, there is a unique bijection $\alpha : Y \to X$ such that $\psi_i = \phi_i \circ \alpha$ for all i.

Thus up to natural identification there is a unique inverse limit for any inverse system.

PROOF: The proof of (ii) is essentially identical to the proof of XIII.14.1.5.(ii), and is left to the reader.

The argument for (i) is somewhat simpler than for direct limits once infinite Cartesian products have been defined (). Let Z be the Cartesian product of the X_i, and define

$$X = \{(\cdots x_i \cdots) : x_i = \phi_{j,i}(x_j) \text{ for all } i, j \in I, i < j\} \subseteq \prod_{i \in I} X_i = Z$$

(the elements of X are called *coherent threads* in Z). For each i, let ϕ_i be the restriction to X of the i'th coordinate map, i.e.

$$\phi_i((\cdots x_i \cdots)) = x_i \ .$$

It is obvious from the coherence that $\phi_i = \phi_{j,i} \circ \phi_j$ if $i < j$.

To show the universal property, let (Y, ψ_i) satisfy the coherence condition. Simply define $\alpha : Y \to X$ by

$$\alpha(y) = (\cdots \psi_i(y) \cdots) \ .$$

Then clearly $\psi_i = \phi_i \circ \alpha$ for all i, and α is the only possible function from Y to X with this property. 👍

XIII.14.2.6. PROPOSITION. Let $(X, \phi_i) = \varprojlim(X_i, \phi_{j,i})$. If $x, x' \in X$, then $x = x'$ if and only if $\phi_i(x) = \phi_i(x')$ for all i.

XIII.14.2.7. EXAMPLES. (i) Let X be a set and ι the identity map on X. Let I be a directed set. For $i \in I$ set $X_i = X$, and for $i < j$ set $\phi_{j,i} = \iota$. Then $(X_i, \phi_{j,i})$ is an inverse system over I, and (X, ι) is an inverse limit for $(X_i, \phi_{j,i})$.

(ii) Let Y be a set, and (X_n) a decreasing sequence of subsets of Y. Let $\phi_{n+1,n}$ be the inclusion map from X_{n+1} to X_n. Let $X = \cap_n X_n$ and ϕ_n the inclusion map from X to X_n. Then $(X_n, \phi_{n+1,n})$ is an inverse system over $\mathbb{N}$, and (X, ϕ_n) is an inverse limit for $(X_n, \phi_{n+1,n})$. Here $\mathbb{N}$ can be replaced by an arbitrary index set i, if $X_j \subseteq X_i$ whenever $i < j$.

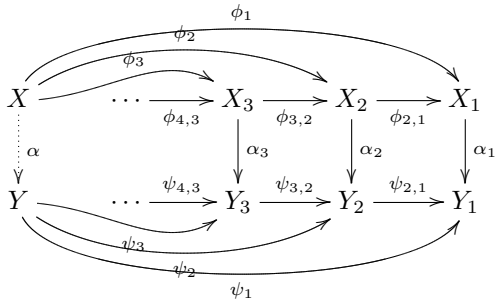
(iii) As a special case of (ii), let $X_n = \{k \in \mathbb{N} : k \geq n\}$. Then $(X_n, \phi_{n+1,n})$ is an inverse system of nonempty sets with $\varprojlim(X_n, \phi_{n+1,n}) = \emptyset$.

It can even happen that the inverse limit of an inverse system of nonempty sets with surjective connecting maps is empty (Exercise XIII.14.5.5.(b)), but not if the index set is $\mathbb{N}$ (Exercise XIII.14.5.5.(a)).

We will see much more interesting examples later.

Induced Functions and Passage to Subsystems

Induced functions and passage to subsystems in inverse limits works almost identically to the direct limit case.

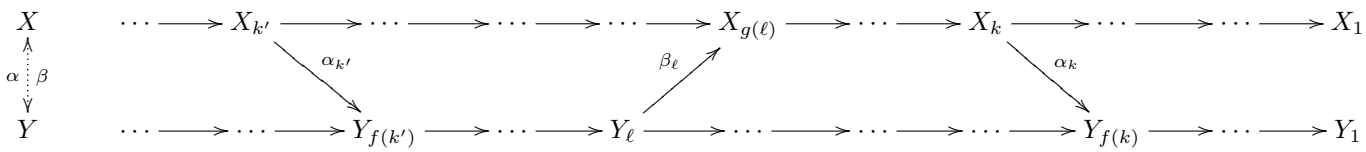


XIII.14.2.8. Suppose $(X_n, \phi_{n+1,n})$ is an inverse system over $\mathbb{N}$. Let (k_n) be a strictly increasing sequence in $\mathbb{N}$, and let $Y_n = X_{k_n}$, $\psi_{n+1,n} = \phi_{k_{n+1},k_n}$. If $(X, \phi_n) = \varprojlim(X_n, \phi_{n+,n})$ and $(Y, \psi_n) = \varprojlim(Y_n, \psi_{n,n+1})$, we will show there is a natural bijection between X and Y. For each n, set $\alpha_n = \phi_{k_n} : X \to Y_n = X_{k_n}$; there is then a unique $\alpha : X \to Y$ such that $\alpha_n = \psi_n \circ \alpha$ for all n. If $\beta_n = \phi_{k_n,n} \circ \psi_n : Y \to X_n$ and $\beta : Y \to X$ is the unique function such that $\beta_n = \phi_n \circ \beta$, we have

$$\phi_n \circ \beta \circ \alpha = \beta_n \circ \alpha = \phi_{k_n,n} \circ \psi_n \circ \alpha = \phi_{k_n,n} \circ \alpha_n = \phi_{k_n,n} \circ \phi_{k_n} = \phi_n$$

$$\psi_n \circ \alpha \circ \beta = \alpha_n \circ \beta = \phi_{k_n} \circ \beta = \beta_{k_n} = \phi_{k_{k_n},k_n} \circ \psi_{k_n} = \phi_{k_{k_n},k_n} \circ \phi_{k_{k_n}} = \phi_{k_n} = \psi_n$$

so we have $\beta \circ \alpha = \iota_X$ and $\alpha \circ \beta = \iota_Y$, i.e. α and β are mutually inverse bijections.



XIII.14.2.9. Let $(X_i, \phi_{j,i})$ and $(Y_i, \psi_{j,i})$ be inverse systems over the same index set I. Suppose there is for each i a function $\alpha_i : X_i \to Y_i$ such that $\psi_{j,i} \circ \alpha_j = \alpha_i \circ \phi_{j,i}$ for all $i < j$. Let $(X, \phi_i) = \varprojlim(X_i, \phi_{j,i})$, $(Y, \psi_i) = \varprojlim(Y_i, \psi_{j,i})$. The maps $\alpha_i \circ \psi_i$ are a coherent family of maps from X to the Y_i, so by the universal property there is a unique function $\alpha : X \to Y$ such that $\psi_i \circ \alpha = \alpha_i \circ \phi_i$ for all i. The function α is called the *function induced by the* α_i. For $I = \mathbb{N}$ we have a commutative diagram:

XIII.14.2.10. Here is the general procedure including both XIII.14.2.8. and XIII.14.2.9.. Let I and J be directed sets, and $(X_i, \phi_{i',i})$ and $(Y_j, \psi_{j',j})$ be inverse systems over I and J respectively. Let K be a cofinal subset of I, and f a directed function () from K to J, which for simplicity we will take to be order-preserving (this assumption can be eliminated at some technical cost, in the manner of Exercise II.4.5.3.). Suppose we have a compatible set (α_k) of functions $\alpha_k : X_k \to Y_{f(k)}$ (i.e. if $k < k'$ we have $\alpha_k \circ \phi_{k',k} = \psi_{f(k'),f(k)} \circ \alpha_{k'}$). For $j \in J$, define $\theta_j : X \to Y_j$ by $\theta_j = \psi_{f(k),j} \circ \alpha_k \circ \phi_k$ for any $k \in K$, $j < f(k)$ (by compatibility this is well defined independent of the choice of k). The θ_j are a compatible family of functions from X to the Y_j, so there is a unique induced map $\alpha : X \to Y$ such that $\psi_j \circ \alpha = \theta_j$ for all j. This is the function induced by f and the α_k.

XIII.14.2.11. Proposition. Let I and J be directed sets, and $(X_i, \phi_{i',i})$ and $(Y_j, \psi_{j',j})$ be inverse systems over I and J respectively, with inverse limits (X, ϕ_i) and (Y, ψ_j). Let K and L be cofinal subsets of I and J respectively, and $f : K \to J$ and $g : L \to I$ order-preserving directed maps. Let $\alpha_k : X_k \to Y_{f(k)}$ and $\beta_\ell : Y_\ell \to X_{g(\ell)}$ be compatible families of maps, with $\beta_\ell \circ \psi_{f(k),\ell} \circ \alpha_k = \phi_{k,g(\ell)}$ whenever $k \in K$, $\ell \in L$, $\ell < f(k)$ and $k < g(\ell)$, and $\alpha_k \circ \phi_{g(\ell),k} \circ \beta_\ell = \psi_{\ell,f(k)}$ whenever $k < g(\ell)$ and $\ell < f(k)$. Then the induced functions $\alpha : X \to Y$ and $\beta : Y \to X$ are mutually inverse bijections.

The proof is very similar to the proof of XIII.14.1.7., and is left to the reader. Pictorially, if $I = J = \mathbb{N}$, we have a commutative diagram:

XIII.14.2.12. Like direct limits, inverse limits commute with taking subspaces. Let $(X_i, \phi_{j,i})$ be an inverse system of sets over I, and for each i suppose $Y_i \subseteq X_i$ and $\phi_{j,i}(Y_j) \subseteq Y_i$ whenever $i < j$. Set

$\psi_{j,i} = \phi_{j,i}|_{Y_j} : Y_j \to Y_i$ for $i < j$. Then $(Y_i, \psi_{j,i})$ is an inverse system of sets over I, and the inclusion maps $\beta_i : Y_i \to X_i$ induce a function $\beta : Y \to X$, where $(X, \phi_i) = \varprojlim(X_i, \phi_{j,i})$ and $(Y, \psi_i) = \varprojlim(Y_i, \psi_{j,i})$. The next proposition is obvious:

XIII.14.2.13. PROPOSITION. The map $\beta : Y \to X$ is injective; thus we may write $\varprojlim(Y_i, \psi_{j,i}) \subseteq \varprojlim(X_i, \phi_{j,i})$. (Informally, inverse limits of sets commute with taking subsets.)

XIII.14.3. Direct Limits in Topology

If $(X_i, \phi_{i,j})$ is a direct system over a directed set I, and each X_i is a topological space and all $\phi_{i,j}$ are continuous, then we want to put a topology on the direct limit X so that all the maps in Definition XIII.14.1.4. are continuous. So we need each ϕ_i continuous, and for the universal property to hold the topology must be the strongest one with this property, i.e. the topology on X is induced by the functions ϕ_i in the sense of ().

XIII.14.3.1. DEFINITION. Let $(X_i, \phi_{i,j})$ be a direct system of topological spaces over a directed set I, i.e. each X_i is a topological space and each $\phi_{i,j} : X_i \to X_j$ is continuous for $i < j$. The *inductive limit topology* on $X = \varinjlim(X_i, \phi_{i,j})$ is the topology on X induced by the ϕ_i, i.e. $U \subseteq X$ is open if and only if $\phi_i^{-1}(U)$ is open in X_i for all i.

It is easily checked (cf. ()) that this is a topology on X and that each ϕ_i is continuous.

XIII.14.3.2. PROPOSITION. Let $(X_i, \phi_{i,j})$ be a direct system of topological spaces, with $(X, \phi_i) = \varinjlim(X_i, \phi_{i,j})$. Give X the inductive limit topology. If Y is a topological space and for each i there is a continuous function $\psi_i : X_i \to Y$ such that $\psi_i = \psi_j \circ \phi_{i,j}$ for any i, j with $i < j$, then the unique function $\alpha : X \to Y$ such that $\psi_i = \alpha \circ \phi_i$ for all i is continuous.

PROOF: Let V be an open set in Y, and $U = \alpha^{-1}(V)$. Then $\phi_i^{-1}(U) = \psi_i^{-1}(V)$ is open in X_i for each i. Thus U is open in X by definition of the inductive limit topology. 👍

XIII.14.3.3. There is almost nothing one can say about properties of the inductive limit topology in general; it can be quite pathological (cf. Example XIII.14.3.4.(i)). See [], [], ... for other examples. But the inductive limit topology tends to be fairly strong, as Example XIII.14.3.4.(ii) indicates.

XIII.14.3.4. EXAMPLES. (i) Let X be a set, and $\mathcal{T}_1, \mathcal{T}_2, \ldots$ a sequence of topologies on X with $\mathcal{T}_{n+1}$ weaker than $\mathcal{T}_n$ for all n. Let X_n be X with the topology $\mathcal{T}_n$ for each n, and let $\phi_{n,n+1}$ be the identity map on X. Then $\phi_{n,n+1}$ is continuous. The direct limit is again X, and the inductive limit topology is $\mathcal{T} = \cap_n \mathcal{T}_n$. If each $\mathcal{T}_n$ is T_1, then $\mathcal{T}$ is also T_1; but if each $\mathcal{T}_n$ is Hausdorff (even metrizable), then $\mathcal{T}$ is not necessarily Hausdorff ().

(ii) Here is a common situation which can be generalized in several ways. Let (X_n, ρ_n) be a metric space for each n, and $\phi_{n,n+1}$ an isometry of X_n onto a closed subset of X_{n+1}. There is an induced metric ρ on the direct limit X, since we can identify X_n with a closed subset of X, $X_n \subseteq X_{n+1}$, $X = \cup_n X_n$. It might appear that the inductive limit topology is the topology induced by ρ. This is sometimes true, e.g. if

$X_n = \left[\frac{1}{n}, 1\right]$ with the usual metric, then $X \cong (0,1]$ with the usual topology. But it is false in general. In fact, the inductive limit topology is strictly stronger then the ρ-topology in general, and is often not even first countable, so sequences are inadequate to describe the topology. An example is obtained by taking $X_n = \mathbb{R}^n$ with the usual metric (or the p-metric for $1 \leq p \leq \infty$), identifying $\mathbb{R}^n$ with $\mathbb{R}^n \times \{0\} \subseteq \mathbb{R}^{n+1}$. The direct limit can be described in this case as c_{oo}, the set of sequences of real numbers which are eventually 0. XIII.14.3.5. implies that a sequence in c_{oo} (i.e. a sequence of sequences) converges in the inductive limit topology if and only if there is a fixed n such that all the terms in each sequence vanish after the n'th place and the sequence of k'th coordinates converges for $1 \leq k \leq n$. The inductive limit topology on c_{oo} is not first countable: if $\sigma = (\epsilon_n)$ is any sequence of positive numbers, let U_σ be the set of all sequences $(x_1, x_2, \dots)$ in c_{oo} such that $|x_n| < \epsilon_n$ for all n. Then $U_\sigma \cap \mathbb{R}^n$ is open in $\mathbb{R}^n$ for all n, hence U_σ is open in the inductive limit topology. In fact, the U_σ form a local base at 0 for the inductive limit topology. But there is no countable local base at 0, since for any countable set $\{\sigma_k : k \in \mathbb{N}\}$ of such sequences, there is a σ whose terms go to 0 faster than those of any σ_k ().

In the situation of XIII.14.3.4., we have the following result for sequences (which does not generalize to nets):

XIII.14.3.5. Proposition. Let (X_n, ρ_n) be a metric space for each n, and $\phi_{n,n+1}$ an isometry of X_n onto a closed subset of X_{n+1}. Let $X = \varinjlim(X_n, \phi_{n,n+1})$. Give X the inductive limit topology $\mathcal{T}$, and identify X_n with a (closed) subset of X for each n. If (x_k) is a sequence in X, $x \in X$, then $x_k \to x$ in the $\mathcal{T}$-topology if and only if there is an n such that $x_k \in X_n$ for all k, $x \in X_n$, and $x_n \to x$ in X_n.

XIII.14.3.6. **Caution:** Suppose $(X_i, \phi_{i,j})$ is a direct system of topological spaces, and for each i we have $Y_i \subseteq X_i$, with $\phi_{i,j}(Y_i) \subseteq Y_j$ for $i < j$. Set $\psi_{i,j} = \phi_{i,j}|_{Y_i} : Y_i \to Y_j$ for $i < j$. Give Y_i the induced topology from X_i. Then $(Y_i, \psi_{i,j})$ is a direct system of topological spaces. If β_i is the inclusion map of Y_i into X_i for each i, there is an induced map $\beta : Y \to X$, where $(X, \phi_i) = \varinjlim(X_i, \phi_{i,j})$ and $(Y, \psi_i) = \varinjlim(Y_i, \psi_{i,j})$. The map β is injective by XIII.14.1.12. and continuous by XIII.14.3.2..

However, β is not a homeomorphism onto its image in general. For example (from [Dug78]), let each X_n be $[0,1]$ with its usual topology, and let $\phi_{n,n+1}$ be the identity map. Let $Y_n = \{0\} \cup \left(\frac{1}{n}, 1\right]$. Then X and Y can both be identified with $[0,1]$ with β the identity map. X has the usual topology on $[0,1]$, but Y has a strictly stronger topology, since $\{0\}$ is open in Y.

Thus direct limits of topological spaces do *not* commute with taking subspaces in general.

XIII.14.4. Inverse Limits in Topology

XIII.14.4.1. Inverse limits in topology are somewhat better behaved than direct limits. Suppose $(X_i, \phi_{j,i})$ is an inverse system over a directed set I, and each X_i is a topological space and all $\phi_{j,i}$ are continuous. Since the inverse limit (X, ϕ_i) is constructed as a subset of the Cartesian product, the obvious topology to use on X is the restriction of the product topology; this coincides with the topology defined by the maps ϕ_i (weakest topology for which all ϕ_i are continuous; cf. ()). This topology is called the *inverse limit topology*, but is rarely referred to by name since it is the only reasonable topology on the inverse limit. Another way to describe this topology is: if (x_σ) is a net in X and $x \in X$, then $x_\sigma \to x$ in X if and only if $\phi_i(x_\sigma) \to \phi_i(x)$ in X_i for all i ().

XIII.14.4.2. PROPOSITION. Let $(X_i, \phi_{j,i})$ be an inverse system of topological spaces, with $(X, \phi_i) = \varprojlim(X_i, \phi_{i,j})$. Give X the inverse limit topology. If Y is a topological space and for each i there is a continuous function $\psi_i : Y \to X_i$ such that $\psi_i = \phi_{j,i} \circ \psi_j$ for any i, j with $i < j$, then the unique function $\alpha : Y \to X$ such that $\psi_i = \phi_i \circ \alpha$ for all i is continuous.

PROOF: Since the inverse limit topology on X is generated by sets of the form $\phi_i^{-1}(U)$, where U is open, it suffices to show that $\alpha^{-1}(\phi_i^{-1}(U))$ is open for any open $U \subseteq X_i$. But $\alpha^{-1}(\phi_i^{-1}(U)) = \psi_i^{-1}(U)$, which is open since ψ_i is continuous. 👍

XIII.14.4.3. Inverse limits behave better than direct limits with respect to taking subspaces. Suppose $(X_i, \phi_{j,i})$ is an inverse system of topological spaces, and for each i we have $Y_i \subseteq X_i$, with $\phi_{j,i}(Y_j) \subseteq Y_i$ for $i < j$. Set $\psi_{j,i} = \phi_{j,i}|_{Y_j} : Y_j \to Y_i$ for $i < j$. Give Y_i the induced topology from X_i. Then $(Y_i, \psi_{j,i})$ is an inverse system of topological spaces. If β_i is the inclusion map of Y_i into X_i for each i, there is an induced map $\beta : Y \to X$, where $(X, \phi_i) = \varprojlim(X_i, \phi_{j,i})$ and $(Y, \psi_i) = \varprojlim(Y_i, \psi_{j,i})$. The map β is injective by XIII.14.2.13. and continuous by XIII.14.4.2.. In contrast to the direct limit case (XIII.14.3.6.), β is a homeomorphism onto its image in the inverse limit case, as follows immediately from the fact that if $\prod_i Y_i$ is regarded as a subset of $\prod_i X_i$, the relative topology on $\prod_i Y_i$ from the product topology on $\prod_i X_i$ is exactly the product topology on $\prod_i Y_i$ (). Thus inverse limits of topological spaces *do* commute with taking subspaces.

XIII.14.4.4. If each X_i is Hausdorff (resp. T_0, T_1, regular, completely regular), so is the inverse limit, since these separation properties are preserved under products and taking subspaces. Normality is not, however, preserved in general. An inverse limit of a sequence of metrizable spaces is metrizable.

XIII.14.4.5. PROPOSITION. Let $(X_i, \phi_{j,i})$ be an inverse system of Hausdorff spaces. Then the inverse limit is a closed subset of $\prod_i X_i$.

PROOF: Let (x_σ) be a net in $X = \varprojlim(X_i, \phi_{j,i})$ with $x_\sigma \to x \in \prod_i X_i$. Write $x_\sigma = (\cdots x_i^\sigma \cdots)$, $x = (\cdots x_i \cdots)$. Suppose $i, j \in I$, $i < j$. Then, since coordinate projections are continuous, we have $x_i^\sigma \to x_i$ and $x_j^\sigma \to x_j$. Since $\phi_{j,i}$ is continuous, $x_i^\sigma = \phi_{j,i}(x_j^\sigma) \to \phi_{j,i}(x_j)$. By uniqueness of limits in Hausdorff spaces, $x_i = \phi_{j,i}(x_j)$. Thus $x \in X$. 👍

Combining this result with Tikhonov's theorem (), we obtain:

XIII.14.4.6. COROLLARY. Let $(X_i, \phi_{j,i})$ be an inverse system of compact Hausdorff spaces. Then $\varprojlim(X_i, \phi_{j,i})$ is also a compact Hausdorff space.

XIII.14.4.7. The conclusion of XIII.14.4.5. fails in general if the X_i are not Hausdorff (e.g. if they have the indiscrete topology). But it is nonetheless true that an inverse limit of compact spaces is compact (XIII.14.5.6.).

Inverse limits of compact Hausdorff spaces behave somewhat better than general inverse limits. For example:

XIII.14.4.8. PROPOSITION. Let $(X_i, \phi_{j,i})$ be an inverse system of compact Hausdorff spaces over a directed set I, and $(X, \phi_i) = \varprojlim(X_i, \phi_{i,j})$. For each i set $Y_i = \cap_{j>i}\phi_{j,i}(X_j) \subseteq X_i$. Then for each i we have that $\phi_i(X) = Y_i$. In particular, if each X_i is nonempty, then X is nonempty.

PROOF: (AC) Note that Y_i is compact, and nonempty if all X_i are nonempty. Assume all X_i are nonempty. Fix $i_0 \in I$, and let $\mathcal{F}$ be the collection of all finite subsets of I containing i_0. Let $x_{i_0} \in Y_{i_0}$. Set $Z = \prod_i X_i$, and for each $F \in \mathcal{F}$ let Z_F be the set of all $(\cdots x_i \cdots) \in Z$ such that, whenever $i, j \in F$, $i < j$, we have $x_i = \phi_{j,i}(x_j)$, and x_{i_0} is the specified element. Then Z_F is a nonempty compact subset of Z [choose $j \in I$ such that $i < j$ for all $i \in F$, and let $x_j \in X_j$ with $\phi_{j,i_0}(x_j) = x_{i_0}$; set $x_i = \phi_{j,i}(x_j)$ for each $i \in F$]. The collection $\{Z_F : F \in \mathcal{F}\}$ has the finite intersection property, so the intersection is nonempty, and any point $x \in \cap_F Z_F$ is in the inverse limit X and satisfies $\phi_{i_0}(x) = x_{i_0}$. Thus $\phi_i(X)$ contains Y_i, and the reverse containment is trivial (this containment holds in general inverse limits). 👍

XIII.14.4.9. This result fails for general inverse limits (Exercise XIII.14.5.6.).

As a companion, it is easy to recognize inverse limits in the compact Hausdorff case:

XIII.14.4.10. PROPOSITION. Let $(X_i, \phi_{j,i})$ be an inverse system of compact Hausdorff spaces over a directed set I, and $(X, \phi_i) = \varprojlim(X_i, \phi_{i,j})$. For each i set $Y_i = \cap_{j>i}\phi_{j,i}(X_j) \subseteq X_i$. Let Y be a compact Hausdorff space, and ψ_i a compatible family of continuous functions from Y onto Y_i (i.e. $\psi_i = \phi_{j,i} \circ \psi_j$ for $i < j$ and $\psi_i(Y) = Y_i$ for all i), which separate points, i.e. if $y \neq y'$ there is an i with $\psi_i(y) \neq \psi_i(y')$. Then (Y, ψ_i) is an inverse limit for $(X_i, \phi_{j,i})$.

PROOF: Let $(X, \phi_i) = \varprojlim(X_i, \phi_{j,i})$, and $\alpha : Y \to X$ the induced map. It suffices to show that α is a bijection since it is continuous (). Since the ψ_i separate points, α is injective. To show surjectivity, let $x = (\cdots x_i \cdots) \in X$. Then $x_i \in Y_i$ for all i. For each i let $y_i \in Y$ with $\psi_i(y_i) = x_i$. Then (y_i) is a net in Y; let y be a cluster point. Since

$$\psi_i(y_j) = \phi_{j,i}(\psi_j(y_j)) = \phi_{j,i}(x_j) = x_i$$

for $i < j$, we have $\psi_i(y) = x_i$ for all i by continuity, so $\alpha(y) = x$. 👍

XIII.14.4.11. EXAMPLE. For each n let X_n be a finite set with 2^n points, with the discrete topology. We may conveniently take X_n to be the set of all n-tuples of 0's and 1's. Let $\phi_{n+1,n} : X_{n+1} \to X_n$ be a function for which the inverse image of each point of X_n consists of exactly two points. For example, we may take

$$\phi_{n+1,n}((d_1, \ldots, d_n, d_{n+1})) = (d_1, \ldots, d_n)$$

where $(d_1, \ldots, d_{n+1})$ is an $(n+1)$'tuple of 0's and 1's. The inverse image $(X, \phi_n) = \varprojlim(X_n, \phi_{n+1,n})$ is a compact Hausdorff space which is naturally homeomorphic to the Cantor set: it can be thought of as the set of all sequences of 0's and 1's, with the topology of coordinatewise convergence, with

$$\phi_n((d_1, d_2, \ldots)) = (d_1, \ldots, d_n) \ .$$

In fact it is easy to conclude from XIII.14.4.10. that the Cantor set with these maps is an inverse limit.

XIII.14.4.12. EXAMPLES. Some of the examples from () can be easily written as inverse limits of "nicer" spaces by projection.

(i) Let X be one of the spaces $X_{\boldsymbol{k}}$ of XIII.19.5.1.. Let X_n be the subset of X consisting of the horizontal line and the "whiskers" whose basepoint has x-coordinate $\geq \frac{1}{n}$. Define $\phi_{n+1,n} : X_{n+1} \to X_n$ by mapping all the points on the whiskers with basepoint $\left(\frac{1}{n+1}, 0\right)$ to the point $\left(\frac{1}{n+1}, 0\right)$. Then $\varprojlim(X_n, \phi_{n+1,n})$ is homeomorphic to X, and the map $\phi_n : X \to X_n$ just sends all the points of each whisker whose basepoint has x-coordinate $< \frac{1}{n}$ to the basepoint of the whisker.

(ii) Similarly, let X be the Hawaiian earring (XIII.19.5.8.). Let X_n be the subset of X consisting only of the first n circles (with radius $\geq \frac{1}{n}$). Define $\phi_{n+1,n} : X_{n+1} \to X_n$ by mapping all the points on the $(n+1)$'st circle to $(0,0)$. Then $\varprojlim(X_n, \phi_{n+1,n})$ is homeomorphic to X, and the map $\phi_n : X \to X_n$ just sends all the points of each circle of radius $< \frac{1}{n}$ to $(0,0)$.

(iii) Let X be the infinite broom (Exercise XIII.13.9.9.). For each n let X_n be the subset of X consisting only of the line segments from the origin to $\left(1, \frac{1}{k}\right)$ for $1 \leq k \leq n$. Define $\phi_{n+1,n} : X_{n+1} \to X_n$ by projecting the $(n+1)$'st line segment upwards onto the n'th and leaving the points of X_n fixed. Then X is naturally homeomorphic to $\varprojlim(X_n, \phi_{n+1,n})$, with ϕ_n the projection of all segments with right endpoint below $\left(1, \frac{1}{n}\right)$ upwards onto the n'th segment.

(iv) Let X be the topologist's sine curve (XIII.19.5.5.). Let X_n be the subset of $\mathbb{R}^2$ obtained by taking the part of X to the right of the vertical line $x = \frac{2}{4n+1}$ and the vertical line segment between $\left(\frac{2}{4n+1}, -1\right)$ and $\left(\frac{2}{4n+1}, 1\right)$. Then X_n is homeomorphic to $[0,1]$. Define $\phi_{n+1,n} : X_{n+1} \to X_n$ by projecting the points with x-coordinates $< \frac{2}{4n+1}$ horizontally to the right onto the line $x = \frac{2}{4n+1}$ and leaving the other points fixed. Then X is naturally homeomorphic to $\varprojlim(X_n, \phi_{n+1,n})$, with ϕ_n the projection of all points with x-coordinates $< \frac{2}{4n+1}$ horizontally to the right onto the line $x = \frac{2}{4n+1}$. Thus X is an inverse limit of copies of $[0,1]$. See XIII.14.4.18. for more examples of spaces which can be written as inverse limits of copies of $[0,1]$.

XIII.14.4.13. EXAMPLES. For $m \in \mathbb{N}$, write $\mathbb{Z}/m\mathbb{Z}$ for the cyclic group with m elements (we usually denote this group by $\mathbb{Z}_m$, but this notation will be reserved for something else here). Let $\boldsymbol{a} = (a_1, a_2, \dots)$ be a sequence in $\mathbb{N} \setminus \{1\}$ with $a_k | a_{k+1}$ for all k. Consider the inverse system

$$\cdots \xrightarrow{\pi_{4,3}} \mathbb{Z}/a_3\mathbb{Z} \xrightarrow{\pi_{3,2}} \mathbb{Z}/a_2\mathbb{Z} \xrightarrow{\pi_{2,1}} \mathbb{Z}/a_1\mathbb{Z}$$

where $\pi_{n+1,n}$ is the quotient map from $\mathbb{Z}/a_{n+1}\mathbb{Z}$ to $\mathbb{Z}/a_n\mathbb{Z}$. Let $(\mathbb{Z}_{\boldsymbol{a}}, \pi_n)$ be the inverse limit. Then $\mathbb{Z}_{\boldsymbol{a}}$ is a compact totally disconnected abelian topological group. If $a_n = p^n$ for a fixed prime p, we write $\mathbb{Z}_p$ for $\mathbb{Z}_{\boldsymbol{a}}$; $\mathbb{Z}_p$ is called the *p-adic integers* (cf. ()).

There is a natural quotient map ρ_n from $\mathbb{Z}$ to $\mathbb{Z}/a_n\mathbb{Z}$ for each n. The ρ_n define a homomorphism $\rho : \mathbb{Z} \to \mathbb{Z}_{\boldsymbol{a}}$. If m is in the kernel of ρ, then $a_n | m$ for all n, hence $m = 0$ and ρ is injective. But ρ is not surjective: in fact, $\mathbb{Z}_{\boldsymbol{a}}$ has cardinality $2^{\aleph_0}$ (it is homeomorphic to the Cantor set by ()). However, $\rho(\mathbb{Z})$ is dense in $\mathbb{Z}_{\boldsymbol{a}}$ (XIII.14.4.19.).

The group $\mathbb{Z}_{\boldsymbol{a}}$ is often, but not always, torsion-free (XIII.14.5.9.). In particular, $\mathbb{Z}_p$ is torsion-free. $\mathbb{Z}_p$ and more generally $\mathbb{Z}_{\boldsymbol{a}}$ has a natural structure as a topological ring, but this structure is not easily definable from the inverse limit construction.

There are several results about writing a general space as an inverse limit of "nice" spaces. For example:

XIII.14.4.14. THEOREM. Let X be a compact metrizable space. Then there is an inverse system $(X_n, \phi_{n+1,n})$ over $\mathbb{N}$, with each X_n a smooth compact manifold with boundary and $\phi_{n+1,n}$ a smooth map for each n, with X homeomorphic to $\varprojlim(X_n, \phi_{n+1,n})$.

PROOF: We may identify X with a (compact) subset of the Hilbert cube (). Fix a sequence (ϵ_n) with $0 < \epsilon_{n+1} < \frac{\epsilon_n}{4}$ for all n. Let Y_n be the projection of X onto the first n coordinates, and regard Y_n as a subset of $[0,1]^n \subseteq \mathbb{R}^n$. Let U_n be a neighborhood of Y_n in $\mathbb{R}^n$ as in XIII.23.10.1. with $\epsilon = \epsilon_n$, and set $X_n = \bar{U}_n$. Since the projection from $\mathbb{R}^{n+1}$ to $\mathbb{R}^n$ is a contraction, it maps X_{n+1} into X_n. Let $\phi_{n+1,n}$ be the restriction of the projection map to X_{n+1}. Then $(X_n, \phi_{n+1,n})$ is an inverse system of smooth compact manifolds with boundary, with smooth connecting maps.

We show that X is homeomorphic to $\varprojlim(X_n, \phi_{n+1,n})$. For each n let ψ_n be the restriction to X of the projection from the Hilbert cube to $[0,1]^n$; then $\psi_n(X) = Y_n$ by definition of Y_n, and the conditions of XIII.14.4.10. are satisfied. 👍

If X is a compact subset of $\mathbb{R}^m$, a simplified version of the argument shows that the X_n can be taken to be m-dimensional.

XIII.14.4.15. There are two drawbacks to this result, however:

(i) The connecting maps are not surjective.

(ii) If X is finite-dimensional, the dimensions of the X_n may be much larger than $dim(X)$. (If $dim(X) = d$, X embeds in $\mathbb{R}^{2d+1}$ by the Whitney Embedding Theorem (), so the X_n can be chosen to have dimension $\leq 2d+1$.)

These difficulties cannot be avoided if one wants to write X as an inverse limit of smooth manifolds with boundary. But if we slightly more generally allow the X_n to be polyhedra (), we can do better:

XIII.14.4.16. THEOREM. Let X be a compact metrizable space. Then there is an inverse system $(X_n, \phi_{n+1,n})$ over $\mathbb{N}$, with each X_n a polyhedron and $\phi_{n+1,n}$ a surjective piecewise-linear map for each n, with X homeomorphic to $\varprojlim(X_n, \phi_{n+1,n})$. If $dim(X) = d < \infty$, then the X_n can be chosen so that $dim(X_n) = d$ for all n.

The proof is involved and uses some machinery, and will be given in (). This result was first proved by H. FREUDENTHAL in 1937 [Fre37]. The examples in XIII.14.4.11. and XIII.14.4.12. are examples of writing compact metrizable spaces as inverse limits of polyhedra.

XIII.14.4.17. EXAMPLES. **(Solenoids.)** Let $\mathbb{T}$ be the unit circle in the plane, regarded as the compact topological group of complex numbers of absolute value 1. For each n, let $X_n = \mathbb{T}$ and $\phi_{n+1,n} : X_{n+1} \to X_n$ defined by $\phi_{n+1,n}(z) = z^2$. Then $(X_n, \phi_{n+1,n})$ is an inverse system of compact Hausdorff spaces. Let $(X, \phi_n) = \varprojlim(X_n, \phi_{n,n+1})$. Then X has a natural structure as a compact Hausdorff space which is an abelian topological group (XIII.14.5.2.). In fact, it is easily seen using XIII.14.4.10. that X is homeomorphic to the solenoid (XIII.19.5.16.) of type 2^∞. Thus a solenoid is homeomorphic to an inverse limit of circles.

The circle $\mathbb{T}$ can be regarded as $\mathbb{R}/m\mathbb{Z}$ for any $m \in \mathbb{N}$. Thus we may regard the above X as

$$\varprojlim(\mathbb{R}/2^{n-1}\mathbb{Z}, \pi_{n+1,n})$$

where $\pi_{n+1,n} : \mathbb{R}/2^n\mathbb{Z} \to \mathbb{R}/2^{n-1}\mathbb{Z}$ is the natural quotient map. We have a commutative diagram

$$\begin{array}{ccccccccccc}
\cdots & \xrightarrow{\iota} & \mathbb{R} & \xrightarrow{\iota} & \cdots & \xrightarrow{\iota} & \mathbb{R} & \xrightarrow{\iota} & \mathbb{R} & \xrightarrow{\iota} & \mathbb{R} \\
 & & \downarrow{\scriptstyle \pi} & & & & \downarrow{\scriptstyle \pi} & & \downarrow{\scriptstyle \pi} & & \downarrow{\scriptstyle \pi} \\
\cdots & \xrightarrow{\pi_{n+1,n}} & \mathbb{R}/2^{n-1}\mathbb{Z} & \xrightarrow{\pi_{n,n-1}} & \cdots & \xrightarrow{\pi_{4,3}} & \mathbb{R}/4\mathbb{Z} & \xrightarrow{\pi_{3,2}} & \mathbb{R}/2\mathbb{Z} & \xrightarrow{\pi_{2,1}} & \mathbb{R}/\mathbb{Z}
\end{array}$$

which induces a continuous group homomorphism $\alpha : \mathbb{R} \to X$, which is injective. The range of α is dense in X by XIII.14.4.19., but is not all of X: the range consists of all threads (x_n), where $x_n \to 1$ in $\mathbb{T}$ when $\mathbb{R}/2^{n-1}\mathbb{Z}$ is identified with $\mathbb{T}$. Also, α is not a homeomorphism onto its image: for example, we have $\alpha(2^n) \to \alpha(0)$ in X. In fact, the range of α, which is a subgroup of X, is exactly the path component of the identity of X. The other path components of X are exactly the cosets of $\alpha(\mathbb{R})$ in X.

The other solenoids can be constructed by taking $\phi_{n+1,n}(z) = z^{k_n}$ for a sequence (k_n) in $\mathbb{N} \setminus \{1\}$.

XIII.14.4.18. Examples. (i) **Knaster bucket-handle.** (cf. XIII.19.5.31.) The Knaster bucket-handle can be written as an inverse limit of copies of $[0,1]$ by taking for each $\phi_{n+1,n}$ the piecewise-linear map from $[0,1]$ to $[0,1]$ with $\phi_{n+1,n}(0) = \phi_{n+1,n}(1) = 0$ and $\phi_{n+1,n}\left(\frac{1}{2}\right) = 1$:

Other bucket-handles can be constructed similarly as inverse limits by taking a sequence (k_n) of natural numbers ≥ 2 and letting $\phi_{n+1,n}$ be the sawtooth function taking values 0 and 1 alternately at the numbers $\frac{m}{k_n}$. The homeomorphism class of the bucket-handle is exactly determined by the equivalence class (XIII.19.5.24.) of the supernatural number $\prod_n k_n$ []. There is a qualitative difference between bucket-handles for which infinitely many k_n are even and ones with only finitely many even k_n (up to equivalence, ones with all k_n odd): the latter have two "endpoints" while the former have only one.

(ii) **Pseudo-Arc.** The pseudo-arc (XIII.19.5.32.) can also be written as an inverse limit of copies of $[0,1]$. The maps $\phi_{n+1,n}$ can also be taken to be piecewise-linear, but zigzag up and down similarly to the definition of a crooked embedding:

See [] for details.

XIII.14.4.19. Proposition. Let $(X_i, \phi_{j,i})$ be an inverse system of topological spaces, and $(X, \phi_i) = \varprojlim(X_i, \phi_{j,i})$. If $D \subseteq X$, then D is dense in X if and only if $\phi_i(D)$ is dense in $\phi_i(X) \subseteq X_i$ for all i.

Proof: If D is dense in X, then $\phi_i(D)$ is dense in $\phi_i(X)$ for all i by (). Conversely, suppose $\phi_i(D)$ is dense in $\phi_i(X)$ for each i. Fix $x \in X$. Let J be the set of all triples (i, U, y), where $i \in I$, U is an open neighborhood of $\phi_i(x)$ in X_i, and $y \in D$, $\phi_i(y) \in U$. Set $(i, U, y) < (i', V, y')$ if $i < i'$ and $\phi_{i',i}(V) \subseteq U$. Then J is a directed set. For $j = (i, U, y) \in J$ set $y_j = y$. Then (y_j) is a net in D, and $y_j \to x$ since $\phi_i(y_j) \to \phi_i(x)$ for all i. Thus D is dense in X. ☝

In particular, if $\phi_i(D) = X_i$ for all i, then D is dense in X (this has a simplified direct proof using AC); but D can be a proper subset of X (XIII.14.4.17.).

XIII.14.5. Exercises

XIII.14.5.1. Modify the definition of direct and inverse systems and limits by also defining $\phi_{i,i}$ to be the identity map on X_i for each i, and replacing $<$ by $\leq$ throughout. Show that this modified definition also works over directed sets which are not properly directed. Describe the limit if the index set is not properly directed.

XIII.14.5.2. (a) Let I be a directed set and G_i a group for each i, with $\phi_{i,j} : G_i \to G_j$ a homomorphism for $i < j$. Let $(G, \phi_i) = \varinjlim(G_i, \phi_{i,j})$. Show that G has a unique group structure making each ϕ_i a homomorphism.

(b) If each G_i is abelian, show that G is abelian. What about the converse?

(c) Do the same if each G_i is a ring, vector space, or topological group.

(d) Do the analog of (a)–(c) for inverse systems and limits.

XIII.14.5.3. [Dug78] Let $\mathbb{T}$ be the unit circle in the plane, regarded as the compact topological group of complex numbers of absolute value 1. For each n, let $X_n = \mathbb{T}$ and $\phi_{n,n+1} : X_n \to X_{n+1}$ defined by $\phi_{n,n+1}(z) = z^2$. Then $(X_n, \phi_{n,n+1})$ is a direct system of compact Hausdorff spaces. Let $(X, \phi_n) = \varinjlim(X_n, \phi_{n,n+1})$. Then X has a natural structure as a topological group (XIII.14.5.2.).

(a) Let H be the subgroup of $\mathbb{T}$ consisting of all roots of unity whose order is a power of 2. Show that X can be naturally identified with $\mathbb{T}/H$.

(b) Show that the inductive limit topology on X is the indiscrete topology.

(c) Repeat the exercise if $\phi_{n,n+1}(z) = z^{k_n}$ for an arbitrary sequence (k_n) in $\mathbb{N} \setminus \{1\}$.

XIII.14.5.4. Construct an explicit countable subset A of c_{oo} such that 0 is in the closure of A in the inductive limit topology, but there is no sequence in A converging to 0. [For $n, m \in \mathbb{N}$, consider the sequence with first term $\frac{1}{n}$, n'th term $\frac{1}{m}$, and all other terms 0.]

XIII.14.5.5. (a) Show (using DC) that if $(X_n, \phi_{n+1,n})$ is an inverse system of nonempty sets over $\mathbb{N}$, and each $\phi_{n+1,n}$ is surjective, and $(X, \phi_n) = \varprojlim(X_n, \phi_{n+1,n})$, then X is nonempty and each ϕ_n is surjective.

(b) (I. Farah) For each $\alpha < \omega_1$ let X_α be the set of all injective functions from α to $\mathbb{N}$ for which the complement of the range is infinite. If $\alpha < \beta$, let $\phi_{\beta,\alpha} : X_\beta \to X_\alpha$ be defined by $\phi_{\beta,\alpha}(f) = f|_\alpha$. Then $(X_\alpha, \phi_{\beta,\alpha})$ is an inverse system of nonempty sets over the directed (well-ordered) set ω_1. Show that each connecting map $\phi_{\beta,\alpha}$ is surjective, but $\varprojlim(X_\alpha, \phi_{\beta,\alpha}) = \emptyset$.

XIII.14.5.6. (a) If $(X_i, \phi_{j,i})$ is an inverse system of nonempty compact spaces, show that the inverse limit can be empty if the X_i are not Hausdorff. [Give the sets in XIII.14.2.7.(iii) or XIII.14.5.5.(b) the indiscrete topology or the finite complement topology.]

(b) Prove (using AC) that an inverse limit of compact spaces is compact (regarding $\emptyset$ as a compact space) by adapting the proof of Tikhonov's theorem.

XIII.14.5.7. Let $(X_n, \phi_{n+1,n})$ be an inverse system over $\mathbb{N}$ of nonempty finite sets with the discrete topology, and $(X, \phi_n) = \varprojlim(X_n, \phi_{n+1,n})$.

(a) If $\phi_{n+1,n}^{-1}(p)$ has at least two elements for each n and each $p \in X_n$, show that X is homeomorphic to the Cantor set [use ()].

(b) Let $X_n = \{k \in \mathbb{N} : k \leq n\}$, and define $\phi_{n+1,n}(k) = k$ for $k \leq n$, $\phi_{n+1,n}(n+1) = n$. Show that $\varprojlim(X_n, \phi_{n+1,n})$ is naturally homeomorphic to the one-point compactification of $\mathbb{N}$ (equivalently, to $\{0\} \cup \{\frac{1}{n} : n \in \mathbb{N}\} \subseteq \mathbb{R}$).

XIII.14.5.8. Let G be a group, I a directed set, and $\{H_i : i \in I\}$ a collection of normal subgroups of G with $H_j \subseteq H_i$ for $i < j$. Set $G_i = G/H_i$ for all i. Then there is a natural quotient map $\pi_j, i : G_j = G/H_j \to G/H_i = G_i$ for $i < j$, and $(G_i, \pi_{j,i})$ is an inverse system of groups. Set $(\bar{G}, \pi_i) = \varprojlim(G_i, \pi_{j,i})$. Then $\bar{G}$ is a group, and there is a homomorphism $\alpha : G \to \bar{G}$.

(a) Show that the kernel of α is exactly $\cap_i H_i$. In particular, α is injective if (and only if) $\cap_i H_i = \{e_G\}$.

(b) Show that α is not surjective in general (cf. XIII.14.4.13., XIII.14.4.17.).

(c) If each G_i has a topology making it into a compact (Hausdorff) topological group, with the $\pi_{j,i}$ continuous, then $\bar{G}$ is a compact (Hausdorff) topological group in the inverse limit topology.

(d) If each G_i is finite, give G_i the discrete topology. Then $\bar{G}$ is a compact totally disconnected (zero-dimensional) topological group. Every compact totally disconnected topological group arises in this manner as an inverse limit of finite groups ().

We may regard $\bar{G}$ as a "completion" of G with respect to the subgroups H_i. The examples of XIII.14.4.13., XIII.14.4.17., and **??** are special cases.

XIII.14.5.9. Let $\mathbb{Z}_{\boldsymbol{a}}$ be the $\boldsymbol{a}$-adic numbers as defined in XIII.14.4.13.. Show that $\mathbb{Z}_{\boldsymbol{a}}$ is torsion-free if and only if the supernatural number $a_1 \prod_n \frac{a_{n+1}}{a_n}$ (="$\lim_{n\to\infty} a_n$") has all exponents either 0 or ∞. [Use that $\mathbb{Z}/mn\mathbb{Z} \cong \mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z}$ if m and n are relatively prime () and XIII.14.5.11..]

XIII.14.5.10. Work out the details of writing the Cantor set, the Hawaiian earring, the infinite broom, the topologist's sine curve, solenoids, Knaster bucket-handles, and the pseudo-arc as inverse limits as described in XIII.14.4.11., XIII.14.4.12., XIII.14.4.17., and XIII.14.4.18..

XIII.14.5.11. Let I be an infinite index set (not ordered or directed). For each $i \in I$, let X_i be a set. Let $\mathcal{F}$ be the set of all finite subsets of I, directed by inclusion. For each $F \in \mathcal{F}$, define

$$Z_F = \prod_{i \in F} X_i$$

and if $F \subseteq G \in \mathcal{F}$, let $\pi_{G,F} : Z_G \to Z_F$ be the projection onto the coordinates in F. Show that

$$\left(\prod_{i \in I} X_i, \pi_F \right)$$

is an inverse limit for (Z_F, π_F), where π_F is the natural projection from $\prod_{i \in I} X_i$ onto $\prod_{i \in F} X_i$. If each X_i is a topological space, show that the inverse limit topology is the product topology.

Thus, once finite Cartesian products have been defined, infinite Cartesian products may be regarded as a special case of inverse limits. (However, this is not a logically sound way to *define* infinite Cartesian products, since infinite Cartesian products are used to construct inverse limits so there is a circularity problem.)

XIII.14.5.12. Restricted Direct Products. Let I be an infinite index set (not ordered or directed). For each $i \in I$, let X_i be a locally compact Hausdorff space and Y_i a compact open (hence clopen) subset of X_i. Let $\mathcal{F}$ be the set of all finite subsets of I, directed by inclusion. For each $F \in \mathcal{F}$, define

$$Z_F = \left\{ (\cdots x_i \cdots) \in \prod_i X_i : x_i \in Y_i \text{ for all } i \notin F \right\} \subseteq \prod_{i \in I} X_i$$

and give Z_F the restriction of the product topology. Then

$$Z_F \cong \prod_{i \in F} X_i \times \prod_{i \in I \setminus F} Y_i$$

and thus Z_F is locally compact by (). If $F \subseteq G \in \mathcal{F}$, the inclusion $\phi_{F,G}$ of Z_F into Z_G is a homeomorphism onto a clopen subset of Z_G. Let

$$(Z, \phi_F) = \varinjlim (Z_F, \phi_{F,G})$$

with the inductive limit topology. Z is called the *restricted direct product of the X_i with respect to the Y_i*, denoted

$$Z = \prod_{i \in I}{}' (X_i, Y_i) \ .$$

(a) As a set, Z can be identified with the subset $\cup_F Z_F$ of $\prod_i X_i$, the set of tuples $(\cdots x_i \cdots)$ with $x_i \in Y_i$ for all but finitely many i.

(b) Show that Z is locally compact and the image $\phi_F(Z_F)$ of Z_F is a clopen subset (homeomorphic to Z_F) for each $F \in \mathcal{F}$.

(c) Show that the inductive limit topology on Z is strictly stronger than the restriction to Z of the product topology if $Y_i \neq X_i$ for infinitely many i. [The image $\phi_F(Z_F)$ is not open in Z in the product topology.]

Restricted direct products are often used where the X_i have additional structure such as a topological group (). Here is one especially important application. The completions of the rational numbers $\mathbb{Q}$ to topological fields are precisely $\mathbb{R}$ and the p-adic numbers $\mathbb{Q}_p$ for primes p. Each of these is locally compact. The topological field $\mathbb{Q}_p$ contains the ring $\mathbb{Z}_p$ of p-adic integers as a compact open subring. Form

$$\mathbb{A}_{\mathbb{Q}} = \mathbb{R} \times \prod_p{}' (\mathbb{Q}_p, \mathbb{Z}_p)$$

which is naturally a locally compact topological ring, called the *ring of adeles of* $\mathbb{Q}$. There is a natural embedding of $\mathbb{Q}$ into $\mathbb{A}_{\mathbb{Q}}$, whose image turns out to be dense. A similar construction can be done for any algebraic number field (finite extension of $\mathbb{Q}$). Rings of adeles are important in number theory; cf. [].

XIII.14.5.13. (a) If X and Y are sets, use the notation Y^X for the set of all functions from X to Y. If $(X_i, \phi_{i,j})$ is a direct system of sets over I, and Y is a set, for $i < j$ define $\phi^*_{j,i} : Y^{X_j} \to Y^{X_i}$ by

$$\phi^*_{j,i}(f) = f \circ \phi_{i,j} \ .$$

Then $(Y^{X_i}, \phi^*_{j,i})$ is an inverse system of sets over I. If (X, ϕ_i) is a direct limit for $(X_i, \phi_{i,j})$, show that (Y^X, ϕ^*_i) is an inverse limit for $(Y^{X_i}, \phi^*_{j,i})$, where $\phi^*_i(f) = f \circ \phi_i$. Thus we may write

$$\varprojlim (Y^{X_i}, \phi^*_{j,i}) \cong Y^{\varinjlim (X_i, \phi_{i,j})} \ .$$

(b) If X and Y are topological spaces, use the notation Y^X for the set of all continuous functions from X to Y. If $(X_i, \phi_{i,j})$ is a direct system of topological spaces over I, and Y is a topological space, for $i < j$ define $\phi^*_{j,i} : Y^{X_j} \to Y^{X_i}$ by

$$\phi^*_{j,i}(f) = f \circ \phi_{i,j} \ .$$

Then $(Y^{X_i}, \phi^*_{j,i})$ is an inverse system of topological spaces over I. If (X, ϕ_i) is a set-theoretic direct limit for $(X_i, \phi_{i,j})$, show that (Y^X, ϕ^*_i) is a set-theoretic inverse limit for $(Y^{X_i}, \phi^*_{j,i})$, where $\phi^*_i(f) = f \circ \phi_i$. If all the spaces of functions are given the topology of pointwise convergence, show that the topology on Y^X is the inverse limit topology.

(c) If $(X_i, \phi_{j,i})$ is an inverse system of sets over I, and Y is a set, for $i < j$ define $\phi^*_{i,j} : Y^{X_i} \to Y^{X_j}$ by

$$\phi^*_{i,j}(f) = f \circ \phi_{j,i} \ .$$

Then $(Y^{X_i}, \phi^*_{i,j})$ is a direct system of sets over I. If (X, ϕ_i) is an inverse limit for $(X_i, \phi_{j,i})$, is it true that (Y^X, ϕ^*_i) is a direct limit for $(Y^{X_i}, \phi^*_{i,j})$, where $\phi^*_i(f) = f \circ \phi_i$? What is the relation between the two? What if the sets are topological spaces with modifications as in (b)?

XIII.14.5.14. Consider inverse limits $\varprojlim (X_n, \phi_{n+1,n})$ of Hausdorff spaces over $\mathbb{N}$. Let P be a property which is preserved under countable products and closed subspaces. Then if each X_n has P, so does the inverse limit. Examples of such properties are: first countability, second countability, metrizability, and compactness (cf. ()).

XIII.14.5.15. Uniqueness of the Cantor Set. A compactum is *perfect* if it has no isolated points. Prove the following theorem:

THEOREM. Every perfect zero-dimensional metrizable compactum is homeomorphic to the Cantor set.

(a) If X is a perfect zero-dimensional compactum, prove by induction that for each $k \in \mathbb{N}$, X can be partitioned into exactly k nonempty perfect clopen subsets.

(b) Let (X, ρ) be a perfect zero-dimensional compact metric space. For any $\epsilon > 0$, for all sufficiently large k X can be partitioned into exactly k nonempty perfect clopen subsets, each of diameter $< \epsilon$.

(c) Let (X, ρ) be a perfect zero-dimensional compact metric space. Let $\mathcal{P}_1$ be a partition of X into k_1 nonempty perfect clopen subsets $\{X_{1,1}, \ldots, X_{1,k_1}\}$, each of diameter < 1, where k_1 is a power of 2. Now divide each $X_{1,r}$ into k_2 nonempty perfect clopen sets, each of diameter $< \frac{1}{2}$, where k_2 is a power of 2. To avoid unwieldy notation, denote these sets by $\mathcal{P}_2 = \{X_{2,1}, \ldots, X_{2,m_2}\}$, where $m_2 = k_1 k_2$ is also a power of 2. Continue inductively to successively partition X into $\mathcal{P}_n = \{X_{n,1}, \ldots, X_{n,m_n}\}$ consisting of nonempty

perfect clopen sets of diameter $< \frac{1}{n}$, with m_n a power of 2, each partition refining the previous one and each set in the previous partition divided into the same number of subsets (a power of 2) in the new one.

(d) For each n let Y_n be a finite discrete space with m_n points, and let α_n be the map from X to Y_n sending the points of $X_{n,r}$ to the r'th point, i.e. identifying Y_n with the sets in $\mathcal{P}_n$. Let ϕ_{n+1} be the obvious map from Y_{n+1} to Y_n sending a point corresponding to a set in $\mathcal{P}_{n+1}$ to the point corresponding to the containing set in $\mathcal{P}_n$. Obtain a commutative diagram

$$\begin{array}{ccccccccc} X & & \cdots & \xrightarrow{id} & X & \xrightarrow{id} & X & \xrightarrow{id} & X \\ \vdots\,\alpha & & & & \downarrow{\scriptstyle \alpha_3} & & \downarrow{\scriptstyle \alpha_2} & & \downarrow{\scriptstyle \alpha_1} \\ Y & & \cdots & \xrightarrow{\phi_4} & Y_3 & \xrightarrow{\phi_3} & Y_2 & \xrightarrow{\phi_2} & Y_1 \end{array}$$

(e) Show that the induced map α from X to $Y = \varprojlim(Y_n, \phi_{n+1})$ is a homeomorphism, and that Y is homeomorphic to the Cantor set (XIII.14.4.11.).

XIII.14.5.16. Let Y be a zero-dimensional metrizable compactum, and K the Cantor set.

(a) Show that $Y \times K$ is a perfect zero-dimensional metrizable compactum, hence homeomorphic to K (XIII.14.5.15.).

(b) The first coordinate projection maps $Y \times K$ onto Y. Conclude that Y is a continuous image of K. Compare to XIII.13.6.7.(vi).

XIII.14.5.17. Prove the following theorem:

THEOREM. Every metrizable compactum is a continuous image of the Cantor set.

(a) Let (X, ρ) be a compact metric space. There is a finite open cover $\mathcal{U}_1$ of X where each $U \in \mathcal{U}_1$ has diameter < 1. Let Y_1 be the separated union of the $\{\bar{U} : U \in \mathcal{U}_1\}$. Then Y_1 is a compact metrizable space, using the restriction of ρ to each $\bar{U}$ and setting the distance between points of different $\bar{U}$ equal to 1. The $\bar{U}$ are clopen in Y_1. There is an obvious map α_1 from Y_1 onto X which is the identity on each $\bar{U}$.

(b) Similarly take a finite cover of each $\bar{U}$ by open sets of diameter $< \frac{1}{2}$ and let Y_2 be the separated union of the closures of all the sets covering the sets in Y_1. There is an obvious map ϕ_2 from Y_2 onto Y_1, and thus a map $\alpha_2 = \alpha_1 \circ \phi_2$ from Y_2 onto X. Continue inductively to get metrizable compacta Y_n, with each component of diameter $< \frac{1}{n}$, and a commutative diagram of inverse systems

$$\begin{array}{ccccccccc} Y & & \cdots & \xrightarrow{\phi_4} & Y_3 & \xrightarrow{\phi_3} & Y_2 & \xrightarrow{\phi_2} & Y_1 \\ \vdots\,\alpha & & & & \downarrow{\scriptstyle \alpha_3} & & \downarrow{\scriptstyle \alpha_2} & & \downarrow{\scriptstyle \alpha_1} \\ X & & \cdots & \xrightarrow{id} & X & \xrightarrow{id} & X & \xrightarrow{id} & X \end{array}$$

with $Y = \varprojlim(Y_n, \phi_{n+1})$ compact and metrizable and the induced map α surjective.

(c) Show that Y is zero-dimensional. [If p and q are distinct points of Y, there is an n such that the images in Y_n are distinct, and hence there is an $m > n$ such that the images are in different components.]

(d) Y need not be perfect. But by XIII.14.5.16., Y is a continuous image of the Cantor set.

XIII.14.5.18. The Hahn-Mazurkiewicz Theorem [,]. Prove the following theorem:

THEOREM. [HAHN-MAZURKIEWICZ THEOREM] A metrizable compactum X is a continuous image of $[0,1]$ if and only if X is connected and locally connected.

(a) A continuous image of $[0,1]$ is a connected, locally connected metrizable compactum ().

(b) If (X,ρ) is a locally connected compact metric space, show that X is *uniformly locally path connected*: For any $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $p, q \in X$ with $\rho(p,q) < \delta$, there is a path γ from p to q with $diam(\gamma) < \epsilon$. [Use ().]

(c) Let X be a connected, locally connected metrizable compactum. Regard the Cantor set K as a subset of $[0,1]$ in the usual way. Let ϕ be a map of K onto X (XIII.14.5.17.). Extend ϕ to a continuous function from $[0,1]$ onto X by successively defining it on each subinterval of $[0,1] \setminus K$ (note that X is path-connected by XIII.13.9.11. and XIII.13.9.17.), using (b) to obtain continuity of the extension.

XIII.14.5.19. Let $(X_i, \phi_{j,i})$ be an inverse system of compact Hausdorff spaces, X the inverse limit, and $\phi_i : X \to X_i$ the induced map for each i. Show that for each open neighborhood U of the diagonal in $X \times X$ there is an i such that $x, y \in X$ and $\phi_i(x) = \phi_i(y)$ implies $(x,y) \in U$. [If not, there is a U such that for each i there is $(x_i, y_i) \notin U$ with $\phi_i(x_i) = \phi_i(y_i)$. Let (x,y) be a cluster point of the net $((x_i, y_i))$. Show that $\phi_i(x) = \phi_i(y)$ for all i, so $x = y$, a contradiction.] In particular, if X is metrizable by a metric ρ, then for every $\epsilon > 0$ there is an i such that $x, y \in X$ and $\phi_i(x) = \phi_i(y)$ implies $\rho(x,y) < \epsilon$.

XIII.15. Uniform Spaces

The theory of uniform spaces and uniform structures fits somewhere between the theories of metric spaces and topological spaces. They are more general than metric spaces, but similarly give notions of uniform convergence and uniform continuity which are absent in general topological spaces. There is an underlying topology defined by a uniform structure, but the uniform structure is finer than the underlying topology since in general many different uniform structures can give the same topology, just as with metrics. Not every topology comes from a uniform structure; the ones that do turn out to be precisely the completely regular topologies.

There are two seemingly different standard approaches to the theory of uniform structures which turn out to be equivalent. One is based on metric spaces, the other on topological groups. The second approach seems more general, and it is remarkable that the two are actually the same (under some mild Choice assumptions).

The first approach uses a suitable family of pseudometrics. In the second approach, a uniform structure on a set X is a set of "neighborhoods" of the diagonal $\Delta = \{(x, x) : x \in X\}$ in $X \times X$, satisfying certain natural properties. Such a neighborhood W gives a uniform notion of closeness in X: x and y are "W-close" if $(x, y) \in W$. The two prototype examples of such systems are:

(i) If (X, ρ) is a metric space, then for every $\epsilon > 0$ there is a corresponding "neighborhood"

$$W_\epsilon^\rho = \{(x, y) : \rho(x, y) < \epsilon\}$$

of Δ in $X \times X$.

(ii) If X is a topological group, and U is a neighborhood of the identity element in X, then there is a corresponding "neighborhood"

$$W_U = \{(x, y) : xy^{-1} \in U\}$$

of Δ in $X \times X$.

If $X = \mathbb{R}$, these two types of neighborhoods are essentially the same if $\mathbb{R}$ is regarded as a metric space with the standard metric, or as a topological group under addition; a typical "neighborhood" of Δ is

$$\{(x, y) \in \mathbb{R}^2 : |x - y| < \epsilon\}$$

for some fixed $\epsilon > 0$, which is geometrically an open strip of uniform width around the line $y = x$.

Uniform spaces in the modern sense were first defined and studied by A. Weil [Wei37].

XIII.15.1. Topologies and Uniform Structures Defined by Pseudometrics

A straightforward but powerful generalization of a metric space is a space with a family of pseudometrics. Recall () that a *pseudometric* on a set X is a function $\rho : X \times X \to [0, \infty)$ with all the properties of a metric except that $\rho(x, y) = 0$ does not necessarily imply that $x = y$.

XIII.15.1.1. A family of pseudometrics on a set X is simply a set $\mathcal{P} = \{\rho_i : i \in I\}$ of pseudometrics on X. The family $\mathcal{P}$ is called *separating* if $\rho_i(x, y) = 0$ for all i implies that $x = y$, i.e. for any distinct $x, y \in X$ there is an i such that $\rho_i(x, y) > 0$.

Note that a single metric on a set can be regarded as a separating family of pseudometrics with one element.

We will think of a family of pseudometrics on a set X as defining a *uniform structure* on X; this will be made precise in ().

XIII.15.1.2. To each pseudometric ρ on a set X we can associate open balls $B_\epsilon^\rho(x) = \{y \in X : \rho(x,y) < \epsilon\}$, just as in the metric case. If we have a family $\mathcal{P}$ of pseudometrics, we may take the set of all open balls with respect to the pseudometrics in $\mathcal{P}$ as a subbase for a topology, called the *topology induced by* $\mathcal{P}$, denoted $\mathcal{T}_\mathcal{P}$. These open balls do not form a base for $\mathcal{T}_\mathcal{P}$ in general if $\mathcal{P}$ contains more than one pseudometric, but finite intersections do, i.e. sets of the form

$$B_\epsilon^F(x) = \{y \in X : \rho_i(x,y) < \epsilon \text{ for all } i \in F\}$$

where F is a finite subset of I and $\epsilon > 0$, form a base for $\mathcal{T}_\mathcal{P}$, i.e. a subset U of X is open if and only if, for every $x \in U$, there is a finite subset F of I and and $\epsilon > 0$ such that $B_\epsilon^F(x) \subseteq U$. (We will also use the analogous notation $B_\epsilon^\mathcal{F}(x)$, for a finite subset $\mathcal{F}$ of $\mathcal{P}$.)

Exactly as in the metric case (), using the triangle inequality every open ball has this property, hence is an open set.

XIII.15.1.3. Convergence in the topology $\mathcal{T}_\mathcal{P}$ is easily described. If (x_i) is a net in X and $x \in X$, then $x_i \to x$ in $(X, \mathcal{T}_\mathcal{P})$ if and only if $\rho(x_i, x) \to 0$ for every $\rho \in \mathcal{P}$, i.e. if and only if for every $\rho \in \mathcal{P}$ and $\epsilon > 0$ there is an i_0 such that $\rho(x_i, x) < \epsilon$ for all $i \geq i_0$.

The next observation generalizes the fact that a metrizable topology is Hausdorff:

XIII.15.1.4. PROPOSITION. Let $\mathcal{P}$ be a family of pseudometrics on a set X. Then the following are equivalent:

(i) $\mathcal{T}_\mathcal{P}$ is T_0.

(ii) $\mathcal{T}_\mathcal{P}$ is Hausdorff.

(iii) $\mathcal{P}$ is separating.

PROOF: If $\mathcal{P}$ is separating, for any $x, y \in X$, $x \neq y$, let $\rho \in \mathcal{P}$ with $\rho(x,y) > 0$, and set $\epsilon = \frac{\rho(x,y)}{2}$. Then $B_\epsilon^\rho(x)$ and $B_\epsilon^\rho(y)$ are disjoint open neighborhoods of x and y, so $\mathcal{T}_\mathcal{P}$ is Hausdorff. If $\mathcal{P}$ is not separating, let $x, y \in X$, $x \neq y$, with $\rho(x,y) = 0$ for all $\rho \in \mathcal{P}$. Then any open set containing x also contains y and vice versa, so $\mathcal{T}_\mathcal{P}$ is not T_0. 👍

Uniform Domination and Saturated Families

We need some tools to compare families of pseudometrics, generalizations of the notions of uniform domination and uniform equivalence of metrics ().

XIII.15.1.5. DEFINITION. Let $\rho_1, \ldots, \rho_n, \sigma$ be pseudometrics on a set X. Then σ is *uniformly dominated by* $\{\rho_1, \ldots, \rho_n\}$ if for every $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $x, y \in X$ and $\rho_k(x,y) < \delta$ for $1 \leq k \leq n$, then $\sigma(x,y) < \epsilon$.

If $\mathcal{P}$ is a family of pseudometrics on X, then σ is *uniformly dominated by* $\mathcal{P}$ if for every $\epsilon > 0$ there is a $\delta > 0$ and a finite subset $\{\rho_1, \ldots, \rho_n\}$ of $\mathcal{P}$ such that, whenever $x, y \in X$ and $\rho_k(x,y) < \delta$ for $1 \leq k \leq n$, then $\sigma(x,y) < \epsilon$.

If $\mathcal{P}$ and $\mathcal{Q}$ are families of pseudometrics on X, then $\mathcal{Q}$ is *uniformly dominated by* $\mathcal{P}$ if every $\sigma \in \mathcal{Q}$ is uniformly dominated by $\mathcal{P}$. $\mathcal{P}$ and $\mathcal{Q}$ are *uniformly equivalent* if each is uniformly dominated by the other.

A family $\mathcal{P}$ of pseudometrics on X is *saturated* if every pseudometric on X which is uniformly dominated by $\mathcal{P}$ is in $\mathcal{P}$.

XIII.15.1.6. PROPOSITION. Let $\mathcal{P}$ be a family of pseudometrics on a set X. Then there is a smallest saturated family $\bar{\mathcal{P}}$ of pseudometrics on X containing $\mathcal{P}$. $\bar{\mathcal{P}}$ consists precisely of all pseudometrics on X which are uniformly dominated by $\mathcal{P}$.

If $\mathcal{Q}$ is another family of pseudometrics on X, then $\mathcal{Q}$ is uniformly dominated by $\mathcal{P}$ if and only if $\bar{\mathcal{Q}} \subseteq \bar{\mathcal{P}}$, and $\mathcal{P}$ and $\mathcal{Q}$ are uniformly equivalent if and only if $\bar{\mathcal{P}} = \bar{\mathcal{Q}}$. In particular, $\mathcal{P}$ and $\bar{\mathcal{P}}$ are uniformly equivalent.

The proof is left as an exercise (Exercise ()).

XIII.15.1.7. PROPOSITION. Let $\mathcal{P}$ and $\mathcal{Q}$ be families of pseudometrics on a set X. If $\mathcal{Q}$ is uniformly dominated by $\mathcal{P}$, then $\mathcal{T}_{\mathcal{P}}$ is stronger than $\mathcal{T}_{\mathcal{Q}}$. If $\mathcal{P}$ and $\mathcal{Q}$ are uniformly equivalent, then $\mathcal{T}_{\mathcal{P}} = \mathcal{T}_{\mathcal{Q}}$. In particular, $\mathcal{T}_{\bar{\mathcal{P}}} = \mathcal{T}_{\mathcal{P}}$.

PROOF: Let $\sigma \in \mathcal{Q}$, $x \in X$, and $\epsilon > 0$. Choose $\delta > 0$ and $\mathcal{F} = \{\rho_1, \ldots, \rho_n\}$ as in the definition. Then $B^{\mathcal{F}}_{\delta}(x) \subseteq B^{\sigma}_{\epsilon}(x)$. 👍

XIII.15.1.8. The converse of XIII.15.1.7. is false in general: families of pseudometrics generating the same topology need not be uniformly equivalent, even if they are singletons (metrics can be equivalent but not uniformly equivalent ()). Two families of pseudometrics generating the same topology are called *equivalent*. Equivalent but not uniformly equivalent families generate the same topology, but different uniform structures; thus uniform structures are more delicate than topologies.

XIII.15.1.9. In light of XIII.15.1.7., there is no loss of generality in considering only saturated families of pseudometrics. There is some technical advantage in working with saturated families: for example, the open balls form a base for the underlying topology instead of just a subbase. In fact, the open balls from a saturated family frequently give all, or almost all, of the open sets in the topology (they precisely give all the cozero sets, hence all open F_σ's if the space is normal). And the ϵ can be dispensed with in considering open balls from a saturated family $\mathcal{P}$: since a saturated family of pseudometrics is closed under nonnegative scalar multiples, any ball of the form $B^{\rho}_{\epsilon}(x)$ for $\rho \in \mathcal{P}$ is of the form $B^{\sigma}_{1}(x)$ for some $\sigma \in \mathcal{P}$ (specifically, $\sigma = \epsilon\rho$), so only balls of radius 1 need be considered.

Uniform Continuity

Uniform structures give a notion of uniform continuity and uniform convergence for functions between uniform spaces.

XIII.15.1.10. DEFINITION. Let X and Y be sets, and $\mathcal{P}$ and $\mathcal{Q}$ sets of pseudometrics on X and Y respectively. A function $f : X \to Y$ is $(\mathcal{P}, \mathcal{Q})$-*uniformly continuous* if, for each $\sigma \in \mathcal{Q}$ the pseudometric $\rho_{f,\sigma}$ on X is uniformly dominated by $\mathcal{P}$, where

$$\rho_{f,\sigma}(p, q) = \sigma(f(p), f(q)) \ .$$

XIII.15.1.11. In other words, f is uniformly continuous if and only if for each $\sigma \in \mathcal{Q}$ and $\epsilon > 0$, there is a $\delta > 0$ and $\rho_1, \ldots, \rho_n \in \mathcal{P}$ such that, whenever $\rho_k(x, y) < \delta$ for $1 \leq k \leq n$, then $\sigma(f(p), f(q)) < \epsilon$.

If $\mathcal{P}$ and $\mathcal{Q}$ are singletons consisting of metrics, this is precisely the usual notion of uniform continuity with respect to the metrics (). The condition in the definition works equally for a finite set $\{\sigma_1, \ldots, \sigma_m\}$ of pseudometrics in $\mathcal{Q}$.

XIII.15.1.12. PROPOSITION. Let X, Y, Z be sets, and $\mathcal{P}, \mathcal{Q}, \mathcal{R}$ sets of pseudometrics on X, Y, Z respectively. If $f : X \to Y$ is $(\mathcal{P}, \mathcal{Q})$-uniformly continuous and $g : Y \to Z$ is $(\mathcal{Q}, \mathcal{R})$-uniformly continuous, then $g \circ f$ is $(\mathcal{P}, \mathcal{R})$-uniformly continuous.

$(\mathcal{P}, \mathcal{Q})$-Uniform continuity depends on $\mathcal{P}$ and $\mathcal{Q}$ only up to uniform equivalence:

XIII.15.1.13. PROPOSITION. Let X and Y be sets, and $\mathcal{P}$ and $\mathcal{Q}$ sets of pseudometrics on X and Y respectively. A function $f : X \to Y$ is $(\mathcal{P}, \mathcal{Q})$-uniformly continuous if and only if it is $(\bar{\mathcal{P}}, \bar{\mathcal{Q}})$-uniformly continuous. Thus if $\mathcal{P}_1$ and $\mathcal{P}_2$ [resp. $\mathcal{Q}_1$ and $\mathcal{Q}_2$] are uniformly equivalent families of pseudometrics on X [resp. Y], and $f : X \to Y$, then f is $(\mathcal{P}_1, \mathcal{Q}_1)$-uniformly continuous if and only if it is $(\mathcal{P}_2, \mathcal{Q}_2)$-uniformly continuous.

More generally, we have:

XIII.15.1.14. PROPOSITION. Let X and Y be sets. If $\mathcal{P}_1$ and $\mathcal{P}_2$ [resp. $\mathcal{Q}_1$ and $\mathcal{Q}_2$] are families of pseudometrics on X [resp. Y] such that $\mathcal{P}_1$ uniformly dominates $\mathcal{P}_2$ and $\mathcal{Q}_2$ uniformly dominates $\mathcal{Q}_1$, and $f : X \to Y$ is $(\mathcal{P}_2, \mathcal{Q}_2)$-uniformly continuous, then f is $(\mathcal{P}_1, \mathcal{Q}_1)$-uniformly continuous.

Uniformly continuous functions are continuous:

XIII.15.1.15. PROPOSITION. Let X and Y be sets, and $\mathcal{P}$ and $\mathcal{Q}$ sets of pseudometrics on X and Y respectively. If a function $f : X \to Y$ is $(\mathcal{P}, \mathcal{Q})$-uniformly continuous, then f is continuous for $\mathcal{T}_{\mathcal{P}}$ and $\mathcal{T}_{\mathcal{Q}}$.

The converse is false in general, even if $\mathcal{P}$ and $\mathcal{Q}$ are singletons.

Uniform Convergence

Let X and Y be sets, and $\mathcal{Q}$ a set of pseudometrics on Y. Let (f_i) be a net of functions from X to Y, and f a function from X to Y. We do not make any continuity assumptions on the f_i or f; indeed, X need not have any uniform or topological structure.

XIII.15.1.16. DEFINITION. We say $f_i \to f$ *$\mathcal{Q}$-uniformly* if for every $\sigma \in \mathcal{Q}$ and $\epsilon > 0$, there is a i_0 such that $\sigma(f_i(x), f(x)) < \epsilon$ for all $i \geq i_0$ and all $x \in X$.

If $\mathcal{Q} = \{\sigma\}$, this definition agrees with the one in ().

The next result generalizes () and ().

XIII.15.1.17. Let X and Y be sets, and $\mathcal{P}$ and $\mathcal{Q}$ sets of pseudometrics on X and Y respectively. Let (f_i) be a net of functions from X to Y converging $(\mathcal{P}, \mathcal{Q})$-uniformly to $f : X \to Y$. Then:

(i) If each f_i is $(\mathcal{T}_\mathcal{P}, \mathcal{T}_\mathcal{Q})$-continuous, then f is $(\mathcal{T}_\mathcal{P}, \mathcal{T}_\mathcal{Q})$-continuous.

(ii) If each f_i is $(\mathcal{P}, \mathcal{Q})$-uniformly continuous, then f is $(\mathcal{P}, \mathcal{Q})$-uniformly continuous.

Bounded Pseudometrics

XIII.15.1.18. If ρ is a pseudometric on a set X, then $\tilde{\rho}$, defined by

$$\tilde{\rho}(x, y) = \min\{\rho(x, y), 1\}$$

is a bounded pseudometric on X which is uniformly equivalent to ρ. So if $\mathcal{P}$ is a family of pseudometrics on X, define

$$\tilde{\mathcal{P}} = \{\tilde{\rho} : \rho \in \mathcal{P}\} \ .$$

Then $\tilde{\mathcal{P}}$ is a family of bounded pseudometrics which is uniformly equivalent to $\mathcal{P}$. (Note, however, that $\tilde{\mathcal{P}}$ is never saturated unless $\mathcal{P} = \{0\}$, so if $\mathcal{P}$ is saturated and nonzero, then $\tilde{\mathcal{P}} \neq \mathcal{P}$; in fact, $\tilde{\mathcal{P}}$ is a proper subset of $\mathcal{P}$ in this case.) Thus we may always work with families of pseudometrics taking values in $[0, 1]$.

Countably Generated Families of Pseudometrics

XIII.15.1.19. If $\mathcal{P} = \{\rho_1, \rho_2, \dots\}$ is a countable family of pseudometrics on a set X, define a pseudometric σ by

$$\sigma(x, y) = \sum_{k=1}^{\infty} 2^{-k} \tilde{\rho}_k(x, y)$$

(it is routine and straightforward to verify that σ is a pseudometric).

XIII.15.1.20. PROPOSITION. The pseudometric σ is finitely uniformly dominated by $\mathcal{P}$.

PROOF: Let $\epsilon > 0$. Choose n so that $2^{-n+1} < \epsilon$. Set $\delta = \frac{\epsilon}{2n}$, and $\mathcal{F} = \{\rho_1, \dots, \rho_n\}$. Then, if $x, y \in X$ satisfy $\rho_k(x, y) < \delta$ for $1 \leq k \leq n$, we have

$$\sigma(x, y) = \sum_{k=1}^{n} 2^{-k} \tilde{\rho}_k(x, y) + \sum_{k=n+1}^{\infty} 2^{-k} \tilde{\rho}_k(x, y) < n\delta + 2^{-n} < \epsilon \ .$$

XIII.15.1.21. Conversely, it is obvious that each ρ_k is finitely uniformly dominated by $\mathcal{Q} = \{\sigma\}$. So $\mathcal{Q}$ is a singleton family which is uniformly equivalent to $\mathcal{P}$, so in particular $\mathcal{T}_\mathcal{Q} = \mathcal{T}_\mathcal{P}$. Thus a uniform structure generated by a countable family of pseudometrics is equivalent to the uniform structure generated by a singleton.

The pseudometric σ is a metric if and only if $\mathcal{P}$ is separating. Thus the uniform structure generated by a countable separating family of pseudometrics is also generated by a single metric. In particular, a topology defined by a countable separating family of pseudometrics is metrizable.

XIII.15.1.22. Slightly more generally, a family $\mathcal{P}$ of pseudometrics is *countably generated* if there is a countable family $\mathcal{Q}$ of pseudometrics uniformly equivalent to $\mathcal{P}$. A uniform structure generated by a countably generated family of pseudometrics is also generated by one pseudometric (one metric if the family is separating).

XIII.15.1.23. So the theory of uniform structures generated by families of pseudometrics is technically only a true generalization of the theory of metric spaces in that it allows families of pseudometrics which are not countably generated (as well as families which are not separating). However, as a practical matter the theory has merit even in the countably generated case: a metrizable space often has no *natural* metric, and a choice of a metric is arbitrary; but it may, and often does, have a natural family of pseudometrics generating the topology (cf. ()).

Pseudometrics and Real-Valued Functions

There is an intimate connection between pseudometrics and real-valued functions on a set.

XIII.15.1.24. Let X be a set. If f is a function from X to $\mathbb{R}$, then there is a naturally associated pseudometric ρ_f defined by

$$\rho_f(x, y) = |f(x) - f(y)| \ .$$

Conversely, if ρ is a pseudometric on X, and $x \in X$, there is an associated nonnegative real-valued function $f_{\rho,x}$ defined by

$$f_{\rho,x}(y) = \rho(x, y) \ .$$

XIII.15.1.25. If $f : X \to \mathbb{R}$ is a function, then f is (essentially by definition) uniformly continuous with respect to any family of pseudometrics on X containing ρ_f (and the usual metric on $\mathbb{R}$). Conversely, if ρ is a pseudometric on X, then it follows easily from the triangle inequality that, for any $x \in X$, $f_{\rho,x}$ is uniformly continuous with respect to any family of pseudometrics on X containing ρ.

XIII.15.1.26. Proposition. Let $\mathcal{P}$ be a family of pseudometrics on a set X. Then $\mathcal{T}_\mathcal{P}$ is the weakest topology on X making each function $f_{\rho,x}$ continuous, for all $\rho \in \mathcal{P}$ and $x \in X$.

XIII.15.1.27. COROLLARY. Let $\mathcal{P}$ be a separating family of pseudometrics on a set X. Then the topology $\mathcal{T}_{\mathcal{P}}$ is completely regular. Conversely, every completely regular space has a separating family of pseudometrics giving its topology.

PROOF: The proof is similar to the proof of (). Replacing $\mathcal{P}$ by $\tilde{\mathcal{P}}$ if necessary, we may assume every $\rho \in \mathcal{P}$ takes values in $[0,1]$, so $f_{\rho,x}$ takes values in $[0,1]$ for all ρ and x. Let $\mathcal{S}$ be the set of all $f_{\rho,x}$ for $\rho \in \mathcal{P}$, $x \in X$, and set $Z = [0,1]^{\mathcal{S}}$. Then Z is a compact Hausdorff space.

Define $\phi : X \to Z$ as follows. For each $y \in X$, let $\phi(y)$ be the point in Z whose $f_{\rho,x}$'th coordinate is $f_{\rho,x}(y) = \rho(x,y)$. Then ϕ is continuous for $\mathcal{T}_{\mathcal{P}}$ since its composition with each coordinate map is continuous, and ϕ is one-to-one since $\mathcal{P}$ is separating. The restriction of the topology on Z to $\phi(X)$ gives a topology on $\phi(X) \cong X$ which is weaker than $\mathcal{T}_{\mathcal{P}}$ for which each $f_{\rho,x}$ is continuous; thus this topology is exactly $\mathcal{T}_{\mathcal{P}}$, i.e. ϕ is a homeomorphism onto its image. Thus $(X, \mathcal{T}_{\mathcal{P}})$ is homeomorphic to a subspace of a compact Hausdorff space.

Conversely, if X is completely regular, for each $x \in X$ and open neighborhood U of x there is a function $f_{x,U}$ with $f_{x,U}(x) = 1$ and $f_{x,U} = 0$ on U^c. It is easily checked that the corresponding set of pseudometrics define the topology of X. 👍

Pseudometrics and Continuous Functions

XIII.15.1.28. Now let $(X, \mathcal{T})$ be a topological space. Set

$$\mathcal{C} = \{\rho_f : f \text{ is a continuous function from } X \text{ to } \mathbb{R}\}$$

$$\mathcal{C}^* = \{\rho_f : f \text{ is a continuous function from } X \text{ to } [0,1]\} .$$

Then the topologies $\mathcal{T}_{\mathcal{C}}$ and $\mathcal{T}_{\mathcal{C}^*}$ coincide and are weaker than $\mathcal{T}$. $\mathcal{T}_{\mathcal{C}}$ may be strictly weaker: if $\mathcal{C}$ (or equivalently $\mathcal{C}^*$) is separating, i.e. if continuous functions from X to $\mathbb{R}$ separate points of X, then $\mathcal{T}_{\mathcal{C}}$ is completely regular, but $\mathcal{T}$ need not be completely regular even if it is regular (XIII.7.10.21.). $\mathcal{T}_{\mathcal{C}}$ is the strongest completely regular topology weaker than $\mathcal{T}$ (if $\mathcal{C}$ is separating); in particular, $\mathcal{T} = \mathcal{T}_{\mathcal{C}}$ if $\mathcal{T}$ is completely regular. If $\mathbb{R}$ is given its uniform structure from the usual metric ρ, then every continuous function from X to $\mathbb{R}$ is $(\mathcal{C}, \rho)$-uniformly continuous, and every bounded continuous function from X to $\mathbb{R}$ is $(\mathcal{C}^*, \rho)$-uniformly continuous.

XIII.15.1.29. Even if $(X, \mathcal{T})$ is metrizable, the families $\mathcal{C}$ and $\mathcal{C}^*$ are not countably generated in general, and thus are not uniformly equivalent to a singleton family. The families $\mathcal{C}$ and $\mathcal{C}^*$ are not saturated in general.

The pseudometrics in $\mathcal{C}^*$ are all bounded, and the ones in $\mathcal{C}$ are not in general. One might think that $\mathcal{C}^*$ is essentially the same as $\tilde{\mathcal{C}}$ (XIII.15.1.18.), but this is usually not correct; in fact, $\mathcal{C}^*$ is not even uniformly equivalent to $\tilde{\mathcal{C}}$ (which is uniformly equivalent to $\mathcal{C}$) in general (). ✋

Products of Pseudometric Uniform Structures

XIII.15.1.30. Let $\{X_i : i \in I\}$ be an indexed collection of sets, and for each i let $\mathcal{P}_i$ be a set of pseudometrics on X_i. Set $X = \prod_{i \in I} X_i$, and for each i let π_i be the coordinate projection from X to X_i. Then π_i is surjective for each i (if $X \neq \emptyset$), cf. II.6.4.14.. For each i define

$$\mathcal{P}_i \circ \pi_i = \{\rho \circ (\pi_i \times \pi_i) : \rho \in \mathcal{P}_i\}$$

i.e. $\mathcal{P}_i \circ \pi_i$ consists of all pseudometrics on X of the form $\sigma((x_j),(y_j)) = \rho(x_i, y_i)$ for $\rho \in \mathcal{P}_i$, and set $\mathcal{P} = \cup_{i\in I}(\mathcal{P}_i \circ \pi_i)$. Then $\mathcal{P}$ is a set of pseudometrics on X. The uniform structure on X from $\mathcal{P}$ is called the *product uniform structure*.

XIII.15.1.31. PROPOSITION. (i) The topology $\mathcal{T}_{\mathcal{P}}$ is the product topology of the $\mathcal{T}_{\mathcal{P}_i}$.
(ii) If Y is a set and $\mathcal{Q}$ a set of pseudometrics on Y, then a function $f : Y \to X$ is $(\mathcal{Q}, \mathcal{P})$-uniformly continuous if and only if $\pi_i \circ f$ is $(\mathcal{Q}, \mathcal{P}_i)$-uniformly continuous for each $i \in I$.

XIII.15.2. General Uniform Structures

We now turn to the second approach which seems to be more general, although it turns out to actually be equivalent (under a mild Choice assumption). This approach is due to BOURBAKI [Bou40]; our exposition is adapted from [Kel75].

XIII.15.2.1. DEFINITION. Let X be a set. A *uniform structure*, or *uniformity*, on X is a nonempty set $\mathfrak{U}$ of subsets of $X \times X$, called *entourages*, such that

(i) Every $U \in \mathfrak{U}$ contains the diagonal $\Delta = \{(x, x) : x \in X\}$.

(ii) If $U \in \mathfrak{U}$, then $U^{-1} = \{(y, x) : (x, y) \in U\} \in \mathfrak{U}$.

(iii) If $U, V \in \mathfrak{U}$, then $U \cap V \in \mathfrak{U}$.

(iv) For every $U \in \mathfrak{U}$, there is a $V \in \mathfrak{U}$ with $V \circ V \subseteq U$.

(v) If $U \in \mathfrak{U}$ and $U \subseteq V \subseteq X \times X$, then $V \in \mathfrak{U}$.

The uniform structure $\mathfrak{U}$ is *separating* if $\cap_{U\in\mathfrak{U}} U = \Delta$.

A pair $(X, \mathfrak{U})$, where X is a set and $\mathfrak{U}$ a uniform structure on X, is called a *uniform space*.

XIII.15.2.2. The entourages (elements of $\mathfrak{U}$) are relations on X, and by (i) the relations are reflexive. The composition in (iv) is in the sense of relations, i.e.

$$V \circ V = \{(x, z) : x, z \in X, \exists y \in X \text{ with } (x, y), (y, z) \in V\} .$$

Such composition is associative. Note that if $U, V \in \mathfrak{U}$, then $U, V \subseteq U \circ V$ since $\Delta \subseteq U, V$. So if $U \in \mathfrak{U}$, there is a $V \in \mathfrak{U}$ with $V \circ V \subseteq U$, and a $W \in \mathfrak{U}$ with $W \circ W \subseteq V$. Thus

$$W \circ W \circ W \subseteq W \circ W \circ W \circ W \subseteq V \circ V \subseteq U$$

and similarly for each n there is a $Z \in \mathfrak{U}$ with $Z^n = Z \circ \cdots \circ Z$ (n times) $\subseteq U$.

By (i), (iii), and (v), a uniform structure is a filter () on $X \times X$. The elements of $\mathfrak{U}$ should be thought of as "neighborhoods of Δ" in $X \times X$; condition (iv) is a weak version of the triangle inequality. The sets in $\mathfrak{U}$ should not necessarily be considered "open" sets: indeed, in general, there is no topology in the picture (yet!)

XIII.15.2.3. Any set X has a largest uniformity, namely the collection of all subsets of $X \times X$ containing Δ, called the *discrete uniformity*, and a smallest uniformity, $\{X \times X\}$, called the *indiscrete uniformity*. The discrete uniformity is separating, but the indiscrete one not unless X is a singleton.

Bases and Subbases

XIII.15.2.4. If X is a set, then a union or intersection of uniformities is not necessarily a uniformity (the problem with unions is (iii), and the problem with intersections is (iv)), and if $\mathcal{S}$ is a collection of subsets of $X \times X$ containing Δ, there is not in general a smallest uniformity on X containing $\mathcal{S}$. But we can still define bases and subbases for uniformities in a way analogous to the definitions for topologies, but somewhat simpler since there is no notion of a local base (in fact, there is no notion of "local" in uniform spaces – everything is "uniform"!)

XIII.15.2.5. Definition. Let $\mathfrak{U}$ be a uniform structure on a set X.

(i) A subset $\mathfrak{B}$ of $\mathfrak{U}$ is a *base* for $\mathfrak{U}$ if for every $U \in \mathfrak{U}$ there is a $B \in \mathfrak{B}$ with $B \subseteq U$ (i.e. $\mathfrak{B}$ is a filterbase for $\mathfrak{U}$).

(ii) A subset $\mathfrak{S}$ of $\mathfrak{U}$ is a *subbase* for $\mathfrak{U}$ if the set of finite intersections of elements of $\mathfrak{S}$ is a base for $\mathfrak{U}$.

XIII.15.2.6. If $\mathfrak{B}$ is a base for a uniformity $\mathfrak{U}$, the uniformity $\mathfrak{U}$ is uniquely determined by $\mathfrak{B}$ as the set of all subsets of $X \times X$ containing an element of $\mathfrak{B}$, and $\mathfrak{U}$ is the smallest uniformity containing $\mathfrak{B}$. Similarly, if $\mathfrak{S}$ is a subbase for $\mathfrak{U}$, then $\mathfrak{U}$ is uniquely determined as the smallest uniformity containing $\mathfrak{S}$.

There is a clean description of which subsets of $X \times X$ are bases for uniformities:

XIII.15.2.7. Proposition. Let X be a set and $\mathfrak{B}$ a collection of subsets of $X \times X$. Then $\mathfrak{B}$ is a base for a uniformity on X (which is unique) if and only if $\mathfrak{B}$ has the following properties:

(i) $\Delta \subseteq B$ for all $B \in \mathfrak{B}$.

(ii) If $B \in \mathfrak{B}$, then there is a $C \in \mathfrak{B}$ with $C \subseteq B^{-1}$.

(iii) If $B_1, B_2 \in \mathfrak{B}$, there is a $C \in \mathfrak{B}$ with $C \subseteq B_1 \cap B_2$.

(iv) For any $B \in \mathfrak{B}$, there is a $C \in \mathfrak{B}$ with $C \circ C \subseteq B$.

Conditions (ii)–(iv) can be combined into one condition:

(v) If $B_1, B_2 \in \mathfrak{B}$, there is a $C \in \mathfrak{B}$ with $C \circ C \subseteq (B_1 \cap B_1^{-1}) \cap (B_2 \cap B_2^{-1})$.

There is not a clean characterization for which collections of subsets of $X \times X$ are subbases for a uniformity (XIII.15.2.1.(iv) makes it clumsy to give a characterization). However, there is a useful set of sufficient conditions:

XIII.15.2.8. PROPOSITION. Let X be a set and $\mathfrak{S}$ a collection of subsets of $X \times X$. Then $\mathfrak{S}$ is a subbase for a uniformity on X (which is uniquely defined) if $\mathfrak{S}$ has the following properties:

(i) $\Delta \subseteq S$ for all $S \in \mathfrak{S}$.

(ii) If $S \in \mathfrak{S}$, then there is a $T \in \mathfrak{S}$ with $T \subseteq S^{-1}$.

(iii) For any $S \in \mathfrak{S}$, there is a $T \in \mathfrak{S}$ with $T \circ T \subseteq S$.

The union of any collection of uniformities (or subbases for uniformities) is a subbase for a uniformity.

XIII.15.2.9. A subset U of $X \times X$ is *symmetric* if $U = U^{-1}$ (i.e. the relation is symmetric). If $V \circ V \subseteq U$, then $V^{-1} \circ V^{-1} \subseteq U^{-1}$, and so $(V \cap V^{-1}) \circ (V \cap V^{-1}) \subseteq U \cap U^{-1}$. It follows that if $\mathfrak{B}$ is a base for a uniformity $\mathfrak{U}$, and we set

$$\mathfrak{B}_s = \{B \cap B^{-1} : B \in \mathfrak{B}\}$$

then $\mathfrak{B}_s$ is a base for $\mathfrak{U}$ consisting of symmetric sets. A similar statement holds for subbases. Thus we can almost entirely restrict attention to symmetric sets in the theory of uniform spaces.

The Uniformity of a Set of Pseudometrics

One of the most fundamental examples of a uniform structure is generated by a family of pseudometrics. In fact, it turns out (under a mild Choice hypothesis) that every uniformity is of this form.

XIII.15.2.10. Let X be a set and $\mathcal{P}$ a set of pseudometrics on X. For each $\rho \in \mathcal{P}$ and $r > 0$, set

$$V_r^\rho = \{(x, y) \in X \times X : \rho(x, y) < r\} .$$

If $\rho \in \mathcal{P}$ and $r, s > 0$, then $V_r^\rho \circ V_s^\rho \subseteq V_{r+s}^\rho$ by the triangle inequality, and in particular $V_{r/2}^\rho \circ V_{r/2}^\rho \subseteq V_r^\rho$ (this is motivation for including (iv) in definition XIII.15.2.1. and for calling it a "weak triangle inequality"). Thus

$$\mathfrak{S}_\mathcal{P} = \{V_r^\rho : \rho \in \mathcal{P}, r > 0\}$$

satisfies XIII.15.2.8.. It obviously satisfies (i) and (ii) (in fact, $[V_r^\rho]^{-1} = V_r^\rho$), so $\mathfrak{S}$ is a subbase for a unique uniformity $\mathfrak{U}_\mathcal{P}$ on X, called the *uniformity of* $\mathcal{P}$ or the *uniformity generated by* $\mathcal{P}$. If $\mathcal{P} = \{\rho\}$, write $\mathfrak{U}_\rho$ for $\mathfrak{U}_{\{\rho\}}$. In this case, $\mathfrak{S}_\rho$ is a base for $\mathfrak{U}_\rho$.

XIII.15.2.11. If $\mathcal{P}$ is a set of pseudometrics on a set X, σ is a pseudometric on X, and $\epsilon > 0$, if σ is uniformly dominated by $\mathcal{P}$ there are $\rho_1, \ldots, \rho_n \in \mathcal{P}$ and $\delta > 0$ such that $V_\delta^{\rho_1} \cap \cdots \cap V_\delta^{\rho_n} \subseteq V_\epsilon^\sigma$, and hence $V_\epsilon^\sigma \in \mathfrak{U}_\mathcal{P}$. So $\mathfrak{U}_\sigma \subseteq \mathfrak{U}_\mathcal{P}$. The converse is true by the same argument. It follows that if $\mathcal{Q}$ is another set of pseudometrics on X, then $\mathfrak{U}_\mathcal{Q} \subseteq \mathfrak{U}_\mathcal{P}$ if and only if $\mathcal{Q}$ is uniformly dominated by $\mathcal{P}$. Thus $\mathfrak{U}_\mathcal{Q} = \mathfrak{U}_\mathcal{P}$ if and only if $\mathcal{P}$ and $\mathcal{Q}$ are uniformly equivalent. In particular, $\mathfrak{U}_\mathcal{P} = \mathfrak{U}_{\bar{\mathcal{P}}}$, and $\bar{\mathcal{P}}$ is the unique saturated set of pseudometrics generating $\mathfrak{U}_\mathcal{P}$.

XIII.15.2.12. DEFINITION. If $\mathfrak{U}$ is a uniform structure on a set X, and $\bar{\mathcal{P}}$ is a saturated set of pseudometrics on X for which $\mathfrak{U} = \mathfrak{U}_{\bar{\mathcal{P}}}$, then $\bar{\mathcal{P}}$ is the unique saturated set with this property and is called the *gauge* of $\mathfrak{U}$ (some references spell this *gage*).

We will see later () that (under a mild Choice assumption) every uniform structure has a gauge.

The Topology of a Uniformity

If $\mathfrak{U}$ is a uniform structure on a set X, $\mathfrak{U}$ induces a compatible topology on X. If $S \subseteq X \times X$, for $x \in X$ we will use the notation $S[x]$ to denote $S(\{x\}) = \{y \in X : (x, y) \in S\}$.

XIII.15.2.13. DEFINITION. Let $\mathfrak{U}$ be a uniform structure on X. Let $\mathcal{T}_{\mathfrak{U}}$ be the collection of all sets V with the property that for every $x \in V$, there is a $U \in \mathfrak{U}$ with $U[x] \subseteq V$.

This definition is the analog of the definition of the topology of a metric space: a set is open if and only if it contains an open ball around each of its points. In fact, it is easily seen that if $\mathcal{P}$ is a set of pseudometrics on X, then $\mathcal{T}_{\mathfrak{U}_{\mathcal{P}}} = \mathcal{T}_{\mathcal{P}}$ as defined in XIII.15.1.2..

The condition can be equivalently expressed using a base $\mathfrak{B}$ for $\mathfrak{U}$: $V \in \mathcal{T}_{\mathfrak{U}}$ if and only if, for each $x \in V$, there is a $B \in \mathfrak{B}$ with $B[x] \subseteq V$.

XIII.15.2.14. PROPOSITION. Let $(X, \mathfrak{U})$ be a uniform space. Then

(i) $\mathcal{T}_{\mathfrak{U}}$ is a topology on X.

(ii) Every set in $\mathfrak{U}$ is a neighborhood of Δ with respect to the product topology on $X \times X$, and $\mathcal{T}_{\mathfrak{U}}$ is the smallest topology on X for which this holds.

XIII.15.2.15. Note though that the sets in $\mathfrak{U}$ are not generally open in the product topology, because of XIII.15.2.1.(v) (we use the convention from () that neighborhoods are not necessarily open).

XIII.15.2.16. PROPOSITION. Let $(X, \mathfrak{U})$ be a uniform space, and $\mathcal{T}_{\mathfrak{U}}$ the corresponding uniform topology. The following are equivalent:

(i) $\mathcal{T}_{\mathfrak{U}}$ is T_0.

(ii) $\mathcal{T}_{\mathfrak{U}}$ is Hausdorff.

(iii) $\mathfrak{U}$ is separating.

XIII.15.2.17. Let $\mathcal{T}$ be a topology on X. If there is a uniformity $\mathfrak{U}$ such that $\mathcal{T}_{\mathfrak{U}} = \mathcal{T}$, we say $\mathfrak{U}$ is an *admissible* uniform structure for $\mathcal{T}$ or that $\mathcal{T}$ *admits* the structure $\mathfrak{U}$. A topology which admits a uniform structure is called *uniformizable*. We will show () that a Hausdorff topology is uniformizable if and only if it is completely regular. Thus a fourth equivalent condition can be added to XIII.15.2.16.:

(iv) $\mathcal{T}_{\mathfrak{U}}$ is completely regular.

XIII.15.2.18. EXAMPLE. A (completely regular) topology admits many uniform structures in general. Here is a simple example. Let ρ be the discrete metric on $\mathbb{N}$ (), and $\mathfrak{U}_\rho$ the corresponding uniformity. Let σ be the metric on $\mathbb{N}$ with $\sigma(m,n) = \left|\frac{1}{m} - \frac{1}{n}\right|$. Then $\mathcal{T}_{\mathfrak{U}_\rho}$ and $\mathcal{T}_{\mathfrak{U}_\sigma}$ are both the discrete topology, i.e. the discrete topology admits both $\mathfrak{U}_\rho$ and $\mathfrak{U}_\sigma$ (in fact, the discrete topology on any set admits the discrete uniformity). But $\mathfrak{U}_\rho$ is the discrete uniformity and $\mathfrak{U}_\sigma$ is not, e.g. $\Delta \notin \mathfrak{U}_\sigma$. In this case, the discrete uniformity is obviously the largest admissible uniformity for the discrete topology, and $\mathfrak{U}_\sigma$ turns out to be the smallest admissible uniformity (XIII.15.10.20.); there are many other admissible uniformities for the discrete topology on $\mathbb{N}$, in fact $2^{2^{\aleph_0}}$ such uniformities (XIII.15.12.3.).

Thus uniform structures are more delicate than topologies in general. Every completely regular topology admits a largest uniformity (XIII.15.5.4.), but not generally a smallest uniformity (XIII.15.12.4.).

Open and Closed Entourages

Let $\mathfrak{U}$ be a uniform structure on a set X. We characterize entourages which are either open or closed for the product topology, and show there are enough of each to form a base for $\mathfrak{U}$.

XIII.15.2.19. LEMMA. Let X be a set, and $A, B \subseteq X \times X$. If A is symmetric, then

$$A \circ B \circ A = \bigcup \{A[x] \times A[y] : (x,y) \in B\} .$$

PROOF:

$$\begin{aligned} A \circ B \circ A &= \{(u,v) \in X \times X : \exists (x,y) \in B \text{ with } (u,x) \in A \text{ and } (y,v) \in A\} \\ &= \{(u,v) \in X \times X : \exists (x,y) \in B \text{ with } u \in A[x] \text{ and } v \in A[y]\} \end{aligned}$$

since A is symmetric. 👍

XIII.15.2.20. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space and $\mathfrak{U}$ an admissible uniformity for $\mathcal{T}$. If $A \subseteq X$, then

$$A^\circ = B := \{x \in X : \exists U \in \mathfrak{U} \text{ with } U[x] \subseteq A\} .$$

PROOF: We have $B \subseteq A$, and every open subset of A is contained in B, so we need only show that B is open. Let $x \in B$. Then there is a $U \in \mathfrak{U}$ with $U[x] \subseteq A$, and $V \in \mathfrak{U}$ with $V \circ V \subseteq U$. If $y \in V[x]$, then

$$V[y] \subseteq (V \circ V)[x] \subseteq U[x] \subseteq A$$

so $y \in B$. 👍

XIII.15.2.21. COROLLARY. Let $(X, \mathcal{T})$ be a topological space and $\mathfrak{U}$ an admissible uniformity for $\mathcal{T}$. If $\mathfrak{B}$ is a base for $\mathfrak{U}$, then for each $x \in X$ the set

$$\{B[x] : B \in \mathfrak{B}\}$$

is a local base for $\mathcal{T}$ at x.

XIII.15.2.22. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space and $\mathfrak{U}$ an admissible uniformity for $\mathcal{T}$. Give $X \times X$ the product topology. Then for each $U \in \mathfrak{U}$ we have $U^\circ \in \mathfrak{U}$. Thus the symmetric open sets in $\mathfrak{U}$ form a base for $\mathfrak{U}$.

PROOF:

$$U^\circ = \{(x, y) \in X \times X : \exists V, W \in \mathfrak{U} \text{ with } V[x] \times W[y] \subseteq U\} .$$

Since $V \cap W \in \mathfrak{U}$ for any such V and W, we have

$$U^\circ = \{(x, y) \in X \times X : \exists V \in \mathfrak{U} \text{ with } V[x] \times V[y] \subseteq U\} .$$

There is a symmetric $V \in \mathfrak{U}$ with $V \circ V \circ V \subseteq U$, and

$$V \circ V \circ V = \bigcup \{V[x] \times V[y] : (x, y) \in V\}$$

by Lemma XIII.15.2.19.. Thus $V \subseteq U^\circ$, and since $V \in \mathfrak{U}$ we have $U^\circ \in \mathfrak{U}$. 👍

XIII.15.2.23. PROPOSITION. Let $(X, \mathcal{T})$ be a topological space and $\mathfrak{U}$ an admissible uniformity for $\mathcal{T}$.
(i) If $A \subseteq X$, then

$$\bar{A} = \bigcap \{U(A) : U \in \mathfrak{U}\} .$$

(ii) If $X \times X$ has the product topology, and $E \subseteq X \times X$, then

$$\bar{E} = \bigcap \{U \circ E \circ U : U \in \mathfrak{U}\} .$$

PROOF: (i) If $x \in X$, then $x \in \bar{A}$ if and only if $U[x] \cap A \neq \emptyset$ for every symmetric $U \in \mathfrak{U}$. But $U[x] \cap A \neq \emptyset$ if and only if $x \in U^{-1}(A) = U(A)$.
(ii) If $(x, y) \in X \times X$, then $(x, y) \in \bar{E}$ if and only if $(U[x] \times U[y]) \cap E \neq \emptyset$ for every symmetric $U \in \mathfrak{U}$. If $U \in \mathfrak{U}$ is symmetric, then

$$(U[x] \times U[y]) \cap E \neq \emptyset \iff (x, y) \in U[z] \times U[w] \text{ for some } (z, w) \in E$$

$$\iff (x, y) \in \bigcup \{U[z] \times U[w] : (z, w) \in E\} \iff (x, y) \in U \circ E \circ U$$

by Lemma XIII.15.2.19.. Thus $\bar{E} = \bigcap \{U \circ E \circ U : U \in \mathfrak{U}\}$. 👍

XIII.15.2.24. Corollary. Let $(X, \mathcal{T})$ be a topological space and $\mathfrak{U}$ an admissible uniformity for $\mathcal{T}$. Give $X \times X$ the product topology. Then the symmetric closed sets in $\mathfrak{U}$ form a base for $\mathfrak{U}$.

Proof: Let $U \in \mathfrak{U}$. Then there is a symmetric $V \in \mathfrak{U}$ with $V \circ V \circ V \subseteq U$. Then $\bar{V} \subseteq V \circ V \circ V \subseteq U$, and $\bar{V} \in \mathfrak{U}$ since $V \in \mathfrak{U}$ and $V \subseteq \bar{V}$. 👍

XIII.15.3. The Covering Approach

A third approach to uniform spaces was developed by J. Tukey [Tuk40], using sets of "uniform" open covers of X instead of entourages or pseudometrics.

XIII.15.3.1. Definition. Let X be a set. A *covering uniformity* of X is a family $\mathscr{U}$ of coverings of X, with the properties that

(i) If $\mathcal{U}, \mathcal{V} \in \mathscr{U}$, then $\mathcal{U} \vee \mathcal{V} = \{U \cap V : U \in \mathcal{U}, V \in \mathcal{V}\} \in \mathscr{U}$.

(ii) If $\mathcal{U} \in \mathscr{U}$, there is a $\mathcal{V} \in \mathscr{U}$ which star-refines $\mathcal{U}$ ().

(iii) If $\mathcal{U}$ is a cover of X and there is a $\mathcal{V} \in \mathscr{U}$ which refines $\mathcal{U}$, then $\mathcal{U} \in \mathscr{U}$.

A covering in $\mathscr{U}$ is called a *uniform covering* or *even covering* of X. Conditions (i) and (ii) can be combined into

(iv) If $\mathcal{U}, \mathcal{V} \in \mathscr{U}$, there is a $\mathcal{W} \in \mathscr{U}$ which star-refines both $\mathcal{U}$ and $\mathcal{V}$.

Note that X is not assumed to have a topology, so the coverings are not "open coverings" (in fact this does not make sense in general); but see ().

XIII.15.3.2. Example. Here is the prototype example. Let (X, ρ) be a metric space, and let $\mathscr{U}_\rho$ be the collection of all coverings of X with positive Lebesgue number (), i.e. all coverings $\mathcal{U}$ such that there is an $\epsilon > 0$ for which, for every $x \in X$, there is a $U \in \mathcal{U}$ with $B^\rho_\epsilon(x) \subseteq U$. The covering of X by all open balls of radius ϵ is such a cover. If $\mathcal{U}$ is a cover with Lebesgue number ϵ, then the covering of X by all open balls of radius $\epsilon/2$ star-refines $\mathcal{U}$. Thus $\mathscr{U}_\rho$ is a uniform covering of X.

Bases

XIII.15.3.3. A collection $\mathscr{B}$ of covers of a set X is a *base* for a uniform covering $\mathscr{U}$ of X if $\mathscr{B} \subseteq \mathscr{U}$ and every $\mathcal{U} \in \mathscr{U}$ is refined by some $\mathcal{B} \in \mathscr{B}$. Subbases can be defined similarly. A collection $\mathscr{B}$ of covers of X is a base for a uniform cover if and only if

For every $\mathcal{B}_1, \mathcal{B}_2 \in \mathscr{B}$ there is a $\mathcal{C} \in \mathscr{B}$ which star-refines both $\mathcal{B}_1$ and $\mathcal{B}_2$.

The Topology of a Uniform Covering

XIII.15.3.4. If $\mathscr{B}$ is a base for a uniform covering $\mathcal{U}$ of a set X, then

$$\bigcup_{\mathcal{B}\in\mathscr{B}} \mathcal{B}$$

is a base for a topology $\mathcal{T}_{\mathscr{B}}$ on X. If $\mathscr{C}$ is another base for $\mathscr{U}$, then $\mathcal{T}_{\mathscr{C}} = \mathcal{T}_{\mathscr{B}}$; in particular, $\mathcal{T}_{\mathscr{B}} = \mathcal{T}_{\mathscr{U}}$ for any base $\mathscr{B}$ for $\mathscr{U}$. This is called the *uniform topology* for $\mathscr{U}$.

XIII.15.3.5. Example. If (X, ρ) is a metric space and $\mathscr{U}_\rho$ is the uniform cover of XIII.15.3.2., then $\mathcal{T}_{\mathscr{U}_\rho} = \mathcal{T}_\rho$ is the metric topology.

Covering Uniformities vs. Entourage Uniformities

There is a natural one-one correspondence between covering uniformities on a set X and uniformities on X in the sense of ().

XIII.15.3.6. If $\mathfrak{U}$ is a uniformity on a set X, then for each $U \in \mathfrak{U}$ the set

$$\mathcal{U} = \{U[x] : x \in X\}$$

is a covering of X. If $V \in \mathfrak{U}$, then the condition $V \circ V \subseteq U$ exactly corresponds to the condition that $\mathcal{V}$ star-refines $\mathcal{U}$. Thus if $\mathscr{B}_{\mathfrak{U}} = \{\mathcal{U} : U \in \mathfrak{U}\}$, then $\mathscr{B}_{\mathfrak{U}}$ is a base for a covering uniformity $\mathscr{U}(\mathfrak{U})$ on X. (The overuse of the letter U here in various fonts is somewhat tongue-in-cheek but serves a serious purpose, and thus does not violate the admonition of (). We write $\mathscr{U}(\mathfrak{U})$ instead of $\mathscr{U}_{\mathfrak{U}}$ to avoid multiple subscripts below.)

XIII.15.3.7. Conversely, let $\mathscr{U}$ be a covering uniformity on X. For each $\mathcal{U} \in \mathscr{U}$, set

$$B_{\mathcal{U}} = \bigcup_{U\in\mathcal{U}} (U \times U) \subseteq X \times X \ .$$

Then $B_{\mathcal{U}}$ is a symmetric subset of $X \times X$ containing Δ. If $\mathfrak{B}_{\mathscr{U}} = \{B_{\mathcal{U}} : \mathcal{U} \in \mathscr{U}\}$, then $\mathfrak{B}_{\mathscr{U}}$ is a base for a uniformity $\mathfrak{U}(\mathscr{U})$.

XIII.15.3.8. Proposition. (i) If $\mathfrak{U}$ is a uniformity on a set X and $\mathscr{U}(\mathfrak{U})$ the corresponding covering uniformity, then $\mathfrak{U}(\mathscr{U}(\mathfrak{U})) = \mathfrak{U}$.

(ii) If $\mathscr{U}$ is a covering uniformity on a set X and $\mathfrak{U}(\mathscr{U})$ the corresponding uniformity, then $\mathscr{U}(\mathfrak{U}(\mathscr{U})) = \mathscr{U}$.

Thus there is a natural one-one correpondence between uniformities and covering uniformities.

(iii) If $\mathfrak{U}$ and $\mathscr{U}$ are corresponding (i.e. $\mathfrak{U} = \mathfrak{U}(\mathscr{U})$ and hence $\mathscr{U} = \mathscr{U}(\mathfrak{U})$), then $\mathcal{T}_{\mathfrak{U}} = \mathcal{T}_{\mathscr{U}}$.

XIII.15.3.9. Thus all the notions discussed in the previous section have exact translations into covering uniformity language. For example, a topological space $(X, \mathcal{T})$ is uniformizable if and only if there is a covering uniformity $\mathscr{U}$ on X with $\mathcal{T}_{\mathscr{U}} = \mathcal{T}$.

XIII.15.4. Comparing the Definitions

We have seen (XIII.15.3.8.) that the entourage and covering approaches are equivalent. In this section, under a mild Choice assumption, we show they are also equivalent to the pseudometric approach. Thus one is free to use whichever approach is most convenient or more to the author's taste: many authors including Bourbaki [**?**] and Kelley [Kel75] use the entourage approach, Gillman and Jerison [GJ76] the pseudometric approach, and Isbell [Isb64] the covering approach (Isbell calls Tukey's covering approach "heretical" and then proceeds to use it).

In comparing the entourage and pseudometric approaches, we must show that every uniform structure is induced by a family of pseudometrics (i.e. has a gauge). The key technical fact is the following lemma, due to Weil [**?**], which is reminiscent of Urysohn's Lemma (). See [Kel75, 6.12] for a slightly more general version.

XIII.15.4.1. Lemma. [Metrization Lemma] Let X be a set, and $\{U_n : n \geq 0\}$ a sequence of subsets of $X \times X$ such that

$U_0 = X \times X$.

Each U_n is symmetric and contains Δ.

$U_{n+1} \circ U_{n+1} \circ U_{n+1} \subseteq U_n$ for each n.

Then there is a pseudometric ρ on X such that

$$U_n \subseteq \{(x, y) \in X \times X : \rho(x, y) < 2^{-n}\} \subseteq U_{n-1} \text{ for all } n \in \mathbb{N} .$$

Proof: Note that $U_n \subseteq U_{n-1}$ for all $n \in \mathbb{N}$. As a first approximation to ρ, define $f : X \times X \to [0, 1]$ by setting $f(x, y) = 2^{-n}$ if $(x, y) \in U_{n-1} \setminus U_n$ $(n \in \mathbb{N})$, and $f(x, y) = 0$ if $(x, y) \in \cap_n U_n$. We have $f(x, y) = f(y, x)$ for all (x, y).

Now for $(x, y) \in X \times X$ set

$$\rho(x, y) = \inf \left\{ \sum_{j=0}^{n} f(x_j, x_{j+1}) \right\}$$

where the infimum is over all n and finite sequences $(x_0, x_1, \ldots, x_{n+1})$ of points of X with $x_0 = x$ and $x_{n+1} = y$. Then $\rho(x, y) = \rho(y, x)$ for all (x, y) by reversing sequences, and ρ satisfies the triangle inequality by concatenating sequences. Thus ρ is a pseudometric. Since $\rho(x, y) \leq f(x, y)$ for all (x, y), $\rho(x, y) < 2^{-n}$ for $(x, y) \in U_n$, i.e. $U_n \subseteq \{(x, y) \in X \times X : \rho(x, y) < 2^{-n}\}$ for each n.

To complete the proof, we show by complete induction on n that for any sequence $(x_0, x_1, \ldots, x_{n+1})$ we have

$$f(x_0, x_{n+1}) \leq 2 \sum_{j=0}^{n} f(x_j, x_{j+1})$$

from which it follows that if $\rho(x, y) < 2^{-n}$ $(n \in \mathbb{N})$, then $f(x, y) < 2^{-n+1}$ and $(x, y) \in U_{n-1}$. So let $(x_0, x_1, \ldots, x_{n+1})$ be such a sequence, and set

$$a = \sum_{j=0}^{n} f(x_j, x_{j+1}) .$$

Let k be the largest index such that

$$f(x_0, x_1) + \cdots + f(x_{k-1}, x_k) \leq \frac{a}{2}$$

(we could have $k = 0$ if $f(x_0, x_1) > \frac{a}{2}$). Then $k \leq n$. If $k < n$, we have

$$f(x_{k+1}, x_{k+2}) + \cdots + f(x_n, x_{n+1}) \leq \frac{a}{2}$$

and in any event we have $f(x_k, x_{k+1}) \leq a$. By the inductive hypothesis we have $f(x_0, x_k) \leq 2\left(\frac{a}{2}\right) = a$ and $f(k+1, n+1) \leq a$ (these hold even if $k = 0$ or $k = n$).
Let m be the smallest natural number such that $2^{-m} \leq a$. Then $f(x_0, x_k)$, $f(x_k, x_{k+1})$, $f(x_{k+1}, x_{n+1})$ are all $\leq 2^{-m}$, so (x_0, x_k), (x_k, x_{k+1}), (x_{k+1}, x_{n+1}) are all in U_m. Since $U_m \circ U_m \circ U_m \subseteq U_{m-1}$, $(x_0, x_{n+1}) \in U_{m-1}$ and $f(x_0, x_{n+1}) \leq 2^{-m+1} \leq 2a$. 👍

XIII.15.4.2. THEOREM. Let $(X, \mathfrak{U})$ be a uniform space. Then there is a set $\mathcal{P}$ of pseudometrics on X such that $\mathfrak{U} = \mathfrak{U}_{\mathcal{P}}$, i.e. $\mathfrak{U}$ has a gauge.

PROOF: Let $\mathcal{P}$ be the set of all pseudometrics ρ on X with $\mathfrak{U}_\rho \subseteq \mathfrak{U}$. Then $\mathfrak{U}_{\mathcal{P}} \subseteq \mathfrak{U}$. Conversely, if $U = U^{-1} \in \mathfrak{U}$, set $U_0 = X \times X$, $U_1 = U$, and inductively choose $U_n \in \mathfrak{U}$ with $U_n = U_n^{-1}$ and $U_n \circ U_n \circ U_n \subseteq U_{n-1}$ for each n. Apply XIII.15.4.1. to get ρ. Then $\rho \in \mathcal{P}$, and $U \in \mathfrak{U}_\rho \subseteq \mathfrak{U}_{\mathcal{P}}$. Thus $\mathfrak{U} \subseteq \mathfrak{U}_{\mathcal{P}}$. 👍

XIII.15.4.3. Although no Choice is needed for the Metrization Lemma XIII.15.4.1., the Axiom of Dependent Choice is used in the proof of XIII.15.4.2.. Some form of Choice is necessary for this result: if $\mathfrak{U}$ is a uniformity on X and $U \in \mathfrak{U}$, without at least the Countable AC there may be no sequence (U_n) in $\mathfrak{U}$ satisfying the hypotheses of XIII.15.4.1. with $U_1 = U \cap U^{-1}$. In fact, there is a counterexample (XIII.15.10.2.). Few if any of the standard references on uniform spaces acknowledge or recognize this point.

However, no Choice is needed to prove the following crucial special case. This result was essentially proved in [AU23], with the proof simplified in [Fri37], before uniform spaces were defined, and was explicitly stated in [Wei37].

XIII.15.4.4. THEOREM. Let $(X, \mathcal{T})$ be a topological space. Then $(X, \mathcal{T})$ is metrizable if and only if there is a separated uniformity $\mathfrak{U}$ with a countable base which is admissible for $\mathcal{T}$.

PROOF: If $(X, \mathcal{T})$ is metrizable by ρ, then $\mathfrak{U}_\rho$ is a separated uniformity with countable base admissible for $\mathcal{T}$. Conversely, suppose $\mathfrak{U}$ is a separated uniformity admissible for $\mathcal{T}$ with a countable base $\mathfrak{B} = \{B_k : k \in \mathbb{N}\}$. For each k set $V_k = B_1 \cap B_1^{-1} \cap \cdots \cap B_k \cap B_k^{-1}$. Then $\{V_k : k \in \mathbb{N}\}$ is a base for $\mathfrak{U}$ consisting of a decreasing sequence of symmetric sets. Set $U_0 = X \times X$, $U_1 = V_1$, and inductively let U_{n+1} be the first V_k such that $V_k \circ V_k \circ V_k \subseteq U_n \cap V_n$. The U_n are a base for $\mathfrak{U}$ and satisfy the hypotheses of XIII.15.4.1., so there is a corresponding pseudometric ρ. Then $\mathfrak{U}_\rho \subseteq \mathfrak{U}$, and the U_n are all in $\mathfrak{U}_\rho$, so $\mathfrak{U} = \mathfrak{U}_\rho$. Since $\mathfrak{U}$ is separated, we have that $\cap_n U_n = \cap_k V_k = \Delta$, so ρ is a metric. 👍

XIII.15.5. Pullbacks and Fine Uniformities

Pullbacks of Uniformities

XIII.15.5.1. Let $\{(X_i, \mathfrak{U}_i) : i \in I\}$ be a set of uniform spaces, Y a set, and $f_i : Y \to X_i$ a function for all i. For each i set

$$\mathfrak{S}_i = f_i^{-1}(\mathfrak{U}_i) := \{(f_i \times f_i)^{-1}(U) : U \in \mathfrak{U}_i\} \subseteq Y \times Y$$

and set $\mathfrak{S} = \cup_i \mathfrak{S}_i$. Then $\mathfrak{S}$ is a subbase for a uniformity $\mathfrak{V}$ on Y, which is the smallest uniformity on Y making all the f_i uniformly continuous. The uniformity $\mathfrak{V}$ is called the *pullback* of the $\mathfrak{U}_i$ under the f_i (it is not in general a pullback in the category theory sense ()).

Suprema of Uniformities

Unions and intersections of uniformities are not uniformities in general. However, unions behave reasonably and as a consequence, if $(X, \mathcal{T})$ is a uniformizable topological space, there is always a largest uniformity on X admissible for $\mathcal{T}$.

XIII.15.5.2. If $\{\mathfrak{U}_i : i \in I\}$ is a nonempty set of uniformities on a set X, then $\mathfrak{B} = \bigcup_{i\in I} \mathfrak{U}_i$ is a subbase for a uniformity $\mathfrak{U} = \bigvee_{i\in I} \mathfrak{U}_i$ on X. This is the smallest uniformity on X finer than all the $\mathfrak{U}_i$ and is the *supremum* or *join* of the $\mathfrak{U}_i$. The uniformity $\bigvee_{i\in I} \mathfrak{U}_i$ is the pullback of the $\mathfrak{U}_i$ where Y and all the X_i are the same set X and the f_i are all the identity map.

XIII.15.5.3. Proposition. If $\{\mathfrak{U}_i : i \in I\}$ is a nonempty set of uniformities on a set X, and $\mathfrak{U} = \bigvee_{i\in I} \mathfrak{U}_i$, then $\mathcal{T}_{\mathfrak{U}}$ is the weakest topology $\bigvee_{i\in I} \mathcal{T}_{\mathfrak{U}_i}$ on X stronger than all the $\mathcal{T}_{\mathfrak{U}_i}$. In particular, if all the $\mathfrak{U}_i$ are admissible for a topology $\mathcal{T}$, then $\mathfrak{U}$ is also admissible for $\mathcal{T}$.

Fine Uniformities

XIII.15.5.4. Corollary. Let $(X, \mathcal{T})$ be a topological space. If $(X, \mathcal{T})$ is uniformizable, then there is a largest uniformity $\mathfrak{U}_f(\mathcal{T})$ admissible for $\mathcal{T}$, called the *fine uniformity* for $\mathcal{T}$.

Proof: Apply XIII.15.5.3. to the set of all uniformities on X admissible for $\mathcal{T}$ (note this is indeed a set, a subset of $\mathcal{P}(\mathcal{P}(X \times X))$).

XIII.15.5.5. In particular, if $(X, \mathcal{T})$ is completely regular, there is a fine uniformity for $\mathcal{T}$ (the converse is also true under a mild Choice assumption). Note, however, that the fine uniformity for $\mathcal{T}$ does not consist of all neighborhoods of Δ for the product topology in general (XIII.15.12.6.). It also is also not generally the same as the uniformity $\mathfrak{C}$ correspond to the set $\mathcal{C}$ of XIII.15.1.28.. 

Infima of Uniformities

XIII.15.5.6. In contrast, intersections of uniformities do not work reasonably. A uniformizable topological space $(X, \mathcal{T})$ does not have a smallest (coarsest) uniformity admissible for $\mathcal{T}$ in general; in fact, there is a smallest admissible uniformity if and only if $(X, \mathcal{T})$ is locally compact (XIII.15.10.20.).

However, if $\{\mathfrak{U}_i : i \in I\}$ is a set of uniformities on X, there is a largest uniformity $\bigwedge_{i\in I} \mathfrak{U}_i$ contained in $\bigcap_{i\in I} \mathfrak{U}_i$, namely the supremum (join) of all uniformities contained in this intersection. But if $\mathfrak{U}$ and $\mathfrak{V}$ are uniformities on X, $\mathcal{T}_{\mathfrak{U}\wedge\mathfrak{V}}$ is not necessarily $\mathcal{T}_{\mathfrak{U}} \wedge \mathcal{T}_{\mathfrak{V}}$; if $\mathfrak{U}$ and $\mathfrak{V}$ are admissible for a completely regular $\mathcal{T}$, $\mathfrak{U} \wedge \mathfrak{V}$ can even be the indiscrete uniformity (XIII.15.12.4.).

Products of Uniform Spaces

Another important special case of the pullback is product uniformities.

XIII.15.5.7. Let $(X_i, \mathfrak{U}_i)$ be a set of uniform spaces. Set $X = \prod_i X_i$. Assume $X \neq \emptyset$ (this is automatic under AC, but we need no Choice for this construction). For each i let $\pi_i : X \to X_i$ be the i'th coordinate projection. The pullback of the $\mathfrak{U}_i$ to X via π_i is called the *product uniformity* on X. The construction in () is a special case (the general case under a mild Choice assumption).

XIII.15.5.8. Proposition. Let $(X_i, \mathfrak{U}_i)$ be a set of uniform spaces, $X = \prod_i X_i \neq \emptyset$, and $\mathfrak{U}$ the product uniformity on X. Then $\mathcal{T}_{\mathfrak{U}}$ is the product topology on X.

XIII.15.5.9. Corollary. An arbitrary (nonempty) product of uniformizable spaces is uniformizable.

XIII.15.6. Completeness

Completeness is an important notion in metric spaces. The property extends naturally to uniform spaces and can be characterized in various ways; two of the most important is via Cauchy nets and Cauchy filters.

Cauchy Nets

In analogy with Cauchy sequences, a Cauchy net in a uniform space is a net in which the terms are all "close" far enough out in the net. Formally:

XIII.15.6.1. Definition. Let $(X, \mathfrak{U})$ be a uniform space. A net $(x_i)_{i\in I}$ in X is a $\mathfrak{U}$-*Cauchy net* if for every $U \in \mathfrak{U}$ there is an i_0 such that $(x_i, x_j) \in U$ for all $i, j > i_0$.

XIII.15.6.2. Note that if $(X, \mathfrak{U})$ is a uniform space, a net (x_i) converges to x in $(X, \mathcal{T}_{\mathfrak{U}})$ if and only if for every $U \in \mathfrak{U}$ there is an i_0 such that $(x_i, x) \in U$ for all $i > i_0$. Thus every convergent net is a $\mathfrak{U}$-Cauchy net. In both this convergence criterion and XIII.15.6.1. it suffices to let U range over a base or even a subbase for $\mathfrak{U}$.

XIII.15.6.3. Definition. A uniform space $(X, \mathfrak{U})$ is *complete* if every $\mathfrak{U}$-Cauchy net converges (in $(X, \mathcal{T}_{\mathfrak{U}})$) to a point of X.

XIII.15.6.4. While convergence of a net is a topological notion depending (in this context) only on $\mathcal{T}_{\mathfrak{U}}$, the property of being a Cauchy net is a uniform property: if $\mathfrak{U}$ and $\mathfrak{V}$ are uniformities admissible for a topology $\mathcal{T}$, a $\mathfrak{U}$-Cauchy net is not necessarily a $\mathfrak{V}$-Cauchy net (). However, if $\mathfrak{U} \subseteq \mathfrak{V}$, then every $\mathfrak{V}$-Cauchy net is a $\mathfrak{U}$-Cauchy net. In particular, every net in X which is Cauchy for the fine uniformity for $\mathcal{T}$ is $\mathfrak{U}$-Cauchy for every uniformity $\mathfrak{U}$ admissible for $\mathcal{T}$.

XIII.15.6.5. Definition. A uniformizable space $(X, \mathcal{T})$ is *topologically complete* if there is a uniformity $\mathfrak{U}$ on X admissible for $\mathcal{T}$ such that $(X, \mathfrak{U})$ is complete.

XIII.15.6.6. If $(X, \mathcal{T})$ is a topological space and $\mathfrak{U}$ and $\mathfrak{V}$ are uniformities on X admissible for $\mathcal{T}$, with $\mathfrak{U} \subseteq \mathfrak{V}$, and $(X, \mathfrak{U})$ is complete, then by XIII.15.6.4. $(X, \mathfrak{V})$ is complete. In particular, $(X, \mathcal{T})$ is topologically complete if and only if $(X, \mathfrak{U}_f(\mathcal{T}))$ is complete.

Topologically complete spaces are discussed further in ().

The definition of a Cauchy net can be cleanly rephrased in terms of covering uniformities or pseudometrics:

XIII.15.6.7. Proposition. Let $(X, \mathfrak{U})$ be a uniform space, and $\mathscr{U}$ the corresponding covering uniformity. A net $(x_i)_{i \in I}$ in X is a $\mathfrak{U}$-Cauchy net if and only if, for every $\mathcal{U} \in \mathscr{U}$ there is an i_0 and a $U \in \mathcal{U}$ such that x_i and x_j are both in U for all $i, j > i_0$. We will call a net with this property a *$\mathscr{U}$-Cauchy net*.

XIII.15.6.8. Proposition. Let X be a set, $\mathcal{P}$ a set of pseudometrics on X, and $\mathfrak{U}_{\mathcal{P}}$ the corresponding uniformity. A net $(x_i)_{i \in I}$ in X is a $\mathfrak{U}_{\mathcal{P}}$-Cauchy net if and only if, for every $\rho \in \mathcal{P}$ and $\epsilon > 0$ there is an i_0 such that $\rho(x_i, x_j) < \epsilon$ for all $i, j > i_0$. We will call a net with this property a *$\mathcal{P}$-Cauchy net*.

The following generalization of () holds:

XIII.15.6.9. Proposition. Let $(X, \mathcal{T})$ be a (uniformizable) topological space, and $\mathfrak{U}$ a uniformity on X admissible for $\mathcal{T}$. If (x_i) is a $\mathfrak{U}$-Cauchy net and (x_i) has a convergent subnet, then (x_i) converges.

XIII.15.6.10. Corollary. Let $(X, \mathcal{T})$ be a compact Hausdorff space, and $\mathfrak{U}$ a uniformity on X admissible for $\mathcal{T}$. Then $(X, \mathfrak{U})$ is complete.

In fact, if $(X, \mathcal{T})$ is a compact Hausdorff space, then $(X, \mathcal{T})$ is uniformizable (**??**) and there is a unique uniformity admissible for $\mathcal{T}$ (which is the fine uniformity and consists of all neighborhoods of Δ for the product topology). Thus $(X, \mathcal{T})$ is topologically complete.

Cauchy Filters

Because of the correspondence between nets and filters (), things can be rephrased in filter language.

XIII.15.6.11. DEFINITION. Let $(X, \mathfrak{U})$ be a uniform space. A family $\{A_i : i \in I\}$ of subsets of X, indexed by a directed set I, is *eventually small* (in $(X, \mathfrak{U})$) if for every $U \in \mathfrak{U}$ there is an i_0 such that $F_i \times F_i \subseteq U$ for all $i > i_0$.

XIII.15.6.12. DEFINITION. Let $(X, \mathfrak{U})$ be a uniform space. A $\mathfrak{U}$-*Cauchy filter* on $(X, \mathfrak{U})$ is a filter on X which is eventually small when indexed by reverse inclusion. A $\mathfrak{U}$-*Cauchy filterbase* is a filterbase for a Cauchy filter, i.e. an eventually small filterbase.

XIII.15.6.13. If (x_i) is a net in X, then the tail filter () of (x_i) is a $\mathfrak{U}$-Cauchy filter if and only if (x_i) is a $\mathfrak{U}$-Cauchy net.

XIII.15.6.14. PROPOSITION. (i) Let $\mathscr{U}$ be a covering uniformity on X, and $\mathfrak{U}$ the corresponding uniformity. A filter $\mathcal{F}$ on X is a $\mathfrak{U}$-Cauchy filter if and only if for every $\mathcal{U} \in \mathscr{U}$ there is a $U \in \mathcal{U}$ and $F \in \mathcal{F}$ with $F \subseteq U$. The same holds for filterbases. Thus a filter $\mathcal{F}$ on X is a Cauchy filter if and only if for every $\mathcal{U} \in \mathscr{U}$ there is a $U \in \mathcal{U}$ with $U \in \mathcal{F}$.

(ii) Let $\mathcal{P}$ be a set of pseudometrics on X. A filter $\mathcal{F}$ on X is a $\mathfrak{U}_{\mathcal{P}}$-Cauchy filter if and only if, for every $\rho \in \mathcal{P}$ and $\epsilon > 0$, there is a $U \in \mathfrak{U}$ such that $\rho(x, y) < \epsilon$ for all $(x, y) \in U$.

Cauchy Nests

XIII.15.6.15. DEFINITION. Let $(X, \mathfrak{U})$ be a uniform space. A $\mathfrak{U}$-*Cauchy nest* is an eventually small family $\{F_i : i \in I\}$ of nonempty closed subsets of X, directed by reverse inclusion, i.e. $F_j \subseteq F_i$ if $i < j$. A $\mathfrak{U}$-Cauchy nest is *regular* if each F_i is a regular closed set, i.e. the closure of its interior.

XIII.15.6.16. THEOREM. Let $(X, \mathcal{T})$ be a topological space and $\mathfrak{U}$ a uniformity admissible for $\mathcal{T}$. Then the following are equivalent:

(i) $(X, \mathfrak{U})$ is complete.

(ii) Whenever (F_i) is a $\mathfrak{U}$-Cauchy nest in X, then $\cap_{i \in I} F_i$ is nonempty.

(iii) Whenever (F_i) is a regular $\mathfrak{U}$-Cauchy nest in X, then $\cap_{i \in I} F_i$ is nonempty.

PROOF: (i) $\Rightarrow$ (ii): Let (F_i) be a $\mathfrak{U}$-Cauchy nest in X. Let $\mathcal{F}$ be the collection of all subsets of X containing some F_i. Then $\mathcal{F}$ is a filter since the F_i are nonempty and directed by reverse inclusion, and since the F_i are in $\mathcal{F}$ it is eventually small, i.e. a $\mathfrak{U}$-Cauchy filter. Thus $\mathcal{F}$ converges to an $x \in X$, and $x \in F_i$ for all i since F_i is closed.

(ii) $\Rightarrow$ (iii) is trivial.

(iii) $\Rightarrow$ (i): Let $\mathscr{U}$ be the covering uniformity corresponding to $\mathfrak{U}$. Suppose $\mathcal{F}$ is a $\mathfrak{U}$-Cauchy filter on X. For each $\mathcal{U} \in \mathscr{U}$ let $F_{\mathcal{U}}$ be the closure of the union of all $U \in \mathcal{U} \cap \mathcal{F}$ (there is such a U in each $\mathcal{U} \in \mathscr{U}$ since $\mathcal{F}$ is a Cauchy filter). Then $F_{\mathcal{U}}$ is a nonempty regular closed set in X. If $U_0 \in \mathcal{U} \cap \mathcal{F}$, then every $U \in \mathcal{U} \cap \mathcal{F}$ is in $St(U_0)$ since $\mathcal{F}$ is a filter. If $\mathcal{U}, \mathcal{V} \in \mathscr{U}$ and $\mathcal{W} \in \mathscr{U}$ star-star-refines both $\mathcal{U}$ and $\mathcal{V}$, then $F_{\mathcal{W}}$ is contained in some $U \in \mathcal{U}$ and in some $V \in \mathcal{V}$, and in particular $F_{\mathcal{W}}$ is contained in $F_{\mathcal{U}} \cap F_{\mathcal{V}}$. So the $F_{\mathcal{U}}$ are eventually

small and directed under reverse inclusion. Thus, by (iii), there is some $x \in \cap_{\mathcal{U}\in\mathscr{U}} F_{\mathcal{U}}$, and $\mathcal{F}$ must converge to x. 👍

XIII.15.7. Subspace Uniformities and Completeness

XIII.15.7.1. If $(X, \mathfrak{U})$ is a uniform space and $Y \subseteq X$, then

$$\mathfrak{U}_Y = \{U \cap (Y \times Y) : U \in \mathfrak{U}\}$$

is easily seen to be a uniformity on Y, which is separated if $\mathfrak{U}$ is separated. $\mathfrak{U}_Y$ is called the *relative uniformity* or *subspace uniformity* on Y. It is the smallest uniformity $\mathfrak{V}$ on Y such that the inclusion map from Y to X is $(\mathfrak{V}, \mathfrak{U})$-uniformly continuous.

XIII.15.7.2. Proposition. If $(X, \mathfrak{U})$ is a uniform space and $Y \subseteq X$, then $\mathcal{T}_{\mathfrak{U}_Y}$ is the relative topology on Y from $\mathcal{T}_{\mathfrak{U}}$. In particular, every subspace of a uniformizable space is uniformizable.

XIII.15.7.3. More generally, if $(X, \mathfrak{U})$ is a uniform space, Y a set, and $f : Y \to X$ is a function, then

$$\{(f \times f)^{-1}(U) : U \in \mathfrak{U}\}$$

is a base for a uniformity on Y (it is not a uniformity in general), which is the smallest uniformity on Y making f uniformly continuous. (This is the special case of a pullback (XIII.15.5.1.) where I is a singleton.)

There is a straightforward translation into the covering and pseudometric pictures:

XIII.15.7.4. Proposition. (i) Let $\mathscr{U}$ be a covering uniformity on X and $\mathfrak{U}$ the corresponding uniformity. Let $Y \subseteq X$. For each $\mathcal{U} \in \mathscr{U}$ set $\mathcal{U}_Y = \{U \cap Y : U \in \mathcal{U}\}$, and set $\mathscr{U}_Y = \{\mathcal{U}_Y : \mathcal{U} \in \mathscr{U}\}$. Then $\mathscr{U}_Y$ is a covering uniformity on Y, and is the covering uniformity on Y corresponding to $\mathfrak{U}_Y$.
(ii) Let $\mathcal{P}$ be a set of pseudometrics on a set X, and $Y \subseteq X$. Set $\mathcal{P}_Y = \{\rho|_{Y\times Y} : \rho \in \mathcal{P}\}$. Then $\mathcal{P}_Y$ is a set of pseudometrics on Y, and $\mathfrak{U}_{\mathcal{P}_Y} = (\mathfrak{U}_{\mathcal{P}})_Y$.

XIII.15.7.5. Proposition. Let $(X, \mathfrak{U})$ be a uniform space, and $Y \subseteq X$. Then a net (y_i) in Y is $\mathfrak{U}_Y$-Cauchy if and only if it is $\mathfrak{U}$-Cauchy in X.

Completeness and Subspaces

XIII.15.7.6. Proposition. Let $(X, \mathfrak{U})$ be a complete uniform space, and $Y \subseteq X$. Then
(i) If Y is $\mathcal{T}_{\mathfrak{U}}$-closed, then $(Y, \mathfrak{U}_Y)$ is complete.
(ii) If $(X, \mathfrak{U})$ is separated and $(Y, \mathfrak{U}_Y)$ is complete, then Y is $\mathcal{T}_{\mathfrak{U}}$-closed in X.

Proof: (i) Let (y_i) be a $\mathfrak{U}_Y$-Cauchy net. Then (y_i) is $\mathfrak{U}$-Cauchy by XIII.15.7.5., so $y_i \to y$ for some $y \in X$ since $(X, \mathfrak{U})$ is complete. Then $y \in Y$ since Y is $\mathcal{T}_{\mathfrak{U}}$-closed in X, i.e. (y_i) converges in Y.

(ii) Let $x \in \bar{Y}$, and let (y_i) be a net in Y with $y_i \to x$. Then (y_i) is a $\mathfrak{U}$-Cauchy net, so it is $\mathfrak{U}_Y$-Cauchy by XIII.15.7.5.. Since $(Y, \mathfrak{U}_Y)$ is complete, $y_i \to y$ for some $y \in Y$. We have $y = x$ since $\mathcal{T}_{\mathfrak{U}}$ is Hausdorff, so $x \in Y$ and Y is $\mathcal{T}_{\mathfrak{U}}$-closed. 👍

XIII.15.7.7. Example. Part (ii) fails if $(X, \mathfrak{U})$ is not separated.

(i) The simplest example is to take $\mathfrak{U}$ to be the indiscrete uniformity on a set X. Then $(X, \mathfrak{U})$ is trivially complete since every net in X converges. If Y is any subset of X, then $\mathfrak{U}_Y$ is the indiscrete uniformity on Y, hence $(Y, \mathfrak{U}_Y)$ is complete, but Y is not closed in X if it is a proper subset.

(ii) Let $(X, \mathfrak{U})$ be any complete uniform space which is not separated, and let $(x, y) \in \cap_{U \in \mathfrak{U}} U$, $x \neq y$. Then x and y have the same $\mathcal{T}_{\mathfrak{U}}$-neighborhoods in X, so a net in X converges to x if and only if it converges to y. If $Y = X \setminus \{x\}$, then $(Y, \mathfrak{U}_Y)$ is complete, but Y is not closed in X (it is dense).

Completeness of Products

XIII.15.7.8. Proposition. Let $\{(X_i, \mathfrak{U}_i) : i \in I\}$ be a set of separated uniform spaces, with $X = \prod_{i \in I} X_i \neq \emptyset$, and let $\mathfrak{U}$ be the product uniformity () on X. Then $(X, \mathfrak{U})$ is complete if and only if each $(X_i, \mathfrak{U}_i)$ is complete.

Proof: Let $\pi_i : X \to X_i$ be the i'th coordinate projection for each i. Then it is easily checked that (x_λ) is a $\mathfrak{U}$-Cauchy net if and only if $(\pi_i(x_\lambda))$ is a $\mathfrak{U}_i$-Cauchy net for all i. If (x_λ) is a $\mathfrak{U}$-Cauchy net in X, and each $(X_i, \mathfrak{U}_i)$ is complete, then for each i $\pi_i(x_\lambda) \to y_i$ for a unique $y_i \in X_i$. The function $i \mapsto y_i$ defines an element $y \in X$, and $x_\lambda \to y$. Thus $(X, \mathfrak{U})$ is complete. Conversely, if X is nonempty and $(X, \mathfrak{U})$ is complete, fix i and let (y_λ) be a $\mathfrak{U}_i$-Cauchy net in X_i. Let $z = (z_j) \in X$, and define a net (x_λ) in X by

$$(x_\lambda)_j = \begin{cases} y_\lambda & \text{if} \quad j = i \\ z_j & \text{if} \quad j \neq i \end{cases} .$$

Then (x_λ) is a $\mathfrak{U}$-Cauchy net in X, so $x_\lambda \to x$ for some x, and $y_\lambda \to \pi_i(x)$. 👍

The assumption $X \neq \emptyset$, automatic under AC, emphasizes that this is a theorem of ZF. The result is also true if the $(X_i, \mathfrak{U}_i)$ are not separated, but the proof requires the AC since the y_i are not necessarily unique (in fact the statement is equivalent to the AC in this case).

XIII.15.7.9. Corollary. An arbitrary (nonempty) product of topologically complete Hausdorff spaces is topologically complete. (If the AC is assumed, "Hausdorff" can be eliminated.)

XIII.15.7.10. Corollary. Let $\{\mathfrak{U}_i : i \in I\}$ be a family of separated uniformities on a set X, and $\mathfrak{U} = \bigvee_i \mathfrak{U}_i$. Then $(X, \mathfrak{U})$ is complete if and only if each $(X, \mathfrak{U}_i)$ is complete.

Proof: The diagonal subspace X is a closed subspace of $\prod_i (X, \mathfrak{U}_i)$, and $\mathfrak{U}$ is the relative uniformity on this subspace, so the result follows from XIII.15.7.8. and XIII.15.7.6.. 👍

XIII.15.7.11. This result is unclear if "separated" is remoived, even under the AC. Indeed, it is even unclear if $\mathfrak{U}$ and $\mathfrak{V}$ are uniformities on a set X with $\mathcal{T}_{\mathfrak{U}} = \mathcal{T}_{\mathfrak{V}}$, whether $(X, \mathfrak{U} \vee \mathfrak{V})$ is complete if $(X, \mathfrak{U})$ and $(X, \mathfrak{V})$ are complete if they are not separated.

XIII.15.8. Completions of Uniform Spaces

In this section we show that every separated uniform space has an essentially unique completion (non-separated ones have a completion also, but there is no uniqueness, although there is a "minimal" one, cf. XIII.15.12.7.). There are various ways to construct the completion; we will use a method based on Cantor's construction of $\mathbb{R}$ (III.5.2.) by taking points of the completion to be equivalence classes of Cauchy filters. This construction has the advantage, among other things, of avoiding any use of Choice.

XIII.15.8.1. Definition. Let $(X, \mathfrak{U})$ be a separated uniform space. A *completion* of $(X, \mathfrak{U})$ is a separated complete uniform space $(\bar{X}, \bar{\mathfrak{U}})$ and an embedding of X as a dense subspace of $\bar{X}$ such that $\mathfrak{U} = \bar{\mathfrak{U}}_X$.

Construction

We now fix a separated uniform space $(X, \mathfrak{U})$, and let $\mathscr{U}$ be the corresponding covering uniformity on X.

XIII.15.8.2. We first put an equivalence relation on the set $\mathscr{C}$ of $\mathfrak{U}$-Cauchy filters on X. If $\mathcal{F}, \mathcal{G} \in \mathscr{C}$, we say $\mathcal{F} \sim \mathcal{G}$ if for every $\mathcal{U} \in \mathscr{U}$ and $U \in \mathcal{U}$, $U \in \mathcal{F}$ if and only if $U \in \mathcal{G}$ (i.e. U contains an $F \in \mathcal{F}$ if and only if it contains a $G \in \mathcal{G}$). Note that if $\mathcal{F}$ converges to $x \in X$, then $\mathcal{G} \in \mathscr{C}$ satisfies $\mathcal{G} \sim \mathcal{F}$ if and only if $\mathcal{G}$ also converges to x, i.e. a Cauchy filter converges to x if and only if it is equivalent to the neighborhood filter of x.

XIII.15.8.3. Proposition. The relation $\sim$ is an equivalence relation on $\mathscr{C}$.

Proof: The relation $\sim$ is obviously symmetric and transitive, and is reflexive since the filters in $\mathscr{C}$ are Cauchy filters. 👍

XIII.15.8.4. We now take $\bar{X}$ to be the set $\mathscr{C}/\sim = \{[\mathcal{F}] : \mathcal{F} \in \mathscr{C}\}$, where $[\mathcal{F}]$ denotes the equivalence class of $\mathcal{F}$. There is an obvious embedding of X into $\bar{X}$ sending x to the equivalence class of filters converging to x (this map is injective since $(X, \mathfrak{U})$ is separated). We identify X with its image.

XIII.15.8.5. Put a uniform structure on $\bar{X}$ as follows. For each $\mathcal{U} \in \mathscr{U}$ and $U \in \mathcal{U}$, let

$$\bar{U} = \{[\mathcal{F}] : \mathcal{F} \in \mathscr{C} \text{ and } U \in \mathcal{F}\} \subseteq \bar{X}$$

(this is well defined since if $\mathcal{F} \sim \mathcal{G}$, then $U \in \mathcal{F}$ if and only if $U \in \mathcal{G}$). If $x \in X$ and $\mathcal{F}$ is the neighborhood filter of x, then $x = [\mathcal{F}] \in \bar{U}$ if and only if $x \in U$. Thus $\bar{U} \cap X = U$.

Set $\bar{\mathcal{U}} = \{\bar{U} : U \in \mathcal{U}\}$ and $\bar{\mathscr{U}} = \{\bar{\mathcal{U}} : \mathcal{U} \in \mathscr{U}\}$.

XIII.15.8.6. PROPOSITION. $\bar{\mathscr{U}}$ is a covering uniformity on $\bar{X}$, and $\bar{\mathscr{U}}_X = \mathscr{U}$. In particular, $\mathcal{T}_{\mathscr{U}}$ is the relative topology on X from $\mathcal{T}_{\bar{\mathscr{U}}}$, and X is dense in $\bar{X}$.

Let $\bar{\mathfrak{U}}$ be the corresponding uniformity on $\bar{X}$.

XIII.15.8.7. PROPOSITION. $(\bar{X}, \bar{\mathfrak{U}})$ is complete and separated, and thus is a completion of $(X, \mathfrak{U})$.

Uniqueness

We give a general result which implies uniqueness of completions in the separated case:

XIII.15.8.8. PROPOSITION. Let X be a set, and $\mathfrak{U}$ and $\mathfrak{V}$ uniformities on X with $\mathfrak{U} \subseteq \mathfrak{V}$. Suppose $(X, \mathfrak{U})$ is separated (so $(X, \mathfrak{V})$ is also separated). Let $(Y, \tilde{\mathfrak{U}})$ and $(Z, \tilde{\mathfrak{V}})$ be (separated) completions of $(X, \mathfrak{U})$ and $(X, \mathfrak{V})$ respectively. Then there is a unique map $\phi : Z \to Y$ which is continuous for $\mathcal{T}_{\tilde{\mathfrak{V}}}$ and $\mathcal{T}_{\tilde{\mathfrak{U}}}$ and is the identity on X, under the canonical identifications of X with (dense) subspaces of Y and Z. In addition, ϕ is $(\tilde{\mathfrak{V}}, \tilde{\mathfrak{U}})$-uniformly continuous.

PROOF: Uniqueness of ϕ is clear, since Y is Hausdorff and two such continuous functions agree on the dense subset X of Z. We show existence.
Let $z \in Z$, and let $\mathcal{N}_z$ be the $\mathcal{T}_{\tilde{\mathfrak{V}}}$-neighborhood filter of z in Z. Set

$$\mathcal{F}_z = \{V \cap X : V \in \mathcal{N}_z\} .$$

Since X is dense in Z, $\mathcal{F}_z$ is a filter on X. Because $\mathcal{N}_z$ is a $\tilde{\mathfrak{V}}$-Cauchy filter on Z and $\mathfrak{V} = \tilde{\mathfrak{V}}_X$, $\mathcal{F}_z$ is a $\mathfrak{V}$-Cauchy filter on X, hence a $\mathfrak{U}$-Cauchy filter on X. Since $\mathfrak{U} = \tilde{\mathfrak{U}}_X$, $\mathcal{F}_z$ is a $\tilde{\mathfrak{U}}$-Cauchy filterbase on Y. If $\mathcal{G}_z$ is the corresponding $\tilde{\mathfrak{U}}$-Cauchy filter on Y, then $\mathcal{G}_z$ converges to $y \in Y$, which is unique since Y is Hausdorff. Set $\phi(z) = y$. It is routine to check that ϕ has the desired properties. 👍

XIII.15.8.9. COROLLARY. Let $(X, \mathfrak{U})$ be a separated uniform space. Then the completion $(\bar{X}, \bar{\mathfrak{U}})$ of XIII.15.8.7. is the unique (separated) completion of $(X, \mathfrak{U})$, i.e. any completion is uniformly isomorphic to $(\bar{X}, \bar{\mathfrak{U}})$.

PROOF: Let $(Y, \tilde{\mathfrak{U}})$ and $(Z, \hat{\mathfrak{U}})$ be completions of $(X, \mathfrak{U})$. Apply XIII.15.8.8. twice with $\mathfrak{V} = \mathfrak{U}$ to obtain $\phi : Z \to Y$ and $\psi : Y \to Z$. Then $\phi \circ \psi$ and $\psi \circ \phi$ are the identity on X, hence the identity, so ϕ and ψ are uniform isomorphisms. 👍

Absolutely Closed Uniform Spaces

XIII.15.8.10. DEFINITION. Let $(X, \mathfrak{U})$ be a separated uniform space. Then $(X, \mathfrak{U})$ is *absolutely closed* if, whenever $(X, \mathfrak{U})$ is uniformly embedded in a separated uniform space $(Y, \mathfrak{V})$ (i.e. $X \subseteq Y$ and $\mathfrak{U} = \mathfrak{V}_X$), then X is closed in Y.

XIII.15.8.11. PROPOSITION. Let $(X, \mathfrak{U})$ be a separated uniform space. Then $(X, \mathfrak{U})$ is absolutely closed if and only if it is complete.

PROOF: $(X, \mathfrak{U})$ is uniformly embedded in $(\bar{X}, \bar{\mathfrak{U}})$, and if $(X, \mathfrak{U})$ is absolutely closed, then X is dense and closed in $\bar{X}$, hence $X = \bar{X}$ and $(X, \mathfrak{U})$ is complete. Conversely, suppose $(X, \mathfrak{U})$ is complete and uniformly embedded in $(Y, \mathfrak{V})$. Then $(X, \mathfrak{U})$ is also uniformly embedded in $(\bar{Y}, \bar{\mathfrak{V}})$, so X is closed in $\bar{Y}$ by XIII.15.7.6. and hence also closed in Y. Thus $(X, \mathfrak{U})$ is absolutely closed. 👍

XIII.15.9. Metric Spaces

In this section, we specialize to the case of metric spaces (or metrizable uniformizable spaces). We give some additional equivalent conditions for completeness in the sense of XIII.15.6.3..

XIII.15.9.1. We will not assume any form of Choice in this subsection, i.e. we will work in ZF set theory. It is useful to see that almost everything one would want to show, with a single notable exception, can be done without any Choice assumed.

The exception is that without the Countable AC we cannot simply work with Cauchy sequences.

XIII.15.9.2. DEFINITION. Let (X, ρ) be a metric space. then (X, ρ) is *uniformly complete* if $(X, \mathfrak{U}_\rho)$ is a complete uniform space (i.e. if every $\mathfrak{U}_\rho$-Cauchy net converges), and (X, ρ) is *Cauchy complete* if every ρ-Cauchy sequence in X converges (i.e. (X, ρ) is complete in the sense of ()).

There is one additional notion of completeness we will use:

XIII.15.9.3. DEFINITION. Let (X, ρ) be a metric space. Then (X, ρ) is *σ-complete* if, whenever (F_n) is a decreasing sequence of nonempty closed sets in X whose diameters approach zero, then $\cap_n F_n$ is nonempty (it is then necessarily a singleton). (X, ρ) is *regularly σ-complete* if, whenever (F_n) is a decreasing sequence of nonempty regular (XIII.15.6.15.) closed sets in X whose diameters approach zero, then $\cap_n F_n$ is nonempty.

One might think σ-completeness is the same as Cauchy completeness, and it is if the Countable AC is assumed; but they can be different otherwise (the difficulty is that without the Countable AC, a metric space may have "too few" Cauchy sequences, cf. XIII.15.12.8.). The completeness conditions are equivalent in the separable case without any Choice (XIII.15.9.7.).

XIII.15.9.4. Any closed subspace of a σ-complete metric space is obviously σ-complete. Conversely, a σ-complete subspace of a metric space is closed (consider a decreasing sequence of closed balls around a point of the closure).

XIII.15.9.5. PROPOSITION. Let (X, ρ) be a metric space.

(i) If (X, ρ) is σ-complete, then it is Cauchy complete.

(ii) If the Countable AC is assumed and (X, ρ) is Cauchy complete, then it is σ-complete.

PROOF: (i) Let (x_n) be a ρ-Cauchy sequence in X. For each n let F_n be the closure of the set $\{x_k : k \geq n\}$. Then (F_n) is a decreasing sequence of nonempty closed sets in X, whose diameters approach 0 since (x_n) is a Cauchy sequence. Thus $\cap_n F_n = \{x\}$ for some $x \in X$, and $x_n \to x$.

(ii) Let (F_n) be a decreasing sequence of nonempty closed sets whose diameters approach 0. Using Countable AC choose $x_n \in F_n$ for each n. Then (x_n) is a ρ-Cauchy sequence since $x_k \in F_n$ for all n and all $k \geq n$. Thus $x_n \to x$ for some $x \in X$, and $x \in \cap_n F_n$ since the F_n are closed. 👍

The following is a theorem of ZF, i.e. no Choice is assumed. If the Countable AC is assumed, then (vii) is equivalent to the other conditions (XIII.15.9.5.).

XIII.15.9.6. THEOREM. Let (X, ρ) be a metric space. The following are equivalent:

(i) (X, ρ) is absolutely closed.

(ii) (X, ρ) is σ-complete.

(iii) (X, ρ) is regularly σ-complete.

(iv) Whenever (F_i) is a $\mathfrak{U}_\rho$-Cauchy nest in X, then $\cap_{i \in I} F_i$ is nonempty.

(v) Whenever (F_i) is a regular $\mathfrak{U}_\rho$-Cauchy nest in X, then $\cap_{i \in I} F_i$ is nonempty.

(vi) (X, ρ) is uniformly complete.

These conditions imply

(vii) (X, ρ) is Cauchy complete.

PROOF: (iv) $\Rightarrow$ (ii) $\Rightarrow$ (iii) and (iv) $\Rightarrow$ (v) $\Rightarrow$ (iii) are trivial, (iv) $\iff$ (vi) is XIII.15.6.16., and (ii) $\Rightarrow$ (vii) is XIII.15.9.5.. (i) $\Rightarrow$ (vi) since (X, ρ) is then closed and dense in its uniform completion $(\bar{X}, \bar{\rho})$.

(iii) $\Rightarrow$ (i): Suppose (X, ρ) is not absolutely closed. Identify (X, ρ) with a nonclosed subspace of a metric space (Y, ρ'), and let $p \in \bar{X} \setminus X$. For each n let U_n be the intersection of X with the open ball $B_{1/n}$ (in Y) of radius $1/n$ around p, and F_n be the closure of U_n in X. Since p is a limit point of X, each F_n is nonempty, and is a regular closed set in X, and $F_{n+1} \subseteq F_n$, $F_{n+1} \subseteq B_{1/n}$. But

$$\bigcap_n F_n \subseteq X \cap \bigcap_n B_{1/n} = X \cap \{p\} = \emptyset$$

so (X, ρ) is not regularly σ-complete. 👍

XIII.15.9.7. PROPOSITION. Let (X, ρ) be a separable metric space. Then (X, ρ) is σ-complete if and only if it is Cauchy complete.

PROOF: One direction is XIII.15.9.5.. Conversely, suppose (X, ρ) is Cauchy complete. Fix a dense sequence (x_k) in X. Let (F_n) be a regular Cauchy nest in X. For each n let y_n be the first x_k with $x_k \in F_n^\circ$. Since $diam(F_n) \to 0$, (y_n) is a Cauchy sequence in X. If y is the limit, then $y \in \cap_n F_n$. 👍

The proof of the next result is adapted from [KT01]. We describe an algorithm for choosing a point from any nonempty open subset; the algorithm requires one choice of a countable base, but no further choice.

XIII.15.9.8. LEMMA. Let (X, ρ) be a second countable σ-complete metric space. Fix a countable base $\mathcal{U} = \{U_k : k \in \mathbb{N}\}$ for the topology of X consisting of nonempty sets. Then there is a recursive algorithm (depending on $\mathcal{U}$) for choosing an element from each nonempty open set in X.

PROOF: Let W be a nonempty open set in X. Recursively generate a decreasing sequence (F_n) of closed sets as follows. Let V_1 be the the first U_k for which $F_1 := \bar{U}_k \subseteq W$ and $diam(U_k) < 1$ (it is easily seen that there is such a U_k). If V_n and $F_n = \bar{V}_n$ have been defined, let V_{n+1} be the first U_k for which $F_{n+1} := \bar{U}_k \subseteq V_n$ and $diam(U_k) < \frac{1}{n+1}$. Then the F_n form a (regular) Cauchy nest in X. Let x be the unique point in the intersection. We have $x \in F_1 \subseteq W$. 👍

XIII.15.9.9. THEOREM. Let (X, ρ) be a σ-complete metric space. Then (X, ρ) is separable if and only if it is second countable.

PROOF: A separable metric space is second countable (balls of rational radii around a dense set of points form a base for the topology). The converse (indeed, the much more general result that every second countable topological space is separable) is trivial if the Countable AC is assumed. We give a proof in the σ-complete case which requires no Choice.

Fix a countable base $\mathcal{U} = \{U_k : k \in \mathbb{N}\}$ for the topology of X consisting of nonempty sets. For each k we define an $x_k \in U_k$ using the algorithm of XIII.15.9.8.. The sequence (x_k) is dense in X, so (X, ρ) is separable. 👍

XIII.15.9.10. Some completeness is needed here (in the absence of the Countable AC). COHEN constructed an infinite Dedekind-finite subset X of $\mathbb{R}$. X with the relative topology is metrizable and second countable, but not separable since X has no countably infinite subsets at all.

It is unclear whether XIII.15.9.9. holds just under Cauchy completeness. But combining it with XIII.15.9.7. (cf. XIII.15.9.4.), we obtain:

XIII.15.9.11. COROLLARY. Let (X, ρ) be a separable (Cauchy) complete metric space. Then every closed subspace of X is also separable.

PROOF: Any subspace of a second countable space is second countable. 👍

Metric Versions of Local Compactness

There are (at least) two relevant versions of local compactness for metric spaces. The next definition is nonstandard:

XIII.15.9.12. DEFINITION. Let (X, ρ) be a metric space.

(i) (X, ρ) is a *Heine-Borel space* if every closed bounded subset of X is compact.

(ii) (X, ρ) is *compact im kleinen* if there is an $\eta > 0$ such that every closed subset of diameter $\leq \eta$ is compact.

XIII.15.9.13. Note that these are *metric* notions, not topological ones. A Heine-Borel space is compact im kleinen; a metric space which is compact im kleinen is σ-complete, and locally compact as a topological space; a Heine-Borel space is locally compact and σ-compact. The Heine-Borel Theorem of course says that $\mathbb{R}^n$ with its usual metric is a Heine-Borel space.

A space can be Heine-Borel or compact im kleinen under one metric but not under an equivalent metric (XIII.15.9.14.(i)). A space which is compact im kleinen under one metric is compact im kleinen under any uniformly equivalent metric; thus compactness im kleinen is a uniform property.

XIII.15.9.14. Examples. (i) $(0,1)$ with its usual metric is not compact im kleinen (and *a fortiori* not Heine-Borel). But it is homeomorphic to $\mathbb{R}$, which is Heine-Borel.

(ii) $\mathbb{R}$ with the metric $\tilde{\rho}$ defined by $\tilde{\rho}(x,y) = \min(|x-y|,1)$ is compact im kleinen but not Heine-Borel. The metric $\tilde{\rho}$ is uniformly equivalent to the usual metric. Thus the Heine-Borel property is not a uniform property.

(iii) An infinite set with the discrete metric is compact im kleinen but not Heine-Borel. An uncountable set with the discrete metric is compact im kleinen but not σ-compact.

XIII.15.9.15. It can be shown using the Tietze Extension Theorem (XIII.15.12.10.) that every locally compact, σ-compact metrizable space has a metric making it a Heine-Borel space. But it is unclear whether this can be shown without some Choice. It is possible that every locally compact metrizable space has a metric making it compact im kleinen.

XIII.15.10. Compact and Precompact Uniform Spaces

Compact Hausdorff Spaces

XIII.15.10.1. Theorem. Let $(X,\mathcal{T})$ be a compact Hausdorff space. Let $\mathfrak{U}$ be the set of all neighborhoods of $X \times X$ in the product topology. Then $\mathfrak{U}$ is an admissible uniformity for $\mathcal{T}$ on X, and is the unique admissible uniformity on X. In particular, every compact Hausdorff space is uniformizable.

Proof: It follows immediately from XIII.11.4.5. that $\mathfrak{U}$ is an admissible uniformity for $\mathcal{T}$ on X. To show uniqueness, let $\mathfrak{V}$ be an admissible uniformity for $\mathcal{T}$ on X. 👍

XIII.15.10.2. If some Choice (e.g. DC) is assumed, compact Hausdorff spaces are completely regular, so the last statement follows from (); but the above proof does not use any Choice.. If no Choice is assumed, a compact Hausdorff space X can be constructed which is not completely regular (XIII.11.14.20.). Then $\mathfrak{U}$ is a uniformity on X which does not come from a family of pseudometrics (i.e. has no gauge).

XIII.15.10.3. Corollary. Let $(X,\mathcal{T})$ be a (uniformizable) Hausdorff topological space

Totally Bounded Uniformities

XIII.15.10.4. DEFINITION. Let $(X, \mathfrak{U})$ be a uniform space, and $\mathscr{U}$ the corresponding covering uniformity. Then $(X, \mathscr{U})$ is *totally bounded* if every $\mathcal{U} \in \mathscr{U}$ has a finite subcover. $(X, \mathfrak{U})$ is *compact* if $(X, \mathcal{T}_{\mathfrak{U}})$ is compact.

XIII.15.10.5. Being compact is a topological concept, but being totally bounded is a uniform concept: if $\mathfrak{U}$ and $\mathfrak{V}$ are uniformities admissible for a (noncompact) topology $\mathcal{T}$ on X, it can happen that $(X, \mathfrak{U})$ is totally bounded but $(X, \mathfrak{V})$ is not (). A compact uniform space is totally bounded. A totally bounded uniform space is not necessarily compact, since it is far from true that every open cover is a uniform cover (for example, every subspace of a totally bounded uniform space is totally bounded in the subspace uniformity). In the case of a metric space, the space is totally bounded with respect to the metric uniformity if and only if it is totally bounded in the sense of ().

XIII.15.10.6. PROPOSITION. Let $(X, \mathfrak{U})$ be a uniform space, and $\mathscr{U}$ the corresponding covering uniformity. Then $(X, \mathfrak{U})$ is totally bounded if and only if $\mathscr{U}$ has a subbase consisting of finite covers of X.

XIII.15.10.7. PROPOSITION. Let $\mathfrak{U}$ and $\mathfrak{V}$ be uniformities on a set X. If $\mathfrak{U} \subseteq \mathfrak{V}$ and $(X, \mathfrak{V})$ is totally bounded (resp. compact), then $(X, \mathfrak{U})$ is totally bounded (resp. compact).

XIII.15.10.8. PROPOSITION. Let $\{\mathfrak{U}_i : i \in I\}$ be uniformities on a set X, and $\mathfrak{U} = \bigvee_i \mathfrak{U}_i$. Then $(X, \mathfrak{U})$ is totally bounded if and only if each $(X, \mathfrak{U}_i)$ is totally bounded.

XIII.15.10.9. PROPOSITION. Let $\{(X_i, \mathfrak{U}_i) : i \in I\}$ be a set of uniform spaces. Assume $X = \prod_i X_i \neq \emptyset$, and set $(X, \mathfrak{U}) = \prod_i (X_i, \mathfrak{U}_i)$. Then $(X, \mathfrak{U})$ is totally bounded if and only if each $(X, \mathfrak{U}_i)$ is totally bounded.

XIII.15.10.10. PROPOSITION. Let $(X, \mathfrak{U})$ be a separated uniform space. If $(X, \mathfrak{U})$ is totally bounded, so is $(\bar{X}, \bar{\mathfrak{U}})$.

The following theorem requires at least the BPI if not the full AC:

XIII.15.10.11. THEOREM. Let $(X, \mathfrak{U})$ be a uniform space. Then $(X, \mathfrak{U})$ is compact if and only if it is complete and totally bounded.

XIII.15.10.12. COROLLARY. A (separated) uniform space $(X, \mathfrak{U})$ is totally bounded if and only if $(\bar{X}, \bar{\mathfrak{U}})$ is compact.

XIII.15.10.13. As a result, a totally bounded uniform space is often called *precompact*.

XIII.15.10.14. Theorem XIII.15.10.11. cannot be proved without at least the BPI: the statement implies the BPI (Tikhonov's Theorem for Hausdorff Spaces, cf. XIII.15.12.9.). An arbitrary product of separated complete uniform spaces is complete in the product uniformity (XIII.15.7.8.), and an arbitrary product of totally bounded uniform spaces is totally bounded in the product uniformity by XIII.15.10.9.. Thus an arbitrary product of compact Hausdorff spaces is both complete and totally bounded in the product uniformity.

Completions and Compactifications

To make things simpler, in this subsection we will assume the AC (or at least DC+BPI), and only work with separated uniformities. Under these assumptions, all uniform spaces have gauges and all uniformizable spaces are completely regular, a uniform space is compact if and only if it is complete and totally bounded, an arbitrary product of compact uniform spaces is compact, and the completion of a totally bounded uniform space is compact.

XIII.15.10.15. Let $(X,\mathcal{T})$ be a completely regular space. Let $\mathfrak{U}$ and $\mathfrak{V}$ be (necessarily separated) admissible uniformities for $\mathcal{T}$, and $(Y,\bar{\mathfrak{U}})$ and $(Z,\bar{\mathfrak{V}})$ the completions of $(X,\mathfrak{U})$ and $(X,\mathfrak{V})$ respectively. Then $(Y,\bar{\mathfrak{U}})$ and $(Z,\bar{\mathfrak{V}})$ are not necessarily compact (i.e. $(X,\mathfrak{U})$ and $(X,\mathfrak{V})$ are not necessarily totally bounded). If they are not compact, we can have Y and Z homeomorphic over X even if $\mathfrak{U}\neq\mathfrak{V}$ (they could even both be just X, cf. XIII.15.6.6.). However, if one (hence both) are totally bounded, this cannot happen:

XIII.15.10.16. Proposition. In the above situation, if $(X,\mathfrak{U})$ is totally bounded and Y and Z are homeomorphic over X (hence compact, so $(X,\mathfrak{V})$ is also necessarily totally bounded), then $\mathfrak{U}=\mathfrak{V}$.

Proof: We can identify Y and Z and call the space $\bar{X}$. We have $\mathfrak{U}=(\bar{\mathfrak{U}})_X$ and $\mathfrak{V}=(\bar{\mathfrak{V}})_X$. But $\bar{X}$ is compact, so it has a unique admissible uniformity (XIII.15.10.1.), and thus $\bar{\mathfrak{U}}=\bar{\mathfrak{V}}$. 👍

XIII.15.10.17. Corollary. Let $(X,\mathcal{T})$ be a completely regular space. Then there is a one-one correspondence between compactifications of $(X,\mathcal{T})$ and admissible totally bounded uniformities for $\mathcal{T}$. The partially ordered set of admissible totally bounded uniformities for $\mathcal{T}$, ordered by inclusion, is order-isomorphic to the set of equivalence classes of compactifications of $(X,\mathcal{T})$ with the domination partial order ().

XIII.15.10.18. If $(X,\mathcal{T})$ is completely regular, there is a largest compactification of $(X,\mathcal{T})$, βX. Thus there is a largest admissible totally bounded uniformity for $\mathcal{T}$, namely $\mathfrak{C}^*$ (XIII.15.1.28.). There is a smallest totally bounded admissible uniformity for $\mathcal{T}$ if and only if $(X,\mathcal{T})$ is locally compact (XIII.11.14.21.), namely the uniformity from the one-point compactification $X^\dagger$. This is extendible to arbitrary admissible uniformities:

XIII.15.10.19. PROPOSITION. Let $(X, \mathcal{T})$ be a completely regular space, and $\mathfrak{U}$ an admissible uniformity for $\mathcal{T}$. Then the uniformity $\mathfrak{U} \wedge \mathfrak{C}^*$ (XIII.15.5.6.) is admissible for $\mathcal{T}$, and is the largest totally bounded uniformity contained in $\mathfrak{U}$. In particular, every admissible uniformity on X contains an admissible totally bounded uniformity.

XIII.15.10.20. Thus, if $(X, \mathcal{T})$ is a completely regular space, there is always a largest admissible uniformity, the fine uniformity; but there is a minimal admissible uniformity if and only if $(X, \mathcal{T})$ is locally compact, in which case the uniformity from $X^\dagger$ is the smallest admissible uniformity.

XIII.15.11. Topologically Complete Spaces

One of the deepest theorems in the subject of uniform spaces is SHIROTA'S near-characterization of topologically complete spaces as realcompact (XIII.11.13.4.) spaces [**?**]:

XIII.15.11.1. THEOREM. Let $(X, \mathcal{T})$ be a completely regular topological space. Then

(i) If $(X, \mathcal{T})$ is realcompact, then it is topologically complete.

(ii) If $(X, \mathcal{T})$ is topologically complete, and every closed discrete subspace of X has nonmeasurable cardinality (II.10.4.2.), then $(X, \mathcal{T})$ is realcompact.

XIII.15.11.2. Thus if $(X, \mathcal{T})$ is completely regular, and is not of absurdly large size, then it is topologically complete if and only if it is realcompact. The cardinality restriction is necessary: every discrete space is topologically complete (the discrete metric is complete), but a discrete space of measurable cardinality is not realcompact.

XIII.15.11.3. Every completely metrizable space (XIII.10.3.1.) is obviously topologically complete. But a topologically complete metrizable space need not be completely metrizable. In fact:

XIII.15.11.4. THEOREM. Every metrizable topological space is topologically complete.

See [GJ76] for proofs of XIII.15.11.1. and XIII.15.11.4.. The proofs use the AC.

XIII.15.12. Exercises

XIII.15.12.1. Prove all the propositions in this section given without proof.

XIII.15.12.2. Let $(X, \mathfrak{U})$ be a uniform space. Set $R = \cap_{U \in \mathfrak{U}} U$.

(i) Show that R is an equivalence relation on X, and is the equality relation if and only if $\mathfrak{U}$ is separated.

(ii) Let $\tilde{X} = X/R$ be the set of equivalence classes. Show that $\mathfrak{U}$ induces a unique uniformity $\tilde{\mathfrak{U}}$ on $\tilde{X}$.

(c) Show that the topology $\mathcal{T}_{\tilde{\mathfrak{U}}}$ on $\tilde{X}$ is the quotient topology from $\mathcal{T}_{\mathfrak{U}}$, that the quotient map π from X to $\tilde{X}$ is $(\mathfrak{U}, \tilde{\mathfrak{U}})$-uniformly continuous, and that $(\tilde{X}, \mathcal{T}_{\tilde{\mathfrak{U}}})$ is the maximal T_0 quotient () and the maximal Hausdorff quotient () of $(X, \mathcal{T}_{\mathfrak{U}})$.

(d) If $(Y, \mathfrak{V})$ is any separated uniform space, any $f : X \to Y$ which is $(\mathfrak{U}, \mathfrak{V})$-uniformly continuous factors uniquely through $(\tilde{X}, \tilde{\mathfrak{U}})$ as $\tilde{f} \circ \pi$, and $\tilde{f} : \tilde{X} \to Y$ is $(\tilde{\mathfrak{U}}, \mathfrak{V})$-uniformly continuous.

Thus the theory of general uniform spaces can be essentially completely reduced to separated uniform spaces. Some authors even require uniform spaces to be separated, calling a nonseparated uniformity a "preuniformity."

XIII.15.12.3. (a) If X is a set, there are at most $2^{2^{|X|}}$ uniformities on X. [A covering uniformity on X is an element of $\mathcal{P}(\mathcal{P}(X))$.] So there are at most $2^{2^{\aleph_0}}$ uniformities on $\mathbb{N}$.

(b) $\mathbb{N}$ has $2^{2^{\aleph_0}}$ distinct compactifications (XIII.11.14.9.). So there are at least (hence exactly) $2^{2^{\aleph_0}}$ uniformities on $\mathbb{N}$ admissible for the discrete topology (XIII.15.10.17.).

XIII.15.12.4. Uniformities on $\mathbb{Q}$. Give $\mathbb{Q}$ its topology $\mathcal{T}$ from the usual metric (i.e. the relative topology from $\mathbb{R}$). In this problem, say a uniform structure on $\mathbb{Q}$ is *admissible* if it is admissible for $\mathcal{T}$. Since $\mathcal{T}$ is metrizable, there is an admissible uniform structure, in fact many, including the metric uniformity and the uniformities $\mathfrak{C}$ and $\mathfrak{C}^*$ from $\mathcal{C}$ and $\mathcal{C}^*$ (XIII.15.1.28.). In this problem we describe a large family of other admissible uniformities on $\mathbb{Q}$.

(a) Let A be a set of irrational numbers which is dense in $\mathbb{R}$. Let $\mathcal{I}_A$ be the set of intervals in $\mathbb{Q}$ of the form $[a, b] \cap \mathbb{Q} = (a, b) \cap \mathbb{Q}$ for $a, b \in A$, and let

$$F_A = \{\chi_I : I \in \mathcal{I}_A\}$$

be the set of indicator functions of intervals in $\mathcal{I}_A$. Each $I \in \mathcal{I}_A$ is clopen in $\mathbb{Q}$, so the functions in F_A are continuous. Let $\mathcal{P}_A$ be the set of pseudometrics corresponding to the functions in F_A as in XIII.15.1.24.. Then $\mathcal{P}_A \subseteq \mathcal{C}^*$. Let $\mathfrak{U}_A$ be the uniformity on $\mathbb{Q}$ defined by $\mathcal{P}_A$. Show that $\mathfrak{U}_A$ is an admissible uniformity on $\mathbb{Q}$. [$\mathcal{I}_A$ is a base for the topology of $\mathbb{Q}$.] $\mathfrak{U}_A$ is metrizable if and only if A is countable.

(b) Let b, c be irrational numbers with $b < c$, and $I = [b, c] \cap \mathbb{Q}$. Then I is clopen in $\mathbb{Q}$, so $\chi_I \in BC(\mathbb{Q})$. Show that χ_I is $\mathfrak{U}_A$-uniformly continuous if and only if $b, c \in A$, and that the pseudometric ρ_{χ_I} is uniformly dominated by $\mathcal{P}_A$ if and only if $b, c \in A$. Thus if A and B are distinct dense sets of irrationals, then $\mathfrak{U}_A$ and $\mathfrak{U}_B$ are distinct admissible uniformities. Since there are $2^{2^{\aleph_0}}$ dense sets of irrationals in $\mathbb{R}$, there are $2^{2^{\aleph_0}}$ distinct admissible uniformities (by XIII.15.12.3. there are no more than $2^{2^{\aleph_0}}$ since $\mathbb{Q}$ is countable).

(c) Let A and B be sets of irrational numbers dense in $\mathbb{R}$. Show that $\mathfrak{U}_A \vee \mathfrak{U}_B = \mathfrak{U}_{A \cup B}$.

(d) Let A and B be sets of irrational numbers dense in $\mathbb{R}$. Show that there is an admissible uniformity $\mathfrak{V}$ contained in both $\mathfrak{U}_A$ and $\mathfrak{U}_B$ if and only if $A \cap B$ is dense in $\mathbb{R}$, in which case $\mathfrak{U}_{A \cap B} = \mathfrak{U}_A \wedge \mathfrak{U}_B$.

(e) If A and B are disjoint dense sets of irrationals (e.g. $A = \sqrt{2} + \mathbb{Q}$, $B = \pi + \mathbb{Q}$), then $\mathfrak{U}_A \wedge \mathfrak{U}_B$ is the indiscrete uniformity.

There are *many* other admissible uniformities on $\mathbb{Q}$ (but exactly $2^{2^{\aleph_0}}$ in all): for example, any compactification of $\mathbb{R}$ gives one. In fact, by XIII.13.9.16., every completely regular separable first countable space without isolated points gives at least one admissible uniformity (actually many in general; cf. XIII.11.14.24.).

XIII.15.12.5. (a) Let $(X, \mathfrak{U})$ be a uniform space. Prove without any form of Choice (e.g. without using ()) that $(X, \mathcal{T}_{\mathfrak{U}})$ is T_3 (regular if it is T_0, i.e. if $(X, \mathfrak{U})$ is separated).

***(b) In the absence of any form of Choice, give a topological characterization of what (T_0) topological spaces are uniformizable. [Any subspace of a product of compact Hausdorff spaces is uniformizable by **??**,

XIII.15.5.9., and XIII.15.7.2.. Are these the only ones? This class includes all completely regular spaces (XIII.15.1.28.), and all compactly embeddable spaces (homeomorphic to a subspace of a compact Hausdorff space). Note that one needs Tikhonov's theorem for Hausdorff spaces, i.e. the BPI (II.6.3.11.), to obtain that every completely regular space is compactly embeddable.]

XIII.15.12.6. Let $(X, \mathcal{T})$ be a T_0 topological space. Give $X \times X$ the product topology. If the set of all neighborhoods of Δ is a uniformity on X admissible for $\mathcal{T}$, show that $(X, \mathcal{T})$ is collectionwise normal, and in particular normal. [Let $\{E_i\}$ be a collection of closed subsets of X such that each E_i is disjoint from the closed set $F_i = \cup_{j \neq i} E_j$. Let U be the union of the sets $(X \setminus F_i) \times (X \setminus F_i)$. Then U is an open neighborhood of Δ. If there is an open neighborhood V of Δ with $V \circ V \subseteq U$, consider the sets $V(E_i)$.]

Thus, if $(X, \mathcal{T})$ is completely regular but not collectionwise normal (e.g. not normal), then the fine uniformity for $\mathcal{T}$ (XIII.15.5.4.) does not include all neighborhoods of the diagonal.

XIII.15.12.7. Completions of Nonseparated Uniform Spaces. In this problem we outline the modifications needed to construct a completion (the "minimal" one) of a uniform space which is not separated.

(a) Let $(X, \mathfrak{U})$ be a uniform space which is not necessarily separated, and let $\mathscr{C}$ and $\sim$ be as in XIII.15.8.2.. Set

$$\bar{X} = \{(x, [\mathcal{F}]) : \mathcal{F} \in \mathscr{C} \text{ converges to } x\} \cup \{[\mathcal{F}] : \mathcal{F} \in \mathscr{C} \text{ does not converge}\}$$

and identify $x \in X$ with $(x, [\mathcal{F}])$ for a filter $\mathcal{F}$ converging to x, e.g. the neighborhood filter of x. Modify the definition of the uniform structure $\bar{\mathfrak{U}}$ on $\bar{X}$ to this setting, and prove analogs of XIII.15.8.6. and XIII.15.8.7..

(b) Show that if $(Y, \mathfrak{V})$ is a complete uniform space containing $(X, \mathfrak{U})$, then there is a unique $f : Y \to \bar{X}$ which is the identity on X and with $\mathfrak{V} = f^{-1}(\bar{\mathfrak{U}})$. Thus $(\bar{X}, \bar{\mathfrak{U}})$ is the "minimal" completion.

(c) Let $\approx$ be the T_0-equivalence relation, i.e. $x \approx y$ if $\{x\}$ and $\{y\}$ have the same closure (). Show that $(\bar{X}, \bar{\mathfrak{U}})$ is the unique completion with the property that no $y \in \bar{X} \setminus X$ is T_0-equivalent to any other point of $\bar{X}$.

(d) A uniform space can have many "completions." Let $X = (\mathbb{R} \setminus \{0\}) \times \{0, 1\}$, where $\{0, 1\}$ has the indiscrete topology. Then X is uniformizable under the uniformity $\mathfrak{V} = \pi^{-1}(\mathfrak{U})$, where $\mathfrak{U}$ is the usual uniformity on $\mathbb{R} \setminus \{0\}$ and π is the projection of X onto the first coordinate. Then $(Y, \mathfrak{W})$ is a "completion" of $(X, \mathfrak{V})$, where $Y = \mathbb{R} \times \{0, 1\}$ and $\mathfrak{W}$ the preimage under π of the usual metric uniformity on $\mathbb{R}$. In this case, $\bar{X}$ can be identified with $X \cup \{(0, 0)\}$ with $\bar{\mathfrak{U}} = \mathfrak{W}_{\bar{X}}$.

(e) Even a (separated) complete metrizable uniform space can have a larger "completion" which is not separated. Let $(\mathbb{R}, \mathfrak{U})$ be the metric uniform space from the standard metric on $\mathbb{R}$, $Y = \mathbb{R} \times \{0, 1\}$ (where $\{0, 1\}$ has the indiscrete topology), and $\mathfrak{V} = \pi^1(\mathfrak{U})$. Then $(Y, \mathfrak{V})$ is a "completion" of $(\mathbb{R}, \mathfrak{U})$. For a perhaps more interesting example, let $\mathfrak{U}$ be the usual metric uniformity on $\mathbb{R} \setminus \{0\}$. The space Y of XIII.20.1.3.(v) with doubled origin has a compatible uniform structure $\mathfrak{V}$ which makes $(Y, \mathfrak{V})$ a "completion" of $(X, \mathfrak{U})$.

XIII.15.12.8. A Bizarre Metric Space Without Countable AC. [] Let (X_n) be a sequence of pairwise disjoint nonempty sets such that the product of any infinite subcollection is empty (such a sequence can be constructed in a model of ZF (), but is of course incompatible with the Countable AC). Set $X = \cup_n X_n$. Put a metric ρ on X by setting $\rho(x, y) = \frac{1}{n}$ if $x, y \in X_n$, $x \neq y$, and $\rho(x, y) = \frac{1}{n} + \frac{1}{m}$ if $x \in X_n$, $y \in X_m$, $n \neq m$.

(a) Show that ρ is a metric on X, and the metric topology is the discrete topology.

(b) Show that every ρ-Cauchy sequence is eventually constant. [A ρ-Cauchy sequence not eventually constant would have terms in infinitely many X_n.] Thus (X, ρ) is Cauchy complete.

(c) For each n, let $F_n = \cup_{k \geq n} X_k$. Then (F_n) is a decreasing sequence of closed sets in X. Show that $diam(F_n) = \frac{1}{n} + \frac{1}{n+1}$, so $diam(F_n) \to 0$. But $\cap_n F_n = \emptyset$. So (X, ρ) is not σ-complete, hence not uniformly complete.

(d) Suppose each X_k is finite. Let $X^\dagger = X \cup \{\infty\}$ be the one-point compactification of X. Extend ρ to $\bar{\rho}$ on $X^\dagger$ by setting $\bar{\rho}(x, \infty) = \bar{\rho}(\infty, x) = \frac{1}{n}$ if $x \in X_n$. Show that $\bar{\rho}$ is a metric on $X^\dagger$ defining its topology, so $(X^\dagger, \bar{\rho})$ is a compact metric space. X is dense in $X^\dagger$, i.e. ∞ is in the closure of X in $X^\dagger$, but no sequence in X converges to ∞. $(X^\dagger, \bar{\rho})$ is not separable or second countable.

XIII.15.12.9. Another Bizarre Metric Space Without Countable AC. Let (I_n) be a set of Russell socks, a sequence of pairwise disjoint two-element sets such that the product of any infinite subcollection is empty (), and let $I = \cup_n I_n$. Let $X = \{0,1\}^I$, the set of all functions from I to $\{0,1\}$. Put a metric on X as follows. If $f, g \in X$, $f \neq g$, let $n(f,g)$ be the smallest n such that f and g disagree on I_n, and set $\rho(f,g) = 2^{-n(f,g)}$.

(a) Show that ρ (extended by $\rho(f,f) = 0$ for all f) is a metric on X, and the metric topology is the product topology (taking the discrete topology on $\{0,1\}$).

(b) Show that (X, ρ) is uniformly complete and totally bounded. [For completeness, apply XIII.15.7.8. or give a direct argument.]

(c) Show that every $f \in X$ is constant on I_n for all sufficiently large n.

(d) For each n let $J_n = \cup_{k \leq n} I_k$. Let $S_n \subseteq \{0,1\}^{J_n}$ be the set of all functions s from J_n to $\{0,1\}$ for which s is constant on I_n. For $s \in S_n$, set $\ell(s) = n$ and U_s the set of $f \in X$ which extend s. Show that U_s is a clopen set in X.

(e) Let $\mathcal{U}$ be the collection of all U_s for all $s \in \cup_n S_n$. Show that $\mathcal{U}$ is an open cover of X.

(f) Show that $\mathcal{U}$ does not have a finite subcover. [If $\{U_{s_1}, \ldots, U_{s_m}\}$ is a finite subset of $\mathcal{U}$, choose $n > \ell(s_k)$ for all k and let $s \in S_n$ which is not constant on I_k for $k < n$, and extend s to $f \in X$. Then $f \notin U_{s_k}$ for any k.] Thus X is not compact.

This is perhaps the simplest explicit example of a metric space which is uniformly complete and totally bounded, but not compact, and also of a product of compact Hausdorff spaces which is not compact (a metrizable counterexample to Tikhonov's Theorem for Hausdorff spaces). It of course requires a drastic set-theoretic assumption incompatible with the Countable AC or the BPI.

This example appears (cryptically) in [**?**]; the above argument is due to I. Farah.

XIII.15.12.10. Let (X, ρ) be a locally compact, σ-compact metric space. Let (U_n) be an increasing sequence of open sets in X such that $\bar{U}_n$ is compact and contained in U_{n+1}, with $X = \cup_n U_n$.

(a) For each n let $F_n = \bar{U}_n \setminus U_n$. In $X^\dagger$, define a continuous function f from $F = \cup_n F_n \cup \{\infty\}$ by setting $f = \frac{1}{n}$ on F_n and $f(\infty) = 0$. Use the Tietze Extension Theorem to extend f to a continuous function $g : X^\dagger \to [0,1]$ with $g(x) > 0$ for all $x \in X$.

(b) Show that X is homeomorphic to the set

$$\left(x, \frac{1}{g(x)}\right) \subseteq X \times \mathbb{R}$$

and that the product metric is an equivalent metric to ρ making X into a Heine-Borel space.

XIII.16. Order Topology

XIII.16.1. Definition and Properties

XIII.16.1.1. THEOREM. Any subspace of a space with the order topology is completely normal. In particular, any space with the order topology is normal.

PROOF: [Cat06] Let X be an ordered space with the order topology, and let Y be a subspace. We will show that Y has the following stronger property: if $\{A_i : i \in I\}$ is a collection of subsets of Y which are *separated*, i.e. each A_i is disjoint from the closure (in Y) of $\cup_{j \neq i} A_j$, then the A_i have disjoint neighborhoods V_i in Y (Y is said to be *completely collectionwise normal*).

Note that by (), if the A_i are separated in Y, then the A_i are separated in X, and if $\{U_i\}$ are disjoint neighborhoods in X, and $V_i = U_i \cap Y$, then $\{V_i\}$ are disjoint neighborhoods in Y. Thus for the proof we may assume $Y = X$.

Suppose $\{A_i\}$ are separated in X (and in particular disjoint), and set $A = \cup_i A_i$. For each convex component C of $X \setminus A$, choose a point $f(C) \in C$. For $p \in A_i$, p not the largest point of X (if there is one), choose $t_p \in X$ as follows. There is a $u_p > p$ such that $[p, u_p)$ contains no point of $A \setminus A_i$.

> Choose t_p to be a point of $A_i \cap (p, u_p)$ if $A_i \cap (p, u_p)$ is nonempty.
>
> Choose $t_p = u_p$ if $(p, u_p) = \emptyset$.
>
> If $(p, u_p) \neq \emptyset$ but $A_i \cap (p, u_p) = \emptyset$, then (p, u_p) is contained in a unique convex component C of $X \setminus A$; in this case set $t_p = f(C)$.

Similarly, if p is not the smallest point of X, choose $s_p < p$ in the same manner with inequalities reversed. Set $I_p = (s_p, t_p)$. (If p is the largest point of X, set $I_p = (s_p, p]$, and if p is the smallest point of X, set $I_p = [p, t_p)$.) Then I_p is an open interval in X containing p. This defines I_p for each $p \in A$.

For each i, set $U_i = \cup_{p \in A_i} I_p$. Then U_i is an open neighborhood of A_i. We claim the U_i are disjoint. If $x \in U_i \cap U_j$ for $i \neq j$, there are $p \in A_i$ and $q \in A_j$ such that $x \in I_p \cap I_q$. We may suppose $p < q$. Then $s_q < x < t_p$. Since $q \notin I_p$ and $p \notin I_q$, $p < s_q < x < t_p < q$. Thus $t_p \in I_q$, and hence $t_p \notin A_i$, and $(p, t_p) \neq \emptyset$. Similarly, $s_q \notin A_j$ and $(s_q, q) \neq \emptyset$. By the way t_p and s_q were selected, we have $t_p = s_q = f(C)$ for the same convex component C of $X \setminus A$, contradicting that $s_q < t_p$. Thus the U_i are disjoint. 👍

Note that the AC is needed in several places in this proof. In fact, the AC (or something only slightly weaker) is necessary for this result [vD85].

XIII.16.2. Completion of an Order Topology

XIII.17. Function Spaces

XIII.17.1. Function Space Notation

There are several notations for function spaces used in the literature, and the usage is not always consistent. There is one predominant notation:

XIII.17.1.1. Definition. Let X and Y be topological spaces. Denote by Y^X the set of all maps (continuous functions) from X to Y.

XIII.17.1.2. The notation $C(X,Y)$ is also frequently used for Y^X. Some authors use Y^X to denote the set of all functions from X to Y, which we will write $F(X,Y)$. Although it is occasionally useful to consider this set, the set $C(X,Y)$ arises far more often. Our use of Y^X to denote $C(X,Y)$, if done with care, includes all standard examples of this exponential notation:

XIII.17.1.3. Examples. (i) If X has the discrete topology, then for any Y we have $Y^X = C(X,Y) = F(X,Y)$. If X and Y are just sets, with no topology, we can consider them to be topological spaces with the discrete topology so the notation $Y^X = F(X,Y)$ used in set theory is consistent with the topological notation. Note that the topology on Y has no effect on the definition of Y^X as a set in this case.

(ii) If Y is a topological space (or just a set, regarded as a topological space with the discrete topology), and $n \in \mathbb{N}$, we can regard n as the subset $\{1,\dots,n\}$ of $\mathbb{N}$ (or, more commonly and properly in set theory, $\{0,1,\dots,n-1\} \subseteq \mathbb{N}_0$), with the discrete topology. Then Y^n (in the sense of XIII.17.1.1.) is naturally the set of n-tuples of elements of Y, the usual meaning of Y^n. Similarly, $Y^{\mathbb{N}}$ denotes the set of sequences in Y (where $\mathbb{N}$ has its usual discrete topology). This latter set is often, but somewhat less precisely, denoted Y^∞.

(iii) More generally, if κ is a cardinal, we denote by Y^κ the set of all functions from a set of cardinality κ to Y. To be precise, we regard κ as a set of ordinals as in (), and give it the discrete topology. This set Y^κ can be naturally identified with the Cartesian product of κ copies of Y.

(iv) If X is a set, the power set $\mathcal{P}(X)$ is often denoted 2^X. If X is a topological space, 2^X is often used to denote the set of closed subsets of X. Both notations are consistent with XIII.17.1.1. if we give $2 = \{0,1\}$ the Sierpiński space topology with $\{0\}$ open and $\{1\}$ closed. We then identify a continuous function $f : X \to 2$ with the subset $f^{-1}(\{1\})$ of X.

XIII.17.1.4. Both the notations Y^X and $C(X,Y)$ are slight abuses, since the notation does not reflect the topologies of X and Y which are needed to determine Y^X as a set. (The notation $F(X,Y)$ is not ambiguous.) The abuse is the same as in the common statement "Let X be a topological space."

XIII.17.1.5. If X is a topological space, the set $\mathbb{R}^X = C(X,\mathbb{R})$ is usually denoted $C_{\mathbb{R}}(X)$. Similarly, $\mathbb{C}^X = C(X,\mathbb{C})$ is usually denoted $C_{\mathbb{C}}(X)$ or just $C(X)$. Here $\mathbb{R}$ and $\mathbb{C}$ are always assumed to have their usual topologies.

XIII.17.2. U.C. Convergence and the Compact-Open Topology

There are many important notions of convergence for functions, i.e. many topologies on spaces of functions. The most generally useful topology on Y^X is the "topology of uniform convergence on compact sets" ("u.c. convergence") (IV.3.2.). If Y is metrizable, or more generally if the topology on Y comes from a uniform structure, this topology can be defined in a straightforward way; the idea is that a net (f_i) converges to f if and only if, for every compact subset K of X, for sufficiently large i $f_i(x)$ should be close to $f(x)$ for all $x \in K$. Even for a general topological space Y, there is a clean way to define such a topology on Y^X, called the compact-open topology.

XIII.17.2.1. DEFINITION. Let X and Y be topological spaces. The *compact-open topology* on Y^X is the topology generated by the subbase

$$\{U_{K,O} : K \subseteq X \text{ compact}, O \subseteq Y \text{ open}\}$$
$$U_{K,O} = \{f \in Y^X : f(K) \subseteq O\} .$$

XIII.17.2.2. The set of $U_{K,O}$ does not give a base for a topology in general; one needs to take finite intersections. So a basic open set for the compact-open topology is defined by taking a finite number of compact sets $K_1, \ldots, K_n$ in X, a corresponding finite number of open sets $O_1, \ldots, O_n$ in Y, and taking all maps from X to Y such that $f(K_j) \subseteq O_j$ for $1 \leq j \leq n$.

To obtain a base for the compact-open topology, it suffices to let the O's range over a base for the topology of Y.

The compact-open topology can be described in terms of convergence:

XIII.17.2.3. PROPOSITION. Let X and Y be topological spaces. Then a net (f_i) in Y^X converges to $f \in Y^X$ in the compact-open topology if and only if, for every compact subset K of X, and every open set O in Y such that $f(K) \subseteq O$, there is an i_0 such that $f_i(K) \subseteq O$ for all $i \geq i_0$.

The proof is immediate from the definition, and is left to the reader.

Since singleton sets are compact, we obtain:

XIII.17.2.4. PROPOSITION. Let X and Y be topological spaces. If a net (f_i) in Y^X converges to $f \in Y^X$ in the compact-open topology, then $f_i \to f$ pointwise on X, i.e. $f_i(x) \to f(x)$ for all $x \in X$.

PROOF: Let $x \in X$. If O is any neighborhood of $f(x)$ in Y, then $f(\{x\}) \subseteq O$, so there is an i_0 such that $f_i(\{x\}) \subseteq O$ for all $i \geq i_0$, i.e. $f_i(x) \in O$ for $i \geq i_0$. 👍

XIII.17.2.5. The compact-open topology is thus stronger than the topology of pointwise convergence; it is usually strictly stronger. But if every compact subset of X is finite, e.g. if X is discrete, the two topologies coincide. (There are nondiscrete spaces where every compact subset is finite, e.g. XIII.11.14.10.; but such a space cannot have any nontrivial convergent sequences. See ().)

XIII.17.2.6. Corollary. If Y is a topological space and X a set with the discrete topology, then Y^X can be identified with the Cartesian product of κ copies of Y, where $\kappa = card(X)$, and the compact-open topology is the product topology.

XIII.17.2.7. If X and Y are topological spaces, any constant function from X to Y is continuous. The subset C of Y^X of constant functions can be identified with Y. It is immediate from the definitions that this identification is a homeomorphism if C is given the relative compact-open topology. If Y is Hausdorff, then C is closed in Y^X in the compact-open topology. (The converse does not hold in general, e.g. if X is a one-point space.)

We now examine separation properties.

XIII.17.2.8. Proposition. Let X and Y be topological spaces. Give Y^X the compact-open topology.

(i) Y^X is Hausdorff if and only if Y is Hausdorff.

(ii) Y^X is regular if and only if Y is regular.

Proof: Y is homeomorphic to a subset of Y^X (XIII.17.2.7.), so if Y^X is Hausdorff or regular, so is Y. Conversely, suppose Y is Hausdorff, and f and g are distinct elements of Y^X. Then there is an $x \in X$ with $f(x) \neq g(x)$. Let O_1 and O_2 be disjoint open neighborhoods of $f(x)$ and $g(x)$ in Y. Then $U_{\{x\},O_1}$ and $U_{\{x\},O_2}$ are disjoint neighborhoods of f and g in Y^X.

Now suppose Y is regular. Let $f \in Y^X$ and V a compact-open neighborhood of f. Then there are compact sets $K_1, \ldots, K_n$ in X and open sets $O_1, \ldots, O_n \in Y$ with $f(K_j) \subseteq O_j$ for $1 \leq j \leq n$ and

$$U_{K_1,O_1} \cap \cdots \cap U_{K_n,O_n} \subseteq V \ .$$

Fix j. Since $f(K_j)$ is compact, by () there is an open set O'_j in Y with

$$f(K_j) \subseteq O'_j \subseteq \bar{O}'_j \subseteq O_j \ .$$

Then $W = U_{K_1,O'_1} \cap \cdots \cap U_{K_n,O'_n}$ is a neighborhood of f in Y^X. We claim $\bar{W} \subseteq V$. Suppose (g_i) is a net in W and $g_i \to g \in Y^X$. If $x \in K_j$, then $g_i(x) \in O'_j$ for all i, so $g(x) \in \bar{O}'_j \subseteq O_j$. Thus $g \in V$. 👍

XIII.17.2.9. If Y is normal, then Y^X is not necessarily normal: if S is the Sorgenfrey line (XIII.7.10.14.), and $2 = \{0, 1\}$ has the discrete topology, then S is normal, but S^2 is not normal.

XIII.17.2.10. Example. Let X be a topological space. Consider 2^X, where 2 has the Sierpiński topology. Then 2^X can be identified with the set of closed subsets of X as in XIII.17.1.3.(iv). What is the corresponding topology on the collection of closed subspaces? Since 2 is not Hausdorff, limits in 2^X will not be unique. If (E_i) is a net of closed subspaces of X and E a closed subspace of X, then $E_i \to E$ in this topology if and only if, whenever K is a compact subspace of X disjoint from E, then there is an i_0 such

that K is disjoint from E_i for all $i \geq i_0$. In particular, if $E_i \to E$, and $x \notin E$, then there is an i_0 such that $x \notin E_i$ for any $i \geq i_0$. Thus we have

$$\bigcap_i \left[\bigcup_{j \geq i} E_j \right] \subseteq E \ .$$

This condition is in general not sufficient to guarantee that $E_i \to E$, however. It is sufficient that

$$E_0 := \bigcap_i \left[\overline{\bigcup_{j \geq i} E_j} \right] \subseteq E$$

for if E is a closed set containing E_0, and K is a compact set disjoint from E, then K is disjoint from E_0, so if W_i is the complement of $\overline{\cup_{j \geq i} E_j}$ the W_i form an increasing open cover of K, which has a finite subcover, i.e. $K \subseteq W_{i_0}$ for some i_0. Then K is disjoint from E_i for all $i \geq i_0$. Thus $E_i \to E$.

If every point of X has local base of compact neighborhoods, e.g. if X is a locally compact Hausdorff space, $E_i \to E$, and $x \notin E$, then since E is closed x has a compact neighborhood K disjoint from E. Then K is disjoint from E_i for all sufficiently large i, so $x \notin E_0$, i.e. $E_0 \subseteq E$. So in this case $E_i \to E$ if and only if E is a closed set containing E_0.

We now examine the case where Y is metrizable. In this case, the compact-open topology is precisely the topology of u.c. convergence:

XIII.17.2.11. Proposition. Let X be a topological space and (Y, ρ) a metric space. If (f_i) is a net in Y^X, then $f_i \to f \in Y^X$ if and only if, for every compact subset K of X and every $\epsilon > 0$, there is an i_0 such that $\rho(f_i(x), f(x)) < \epsilon$ for all $i \geq i_0$ and all $x \in K$.

Proof: Suppose the ϵ-condition is satisfied. Let K be a compact subset of X and O an open set in Y. Then, since $f(K)$ is compact, there is an $\epsilon > 0$ such that $\rho(f(x), Y \setminus O) \geq \epsilon$ for all $x \in K$. Fix i_0 such that $\rho(f_i(x), f(x)) < \epsilon$ for all $i \geq i_0$ and $x \in K$. Then $f_i(K) \subseteq O$ for all $i \geq i_0$. So $f_i \to f$ in the compact-open topology.

Conversely, if $f_i \to f$ in the compact-open topology, let K be a compact subset of X and $\epsilon > 0$. For each $x \in X$ let V_x be the open ball of radius $\frac{\epsilon}{4}$ centered at $f(x)$. Then finitely many of these balls, say $\{V_{x_1}, \ldots, V_{x_n}\}$, cover $f(K)$ since $f(K)$ is compact. For each j, $1 \leq j \leq n$, let $K_j = K \cap f^{-1}(\bar{V}_{x_j})$ and O_j the open ball of radius $\frac{\epsilon}{3}$ around $f(x_j)$. For each j, K_j is compact and $f(K_j) \subseteq O_j$. There is an i_0 such that $f_i(K_j) \subseteq O_j$ for all j and for all $i \geq i_0$. Thus, if $x \in K$, then $x \in K_j$ for some j, so for any $i \geq i_0$ we have

$$\rho(f_i(x), f(x)) \leq \rho(f_i(x), f_i(x_j)) + \rho(f_i(x_j), f(x_j)) + \rho(f(x_j), f(x)) < \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3} = \epsilon \ .$$

XIII.17.2.12. More generally, if Y has a (separated) uniform structure $\mathcal{U}$, the compact-open topology is the topology of uniform convergence on compact sets (the proof is essentially identical). The topology of u.c. convergence appears to depend on the uniformity, but the compact-open topology (and thus the u.c. topology) only depends on the topology of the uniformity and not on the specific uniformity. This should not be surprising since a continuous image of a compact set is compact, and a compact Hausdorff space has a unique uniformity compatible with its topology.

XIII.17.2.13. If X and Y are topological spaces, the compact-open topology can be defined in the same way on $F(X,Y)$ as in XIII.17.2.1.. The relative topology on the subset $Y^X = C(X,Y)$ is exactly the compact-open topology defined in XIII.17.2.1.. However, the compact-open topology on $F(X,Y)$ does not reasonably coincide with the topology of uniform convergence on compact sets, and Y^X is not closed in $F(X,Y)$ in general. See Exercise XIII.17.4.1..

Joint Continuity

XIII.17.2.14. If X and Y are topological spaces, there is a natural evaluation map from $Y^X \times X$ to Y sending (f,x) to $f(x)$. If $\mathcal{T}$ is a topology on Y^X, giving a product topology on $Y^X \times X$, we discuss continuity of the evaluation map. We will be particularly concerned with the topology $\mathcal{P}$ of pointwise convergence and the stronger compact-open topology $\mathcal{C}$.

XIII.17.2.15. Definition. Let X and Y be topological spaces, $\mathcal{F}$ a subset of Y^X, and A a subset of X. Let $\mathcal{T}$ be a topology on Y^X. Then $\mathcal{T}$ is *jointly continuous on A for $\mathcal{F}$* if the evaluation map $\mathcal{F} \times A \to Y$ is continuous for the product topology. $\mathcal{T}$ is *jointly continuous for $\mathcal{F}$* if it is jointly continuous on X, and *jointly continuous* if it is jointly continuous for Y^X. (One could more generally take $\mathcal{T}$ to be a topology just on $\mathcal{F}$, but this creates technical complications.)

XIII.17.2.16. Under the hypotheses, $\mathcal{T}$ is jointly continuous for $\mathcal{F}$ on A if and only if, whenever (f_i) is a net in $\mathcal{F}$ $\mathcal{T}$-converging to $f \in \mathcal{F}$, and (x_i) (same index set) is a net in A converging to $x \in A$, we have $f_i(x_i) \to f(x)$. This is called *continuous convergence.*

XIII.17.2.17. Examples such as () show that $\mathcal{P}$ is not jointly continuous for Y^X in general, even if X and Y are $[0,1]$.

XIII.17.2.18. Theorem. Let X and Y be topological spaces and $\mathcal{F} \subseteq Y^X$. Then

(i) The topology $\mathcal{C}$ is jointly continuous for $\mathcal{F}$ on compact subsets of X.

(ii) If $\mathcal{T}$ is a topology on $\mathcal{F}$ which is jointly continuous for $\mathcal{F}$ on compact subsets of X, then $\mathcal{T}$ is stronger than $\mathcal{C}$ on $\mathcal{F}$ on compact subsets of X (i.e. the restriction of $\mathcal{T}$ to $\mathcal{F}|_K$ is stronger than the restriction of $\mathcal{C}$ for every compact subset K of X, where $\mathcal{F}|_K$ denotes the restriction to K of the functions in $\mathcal{F}$).

(iii) If X is locally compact (Hausdorff), then $\mathcal{C}$ is jointly continuous for any $\mathcal{F} \subseteq Y^X$, and every jointly continuous topology for $\mathcal{F}$ is stronger than $\mathcal{C}$ on $\mathcal{F}$. In particular, $\mathcal{C}$ is jointly continuous, and every jointly continuous topology is stronger than $\mathcal{C}$.

XIII.17.2.19. This theorem implies that if $\mathcal{P}$ is jointly continuous for $\mathcal{F} \subseteq Y^X$ on compact subsets of X, then $\mathcal{P}$ and $\mathcal{C}$ agree on $\mathcal{F}$ on compact subsets of X, and if X is locally compact and $\mathcal{P}$ is jointly continuous for $\mathcal{F}$, then $\mathcal{P}$ and $\mathcal{C}$ agree on $\mathcal{F}$.

XIII.17.3. The Arzelà-Ascoli Theorem

The Arzelà-Ascoli Theorem gives a useful condition for a set $\mathcal{F}$ of functions between topological spaces X and Y to be subcompact in the compact-open topology. Various versions of the theorem appear in the literature; we will prove a general version and deduce the common versions as special cases, including the versions stated by Arzelà and Ascoli themselves.

For ease of exposition, we will assume the Axiom of Choice. Dependence of the various forms of the theorem on the AC will be discussed at the end of the section. We will also almost exclusively work with Hausdorff spaces; a few things work also in a non-Hausdorff setting. In fact, most spaces will be completely regular (e.g. locally compact Hausdorff).

Our exposition is adapted from [Kel75].

Subcompact Sets

XIII.17.3.1. Definition. Let X be a topological space. A (nonempty) subset A of X is *subcompact* if A is is a subset of a compact subset of X.

XIII.17.3.2. If X is Hausdorff, a subset A of X is subcompact if and only if $\bar{A}$ is compact (since compact subsets of X are closed). This can fail in non-Hausdorff spaces: a compact subspace need not be closed, and its closure need not be compact ().

XIII.17.3.3. Examples. (i) Any compact subset of a topological space X is subcompact.

(ii) A subset of $\mathbb{R}^n$ is subcompact if and only if it is bounded.

(iii) A subset of a complete metric space (or, more generally, a complete uniform space) is subcompact if and only if it is totally bounded. (A totally bounded subset of a uniform space is sometimes called a *precompact* subset. Thus a subcompact subset is precompact, but not necessarily conversely if the uniform space is not complete. A precompact uniform space is one whose completion is compact.)

XIII.17.3.4. Proposition. Let X be a completely regular space, and A a nonempty subset. Then A is subcompact if and only if every net in A has a subnet which converges in X. If X is first countable, then A is subcompact if and only if every sequence in A has a subsequence which converges in X.

Proof: Suppose $\bar{A}$ is not compact. Then $\bar{A}$ is a dense proper subspace of its Stone-Čech compactification $\beta\bar{A}$. A is dense in $\bar{A}$ and hence in $\beta\bar{A}$. If $p \in \beta\bar{A} \setminus \bar{A}$, then there is a net in A converging to p. This net cannot have a cluster point in $\bar{A}$ since $\beta\bar{A}$ is Hausdorff, hence cannot have a cluster point in X. The converse is obvious. 👍

It is unclear how much the completely regular hypothesis can be relaxed.

Even Continuity and Equicontinuity

XIII.17.3.5. DEFINITION. Let X be a topological space, Y a set, $x \in X$, and ρ a pseudometric on Y. A set $\mathcal{F}$ of functions from X to Y is *ρ-equicontinuous at x* if for every $\epsilon > 0$ there is a neighborhood U of x such that $\rho(f(z), f(x)) < \epsilon$ for every $z \in U$. $\mathcal{F}$ is *ρ-equicontinuous* if it is ρ-equicontinuous at x for every $x \in X$. If $A \subseteq X$, then $\mathcal{F}$ is *ρ-equicontinuous on A* if the set of restrictions of the functions in $\mathcal{F}$ to A is ρ-equicontinuous (as functions from A to Y).

If $(Y, \mathcal{V})$ is a uniform space, and $\mathcal{F} \subseteq Y^X$, then $\mathcal{F}$ is *$\mathcal{V}$-equicontinuous* if it is ρ-equicontinuous for every ρ in the gauge of $\mathcal{V}$. When $\mathcal{V}$ is understood, we just say $\mathcal{F}$ is *equicontinuous.* If $A \subseteq X$, then $\mathcal{F}$ is *$\mathcal{V}$-equicontinuous on A* if the set of restrictions of the functions in $\mathcal{F}$ to A is $\mathcal{V}$-equicontinuous (as functions from A to Y).

XIII.17.3.6. If $(Y, \mathcal{V})$ is a uniform space, and $\mathcal{F}$ an equicontinuous set of functions from X to Y, the functions in $\mathcal{F}$ are automatically continuous with respect to the uniform topology on Y. The equicontinuity condition roughly says that for any $x \in X$, if $z \in X$ is close enough to x, then $f(z)$ is uniformly close to $f(x)$ for all $f \in \mathcal{F}$. It is enough to check ρ-equicontinuity for enough ρ's to determine $\mathcal{V}$; in particular, if $\mathcal{V}$ is the uniformity from a metric ρ, then $\mathcal{F}$ is $\mathcal{V}$-equicontinuous if and only if it is ρ-equicontinuous. This is the most common situation in applications.

The equicontinuity condition can be stated without reference to pseudometrics: $\mathcal{F}$ is $\mathcal{V}$-equicontinuous at x if and only if, for every $V \in \mathcal{V}$, there is a neighborhood U of x such that $f(U) \subseteq V[x]$ for all $f \in \mathcal{F}$ (i.e. $(f(z), f(x)) \in V$).

XIII.17.3.7. **Caution:** If $\mathcal{F}$ is equicontinuous on a set A, it does not mean $\mathcal{F}$ is equicontinuous at every $x \in A$, since it is the *restrictions* of the functions to A which are equicontinuous. See V.2.2.2. for the analogous distinction for continuity.

There is a topological version of equicontinuity. The definition is a bit curious but has alternate characterizations, and is useful to work with.

XIII.17.3.8. DEFINITION. Let X and Y be topological spaces, and $\mathcal{F} \subseteq Y^X$. Then $\mathcal{F}$ is *evenly continuous* if, for every $x \in X$, $y \in Y$, and open neighborhood U of Y, there are open neighborhoods V of x and W of y, $W \subseteq U$, such that for all $f \in \mathcal{F}$ with $f(x) \in W$, $f(V) \subseteq U$. If $A \subseteq X$, then $\mathcal{F}$ is *evenly continuous on A* if the set $\mathcal{F}|_A$ of restrictions of the functions in $\mathcal{F}$ to A is evenly continuous as a set of functions from A to Y.

XIII.17.3.9. PROPOSITION. Let X and Y be topological spaces, and $\mathcal{F} \subseteq Y^X$. Then the following are equivalent:

(i) $\mathcal{F}$ is evenly continuous.

(ii) For every $x \in X$, $y \in Y$, and open neighborhood U of Y, there are open neighborhoods V of x and W of y, $W \subseteq U$, such that the evaluation map sends $\{f \in \mathcal{F} : f(x) \in W\} \times V$ into U.

(iii) Whenever (f_i, x_i) is a net in $\mathcal{F} \times X$ such that $x_i \to x \in X$, $f_i(x) \to y \in Y$, then $f_i(x_i) \to y$.

Version (ii) shows the close connection between even continuity and joint continuity of evaluation.

XIII.17.3.10. PROPOSITION. Let X and Y be topological spaces, with Y regular. Let $\mathcal{F} \subseteq Y^X$, and let $\tilde{\mathcal{F}}$ be the closure of $\mathcal{F}$ in the set $F(X,Y)$ of all functions in the topology $\mathcal{P}$ of pointwise convergence. If $\mathcal{F}$ is evenly continuous, then $\tilde{\mathcal{F}}$ is also evenly continuous, and $\mathcal{P}$ is jointly continuous on $\tilde{\mathcal{F}}$. In particular, every function in $\tilde{\mathcal{F}}$ is continuous.

PROOF: Let $x \in X$, $y \in Y$, and U an open neighborhood of y. There is an open neighborhood U' of y such that $\bar{U}' \subseteq U$ since Y is regular. Since $\mathcal{F}$ is evenly continuous, there are neighborhoods V of x and W of y, $W \subseteq U'$, such that for all $f \in \mathcal{F}$ with $f(x) \in W$, $f(V) \subseteq U'$. Let $g \in \tilde{\mathcal{F}}$ with $g(x) \in W$. Let (f_i) be a net in $\mathcal{F}$ converging pointwise to g; then $f_i(x) \in W$ for sufficiently large i since W is open. Thus if $z \in V$, $f_i(z) \in U'$ for sufficiently large i, and since $f_i(z) \to g(z)$, $g(z) \in \bar{U}' \subseteq U$.
For the last statement, note that $\{f \in \tilde{\mathcal{F}} : f(x) \in W\}$ is $\mathcal{P}$-open in $\tilde{\mathcal{F}}$, so $\{f \in \tilde{\mathcal{F}} : f(x) \in W\} \times V$ is open in $\tilde{\mathcal{F}} \times X$. 👍

If the target space is a uniform space, equicontinuity and even continuity are essentially the same thing:

XIII.17.3.11. THEOREM. Let X be a topological space and $(Y, \mathcal{V})$ a separated uniform space. Give Y the uniform topology. Let $\mathcal{F} \subseteq Y^X$. Then
(i) If $\mathcal{F}$ is equicontinuous, then $\mathcal{F}$ is evenly continuous.
(ii) If $\mathcal{F}[x]$ is subcompact for every $x \in X$, and $\mathcal{F}$ is evenly continuous, then $\mathcal{F}$ is equicontinuous. [$\mathcal{F}[x] = \{f(x) : f \in \mathcal{F}\}$.]

This has an interesting consequence:

XIII.17.3.12. COROLLARY. Let X be a topological space, Y a completely regular space, and $\mathcal{F} \subseteq Y^X$ with the property that $\mathcal{F}[x]$ is subcompact for every $x \in X$. If $\mathcal{V}$ and $\mathcal{W}$ are uniform structures for Y compatible with its topology, then $\mathcal{F}$ is $\mathcal{V}$-equicontinuous if and only if $\mathcal{F}$ is $\mathcal{W}$-equicontinuous.

This is reminiscent of the fact that a compact Hausdorff space has a unique compatible uniform structure.

XIII.17.3.13. Equicontinuity (and even continuity) are *pointwise* conditions. As a consequence, if $\mathcal{F}$ is equicontinuous [tesp. evenly continuous] on a neighborhood of each point, it is equicontinuous [resp. evenly continuous]. In particular, if X is locally compact, then $\mathcal{F}$ is equicontinuous if and only if it is equicontinuous on every compact subset of X.

There is a uniform version of equicontinuity:

XIII.17.3.14. DEFINITION. Let $(X,\mathcal{U})$ and $(Y,\mathcal{V})$ be uniform spaces, and $\mathcal{F} \subseteq Y^X$. $\mathcal{F}$ is *uniformly equicontinuous* [*$(\mathcal{U},\mathcal{V})$-uniformly equicontinuous*] if for every $V \in \mathcal{V}$ there is a $U \in \mathcal{U}$ such that $(f(z), f(x)) \in V$ whenever $(z,x) \in U$ and $f \in \mathcal{F}$.

XIII.17.3.15. If $\mathcal{F}$ is uniformly equicontinuous, then it is equicontinuous, and every $f \in \mathcal{F}$ is uniformly continuous. For example, a set $\mathcal{F}$ consisting of only one continuous function f is always equicontinuous, but is uniformly equicontinuous if and only if f is uniformly continuous. Informally, a set $\mathcal{F}$ is uniformly equicontinuous if the functions in $\mathcal{F}$ are "uniformly uniformly continuous."

If (X, ρ) and (Y, σ) are metric spaces and $\mathcal{F} \subseteq Y^X$, then $\mathcal{F}$ is uniformly equicontinuous (with respect to the metric uniformities) if and only if, for every $\epsilon > 0$, there is a $\delta > 0$ such that $\sigma(f(z), f(x)) < \epsilon$ whenever $\rho(x, z) < \delta$ and $f \in \mathcal{F}$.

The next result generalizes the result that a continuous function from a compact space to a uniform space is uniformly continuous ():

XIII.17.3.16. Proposition. Let $(X, \mathcal{U})$ and $(Y, \mathcal{V})$ be uniform spaces with X compact, and $\mathcal{F} \subseteq Y^X$. Then $\mathcal{F}$ is uniformly equicontinuous if and only if it is equicontinuous.

Statement and Proof

Here is our most general version of the Arzelà-Ascoli Theorem. Recall () that a *k-space* is a compactly generated Hausdorff space; any Hausdorff space which is locally compact or first countable is a k-space.

XIII.17.3.17. Theorem. [Arzelà-Ascoli Theorem, General Version] Let X be a k-space and Y a regular space, and let $\mathcal{F} \subseteq Y^X$. Then $\mathcal{F}$ is subcompact in the compact-open topology if and only if

(i) $\mathcal{F}$ is evenly continuous on compact subsets of X.

(ii) $\mathcal{F}[x]$ is subcompact in Y for all $x \in X$.

If these conditions are satisfied, the compact-open closure $\bar{\mathcal{F}}$ coincides with the closure in the topology of pointwise convergence, and the compact-open topology coincides with the topology of pointwise convergence on $\bar{\mathcal{F}}$.

Note that if X is locally compact, then condition (i) is simply that $\mathcal{F}$ is evenly continuous ().

Proof: Let $\tilde{\mathcal{F}}$ be the $\mathcal{P}$-closure of $\mathcal{F}$ in the set $F(X, Y)$ of all functions from X to Y. By (), if K is a compact subset of X, $\tilde{\mathcal{F}}|_K$ consists of continuous functions on K. Thus $\tilde{\mathcal{F}}$ consists of continuous functions from X to Y since X is a k-space, i.e. $\tilde{\mathcal{F}}$ is the $\mathcal{P}$-closure of $\mathcal{F}$ in Y^X.
The set $\tilde{\mathcal{F}}$ is a closed subset of $\prod_{x \in X} \overline{\mathcal{F}[x]}$, which is $\mathcal{P}$-compact by Tikhonov's Theorem (for Hausdorff spaces). Thus $\tilde{\mathcal{F}}$ is $\mathcal{P}$-compact.
We now show that the topologies $\mathcal{P}$ and $\mathcal{C}$ coincide on $\tilde{\mathcal{F}}$. It suffices to show that

$$U_{K,O} = \{f \in \mathcal{F} : f(K) \subseteq O\}$$

is $\mathcal{P}$-open for $K \subseteq X$ compact and $O \subseteq Y$ open. The set

$$U^K_{K,O} = \{f \in \mathcal{F}|_K : f(K) \subseteq O\}$$

is $\mathcal{P}$-open in Y^K by (). The restriction map $\rho : \mathcal{F} \to \mathcal{F}|_K$ is $\mathcal{P}$-continuous, so $\rho^{-1}(U^K_{K,O}) = U_{K,O}$ is $\mathcal{P}$-open.

So $\bar{\mathcal{F}} \subseteq \tilde{\mathcal{F}}$ is $\mathcal{P}$-closed, hence $\mathcal{P}$-compact. Since $\mathcal{F}$ is dense in both, it follows that $\bar{\mathcal{F}} = \tilde{\mathcal{F}}$.

For the converse, suppose $\mathcal{F}$ is $\mathcal{C}$-compact (we may assume $\mathcal{F}$ is closed since by XIII.17.3.10. $\bar{\mathcal{F}}$ also satisfies the hypotheses). Then it is also compact in the weaker $\mathcal{P}$-topology since $\mathcal{P}$ is Hausdorff, and the two topologies agree on $\mathcal{F}$. Thus for any $x \in X$ the set $\mathcal{F}[x]$ is compact since it is the continuous image of $\mathcal{F}$ under evaluation at x, which is a continuous function from $\mathcal{F}$ to Y.

Let K be a compact subset of X. We show that $\mathcal{F}|_K$ is evenly continuous. We have that $\mathcal{F}|_K$ is compact since it is a continuous image of $\mathcal{F}$. Let $x \in K$, $y \in Y$, and let U be an open neighborhood of y. Let W be an open neighborhood of y with $\bar{W} \subseteq U$. Let

$$\mathcal{E} = \{f \in \mathcal{F}|_K : f(x) \in \bar{W}\} .$$

Then $\mathcal{E}$ is a closed set in $\mathcal{F}|_K$, hence compact. The evaluation map $\rho : \mathcal{F}|_K \times K \to Y$ is continuous, so $\rho^{-1}(U)$ is open, and contains the compact set $\mathcal{E} \times \{x\}$. Thus by XIII.11.14.19. there is a (relatively) open set V in K such that $\mathcal{E} \times V \subseteq \rho^{-1}(U)$, i.e. if $f \in \mathcal{F}|_K$ satisfies $f(x) \in W$, then $f(V) \subseteq U$. 👍

XIII.17.3.18. In [Are46b] it is shown that if X is a completely regular space and the compact-open topology on $[0,1]^X$ is jointly continuous, then X is locally compact, suggesting that even continuity on compact subsets does not imply even continuity if X is not locally compact.. But I do not know an example of a k-space X, a regular space Y, and a $\mathcal{C}$-compact $\mathcal{F} \subseteq Y^X$ such that $\mathcal{F}$ is not evenly continuous.

Common Special Cases

A commonly stated version is just the special case of XIII.17.3.17. where the target space Y is completely regular, by XIII.15.1.27. and XIII.17.3.11.:

XIII.17.3.19. Theorem. [Arzelà-Ascoli Theorem, Uniform Version] Let X be a k-space and $(Y, \mathcal{V})$ a separated uniform space, and let $\mathcal{F} \subseteq Y^X$. Then $\mathcal{F}$ is subcompact in the compact-open topology (topology of u.c. convergence) if and only if

(i) $\mathcal{F}$ is equicontinuous on compact subsets of X.

(ii) $\mathcal{F}[x]$ is subcompact in Y for all $x \in X$.

If these conditions are satisfied, the compact-open closure $\bar{\mathcal{F}}$ coincides with the closure in the topology of pointwise convergence, and the topology of u.c. convergence coincides with the topology of pointwise convergence on $\bar{\mathcal{F}}$.

Note that if X is locally compact, then condition (i) is simply that $\mathcal{F}$ is equicontinuous (XIII.17.3.13.).

A commonly stated and used version is the case $Y = \mathbb{R}$:

XIII.17.3.20. THEOREM. [ARZELÀ-ASCOLI THEOREM, REAL VERSION] Let X be a k-space, and let $\mathcal{F} \subseteq \mathbb{R}^X = C_{\mathbb{R}}(X)$. Then $\mathcal{F}$ is subcompact in the topology of u.c. convergence if and only if $\mathcal{F}$ is pointwise bounded and equicontinuous on compact subsets of X.

If these conditions are satisfied, the closure $\bar{\mathcal{F}}$ in the topology of u.c. convergence coincides with the closure in the topology of pointwise convergence, and the topology of u.c. convergence coincides with the topology of pointwise convergence on $\bar{\mathcal{F}}$.

The same statement holds if $\mathbb{R}$ is replaced by $\mathbb{C}$ or $\mathbb{R}^n$ (or any metric space where closed bounded sets are compact).

If X is compact, u.c. convergence is uniform convergence. We state the real version, but XIII.17.3.19. can be restated in the same way.

XIII.17.3.21. THEOREM. [ARZELÀ-ASCOLI THEOREM, COMPACT VERSION] Let X be a compact Hausdorff space, and let $\mathcal{F} \subseteq \mathbb{R}^X = C_{\mathbb{R}}(X)$. Then $\mathcal{F}$ is subcompact in the topology of uniform convergence if and only if $\mathcal{F}$ is uniformly bounded and equicontinuous.

If these conditions are satisfied, the closure $\bar{\mathcal{F}}$ in the topology of uniform convergence coincides with the closure in the topology of pointwise convergence, and the topology of uniform convergence coincides with the topology of pointwise convergence on $\bar{\mathcal{F}}$.

In fact, under the hypotheses, if $\mathcal{F}$ is $\mathcal{C}$-closed, the following are equivalent:

(i) $\mathcal{F}$ is compact.

(ii) $\mathcal{F}$ is pointwise bounded and equicontinuous.

(iii) $\mathcal{F}$ is uniformly bounded and uniformly equicontinuous.

(To show (ii) $\Rightarrow$ (iii), use XIII.17.3.16. and joint continuity.)

We then get the "classic" version of the theorem:

XIII.17.3.22. THEOREM. [ARZELÀ-ASCOLI THEOREM, CLASSIC VERSION] Let X be a compact Hausdorff space, and let $\mathcal{F} \subseteq \mathbb{R}^X = C_{\mathbb{R}}(X)$. If $\mathcal{F}$ is uniformly bounded and equicontinuous, then any sequence in $\mathcal{F}$ has a uniformly convergent subsequence. Any sequence in $\mathcal{F}$ which converges pointwise converges uniformly.

To obtain this from XIII.17.3.21., note that the uniform topology on $C_{\mathbb{R}}(X)$ is metrizable if X is compact ().

XIII.17.3.23. Actually Arzelà's version was the case where X is a closed bounded interval in $\mathbb{R}$, and his proof left much to be desired. Subsequently, Ascoli stated a slightly more general version and gave a more satisfactory proof. We give a direct proof of XIII.17.3.22. if X is metrizable which is essentially the proof of Arzelà and Ascoli (they assumed uniform equicontinuity, which follows from XIII.17.3.16.):

Proof: Let ρ be a metric on X giving its topology. X is separable by (). Let $D = \{x_1, x_2, \dots\}$ be a countable dense set in X. If (f_n) is a sequence in $\mathcal{F}$, then the sequence $(f_n(x_1))$ is bounded since $\mathcal{F}$ is pointwise bounded, so has a convergent subsequence $(f_{k_{n,1}}(x_1))$ by the Bolzano-Weierstrass Theorem. The sequence $(f_{k_{n,1}}(x_2))$ has a convergent subsequence $(f_{k_{n,2}}(x_2))$. Continuing inductively, we successively construct subsequences $(f_{k_{n,m}})$ for each m such that $f_{k_{n,m}}(x_m))$ converges; then $(f_{k_{n,m}}(x_r))$ converges for $1 \leq r \leq m$.

Construct the "diagonal" sequence $(f_{k_{n,n}})$. This is a subsequence of (f_n). We claim that $(f_{k_{n,n}})$ converges uniformly on X. We have that $(f_{k_{n,n}}(x_r))$ converges for all r. Let $\epsilon > 0$. Since X is compact, $\mathcal{F}$ is uniformly equicontinuous by XIII.17.3.16.; so there is a $\delta > 0$ such that whenever $x, y \in X$ and $\rho(x, y) < \delta$, then $|f(x) - f(y)| < \frac{\epsilon}{3}$ for all $f \in \mathcal{F}$. Since X is compact, it can be covered by finitely many open balls of radius $\frac{\delta}{2}$. Thus there is a p such that every $x \in X$ satisfies $\rho(x, x_j) < \delta$ for some j, $1 \leq j \leq p$. There is an n_0 such that

$$|f_{k_{n,n}}(x_j) - f_{k_{m,m}}(x_j)| < \frac{\epsilon}{3}$$

for all $n, m > n_0$ and $1 \leq j \leq p$ (only finitely many such j's).

Let $x \in X$ and $n, m > n_0$. Choose j, $1 \leq j \leq p$, with $\rho(x, x_j) < \delta$. Then

$$|f_{k_{n,n}}(x) - f_{k_{m,m}}(x)| \leq |f_{k_{n,n}}(x) - f_{k_{n,n}}(x_j)| + |f_{k_{n,n}}(x_j) - f_{k_{m,m}}(x_j)| + |f_{k_{m,m}}(x_j) - f_{k_{m,m}}(x)| < \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3} = \epsilon\,.$$

Thus $(f_{k_{n,n}})$ is a uniform Cauchy sequence, hence converges uniformly (). 👍

XIII.17.3.24. Example. A subset of even $[0,1]^{[0,1]}$ can be $\mathcal{P}$-compact and not $\mathcal{C}$-compact (and thus not equicontinuous). Let (f_n) be the sequence of IV.3.2.4.(iii) with peaks of height 1, and let ✋

$$\mathcal{F} = \{f_n : n \in \mathbb{N}\} \cup \{0\}$$

where 0 is the function which is identically 0. More generally, let g be a continuous function from $[0,1]$ to $[0,1]$ which is not identically 0, but with $g(0) = g(1) = 0$, and set $f_n(t) = g(t^n)$. Then $\mathcal{F} = \{f_n : n \in \mathbb{N}\} \cup \{0\}$ is $\mathcal{P}$-compact, but not $\mathcal{C}$-compact or equicontinuous. Of course, the topology of pointwise convergence does not agree with the compact-open topology (topology of uniform convergence) on such an $\mathcal{F}$.

Arzelà-Ascoli and the AC

XIII.17.3.25. It is clear that the general Arzelà-Ascoli Theorem () must require at least the BPI, since Tikhonov's Theorem for Hausdorff spaces is a special case (the case where X is discrete and Y is compact Hausdorff, and $\mathcal{F}$ is all of Y^X, cf. XIII.11.14.23.).

XIII.17.3.26. The direct proof of the classic version given in XIII.17.3.23. seems to require DC to choose the subsequences. But the proof of the Bolzano-Weierstrass Theorem in IV.1.7.1. gives a recipe for specifying a convergent subsequence of a bounded sequence of real numbers which does not require any choice. Since the rest of the proof only requires finitely many choices (the metric ρ and the dense sequence D; all other choices can be made systematically), no Choice is needed for this proof.

XIII.17.4. Exercises

XIII.17.4.1. (a) Let $X = \mathbb{N}^\dagger$, the one-point compactification of $\mathbb{N}$, and let $Y = [0,1]$. Let $f_n : X \to Y$ be the function which is 1 on $\{1,\dots,n\}$ and 0 otherwise, and let f be the function which is 1 on $\mathbb{N}$ and 0 at ∞. Then $f_n \to f$ pointwise, each f_n is continuous, but f is discontinuous. Obviously (f_n) does not converge to f uniformly, hence does not converge uniformly on compact sets since X is compact. Show that $f_n \to f$ in the compact-open topology on $F(X,Y)$.

(b) Let $X = \mathbb{N} \cup \{\alpha\}$ be the space of XIII.11.14.10., and let $Y = [0,1]$. The only compact subsets of X are the finite subsets; thus uniform convergence on compact sets is the same as pointwise convergence. If f_n is defined as above, and f is 1 on $\mathbb{N}$ and $f(\alpha) = 0$, then $f_n \to f$ uniformly on compact sets (pointwise), but each f_n is continuous and f is discontinuous. In this case, $f_n \to f$ also in the compact-open topology on $F(X,Y)$.

(c) Let $X = \mathbb{N}^\dagger$ and $Y = \mathbb{R}$. Define $f : X \to Y$ by $f(k) = k$ for $k \in \mathbb{N}$, and $f(\infty) = 0$. Let $f_n(k) = k - \frac{1}{n}$, and $f_n(\infty) = 0$. Then $f_n \to f$ uniformly. Let

$$O = (-1,1) \cup \bigcup_{k\in\mathbb{N}} \left(k - \frac{1}{k}, k + \frac{1}{k}\right) .$$

Then O is open in Y. We have $f \in U_{X,O}$, but $f_n \notin U_{X,O}$ for any n. Thus (f_n) does not converge to f in the compact-open topology.

With some care, this example can be modified to make $Y = [0,1]$.

(d) Show that the proof of Proposition XIII.17.2.11. shows the following:

PROPOSITION. Let (f_i) be a net of functions from a topological space X to a metric space (Y,ρ), and let f be a function from X to Y. If f is continuous on each compact subset of X, then $f_i \to f$ in the compact-open topology if and only if $f_i \to f$ uniformly on each compact subset K of X.

Note that there is no continuity assumption (or any other assumption) on the f_i. Even the limit function need not be continuous on all of X. (If X is first countable, then continuity on compact subsets implies continuity on all of X (); however, this can fail in general, as in (b).)

(e) If each f_i is continuous (or just continuous on compact sets), and $f_i \to f$ uniformly on compact sets, then f is continuous on compact sets (), and thus $f_i \to f$ in the compact-open topology.

Note that problem 8b in section 9.1 of [**?**] is wrong as stated.

XIII.18. Cantor Sets

The Cantor set, and its variations, is a complicated but interesting closed subset of the unit interval in $\mathbb{R}$. It is well worth while to develop a good understanding of this set, since it is an important gateway to a number of varied aspects of analysis and topology.

XIII.18.1. The Cantor Set

XIII.18.2. Other Cantor Sets

The construction of the Cantor set can be obviously generalized: at each step we only need to remove an open interval from the interior of each of the remaining closed intervals at that step; it does not have to be exactly the middle third (the lengths of the remaining intervals must just approach zero). By varying the lengths of the removed intervals, we can obtain versions of the Cantor set with various measure-theoretic properties.

Symmetric Cantor Sets

We first consider the case where all removed intervals at each stage are centered and of the same length, so that all the remaining intervals at each step will have the same length. This restriction is not necessary, but without it notation becomes unwieldy, and the Cantor sets obtained with the restriction, while quite general, retain a pleasant amount of symmetry and homogeneity.

XIII.18.2.1. Let $\alpha = (\alpha_0, \alpha_1, \alpha_2, \dots)$ be a sequence of real numbers such that $\alpha_0 = 1$ and $0 < \alpha_n < \frac{\alpha_{n-1}}{2}$ for $n \geq 1$. Begin with $K_0 = [0,1]$. Remove an open interval from the middle of K_0 to obtain the set K_1 consisting of two closed intervals of length α_1; the removed interval has length $1 - 2\alpha_1 = \alpha_0 - 2\alpha_1$. Continue inductively: at the n'th stage remove open intervals from the middle of each of the closed intervals in K_{n-1} to obtain 2^n closed intervals of length α_n; the 2^{n-1} removed intervals each have length $\alpha_{n-1} - 2\alpha_n$. Let K_n be the union of the resulting intervals. We have that K_n is a closed subset of $[0,1]$, hence compact (), and $K_{n+1} \subseteq K_n$ for all n.

XIII.18.2.2. Definition. The set $K_\alpha = \cap_n K_n$ is the *Cantor set of type* α.

XIII.18.2.3. We thus obtain a large variety of Cantor sets. The Cantor set of () is the Cantor set of type α, where $\alpha_n = 3^{-n}$ for all n. This set will simply be denoted K and called "the Cantor set," i.e. the phrase "the Cantor set" without additional qualification always means the standard one.

All Cantor sets constructed in this way are topologically the same as the Cantor set, and embedded in $[0,1]$ in the same way:

XIII.18.2.4. Proposition. Let K_α be any Cantor set. Then there is a strictly increasing continuous function $\phi : [0,1] \to [0,1]$ with $\phi(K) = K_\alpha$. In particular, K_α is homeomorphic to K.

We always have $\alpha_n < 2^{-n}$, so $\alpha_n \to 0$ rather rapidly. The faster the α_n converge to 0, the "smaller" the set K_α is. By choosing this rate carefully, one can obtain arbitrary Hausdorff and packing dimensions for K_α:

XIII.18.2.5. THEOREM. Let K_α be a Cantor set of type $\alpha = (\alpha_0, \alpha_1, \alpha_2, \dots)$. Then

(i) The Hausdorff dimension () of K_α is

$$Dim_H(K_\alpha) = \liminf_{n\to\infty} \frac{n \log 2}{-\log \alpha_n} \ .$$

(ii) The packing dimension () of K_α is

$$Dim_P(K_\alpha) = \limsup_{n\to\infty} \frac{n \log 2}{-\log \alpha_n} \ .$$

In particular, if $0 \le s_H \le s_P \le 1$, there is a K_α with $Dim_H(K_\alpha) = s_H$ and $Dim_P(K_\alpha) = s_P$.

XIII.18.2.6. EXAMPLES. (i) If $0 < s < 1$, set $\alpha_n = 2^{-n/s}$ for all n. Then $Dim_H(K_\alpha) = Dim_P(K_\alpha) = s$. (ii) If $\alpha_n = 2^{-n^2}$ for all n, then $Dim_H(K_\alpha) = Dim_P(K_\alpha) = 0$.

XIII.18.2.7. If $Dim_H(K_\alpha) = s$, this result does not give information about $\mathcal{H}^s(K_\alpha)$. By a more delicate analysis, we can make this measure arbitrary as long as $0 < s < 1$ (Since $\mathcal{H}^0$ is counting measure, we have $\mathcal{H}^0(K_\alpha) = \infty$ for all α, and $\mathcal{H}^1$ is Lebesgue measure on $\mathbb{R}$, so $\mathcal{H}^1(K_\alpha) \le \mathcal{H}^1([0,1]) = 1$ for all α). We can do the same for packing measure. We have:

If $Dim_H(K_\alpha) = 1$, we can make K_α have positive Lebesgue measure:

XIII.18.2.8. EXAMPLE. Let $0 < d < 1$. We will construct a K_α such that $\lambda(K_\alpha) = d$. Set

$$c = \frac{3 - 2d}{1 - d} \in (3, \infty)$$

and note that $d = \frac{c-3}{c-2}$. Choose the α_n so that the removed open intervals at the n'th stage have length c^{-n}. This can be done inductively by setting $\alpha_0 = 1$ and solving $c^{-n} = \alpha_n - 2\alpha_{n-1}$ for α_n. If $b = c^{-1}$, we have successively

$$\alpha_1 = \frac{1-b}{2}, \quad \alpha_2 = 1 - b + b^2, \quad \alpha_3 = 2 - 2b + 2b^2 + b^3, \ \cdots$$

At the n'th step, 2^{n-1} intervals of length c^{-n} are removed; hence the complement of K_α in $[0,1]$ has Lebesgue measure

$$\sum_{n=1}^{\infty} \frac{2^{n-1}}{c^n} = \frac{1}{2} \sum_{n=1}^{\infty} \left[\frac{2}{c}\right]^n = \frac{1}{2} \cdot \frac{\frac{2}{c}}{1 - \frac{2}{c}} = \frac{1}{c-2}$$

since the removed intervals are disjoint, and thus we have

$$\lambda(K_\alpha) = 1 - \frac{1}{c-2} = \frac{c-3}{c-2} = d \ .$$

Denote this Cantor set by K_d. We could also take $d = 0$ in this construction ($c = 3$) to get the ordinary Cantor set, although this set does not have Hausdorff dimension 1.

Note that there is no K_α with $\lambda(K_\alpha) = 1$, since for any α we have that $[0,1] \setminus K_\alpha$ is a nonempty open set and thus has strictly positive Lebesgue measure.

More general Hausdorff and packing dimensions

Asymmetric Cantor Sets

For Cantor sets with Lebesgue measure zero, there is a feasible alternate notation which works also in the asymmetric case.

XIII.18.2.9. Let $\lambda = (\lambda_k)$ be a sequence of strictly positive numbers with $\sum_{k=1}^{\infty} \lambda_k = 1$. At the first stage, remove a suitable open interval of length λ_1 from the interior of $I_1 = [0,1]$. It will turn out that there is a uniquely located such subinterval for which the subsequent process works, not necessarily centered in $[0,1]$. This leaves two closed subintervals I_2 and I_3 (numbered from left to right). Remove a suitable open subinterval of length λ_2 from I_2, and one of length λ_3 from I_3, leaving four closed intervals $I_4 - I_7$. Continue the process, and let C_λ be the remaining set at the end. Then C_λ is a Cantor set of Lebesgue measure zero (Exercise ()).

XIII.18.2.10. To make the process work, the lengths of the remaining intervals at each stage must be sums of suitable subseries of the original series. The length of I_2 must be $\sum \lambda_k$, where the k are all numbers of the form $2^m + j$, $0 \le j \le 2^{m-1} - 1$ for $m \ge 1$, and the length of I_3 must be $\sum \lambda_k$, where the k are of the form $2^m + j$, $2^{m-1} \le j \le 2^m - 1$, $m \ge 1$, i.e.

$$\ell(I_2) = \lambda_2 + \lambda_4 + \lambda_5 + \lambda_8 + \lambda_9 + \lambda_{10} + \lambda_{11} + \lambda_{16} + \cdots$$

$$\ell(I_3) = \lambda_3 + \lambda_6 + \lambda_7 + \lambda_{12} + \lambda_{13} + \lambda_{14} + \lambda_{15} + \lambda_{24} + \cdots$$

and these uniquely determine I_2 and I_3 (note that $1 = \ell(I_1) = \lambda_1 + \ell(I_2) + \ell(I_3)$) and hence uniquely determine the interval which must be removed from I_1. Lengths of subsequent intervals are uniquely determined in the same manner.

XIII.18.2.11. The Cantor set C_λ depends on the ordered sequence λ. In rare cases, a reordering of the sequence can yield the same Cantor set; two sequences yielding the same Cantor set must be reorderings of each other.

XIII.18.2.12. The sets K_α which have Lebesgue measure 0 are among the C_λ. In fact, if (α_n) is given, take $\lambda_k = \alpha_{n-1} - 2\alpha_n$ for $2^{n-1} \le k < 2^n$.

More generally, any Cantor set of Lebesgue measure 0 in $[0,1]$ containing 0 and 1 is a C_λ. If C is such a Cantor set, then $U_1 = [0,1] \setminus C$ is a countable union of disjoint open intervals. Let λ_1 be the maximum length of the disjoint subintervals. Remove an interval of length λ_1 from U, leaving open sets U_2 and U_3 on either side. Let λ_2 be the maximum length of an open subinterval in U_2, etc. This generates a sequence (λ_k), and it is easily seen that $C = C_\lambda$ (Exercise ()).

The same construction can be done in any interval $[a,b]$ of $\mathbb{R}$, starting with a series $\sum_{k=1}^{\infty} \lambda_k$ whose sum is $b - a$. Every Cantor subset of $\mathbb{R}$ of Lebesgue measure 0 is such a set, i.e. a translated and scaled version of a C_λ.

The Hausdorff measure and Hausdorff dimension of the C_λ have been studied by a number of authors: [Bor49], [BT54], [CMMS04], [CMPS05], [CHM10].

XIII.18.3. Exercises

XIII.18.3.1. (i) Show that for every $a \in [0,1]$, there is a $b \in [0,1]$ such that $a+b$ and $a-b$ are in K. [Write a in its ternary expansion. Let the n'th digit of the ternary expansion of b be 1 if the n'th digit of the expansion of a is 1, and 0 otherwise.]

(ii) Show that every number in $[0,2]$ can be written as the sum of two elements of K. [If $x \in [0,2]$, set $a = x/2$ and choose b as in (i).] How many ways are there of doing it?

(iii) Conclude from (ii), (), and () that the Hausdorff dimension of K is at least $1/2$. (In fact, by XIII.18.2.5., the Hausdorff dimension of K is $\frac{\log 2}{\log 3} \approx 0.63$.)

XIII.18.4. Space-Filling Curves

In this section, we will show that there is a continuous function from $[0,1]$ *onto* the square $[0,1]^2$. This remarkable fact was first discovered by Peano in -. There are actually many ways to construct such a "space-filling curve"; our approach will be somewhat unconventional, exploiting properties of the Cantor set. For other constructions of space-filling curves, see, for example, [] or [] (or many other references.) Essentially the same construction will yield a continuous function from $[0,1]$ onto $[0,1]^n$ for any n, and even a continuous function from $[0,1]$ onto the Hilbert cube $[0,1]^{\mathbb{N}}$ (an "ultimate space-filling curve").

Recall that the Cantor set K is the subset of $[0,1]$ consisting of all numbers which have a triadic expansion consisting only of 0's and 2's. Every element of K has a unique such expansion. K is an uncountable compact subset of $[0,1]$ which is totally disconnected but without isolated points, which is nowhere dense and has Lebesgue measure 0.

The proof of the next proposition is straightforward and is left to the reader.

XIII.18.4.1. PROPOSITION. The map

$$(a_1, a_2, \dots) \mapsto .a_1 a_2 \cdots$$

is a homeomorphism from $\{0,2\}^{\mathbb{N}}$ onto K.

XIII.18.4.2. Thus K is homeomorphic to a countably infinite product of 2-point spaces. The key fact about K we will need, which follows immediately from this (since $\aleph_0 = n\aleph_0 = \aleph_0^2$), is that K is homeomorphic to $K^2 = K \times K$, and also to K^n for any n and even to $K^{\mathbb{N}}$. An explicit homeomorphism from K to K^2 is given by:

$$\rho(.a_1a_2a_3\cdots) = (.a_1a_3a_5\cdots, .a_2a_4a_6\cdots)$$

where the a_i are the triadic digits, either 0 or 2. A similar homeomorphism can be given from K to K^n for any n. To get a homeomorphism from K to $K^{\mathbb{N}}$, let γ be a bijection from $\mathbb{N} \times \mathbb{N}$ to $\mathbb{N}$, for example $\gamma(m,n) = 2^{m-1}(2n-1)$, and set

$$\sigma(.a_1a_2a_3\cdots) = (\sigma_1(.a_1a_2a_3\cdots), \sigma_2(.a_1a_2a_3\cdots), \sigma_3(.a_1a_2a_3\cdots), \cdots)$$

where $\sigma_m(.a_1a_2a_3\cdots) = .a_{\gamma(m,1)}a_{\gamma(m,2)}a_{\gamma(m,3)}\cdots$. So, for the above γ,

$$\sigma(.a_1a_2a_3\cdots) = (.a_1a_3a_5\cdots, .a_2a_6a_{10}\cdots, .a_4a_{12}a_{20}\cdots, \cdots)$$

XIII.18.4.3. There is a standard continuous function from K onto $[0,1]$, defined by

$$\theta(.a_1a_2a_3\cdots) = .b_1b_2b_3\cdots$$

where the a_n are triadic digits, either 0 or 2, $b_n = a_n/2$ (i.e. $b_n = 0$ if $a_n = 0$ and $b_n = 1$ if $a_n = 2$), and $.b_1b_2b_3\cdots$ is the *binary* expansion of the image number. This function θ is just the restriction of the Cantor function () to K.

Applying θ coordinatewise, we obtain continuous functions θ^n from K^n onto $[0,1]^n$, and $\theta^{\mathbb{N}}$ from $K^{\mathbb{N}}$ onto $[0,1]^{\mathbb{N}}$. Composing these with the homeomorphisms ρ and σ above, we obtain continuous surjective maps

$$\phi = \theta^2 \circ \rho : K \to [0,1]^2, \quad \psi = \theta^{\mathbb{N}} \circ \sigma : K \to [0,1]^{\mathbb{N}}$$

Let ϕ_n $(n = 1, 2)$ be the coordinate functions of ϕ, and ψ_n $(n \in \mathbb{N})$ the coordinate functions of ψ. By (), ϕ_n and ψ_n extend to continuous functions on all of $[0, 1]$ by making them linear on the intervals in $[0, 1] \setminus K$; also call these extensions ϕ_n and ψ_n respectively. Using these as coordinate functions, we obtain surjective continuous functions $\phi : [0, 1] \to [0, 1]^2$ and $\psi : [0, 1] \to [0, 1]^{\mathbb{N}}$, which is what we wanted. Thus:

XIII.18.4.4. THEOREM. There are continuous functions ϕ from $[0, 1]$ onto $[0, 1]^2$, and ψ from $[0, 1]$ onto $[0, 1]^{\mathbb{N}}$.

XIII.18.4.5. The functions we have defined have the following properties:

(1) The coordinate functions are differentiable on $[0, 1] \setminus K$, hence differentiable a.e.

(2) For any $(s_1, s_2) \in [0, 1]^2$, there is a $t \in [0, 1]$ with $\phi_1(t) = s_1$ and $\phi_2(t) = s_2$. Similarly, for any sequence $(s_1, s_2, \cdots)$ in $[0, 1]$, there is a $t \in [0, 1]$ with $\psi_n(t) = s_n$ for all n.

XIII.18.4.6. The functions ϕ and ψ cannot be injective, since if they were they would be homeomorphisms by (); but cubes of different dimensions are not homeomorphic (). However, ϕ is not terribly far from being injective: no point of $[0, 1]^2$ is traversed more than 5 times (the point $(\frac{1}{2}, \frac{1}{2})$ is traversed exactly 5 times, as are countably many other points). Individual coordinate functions are very far from being injective, however. (In fact, see XIII.18.5.3..)

XIII.18.4.7. The coordinate functions ϕ_n and ψ_n, although differentiable a.e., are not of bounded variation. The graphs of ϕ_1 and ϕ_2 look as follows:

The graphs have a somewhat fractal character in that the same patterns are repeated in miniature. However, they are not truly fractal since the scaling factors are different on the horizontal and vertical axes ($\frac{1}{3}$ on the horizontal, $\frac{1}{2}$ on the vertical).

XIII.18.5. Exercises

XIII.18.5.1. Describe the "motion" of $\phi(t)$ through the unit square as t goes from 0 to 1. [First describe $\phi(t)$ for $t \in [\frac{1}{3}, \frac{2}{3}]$, $t \in [\frac{1}{9}, \frac{2}{9}]$, $t \in [\frac{7}{9}, \frac{8}{9}]$, etc., and then find $\phi([0, \frac{1}{3}])$, $\phi([\frac{2}{3}, 1])$, $\phi([0, \frac{1}{9}])$, $\phi([\frac{2}{9}, \frac{1}{3}])$, etc.]

XIII.18.5.2. An occasional attempt is made to define a space-filling curve ω from $[0, 1]$ onto $[0, 1]^2$ by the formula

$$\omega(.b_1b_2b_3\cdots) = (.b_1b_3b_5\cdots, .b_2b_4b_6\cdots)$$

where the b_n (0 or 1) are *binary* digits. Show why this approach does not work. Try to modify the formula to give a well-defined continuous surjection.

XIII.18.5.3. Each of the coordinate functions of ϕ or ψ is a continuous function from $[0, 1]$ to $[0, 1]$ taking each value in $[0, 1]$ uncountably many times. [Fix $a \in [0, 1]$. For each $b \in [0, 1]$ there is a $t_b \in [0, 1]$ such that $\phi(t_b) = (a, b)$, so $\phi_1(t_b) = a$ for all b.]

XIII.18.6. A Plane Curve With Positive Area

It is easy to give examples of topologically one-dimensional, and even zero-dimensional, compact subsets of $\mathbb{R}^2$ which have positive planar (Lebesgue) measure (e.g. XIII.18.6.4.). In this section, we construct a simple closed curve in $\mathbb{R}^2$ (Jordan curve), i.e. a subset of $\mathbb{R}^2$ homeomorphic to S^1, which has positive planar measure.

Such a set, regarded as a curve, must be highly nondifferentiable: the image of a piecewise continuously differentiable curve (or, more generally, a Lipschitz function) has Hausdorff dimension 1, and hence plane measure 0 ().

The first example of a simple closed curve with positive planar measure was given by Osgood in 1902 ([Osg03], complete with color pictures!); another example was constructed by Besicovitch and Schoenberg in [BS61].

Cantor Sets

XIII.18.6.1. Recall one standard construction of Cantor sets in $\mathbb{R}$.

Let α be a real number ≥ 3. The Cantor set K_α is constructed by beginning with the closed unit interval $[0,1]$ and at the n'th stage removing the open subintervals of length α^{-n} centered in each of the 2^{n-1} remaining intervals; K_α is the intersection. K_α is a compact totally disconnected set without isolated points, homeomorphic to a countable product of two-point spaces.

Since the total length of the removed subintervals is

$$\sum_{n=1}^{\infty} \frac{2^{n-1}}{\alpha^n} = \frac{1}{\alpha} \sum_{m=0}^{\infty} \left(\frac{2}{\alpha}\right)^m = \frac{1}{\alpha(1-\frac{2}{\alpha})} = \frac{1}{\alpha-2}$$

we obtain that the (one-dimensional) Lebesgue measure of K_α is

$$1 - \frac{1}{\alpha-2} = \frac{\alpha-3}{\alpha-2}.$$

XIII.18.6.2. The usual Cantor set is K_3, just denoted K. The measure of K is zero. K consists precisely of all elements of $[0,1]$ with a ternary (base 3) decimal expansion consisting only of 0's and 2's, and every element of K has a unique such expansion.

XIII.18.6.3. Given any α and β, there is an evident homeomorphism of $\mathbb{R}$ (strictly increasing function) carrying K_α onto K_β. (Note that this shows the well-known fact () that a homeomorphism of $\mathbb{R}$ need not preserve sets of measure zero.)

XIII.18.6.4. If $K_\alpha^2 = K_\alpha \times K_\alpha$, then K_α^2 is a compact subset of $[0,1]^2$ homeomorphic to K (a specific homeomorphism will be described below.) The planar measure of K_α^2 is

$$\left(\frac{\alpha-3}{\alpha-2}\right)^2.$$

A Wandering Curve

We will construct a homeomorphic image of $[0,1]$ passing through every point of K^2_α; thus if $\alpha > 3$ the image will have positive planar measure.

For notational simplicity, we will describe the construction for $\alpha = 3$. The construction for $\alpha > 3$ can be done directly in an analogous way, or by simply composing the curve for $\alpha = 3$ with a homeomorphism of $\mathbb{R}^2$ sending K^2 onto K^2_α.

XIII.18.6.5. We first define an auxiliary function

$$\psi : \{0\} \cup [1/9, 2/9] \cup [1/3, 2/3] \cup [7/9, 8/9] \cup \{1\} \to [0,1]^2$$

by setting $\psi(0) = (0,0)$, $\psi(1/9) = (0, 1/3)$, $\psi(2/9) = (0, 2/3)$, $\psi(1/3) = (1/3, 2/3)$, $\psi(2/3) = (2/3, 2/3)$, $\psi(7/9) = (1, 2/3)$, $\psi(8/9) = (1, 1/3)$, $\psi(1) = (1,1)$, and letting ψ be linear (affine) on each of the subintervals. See Figure XIII.17.

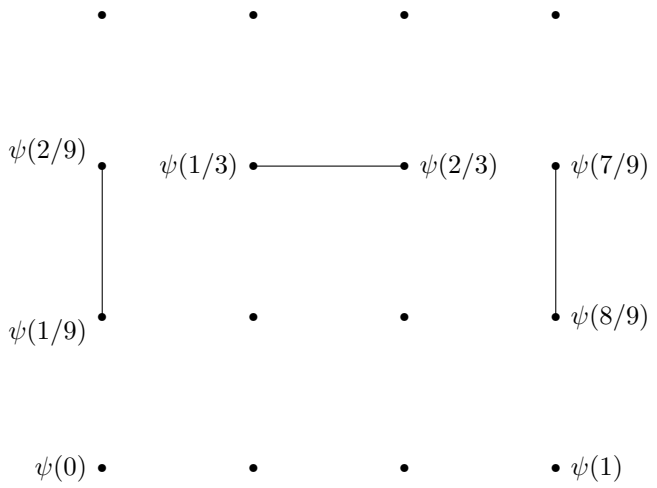


Figure XIII.17: The auxiliary function ψ

XIII.18.6.6. Before defining the curve $\phi : [0,1] \to [0,1]^2$, let us make a definition. A square S with sides parallel to the axes, of length 3^{-n} for some n, will be called *full* if the four corners of S are in the closure of the intersection of K^2 with the interior of S. The whole unit square is full; and if a full square is divided into nine subsquares, it is the four corner subsquares which are also full.

XIII.18.6.7. We will now define ϕ in stages. It is convenient to do the first step of the definition somewhat differently from the others, in order to have $\phi(0) = (1/3, 0)$ and $\phi(1) = (2/3, 0)$; then the segment from $(2/3, 0)$ back to $(1/3, 0)$ can be added to give a simple closed curve. (This segment will be included in the pictures.) So in addition to these definitions of $\phi(0)$ and $\phi(1)$, in the first step we define ϕ on $[1/9, 2/9]$ to map linearly to the segment from $\phi(1/9) = (1/3, 1/3)$ to $\phi(2/9) = (1/3, 2/3)$; define ϕ on $[1/3, 2/3]$ to

map linearly to the segment from $\phi(1/3) = (1/3, 1)$ to $\phi(2/3) = (2/3, 1)$, and similarly ϕ maps $[7/9, 8/9]$ linearly to the segment from $\phi(7/9) = (2/3, 2/3)$ to $\phi(8/9) = (2/3, 1/3)$.

XIII.18.6.8. We now proceed inductively. After the n'th step ϕ is defined except on open intervals of the form $\left(\frac{k}{9^n}, \frac{k+1}{9^n}\right)$, where k is 0,2,6, or 8 mod 9. For each such k, there is a unique full square S with adjacent corners $\phi(k/9^n)$ and $\phi((k+1)/9^n)$, and a unique affine map θ from the unit square onto S with $\theta(0,0) = \phi(k/9^n)$ and $\theta(1,0) = \phi((k+1)/9^n)$. Then for $t \in [1/9, 2/9] \cup [1/3, 2/3] \cup [7/9, 8/9]$ define

$$\phi\left(\frac{k+t}{9^n}\right) = \theta \circ \psi(t)$$

After the third step, the curve looks like Figure XIII.18.

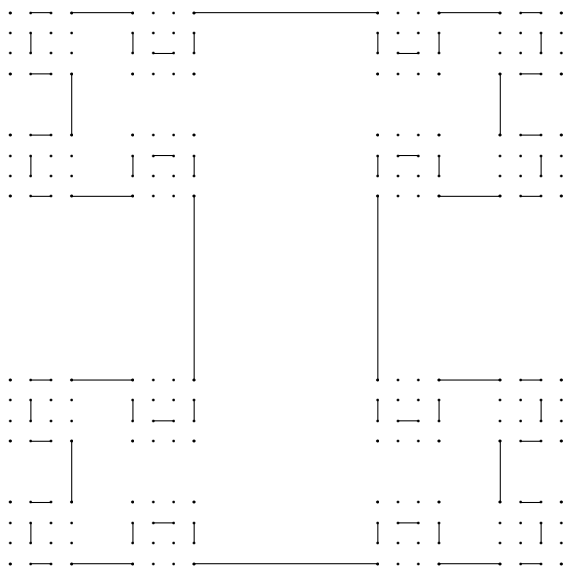

Figure XIII.18: Three steps of the definition of ϕ

XIII.18.6.9. After the inductive construction, ϕ is defined on a dense subset of $[0, 1]$. By construction, if $s, t \in [0, 1]$ and $|s - t| < 9^{-n}$, and $\phi(s)$ and $\phi(t)$ are defined, then $\|\phi(s) - \phi(t)\| < 3^{-n}\sqrt{2}$; thus ϕ is uniformly continuous and extends to a continuous map from all of $[0, 1]$ to $[0, 1]^2$.

XIII.18.6.10. PROPOSITION. The image of ϕ contains K^2.

PROOF: This is obvious, since after the n'th step in the construction every point of K^2 lies within $3^{-n}\sqrt{2}$ of a point on the curve. 👍

XIII.18.6.11. PROPOSITION. The map ϕ is a homeomorphism onto its image.

PROOF: By compactness, it is only necessary to show that ϕ is one-to-one. It clearly maps $[0,1]\backslash K$ one-one into $[0,1]^2\backslash K^2$, so we need only show that ϕ maps K one-one into (actually onto) K^2. This is geometrically clear, but is rather complicated to write down explicitly. In fact, there is a precise (but complicated) formula giving the first n places of the ternary decimal expansion of the two coordinates of $\phi(t)$ $(t \in K)$ in terms of the first $2n$ places of the ternary decimal expansion of t. For example, if $t = .a_1a_2\cdots$, $\phi(t) = (.b_1\cdots, .c_1\cdots)$, where b_1 is always equal to a_1 and $c_1 = a_2$ if $a_1 = 0$, $c_1 = 2 - a_2$ if $a_1 = 2$. It can be checked that if $s, t \in K$ differ in the first $2n$ ternary decimal places, then $\phi(s)$ and $\phi(t)$ differ in the first n ternary decimal places in at least one coordinate. 👍

XIII.18.6.12. The final curve is depicted in Figure XIII.19. The curve has a fractal character in that all of the full squares with sides of length $\leq 1/3$ are similar up to scaling and rotation.

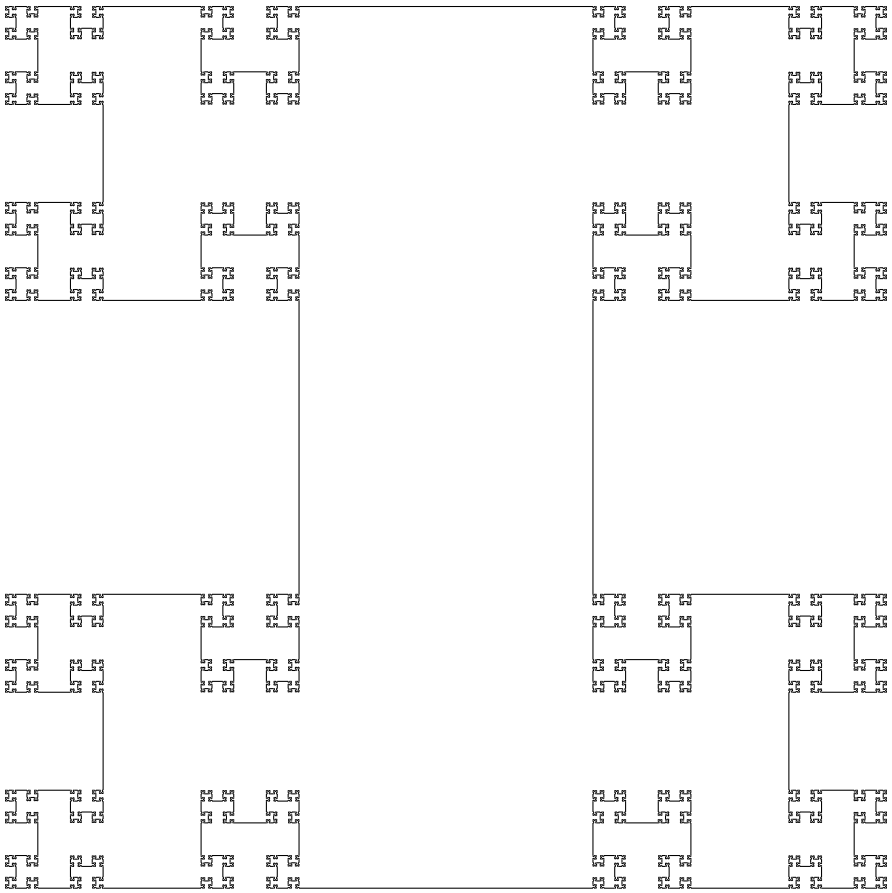

Figure XIII.19: The closed curve ϕ

Connection with Space-Filling Curves

XIII.18.6.13. This construction bears a close resemblance to one version of the Peano space-filling curve (see, for example, [Edg08, p. 64].) We obtain a space-filling curve by composing ϕ with $p \times p$, where p is the usual map from K onto $[0,1]$ given by

$$p(.a_1a_2a_3\cdots) = .b_1b_2b_3\cdots$$

where $.a_1a_2\cdots$ is the ternary decimal expansion of $t \in K$, and $.b_1b_2\cdots$ is the binary decimal expansion of $p(t)$, with $b_n = a_n/2$. The resulting map $(p \times p) \circ \phi$ maps $[0,1]$ continuously onto $[0,1]^2$. (It should be thought of as being constant on the intervals of $[0,1]\backslash K$.)

XIII.18.6.14. The map p is not one-to-one since the binary decimal expansion of dyadic rational numbers is not unique, and any cross section $q : [0,1] \to K$ for p is necessarily discontinuous; however, the map $\sigma = (p \times p) \circ \phi \circ q$ is continuous and independent of q, and maps $[0,1]$ onto $[0,1]^2$. This map σ is a more usual type of space-filling curve.

Summary and Variations

XIII.18.6.15. If C_α is the image of the curve ϕ done for the Cantor set K_α, with the last segment filled in between the endpoints, then C_α is a simple closed curve, contained in $[0,1]^2$, with planar measure at least the measure of K_α^2. Actually, C_α is the union of K_α^2 and a countable number of straight line segments, so the measure of C_α is exactly

$$\left(\frac{\alpha-3}{\alpha-2}\right)^2.$$

This can be any (nonnegative) number less than 1. If α is large enough ($\alpha > 4+\sqrt{2}$ will do), the measure of this curve is greater than the measure of the region inside the curve!

There cannot be a simple closed curve in $[0,1]^2$ of planar measure exactly one, since any nonempty open set in the plane has positive measure.

XIII.18.6.16. The curve C_α is a Jordan curve, but the region inside the curve is an open set in $\mathbb{R}^2$ (homeomorphic to an open disk) which is not a Jordan region () if $\alpha > 3$ since its boundary does not have measure zero.

XIII.18.6.17. The example in [BS61] has the additional property that for any s, t, $0 \le s < t \le 1$, the arc from $\phi(s)$ to $\phi(t)$ has positive planar measure. Our example can be modified to have this property, by replacing each straight line segment by countably many small versions of the curve.

XIII.18.6.18. It would appear that a construction similar to the one of this section can be done in $[0,1]^n$ for any n, giving a simple closed curve passing through every point of K_α^n and thus having positive n-dimensional Lebesgue measure. However, the details might be complicated to write carefully. Perhaps a similar construction can even be done in the Hilbert cube. See [PS92] for a version of Osgood's example in $\mathbb{R}^n$.

XIII.19. The Topology of $\mathbb{R}^n$

XIII.19.1. Invariance of Domain and the Jordan Curve Theorem

In this subsection, we describe two remarkable results about Euclidean space. Both of these fall into the category of facts which at first glance are "intuitively obvious," but which become highly nonobvious when thought about more carefully.

We begin with the original Jordan Curve Theorem in $\mathbb{R}^2$.

XIII.19.1.19. DEFINITION. A *Jordan curve* in $\mathbb{R}^2$ is the image of a one-to-one continuous function from the circle S^1 to $\mathbb{R}^2$. A Jordan curve is also called a *simple closed curve*.

A Jordan curve can also be defined as the image of a continuous function γ from a closed bounded interval $[a, b]$ into $\mathbb{R}^2$ which is one-to-one except that $\gamma(a) = \gamma(b)$. There is no assumption of smoothness or differentiability. Such a "parametrization" of the curve is highly nonunique and is not part of the structure of the curve.

A Jordan curve is intuitively a closed loop in the plane which does not cross itself. In fact, since S^1 is compact and Hausdorff, a Jordan curve is homeomorphic to S^1 by (). (Conversely, any subset of $\mathbb{R}^2$ which is homeomorphic to S^1 is trivially a Jordan curve.) Geometric circles, ellipses, and polygons are elementary examples of Jordan curves. A "figure 8" is not a Jordan curve. For a more complicated example, see Figure XIII.20. For more extreme examples, see Figures XIII.21, XIII.19, and XIII.18.6.17..

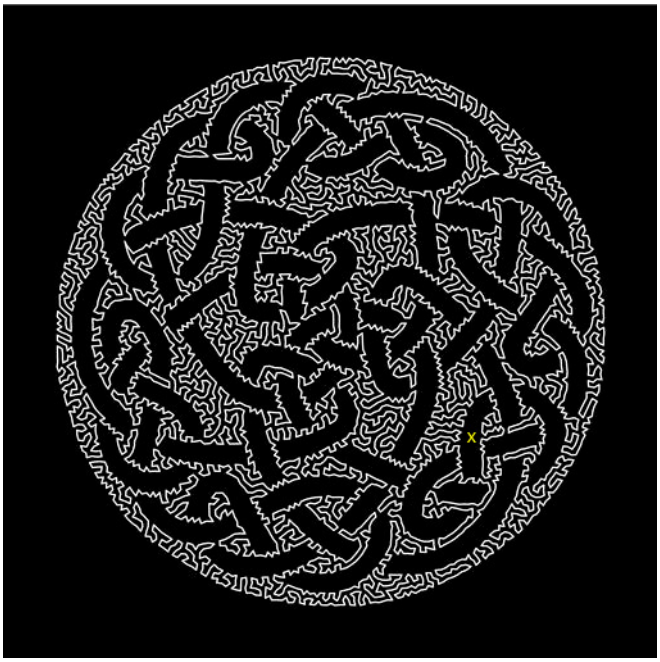

Figure XIII.20: A complicated Jordan curve (in white). Artwork by Robert Bosch

One would intuitively expect that a Jordan curve would divide the plane into two disjoint regions, the "inside" and the "outside" of the curve, just as a geometric circle does. But when more complicated examples are considered, this conclusion is less obvious; for example, is it obvious what is the "inside" and "outside" of the curve in Figure XIII.20? (In particular, is the point marked with the yellow x inside or outside? Try to find a path out from this point.) Nonetheless, it does turn out to be true:

XIII.19.1.20. THEOREM. [JORDAN CURVE THEOREM] Let C be a Jordan curve in $\mathbb{R}^2$. Then $\mathbb{R}^2 \setminus C$ has exactly two connected components, one bounded and one unbounded, whose common boundary is C.

This result is due to C. JORDAN in 1887. It is questionable whether JORDAN'S proof can be regarded as complete; certainly his exposition leaves much to be desired. Conventional wisdom says that JORDAN'S proof was flawed and that the first complete, correct proof was given by O. VEBLEN in 1905; however, this assertion may not stand up under examination [Hal07]. There have been many other proofs given over the years; see [Mae84] for a particularly nice one. We will not give a proof here. If the curve is polygonal or piecewise-smooth, the proof is relatively simple since such a curve locally divides the plane in two parts; however, the general case is difficult since a Jordan curve can be locally pathological such as the example in Figure XIII.21 (although it turns out to still locally divide the plane).

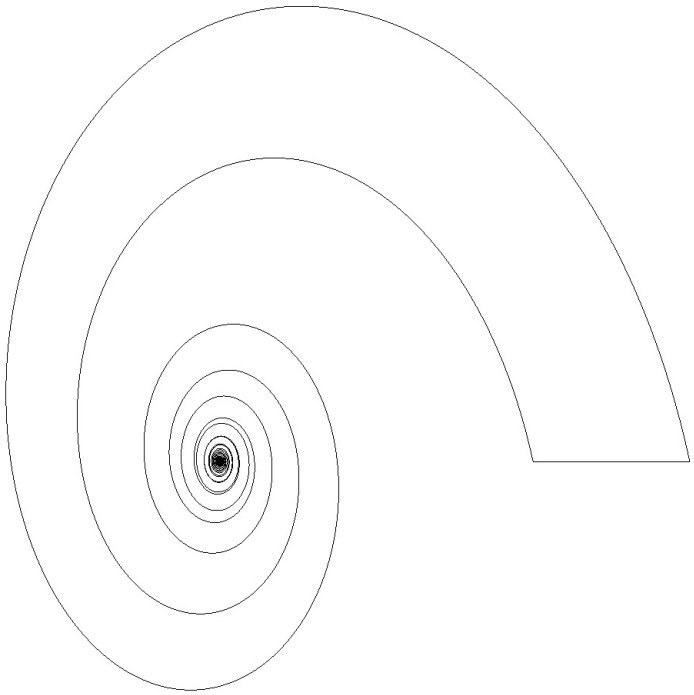

Figure XIII.21: A locally pathological Jordan curve

This curve, made of two intertwined spirals, is only locally pathological at one point, but small copies of the spirals can be successively added densely, replacing small arcs of the curve, to make a curve locally pathological at every point. (Much more complicated local pathology is possible too!)

There is a more refined version of the Jordan Curve Theorem, first proved by A. Schönflies in 1908(?) []. This result is commonly called the Jordan-Schönflies theorem.

XIII.19.1.21. Theorem. [Jordan-Schönflies Theorem] Let S^1 be the unit circle in $\mathbb{R}^2$, and $\gamma : S^1 \to \mathbb{R}^2$ a one-to-one continuous function. Then γ extends to a homeomorphism from $\mathbb{R}^2$ onto $\mathbb{R}^2$.

It is easy to see that the Jordan-Schönflies Theorem implies XIII.19.1.20. (Exercise ()). The conclusion is stronger: the "inside" (bounded component of the complement) is not only connected, but even homeomorphic to the open unit disk (and hence to $\mathbb{R}^2$ itself), and the "outside" (the unbounded component of the complement) is homeomorphic to $\mathbb{R}^2$ with a point removed. It really says that every subset of $\mathbb{R}^2$ homeomorphic to S^1 is topologically embedded in $\mathbb{R}^2$ in the same way.

See XII.8.6.8. for a proof using Complex Analysis, or see [CV98], for example, for a direct proof.

The Jordan Curve Theorem in $\mathbb{R}^n$

One natural approach to generalizing the Jordan curve theorem is to consider subsets of $\mathbb{R}^n$ homeomorphic to S^{n-1}. Such a subset could be called a *Jordan sphere* in $\mathbb{R}^n$ (this is nonstandard terminology, and it is questionable whether the name is really appropriate, so we will avoid using it).

XIII.19.1.22. One might hope in analogy with the Jordan-Schönflies Theorem that a homeomorphism from the unit sphere S^{n-1} in $\mathbb{R}^n$ to a subset C of $\mathbb{R}^n$ would extend to a homeomorphism from $\mathbb{R}^n$ onto $\mathbb{R}^n$, i.e. that all Jordan spheres in $\mathbb{R}^n$ are topologically embedded in the same way, but the example of the "Alexander horned sphere" in $\mathbb{R}^3$ (XIII.19.5.40.) shows that this statement is false in general, and thus the Jordan-Schönflies Theorem is special to $\mathbb{R}^2$. But remarkably, the Jordan Curve Theorem remains true:

XIII.19.1.23. Theorem. [Jordan Curve Theorem in $\mathbb{R}^n$] Let C be a subset of $\mathbb{R}^n$ ($n \geq 2$) homeomorphic to S^{n-1}. Then $\mathbb{R}^n \setminus C$ has exactly two connected components, one bounded and one unbounded, whose common boundary is C.

This theorem is due to Lebesgue and Brouwer. We again omit the proof; see, for example, [].

XIII.19.1.24. The statement is not quite true for $n = 1$. The "unit sphere" S^0 in $\mathbb{R}^1$ consists of two points $\{\pm 1\}$ whose complement has three connected components. But topologists usually state the theorem by replacing $\mathbb{R}^n$ by its one-point compactification S^n (the statement is easily seen to be equivalent; cf. Exercise ()), and this version also applies when $n = 1$.

There is a related result (which is used in the proof of XIII.19.1.23.). Let B^n be the closed unit ball in $\mathbb{R}^n$. Note that B^n is homeomorphic to $[0, 1]^n$.

XIII.19.1.25. THEOREM. Let B be a subset of $\mathbb{R}^n$ ($n \geq 2$) homeomorphic to B^n (i.e. to $[0,1]^n$). Then $\mathbb{R}^n \setminus B$ is connected.

The statement also holds with $\mathbb{R}^n$ replaced by S^n, even for $n = 1$.

XIII.19.1.26. It has been an active project in topology, not yet completed, to generalize the Jordan-Schönflies Theorem to higher dimensions. Restrictions on the embedding maps must, of course, be made. Perhaps the best result so far is that the statement is true for "locally flat" embeddings (embeddings which extend to a thin spherical shell) ([**?**], [**?**]). The result for smooth embeddings is known for $n \neq 4$, but is still open for $n = 4$.

XIII.19.1.27. One might also wonder about subsets of $\mathbb{R}^n$ (or S^n) homeomorphic to S^m for $m < n-1$. Such subsets always have connected complements, but the ways they can be embedded (even leaving out "wild" embeddings such as the Alexander Horned sphere, e.g. restricting to smooth or piecewise-linear embeddings) are very complicated. The study of smooth embeddings of S^1 into $\mathbb{R}^3$ is a fascinating and active branch of modern topology called *knot theory* (XIII.19.5.35.).

Brouwer's Invariance of Domain

A very important consequence of the Jordan Curve Theorem in $\mathbb{R}^n$ is the theorem that open sets in Euclidean space are invariant under homeomorphisms. This result, called *invariance of domain*, was proved by L. BROUWER in 1912 [].

XIII.19.1.28. THEOREM. [INVARIANCE OF DOMAIN] Let U be a nonempty open subset of $\mathbb{R}^n$, and f a one-to-one continuous function from U to $\mathbb{R}^m$. Then

(i) $m \geq n$.

(ii) If $m = n$, then $f(V)$ is open in $\mathbb{R}^n$ for every open subset V of U (in particular, $f(U)$ is open in $\mathbb{R}^n$), i.e. f is an open mapping and a homeomorphism onto its range.

Before outlining the proof, we list some of the most important consequences.

XIII.19.1.29. COROLLARY. Let U be an open subset of $\mathbb{R}^n$. Then any subset of $\mathbb{R}^n$ which is homeomorphic to U is also open.

The next corollary is especially noteworthy:

XIII.19.1.30. COROLLARY. Let U be a nonempty open subset of $\mathbb{R}^n$. Then U is not homeomorphic to any subset of $\mathbb{R}^m$ for any $m < n$. In particular, $\mathbb{R}^n$ is not homeomorphic to $\mathbb{R}^m$ for $n \neq m$.

This result also follows from the fact that any nonempty open set in $\mathbb{R}^n$ is topologically n-dimensional ().

XIII.19.1.31. Corollary. Let U be an open subset of $\mathbb{R}^n$, and $f : U \to \mathbb{R}^n$ a continuous function which is locally one-to-one. Then f is an open mapping.

XIII.19.1.32. We now outline the proof of XIII.19.1.28.; actually we give a complete proof assuming XIII.19.1.23. and XIII.19.1.25.. We first prove (ii), so assume $m = n$. Let $x \in U$, and fix $\epsilon > 0$ with $A = \bar{B}_\epsilon(x) \subseteq U$. Since A is compact and f is one-to-one on A, $B = f(A)$ is homeomorphic to B^n, and hence the open set $\mathbb{R}^n \setminus B$ is connected by XIII.19.1.25.. If $C = f(\partial A)$, then C is homeomorphic to $\partial A \cong S^{n-1}$, and hence the open set $\mathbb{R}^n \setminus C$ has two components. But $D = f(B_\epsilon(x)) = f(A \setminus \partial A)$ is connected since $B_\epsilon(x)$ is connected (), and D and $\mathbb{R}^n \setminus B$ are disjoint connected sets whose union is $\mathbb{R}^n \setminus C$, so they must be the two components. But the components of an open set are open, so D is open in $\mathbb{R}^n$ and contains $f(x)$. This argument can be repeated for any $x \in U$, so $f(U)$ is open. The same argument works for any open subset V of U. Thus the inverse map from $f(U)$ to U is continuous.

To prove (i), Suppose $m < n$. Define $\tilde{f} : U \to \mathbb{R}^n \cong \mathbb{R}^m \times \mathbb{R}^{n-m}$ by $\tilde{f}(x) = (f(x), 0)$. Then $\tilde{f}$ is one-to-one and continuous, but $\tilde{f}(U)$ is not open, a contradiction.

XIII.19.1.33. If U is an open set in $\mathbb{R}^n$ and f is a one-to-one continuous function from U to $\mathbb{R}^m$ ($m \geq n$), then the restriction of f to any compact subset K of U is a homeomorphism from K to $f(K)$ by (). But if $m > n$, f does not give a homeomorphism from U to $f(U)$ in general. For example, there is an evident one-to-one continuous map from $\mathbb{R}$ onto a figure 8 in $\mathbb{R}^2$. There are more dramatic examples: there is a one-to-one continuous function from $\mathbb{R}$ onto a dense subset of the 2-torus (or n-torus for any $n > 1$) obtained by "wrapping around" at an irrational angle (). See also XIII.19.5.19..

XIII.19.2. Orientation

$\mathbb{R}^n$, or any connected open set in $\mathbb{R}^n$, has two orientations. It is a significant and nontrivial fact that a homeomorphism between connected open sets in $\mathbb{R}^n$ must be either orientation-preserving or orientation-reversing everywhere.

XIII.19.2.1. This is easily seen if $n = 1$. If I is an open interval in $\mathbb{R}$, and f is a one-to-one continuous function from I to $\mathbb{R}$, then (V.3.10.15.) f must be either strictly increasing (orientation-preserving everywhere) or strictly decreasing (orientation-reversing everywhere) on I.

XIII.19.2.2. If $n > 1$, we first need a notion of a one-to-one continuous function being locally orientation-preserving or locally orientation-reversing at a point. If U is an open set in $\mathbb{R}^n$ and $\boldsymbol{f}$ a one-to-one continuous function from U to $\mathbb{R}^n$ (hence a homeomorphism onto an open set V in $\mathbb{R}^n$), and $\boldsymbol{x} \in U$, let B be a closed ball in U centered at $\boldsymbol{x}$ and S the boundary sphere of B; then $\boldsymbol{f}(B)$ is a topological n-ball in V with boundary $\boldsymbol{f}(S)$, a topological $(n-1)$-sphere, with $\boldsymbol{y} = \boldsymbol{f}(\boldsymbol{x})$ in the interior of $\boldsymbol{f}(B)$. We can associate an index with this map: by composing $\boldsymbol{f}$ on the left and right with translations, we may assume $\boldsymbol{x} = \boldsymbol{y} = \boldsymbol{0}$, and then composing with radial projections we obtain from $\boldsymbol{f}$ a continuous map from the unit sphere S^{n-1} to itself, which has an index $i(\boldsymbol{f}_S) \in \mathbb{Z}$.

XIII.19.2.3. Proposition. With the above notation, $i(\boldsymbol{f}_S)$ is either $+1$ or -1.

XIII.19.2.4. It is easily seen that, for fixed $\boldsymbol{x}$, the number $i(\boldsymbol{f}_S)$ does not depend on the choice of B (and hence S), since as the radius of B varies the induced maps from S^{n-1} to itself are homotopic. It could *a priori* depend on $\boldsymbol{x}$, so we will denote it $i_{\boldsymbol{f}}(\boldsymbol{x})$.

XIII.19.2.5. DEFINITION. The function $\boldsymbol{f}$ is *locally orientation-preserving* at $\boldsymbol{x}$ if $i_{\boldsymbol{f}}(\boldsymbol{x}) = +1$ and *locally orientation-reversing* at $\boldsymbol{x}$ if $i_{\boldsymbol{f}}(\boldsymbol{x}) = -1$.

XIII.19.2.6. THEOREM. Let U be a connected open set in $\mathbb{R}^n$, and $\boldsymbol{f}$ a one-to-one continuous function from U to $\mathbb{R}^n$. Then $\boldsymbol{f}$ is either locally orientation-preserving at every point of U or locally orientation-reversing at every point of U.

PROOF: The index $i_{\boldsymbol{f}}(\boldsymbol{x})$ is easily seen to be locally constant in $\boldsymbol{x}$, i.e. $i_{\boldsymbol{f}}$ is a locally constant (continuous) function from U to $\{+1, -1\}$. Since U is connected, $i_{\boldsymbol{f}}$ must be constant. 👍

Smooth Maps

There is an important consequence for smooth maps. Suppose $\boldsymbol{f}$ is a one-to-one $\mathcal{C}^1$ function from an open set U in $\mathbb{R}^n$ to $\mathbb{R}^n$. Then $det(D\boldsymbol{f})$ is a continuous function from U to $\mathbb{R}$.

XIII.19.2.7. PROPOSITION. If $\boldsymbol{f}$ is locally orientation-preserving at $\boldsymbol{x} \in U$, then $det(D\boldsymbol{f}(\boldsymbol{x})) \geq 0$; if $\boldsymbol{f}$ is locally orientation-reversing at $\boldsymbol{x} \in U$, then $det(D\boldsymbol{f}(\boldsymbol{x})) \leq 0$.

PROOF: This is equivalent to the statement that if $det(D\boldsymbol{f}(\boldsymbol{x})) > 0$, then $\boldsymbol{f}$ is locally orientation-preserving at $\boldsymbol{x}$, and if $det(D\boldsymbol{f}(\boldsymbol{x})) < 0$, then $\boldsymbol{f}$ is locally orientation-reversing at $\boldsymbol{x}$, which follows from (). 👍

We then obtain, as a corollary of XIII.19.2.6.:

XIII.19.2.8. COROLLARY. Let U be a connected open set in $\mathbb{R}^n$, and $\boldsymbol{f}$ a one-to-one $\mathcal{C}^1$ function from U to $\mathbb{R}^n$. Then either $det(D\boldsymbol{f}(\boldsymbol{x})) \geq 0$ for all $\boldsymbol{x} \in U$ or $det(D\boldsymbol{f}(\boldsymbol{x})) \leq 0$ for all $\boldsymbol{x} \in U$.

There is an alternate proof of XIII.19.2.8. using the Poincaré Lemma (). If $\boldsymbol{f}$ is a diffeomorphism onto its range, the result is trivial by the Intermediate Value Theorem, since $det(D\boldsymbol{f})$ is never zero. But the general result XIII.19.2.8. is definitely nontrivial. (Note that a one-to-one smooth map is not necessarily a diffeomorphism onto its range even if $n = 1$, e.g. $f(t) = t^3$.)

XIII.19.3. $\mathbb{R}^n$ is n-Dimensional

Everyone "knows" that $\mathbb{R}^n$ is n-dimensional. But what does this mean? Specifically, what does "dimension" mean? And how can $\mathbb{R}^n$ be distinguished from $\mathbb{R}^m$ for $m \neq n$ by its properties?

$\mathbb{R}^n$ is a set with several types of structure: algebraic, geometric, topological, and analytic. Efforts have been made to define and/or describe the "dimension" of $\mathbb{R}^n$ in terms of each of these types of structure, and various theories of dimension have been studied in different contexts; the only thing these various theories have in common is that they all assign the *same* number n to $\mathbb{R}^n$, justifying the use of the name "dimension" for all of them.

XIII.19.3.1. Specifically, we have:

(i) The vector space dimension () of $\mathbb{R}^n$ as a real vector space is n.

(ii) The topological dimension () of $\mathbb{R}^n$ as a topological space is n.

(iii) The Hausdorff dimension () of $\mathbb{R}^n$ is n.

XIII.19.3.2. There is one respect in which all Euclidean spaces are the same, however: cardinality. Contrary to Cantor's expectations (he first thought the cardinality of $\mathbb{R}^n$ should be $\aleph_n$), the cardinality of $\mathbb{R}^n$ is $2^{\aleph_0}$ for all n (). Thus some additional structure beyond set theory is needed to distinguish $\mathbb{R}^n$ from $\mathbb{R}^m$ for $n \neq m$.

XIII.19.4. When is $\mathbb{R}^n$ "Similar" to $\mathbb{R}^m$?

In this section, we ask a rather vague and subjective question: for which n and m are $\mathbb{R}^n$ and $\mathbb{R}^m$ "essentially similar"? The answer depends partly on what type of mathematician is answering it.

XIII.19.4.1. Of course, in a certain technical sense, $\mathbb{R}^n$ and $\mathbb{R}^m$ are different for any $n \neq m$ since they are not homeomorphic (or linearly isomorphic); thus they by definition differ in some describable topological (or algebraic) way. But qualitatively all Euclidean spaces, especially ones of large dimension, seem to be "similar." The question is really: how large does n have to be for Euclidean spaces of dimension $\geq n$ all to behave essentially the same way? Is there really such a dividing line at all?

XIII.19.4.2. In calculus or real analysis, the appropriate answer seems to be that all Euclidean spaces of dimension ≥ 2 are essentially similar, but essentially different from $\mathbb{R}^1$. Calculus on $\mathbb{R}^2$ is quite different in character from calculus on $\mathbb{R}^1$, but calculus on $\mathbb{R}^5$, or $\mathbb{R}^{100}$, is not essentially different from calculus on $\mathbb{R}^2$ except for the trivial difference that notation becomes more complicated in larger dimensions. This statement is not unrestrictedly true: there are some features and results of vector analysis which are special to $\mathbb{R}^2$ and $\mathbb{R}^3$, e.g. ones related to cross product, divergence, and curl (); but even these results are mostly just special cases or interpretations of the general Stokes' Theorem (), which holds in any dimension.

There are analytic properties unique to three- and four-dimensional space which arise in mathematical physics, e.g. stability of configurations under a gravitational force satisfying an inverse-square law. However, it is unclear whether we should regard these results as deep mathematical reasons why physical space must be three-dimensional, or space-time four-dimensional, or whether the three-dimensionality of the universe (as we currently perceive and understand it) and the compatibility of physical laws with three-dimensionality are just physical facts not entailed by mathematical considerations.

XIII.19.4.3. A functional analyst might well give an even less discriminating answer: that all finite-dimensional Hilbert spaces (in particular, all Euclidean spaces) are essentially similar and essentially trivial, and the first important distinction is between finite-dimensional and infinite-dimensional Hilbert spaces.

XIII.19.4.4. On the other hand, a topologist would likely say that the Euclidean spaces of dimension ≤ 5 are all essentially different, while those of dimension ≥ 5 are essentially similar. They would probably go on to add that $\mathbb{R}^4$ is "more different" than any of the others, for various reasons (). One can identify simple and important topological differences between $\mathbb{R}^2$ and $\mathbb{R}^3$, e.g. XIII.19.6.3., Classification of closed manifolds, Banach-Tarski, Poincaré Conjecture, and between $\mathbb{R}^3$ and $\mathbb{R}^n$ for $n \geq 5$ (). Topologists even consider "low-dimensional topology" (of dimension ≤ 4) to be a separate subdiscipline.

XIII.19.4.5. There is a qualitative difference between even- and odd-dimensional spaces, however; for example, even and odd spheres are qualitatively different. Only odd spheres have globally nonvanishing vector fields (), only even spheres have orientation-reversing homeomorphisms without fixed points, etc. The differences can be interpreted as reflecting the difference between the complex K-theories of even and odd spheres ().

There are many other differences in the structure of n-manifolds for different n: for example, every n-dimensional PL manifold has a smooth structure (in fact a unique one) if $n \leq 6$, but if $n \geq 7$ there are closed n-dimensional PL-manifolds which do not have a smooth structure. And smooth structures, if they exist, need not be unique. The n-sphere has a unique smooth structure for $n = 1, 2, 3, 5, 6, 12$ and 61, and

more than one for all other $n \leq 126$ except possibly $n = 4$ (open), and all other odd n []. The cases of even $n > 126$ are partially but not completely known.

It may be a stretch to regard the question as including the structure of manifolds of different dimensions, since the definition of a general manifold is rather subtle; but it is less of a stretch to include the structure of spheres, since the n-sphere is just the one-point compactification of $\mathbb{R}^n$, or the unit sphere in $\mathbb{R}^{n+1}$. One might also legitimately consider the topology of open subsets of $\mathbb{R}^n$ (cf. XIII.19.6.6.–XIII.19.6.8.).

XIII.19.4.6. The classification of (convex) regular polytopes is another difference. There are infinitely many in dimension 2, five in dimension 3, six in dimension 4, and three in dimension n for every $n \geq 5$. So besides the three generic ones which occur in every dimension ≥ 3 (the analogs of the tetrahedron, cube, and octahedron), "exotic" ones exist only in dimensions ≤ 4, of different character in each dimension.

XIII.19.4.7. There are more esoteric dimensional restrictions arising from topology. Two 1-spheres (circles) can be linked nontrivially in $\mathbb{R}^n$ if and only if $n = 3$. But if $m > 1$, the question of whether two disjoint (smoothly embedded) m-spheres can be nontrivially linked in $\mathbb{R}^n$ $(n > m)$ is much more subtle: for example, two 50-spheres can be nontrivially linked in $\mathbb{R}^n$ if and only if $52 \leq n \leq 95$ or $98 \leq n \leq 101$ [Rol76]. Smooth embeddings of single spheres (higher-dimensional knots) are also quite subtle.

XIII.19.4.8. An algebraist might say $\mathbb{R}^1$, $\mathbb{R}^2$, $\mathbb{R}^4$, and $\mathbb{R}^8$ are similar to each other and different from all other $\mathbb{R}^n$ because of III.6.3.2.. In fact, for arbitrarily large n, the algebraic structure of $\mathbb{R}^n$ is significantly impacted by the number-theoretic properties of n (`https://mathoverflow.net/questions/34186/does-the-truth-of-any-statement-of-real-matrix-algebra-stabilize-in-sufficiently`), and much of the algebraic structure can be interpreted geometrically.

XIII.19.4.9. In geometric measure theory, there is a significant difference between $\mathbb{R}^n$ for $n \leq 7$ and for $n \geq 8$: if $n \leq 7$, an area-minimizing rectifiable $(n-1)$-current in $\mathbb{R}^n$ is a smooth submanifold (), but this is not necessarily true if $n \geq 8$. See [Mor09, 10.7].

XIII.19.4.10. There is a potentially much higher dividing line from the Borsuk conjecture (or problem): Borsuk asked whether any bounded subset of $\mathbb{R}^n$ is the union of $n+1$ subsets of strictly smaller diameter. The statement is known to be true for $n \leq 3$ and false for $n \geq 64$ (). The smallest n for which the statement fails is in at least one combinatorial sense an important transition point.

XIII.19.4.11. There are also interesting and important questions concerning sphere packings. One tries to fill $\mathbb{R}^n$ with solid equal-size n-balls as densely as possible. The problem is even tricky to state precisely: we first seek the supremum of the density of all possible packings, and then to find a packing (or "all" packings) realizing the supremum (optimal packings; one should impose additional conditions on optimal packings such as some type of incompressibility, part of the difficulty in phrasing the problem carefully). In $\mathbb{R}^2$ a hexagonal lattice is easily shown to give the unique optimal packing. In $\mathbb{R}^3$ the cubic face centered lattice () is optimal (*Kepler's Conjecture*), although the proof is very difficult and was only recently completed [HF11]; it is not the unique optimal packing, although the other optimal packings are easily described variations. Optimal packings are known in dimensions 2, 3, 8, and 24 (and only these other than dimension 1), and are lattice packings in these dimensions. In dimensions 10, 11, and 13 there are irregular (but periodic) packings which are denser than any known lattice packing, and it may be that in these dimensions, and possibly in all sufficiently large dimensions, optimal packings are necessarily irregular and perhaps even aperiodic. It is

not obvious that there even are any optimal packings (i.e. ones realizing the supremum) in every dimension, but there are (). See [CS99] and [**?**] for details. Sphere packing problems in large numbers of dimensions have applications in number theory, coding, algebra, and mathematical physics as well as in geometry.

XIII.19.4.12. As to the general question of whether there exists a "dividing line," many (but certainly not all!) questions or phenomena stabilize for high dimensions and are difficult only due to "accidents of small dimension." From the right point of view, this philosophy applies even to such problems as the notorious one of computing higher homotopy groups $\pi_n(S^q)$ of spheres, which is not completely solved and is perhaps not even completely solvable in principle. Viewed in the usual way, by fixing q and letting n vary, the question can seem intractable. But if we instead fix n and let q vary, the problem stabilizes nicely for $q \geq n$ and the complications can be said to be only due to "accidents of small dimension."

Of course, as seen above, if dividing lines exist at all, they may vary from problem to problem.

XIII.19.4.13. Perhaps the best answer to the original question may be that it simply reflects the limitations of our current knowledge. Even topologists as recently as the 1960s might not have said that $\mathbb{R}^4$ is essentially different from $\mathbb{R}^3$; the most profound differences have all been discovered since then. Mathematicians 100 years from now may regard $\mathbb{R}^{18}$ and $\mathbb{R}^{19}$ (or maybe $\mathbb{R}^{17}$ and $\mathbb{R}^{19}$, to pick prime numbers) as being as different as $\mathbb{R}^3$ and $\mathbb{R}^4$ due to some phenomenon not yet imagined.

XIII.19.4.14. If you want to start some lively discussions, ask your colleagues or instructors this question! I decided to pose the question on MathOverflow (https://mathoverflow.net/questions/267909/when-are-mathbbrn-and-mathbbrm-essentially-similar) and the ensuing discussion has informed and improved my own discussion above.

XIII.19.5. Compact Subsets of $\mathbb{R}^n$

In this section, we describe a number of examples of compact subsets of Euclidean space with unusual, even bizarre, properties. We will state some of the properties of the examples without proof; readers with some topological background are encouraged to verify the asserted properties.

Mathematicians tend to have two types of reactions to examples of this sort. Some find them fascinating; others have more a sense of revulsion and want to sweep them into an obscure corner. I myself have the first reaction. But even if you fall into the second camp, it is still very important to be aware of the existence of such examples, since they graphically illustrate two vital mathematical principles:

(i) The number and variety of mathematical objects, even ones of relatively restricted type such as closed bounded subsets of the plane, is often vast, far beyond the limits of one's initial imagination.

(ii) When proving results about general mathematical objects of a specified type, it is necessary to stick strictly to arguments drawing logical conclusions from explicit axiomatic assumptions, without appeal to intuition or heuristic arguments, especially ones based on pictures or diagrams which may not accurately reflect the full range of possibilities for the objects studied.

Of course, various other examples, such as the examples of continuous and/or differentiable functions with pathological properties which are scattered through this book, also illustrate these principles.

It turns out that subsets similar to some of these occur naturally in mathematics, both pure and applied, such as strange attractors for nonlinear dynamical systems ().

Some of the examples of this section are fractals, and their fractal properties will be examined in ().

Uncountably Many Mutually Nonhomeomorphic Compact Subsets of $\mathbb{R}^2$

XIII.19.5.1. If $\boldsymbol{k} = (k_1, k_2, \dots)$ is a sequence of natural numbers with $k_1 \geq 2$, construct a compact subset $X_{\boldsymbol{k}}$ of $\mathbb{R}^2$ as follows. Begin with the closed segment from $(0,0)$ to $(1,0)$. For each n, add the closed line segments between $\left(\frac{1}{n}, 0\right)$ and $\left(\frac{1}{n+1}, \frac{1}{n(n+m)}\right)$ for $1 \leq m \leq k_n$.

For example, Figure XIII.34 shows $X_{\boldsymbol{k}}$ for $\boldsymbol{k} = (2, 3, 1, 1, 1, \dots)$.
It is clear that $X_{\boldsymbol{k}}$ is a closed bounded subset of $\mathbb{R}^2$. It can be shown with some straightforward elementary topological arguments ("meatball topology," cf. Exercise XIII.19.6.1.) that the $X_{\boldsymbol{k}}$ for distinct sequences $\boldsymbol{k}$ are mutually nonhomeomorphic. Since there are uncountably many $\left(2^{\aleph_0}\right)$ such $\boldsymbol{k}$, there are uncountably many $\left(2^{\aleph_0}\right)$ mutually nonhomeomorphic compact subsets of the plane. Since there are only $2^{\aleph_0}$ closed subsets of $\mathbb{R}^2$, there are exactly $2^{\aleph_0}$ homeomorphism classes of closed bounded subsets of the plane.

Each of the $X_{\boldsymbol{k}}$ is path-connected and topologically one-dimensional. They are even contractible; in fact, they are absolute retracts (dendrites) (). Note that these spaces are quite different from the infinite broom of XIII.13.9.9..

There is an enormous variety of variations possible on this construction.

XIII.19.5.2. There is a more spectacular version of this. Say that two topological spaces are *locally incomparable* if no nonempty open subset of either one can be topologically embedded in the other. Then:

XIII.19.5.3. THEOREM. ([**?**,] cf. [Bor67]) Let $n \in \mathbb{N}$. Then there exist $2^{\aleph_0}$ mutually locally incomparable n-dimensional (compact) absolute retracts in $\mathbb{R}^{n+1}$.

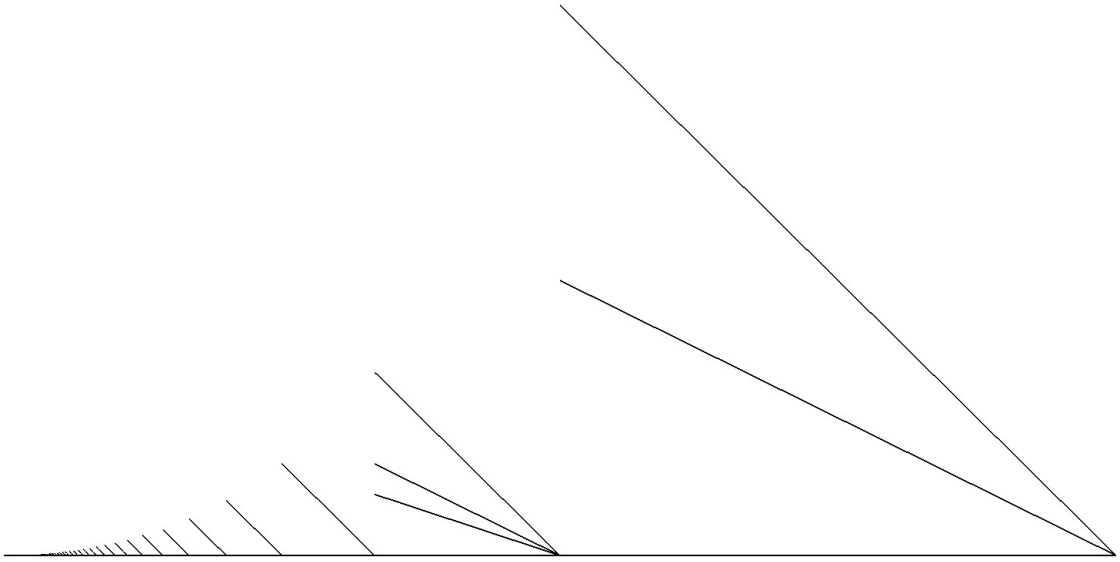

Figure XIII.34: $X_{\boldsymbol{k}}$ for $\boldsymbol{k} = (2, 3, 1, 1, 1, \dots)$.

Uncountably Many Mutually Nonhomeomorphic Compact Subsets of $\mathbb{R}$

XIII.19.5.4. Any countable ordinal () can be order-embedded in $\mathbb{R}$ (). Any countable ordinal which is not a limit ordinal can be embedded as a *compact* subset of $\mathbb{R}$ (with the order topology). There are $\aleph_1$ such ordinals.

However, these are not all distinct topologically. But the ordinals $\omega^\sigma + 1$ are all distinct topologically: the derived series () as a topological space has length σ. This space is countable if σ is countable. Thus there are at least $\aleph_1$ topologically distinct compact countable subsets of $\mathbb{R}$.

It is trickier to explicitly construct $2^{\aleph_0}$ topologically distinct compact subsets of $\mathbb{R}$. Here is a way (cf. [Rei62]). Let K be the Cantor set, and $c_n = 1 - \frac{1}{3^n}$. Then $c_n \in K$, and is the right endpoint of the rightmost open interval I_n removed at the n'th step of the construction of K. Let $\boldsymbol{m} = (m_1, m_2, \dots)$ be a strictly increasing sequence in $\mathbb{N}$, and for each n attach to K a copy of ω^{m_n} in I_n which is relatively closed and converges to c_n (see Figure ()). Let $X_{\boldsymbol{m}}$ be the resulting subset of $\mathbb{R}$. Then $X_{\boldsymbol{m}}$ is a compact totally disconnected subset of $\mathbb{R}$ for each $\boldsymbol{m}$, and the $X_{\boldsymbol{m}}$ are topologically distinct for distinct $\boldsymbol{m}$. There are $2^{\aleph_0}$ such $\boldsymbol{m}$, since they are in one-one correspondence with the infinite subsets of $\mathbb{N}$. See Exercise XIII.19.6.2.. Since there are only $2^{\aleph_0}$ compact subsets of $\mathbb{R}$, there are exactly $2^{\aleph_0}$ homeomorphism classes.

The Topologist's Sine Curve

XIII.19.5.5. Let X be the graph of $y = \sin\left(\frac{\pi}{x}\right)$ for $0 < x \leq 1$ (the right endpoint is not important), along with the closed segment on the y-axis between $(0, -1)$ and $(0, 1)$. Then X is the closure of the graph part, and is a compact subset of $\mathbb{R}^2$. See Figure XIII.35.

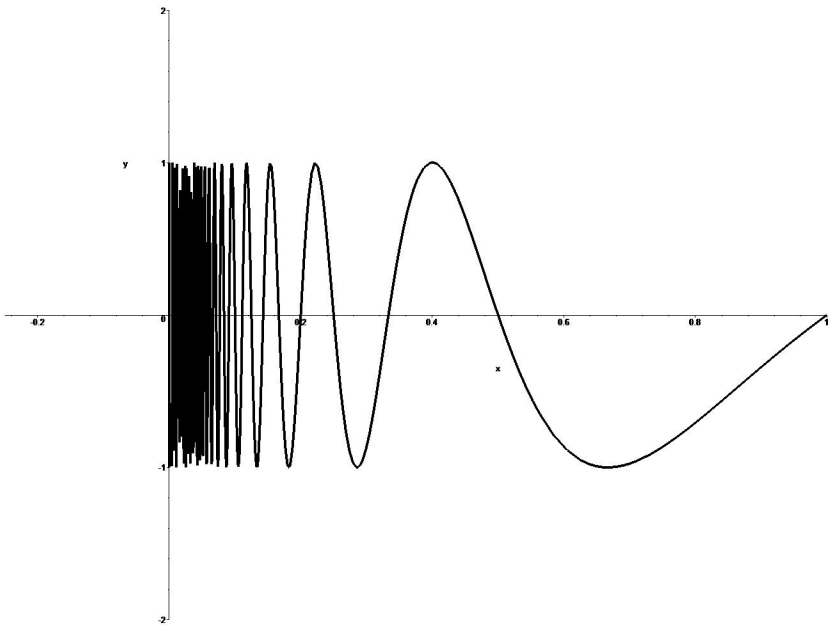

Figure XIII.35: The Topologist's Sine Curve

Since the graph is connected (even path-connected), X is the closure of a connected set and hence is connected (XIII.13.1.9.). However, X is not path-connected; it has two path components, the graph and the segment on the y-axis.

XIII.19.5.6. A variation is to "close up" X by adding an arc connecting $(1, 0)$ with $(0, -1)$. This is often called the "extended topologist's sine curve" or "Warsaw circle." See Figure XIII.36. This space is path-connected but not locally path-connected. In some references, the added arc goes from $(1, 0)$ around to $(0, 0)$ from the left; this space is topologically different but essentially similar.

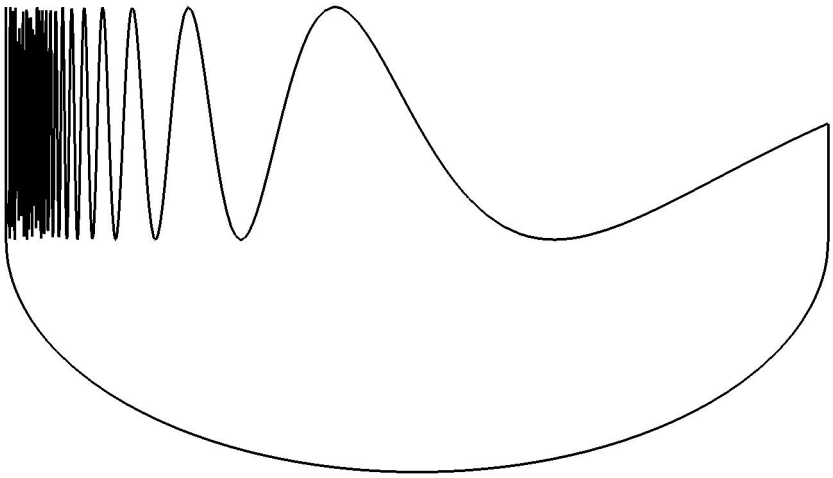

Figure XIII.36: The Extended Topologist's Sine Curve or Warsaw Circle

XIII.19.5.7. The topologist's sine curve can be used to construct a "counterexample" to the Four-Color Theorem (Figure XIII.37). Each of the five regions pictured has a boundary with each of the others which at least contains an entire arc, and thus they must all be colored differently. This shows that the Four-Color Theorem must be stated carefully to rule out examples of this sort (cf. [**?**]).

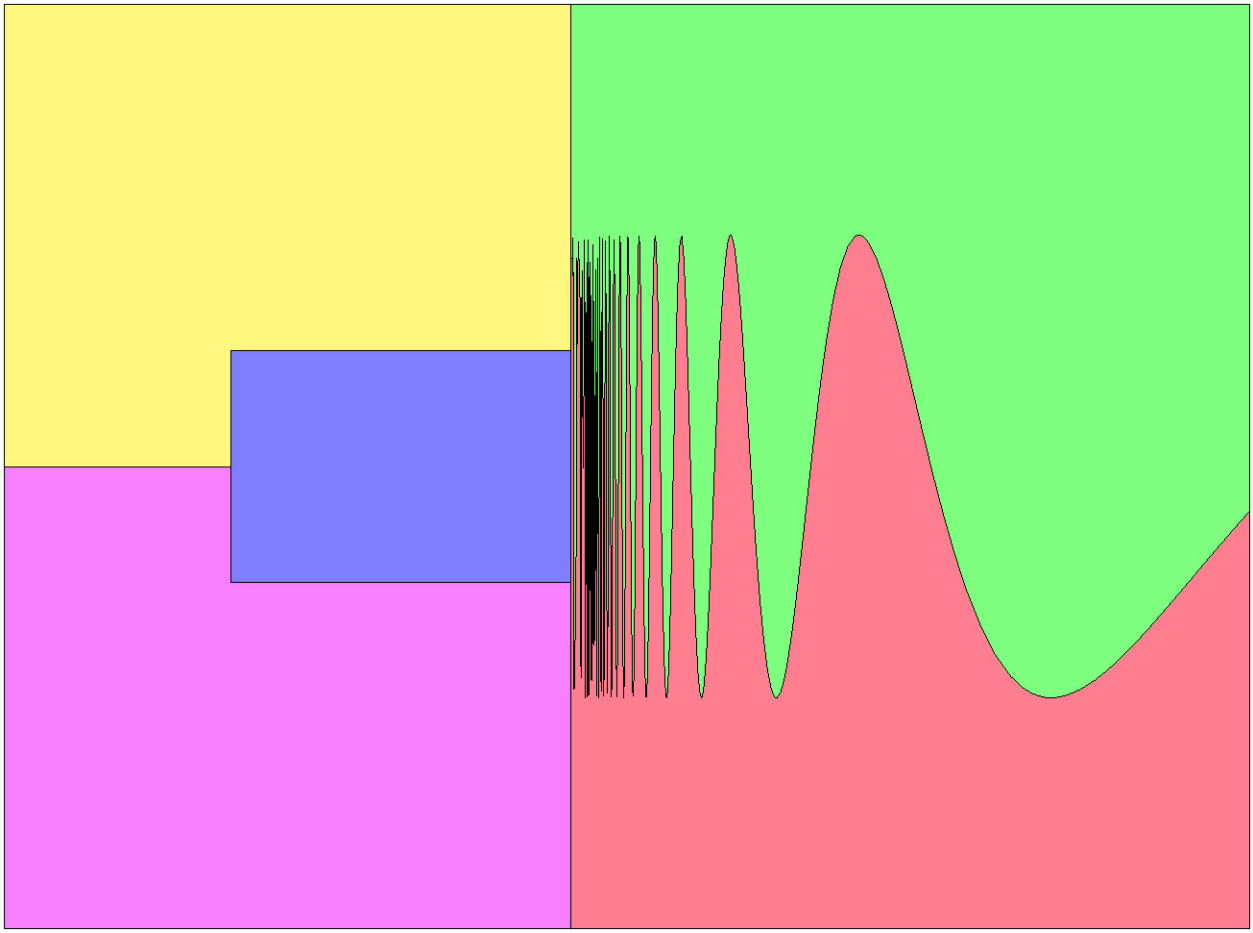

Figure XIII.37: A counterexample to the Four-Color Theorem?

The Hawaiian Earring

XIII.19.5.8. Let X be the union of all circles in $\mathbb{R}^2$ with center $\left(\frac{1}{n}, 0\right)$ and radius $\frac{1}{n}$, for $n \in \mathbb{N}$ (Figure XIII.38).

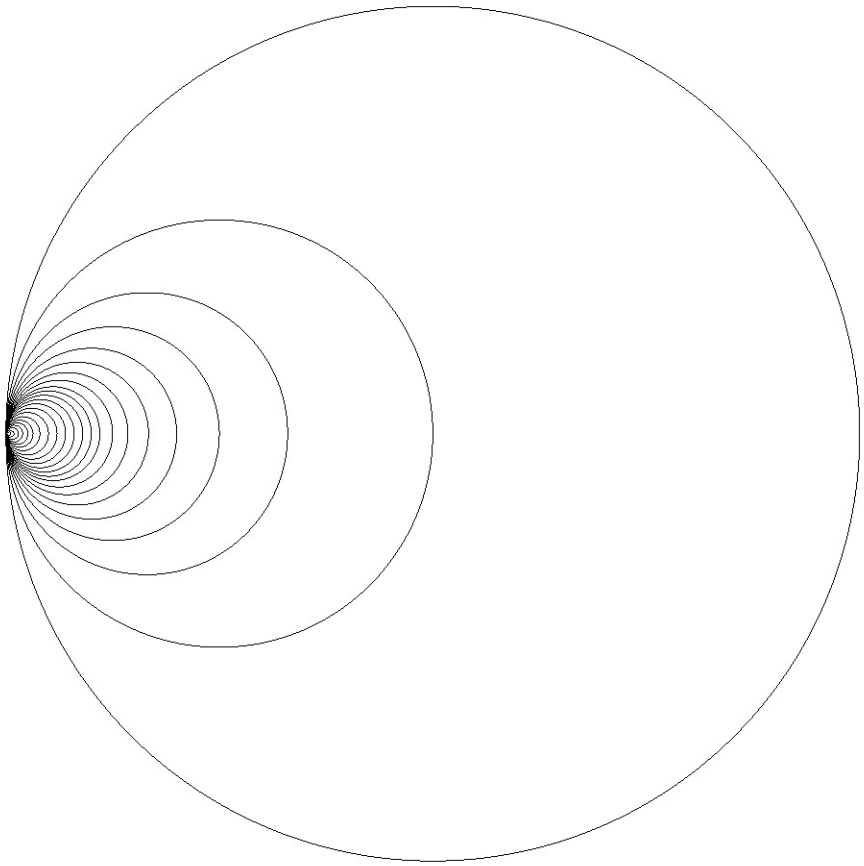

Figure XIII.38: The Hawaiian Earring

The fundamental group of the Hawaiian earring is uncountable: for each subset S of $\mathbb{N}$, there is a loop γ_S which goes around the circle of radius $1/n$ if and only if $n \in S$, and no two of these loops are homotopic.

XIII.19.5.9. Let Y be the union of all circles in $\mathbb{R}^2$ with center $(n, 0)$ and radius n, for $n \in \mathbb{N}$. Then Y is not homeomorphic to X, since it is not compact. The fundamental group of Y is a free group on a countable number of generators. In fact, Y is homotopy equivalent (but not homeomorphic) to an infinite wedge of circles (XIII.9.1.13., XIII.9.5.8.) [collapse a suitable closed neighborhood of $\mathbf{0}$ to a point]. See also XIII.9.5.5..

Subsets Constructed as Intersections

A number of pathological examples can be made by constructing a decreasing sequence of increasingly complicated compact subsets of Euclidean space and taking the intersection. This construction is already familiar in the definition of the Cantor set ().

The Sierpiński Gasket

XIII.19.5.10. This subset of $\mathbb{R}^2$ is constructed as an intersection, and is the first of several straightforward higher-dimensional versions of the Cantor set.

Begin with a (solid) triangle in $\mathbb{R}^2$, say an equilateral triangle. Bisecting each side and connecting the midpoints forms four subtriangles. Remove the (open) middle one. Then repeat the process in each of the three remaining triangles and iterate. The intersection is called the *Sierpiński gasket* (the name is due to B. Mandelbrot; the set is also known as the *Sierpiński triangle* or the *Sierpiński sieve*). It is path-connected, compact, and topologically one-dimensional. See Figure XIII.39 (from http://en.wikipedia.org/wiki/File:Sierpinski_Triangle.svg).

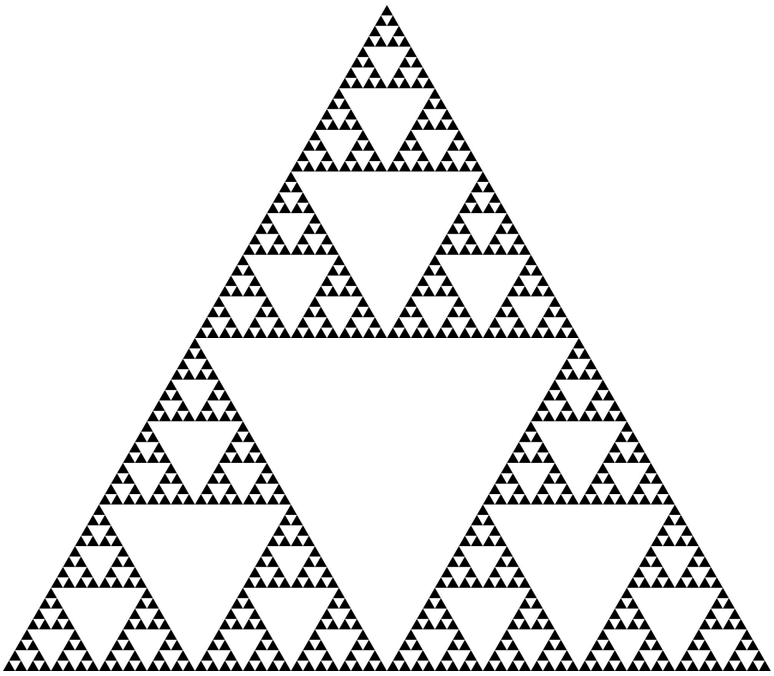

Figure XIII.39: Six steps in the construction of the Sierpiński Gasket

The Sierpiński Carpet

XIII.19.5.11. As a variation, begin with a (solid) square. Divide it into 9 equal-sized squares, and remove the open middle square. Repeat the process in each of the eight remaining squares, and iterate. See

Figure XIII.40 (from http://commons.wikimedia.org/wiki/File:Sierpinski6.png?uselang=fr). This set is called the *Sierpiński carpet*, or *Sierpiński curve*.

Like the Sierpiński gasket, the Sierpiński carpet is topologically one-dimensional.

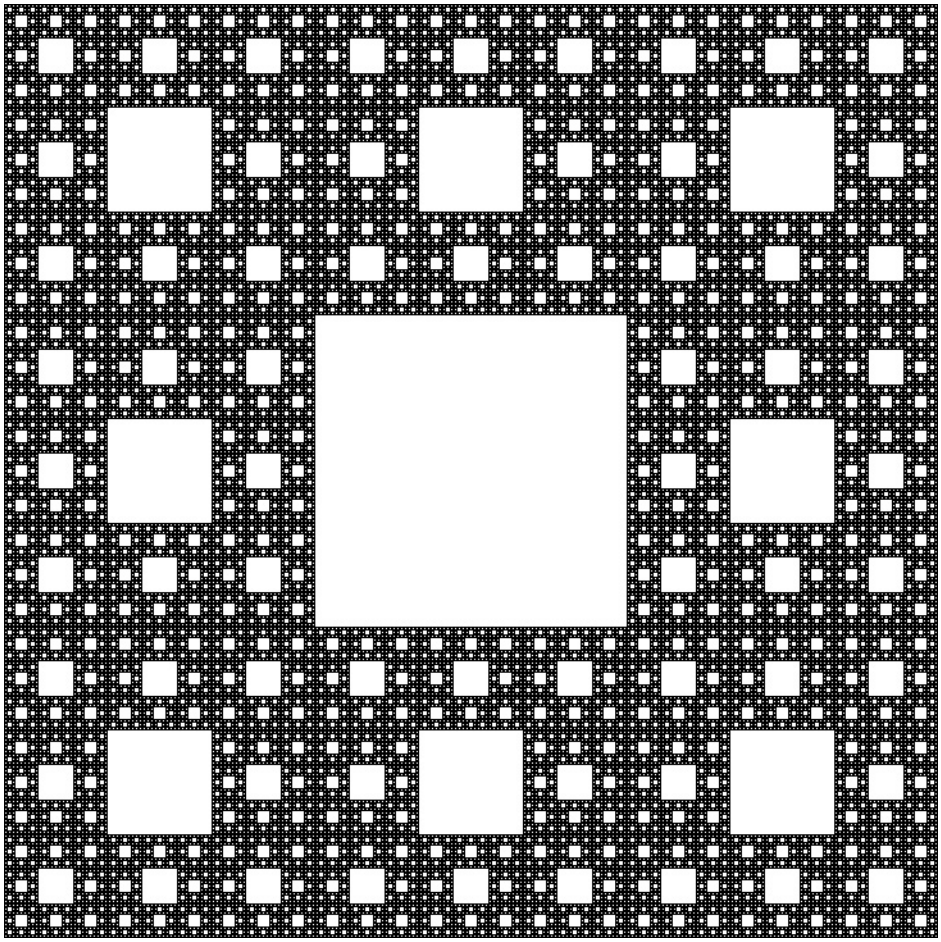

Figure XIII.40: Six steps in the construction of the Sierpiński Carpet

XIII.19.5.12. It is not obvious whether the Sierpiński carpet is homeomorphic to the Sierpiński gasket. In fact, they are not homeomorphic. For each point of the Sierpiński gasket has arbitrarily small open neighborhoods whose boundary consists of finitely many points (no more than 4), while small open neighborhoods of points in the Sierpiński carpet always have uncountably many boundary points. See [Kur68, §51] for a discussion.

XIII.19.5.13. The Sierpiński carpet is universal for one-dimensional compact subsets of the plane: every compact subset of the plane which is topologically one-dimensional is homeomorphic to a subset of

the Sierpiński carpet []. In particular, the Sierpiński gasket is homeomorphic to a subset of the Sierpiński carpet (try to find one!) A pseudo-arc can also be embedded topologically in the Sierpiński carpet.

Swiss Cheese

XIII.19.5.14. The Sierpiński carpet is (topologically) a special case of a general construction: begin with a closed disk in $\mathbb{R}^2$, and remove a sequence of disjoint open disks to obtain a set with empty interior. Such a subset of $\mathbb{R}^2$ is called a *Swiss cheese*. There is a great topological variety among Swiss cheeses; some are similar topologically to the Sierpiński gasket, and some are homeomorphic to the Sierpiński carpet. The one pictured in XIII.41 (from `http://hans.math.upenn.edu/~pstorm/images/round_Sierpinski_carpet.png`) is made in a regular manner and is a fractal; some are much more irregular. As with Cantor sets, Swiss cheeses of positive planar Lebesgue measure can be constructed, as well as ones of zero planar measure; in fact, Swiss cheeses of Hausdorff dimension between 1 and 2 can be constructed, although the exact Hausdorff dimensions are subtle to compute ([Mel66], [Lar66]).

If topological disks are used instead of geometric ones, an even greater variety can be obtained; both the Sierpiński carpet and the Sierpiński gasket are special cases of this construction, as are the Lakes of Wada.

Swiss cheeses are used extensively in the theory of function algebras (); see [FH10] for a good survey, including their topological structure.

One can make higher-dimensional Swiss Cheeses by removing a sequence of open balls from the closed unit ball in $\mathbb{R}^n$.

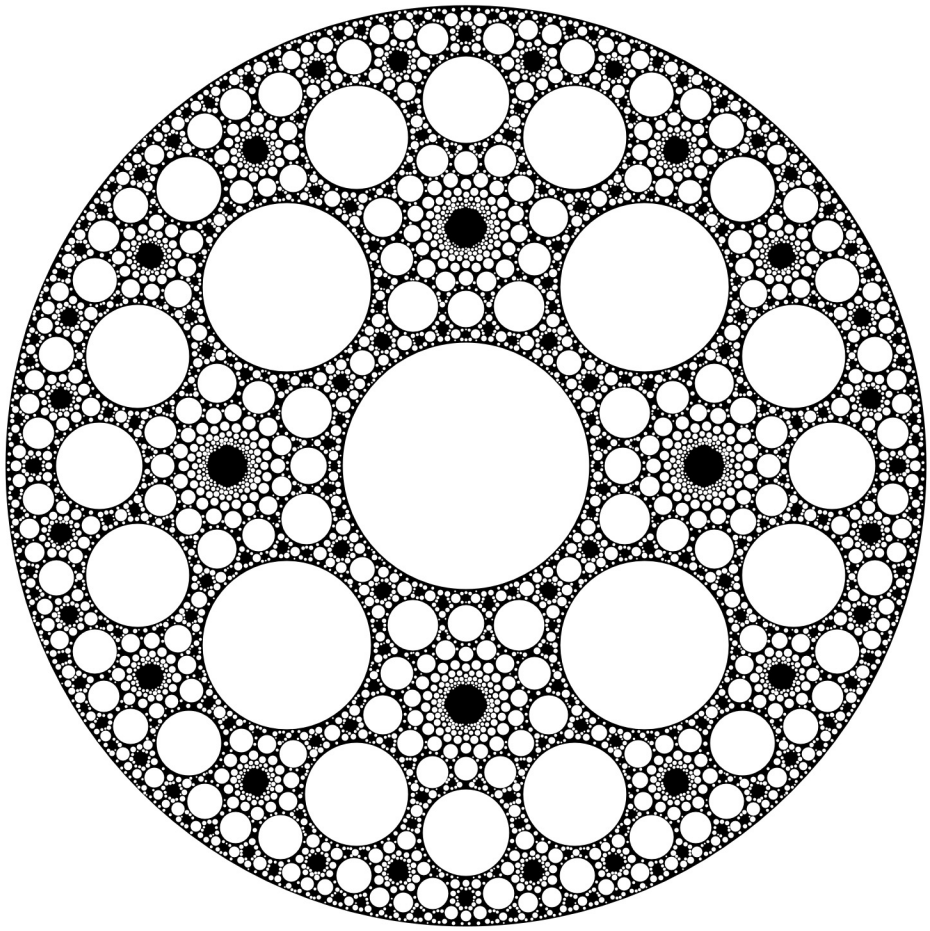

Figure XIII.41: A "Swiss cheese." (Small white disks continue throughout the black spots.)

The Menger Sponge

XIII.19.5.15. There is a three-dimensional analog of the Sierpiński carpet, due to K. Menger [Men26]. Begin with the unit cube in $\mathbb{R}^3$. Dividing each edge in three equal segments leads to a decomposition of the cube into 27 equal-sized subcubes. Remove the central subcube and the central subcubes on each face (i.e. keeping all closed subcubes intersecting an edge of the cube). Seven subcubes are removed in all. Do the same in each of the 20 remaining subcubes and iterate. The intersection is called the *Menger sponge*. Each outside face of the Menger sponge is a copy of the Sierpiński carpet. See Figure XIII.42 (from http://en.wikipedia.org/wiki/File:Menger-Schwamm-farbig.png).

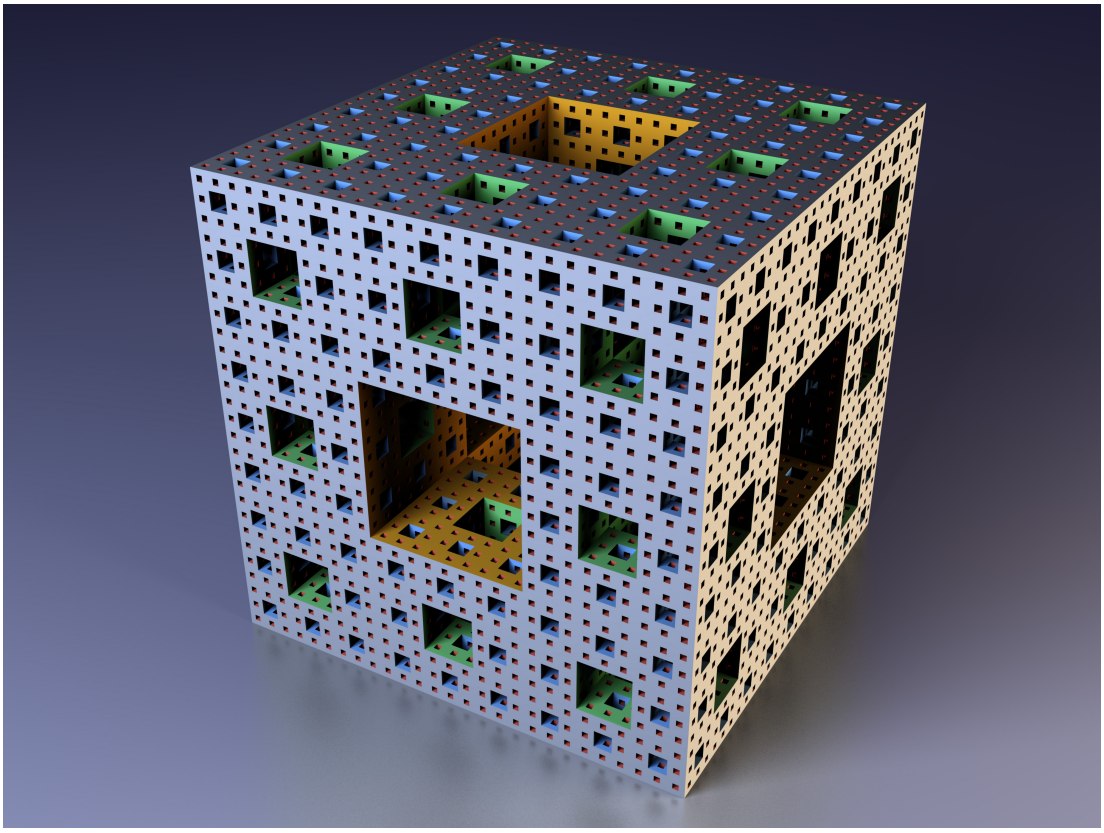

Figure XIII.42: Four steps in the construction of the Menger Sponge

The Menger sponge is compact, connected, locally connected, and topologically one-dimensional. It is universal for one-dimensional separable metrizable spaces: every separable metrizable space of dimension ≤ 1 is homeomorphic to a subset of the Menger sponge [Men26]. Thus the Menger sponge is sometimes called the *Menger Universal Curve* (although it is not a "curve" in any normal sense). It is homogeneous and has a topological characterization [And58].

For any $k, n \in \mathbb{N}_0$, $k < n \leq 2k+1$, there is a similar subset M_k^n of $\mathbb{R}^n$ which is universal for compact subsets of $\mathbb{R}^n$ of dimension $\leq k$ [Šta71]; M_k^{2k+1} is universal for all separable metrizable spaces of dimension

$\leq k$ [Bot63]. M_1^3 is the Menger sponge, M_1^2 the Sierpiński carpet, and M_0^1 the Cantor set. To make M_2^3, begin with the unit cube in $\mathbb{R}^3$, subdivide into 27 subcubes, and just remove the center cube; then iterate.

Sierpiński Pyramids

At least two versions of the Sierpiński Gasket can be made in $\mathbb{R}^3$. Begin with a pyramid with either a triangular or square base. In the triangular case (say, a regular tetrahedron), bisect each edge and keep the four subpyramids whose vertices are one original vertex and the three midpoints of the adjacent edges; then iterate. The intersection is a compact set called the *tetrahedral Sierpiński Pyramid* which is topologically one-dimensional. It has the unusual property that its Hausdorff dimension is an integer (2) which is greater than its topological dimension (see XVII.6.9.3. for another example).

A variation is to begin with a pyramid with square base, bisect the edges, and keep the five subpyramids consisting of the top pyramid with four vertices at the midpoints of the slant edges and the four pyramids with top vertex at one of these midpoints and bottom vertices at a corresponding original vertex, two midpoints of base edges, and the midpoint of the base. See Figure XIII.43, from http://en.wikipedia.org/wiki/File:Sierpinski_pyramid.png.

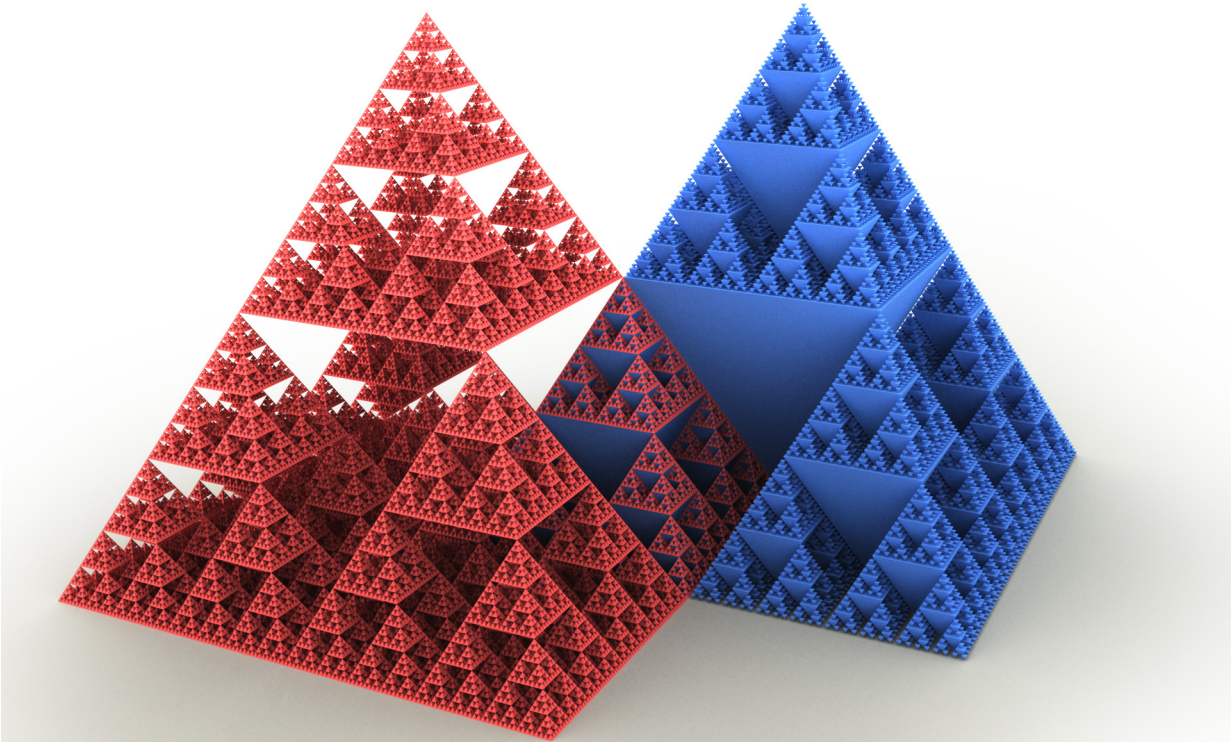

Figure XIII.43: Seven steps in the construction of the Sierpiński Pyramid with square base and its "inverse"

Solenoids

XIII.19.5.16. Let $s = (n_1, n_2, \dots)$ be a sequence of natural numbers with $n_k \geq 2$ for all k. Construct a compact subset of $\mathbb{R}^3$ as follows (in understanding the construction, try taking all n_k to be 2 at first). Let X_0 be a solid torus. Inside X_0 take a thinner solid torus X_1 which "winds around" n_1 times. (Think of wrapping a wire around the "hole" in X_0 n_1 times and connecting the ends of the wire to make a thin solid torus.) See XIII.44 for the case $n_1 = 2$ (from http://en.wikipedia.org/wiki/File:Smale-Williams_Solenoid.png). Now within X_1 take an even thinner solid torus X_2 which wraps around X_1 n_2 times, i.e. every cross-

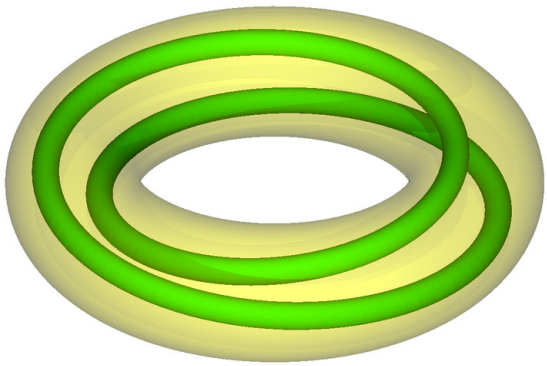

Figure XIII.44: First step in the construction of the solenoid of type $(2, 2, \dots)$

section disk of X_1 will cut X_2 in n_2 cross-sectional disks. Repeat the process countably many times and let $X = \cap_k X_k$. X is called the *solenoid* of type s.

A nice animated construction of the solenoid of type $(2, 2, \dots)$ can be found at http://en.wikipedia.org/wiki/File:Solenoid.gif .

XIII.19.5.17. Solenoids can also be naturally constructed in several other ways. One good way is as inverse limits of circles (XIII.14.4.17.).

XIII.19.5.18. A solenoid is connected but not locally connected: locally, a solenoid looks like $\mathbb{R} \times K$, where K is the Cantor set. In fact, each solenoid can be constructed (up to homeomorphism) from $[0, 1] \times K$ by identifying $\{0\} \times K$ with $\{1\} \times K$ in an appropriate way, e.g. by identifying K with the p-adic integers () and identifying $(1, x)$ with $(0, x + 1)$ (this gives the solenoid of type $(p, p, p, \dots)$). More generally, this can be done using any minimal homeomorphism of K ("flow under a constant function," cf. XIII.9.2.3.), giving additional solenoid-type examples (cf. [**?**]).

XIII.19.5.19. A solenoid is not path-connected. There are uncountably many path components, each of which is dense and a one-to-one continuous image of $\mathbb{R}$. This is seen most easily by viewing the solenoid as an inverse limit as in (), but can also be deduced from the description in XIII.19.5.18. (in this picture, the path components correspond to the cosets of $\mathbb{Z}$ in the p-adic integers).

XIII.19.5.20. Up to homeomorphism, a solenoid depends only on the sequence s. Solenoids corresponding to different sequences are "usually" nonhomeomorphic, but ones corresponding to sequences differing only "slightly" can be homeomorphic.

To give a precise description of the homeomorphism classes, we use the supernatural numbers:

XIII.19.5.21. DEFINITION. A *supernatural number* is an expression of the form

$$\boldsymbol{n} = 2^{e_2}3^{e_3}5^{e_5}\cdots$$

where each prime appears and each exponent e_p is in $\{0\} \cup \mathbb{N} \cup \{\infty\}$.

An ordinary natural number is a supernatural number in which all e_p are finite and all but finitely many are 0. Sometimes we want to exclude the ordinary natural numbers from the supernatural numbers; we call supernatural numbers which are not ordinary natural numbers *infinite*. When writing a supernatural number, we usually leave out all primes with exponent 0; thus if $\boldsymbol{n}$ is the supernatural number with $e_2 = \infty$ and $e_p = 0$ for $p \neq 2$, we write $\boldsymbol{n}$ as 2^∞.

Two supernatural numbers can be multiplied by adding the corresponding exponents. This multiplication extends the ordinary multiplication on $\mathbb{N}$.

We say one supernatural number $\boldsymbol{n}$ *divides* another supernatural number $\boldsymbol{m}$ if $e_p(\boldsymbol{n}) \leq e_p(\boldsymbol{m})$ for all p, i.e. if there is a supernatural number $\boldsymbol{r}$ such that $\boldsymbol{m} = \boldsymbol{nr}$. (Note, however, that $\boldsymbol{r}$ is not necessarily unique, i.e. that there is not a well-defined quotient in general, if the exponents for some p are both infinite.) There is a "largest" supernatural number, the one for which $e_p = \infty$ for all p, and all supernatural numbers divide this one.

Note that the supernatural numbers are not the same thing as the nonstandard natural numbers ${}^*\mathbb{N}$ of ().

XIII.19.5.22. The supernatural numbers are in natural one-one correspondence with the additive subgroups () of $\mathbb{Q}$ containing $\mathbb{Z}$: the group $\mathbb{Z}_{(\boldsymbol{n})}$ is the set of all rational numbers whose denominator divides $\boldsymbol{n}$. For example, $\mathbb{Z}_{(2^\infty)}$ is the set of dyadic rationals (). The group corresponding to the largest supernatural number is $\mathbb{Q}$ itself; $\mathbb{Z}$ corresponds to the supernatural number 1 (i.e. $e_p = 0$ for all p), the smallest supernatural number.

The group $\mathbb{Z}_{(\boldsymbol{n})}$ is cyclic (has a smallest positive element) if and only if $\boldsymbol{n}$ is an ordinary natural number.

XIII.19.5.23. To each sequence (n_k) of natural numbers, there is a naturally associated supernatural number $\prod_k n_k$, for which, for every p, e_p is the sum of the powers of p occurring in the n_k's. This will be an ordinary integer if and only if all but finitely many n_k are 1. Many different sequences can give the same associated supernatural number (for example, reordering the sequence does not change the associated supernatural number, and there are much more drastic changes that work too).

It can be shown without too much difficulty (knowing the first statement of XIII.19.5.20.) that if two sequences give the same supernatural number, the corresponding solenoids are homeomorphic. But it is not quite true that solenoids corresponding to different supernatural numbers are nonhomeomorphic. For a correct statement, we need an equivalence relation on supernatural numbers:

XIII.19.5.24. DEFINITION. Let $\boldsymbol{n}$ and $\boldsymbol{m}$ be supernatural numbers. Then $\boldsymbol{n}$ and $\boldsymbol{m}$ are *equivalent* if there are ordinary natural numbers n and m such that $n\boldsymbol{n} = m\boldsymbol{m}$.

Supernatural numbers $\boldsymbol{n}$ and $\boldsymbol{m}$ are equivalent if and only if only finitely many of their exponents differ, and each by only a finite amount. The supernatural numbers equivalent to any ordinary natural number are precisely all ordinary numbers.

This equivalence is natural because of the following results, the first of which is quite easy:

XIII.19.5.25. Proposition. Two additive subgroups of $\mathbb{Q}$ containing $\mathbb{Z}$ are isomorphic as groups if and only if their associated supernatural numbers are equivalent.

XIII.19.5.26. Theorem. Two solenoids are homeomorphic if and only if their associated supernatural numbers are equivalent.

XIII.19.5.27. Thus the equivalence classes of infinite supernatural numbers exactly parametrize the homeomorphism classes of solenoids. The equivalence class of supernatural numbers can be recovered directly from the intrinsic topology of the solenoid X: the first cohomotopy group $\pi^1(X)$ () is isomorphic to the additive subgroup of $\mathbb{Q}$ associated to the equivalence class of supernatural numbers of X.

XIII.19.5.28. There is another important connection. Any solenoid X can be made into a compact abelian topological group. Its Pontrjagin dual group () is isomorphic to $\pi^1(X)$. The solenoids are the only compact connected one-dimensional Hausdorff spaces besides the circle which can be made into abelian topological groups. See XXIII.5.2.1.(b).

XIII.19.5.29. Solenoids are homogeneous. It was shown in [Hag77] that every homogeneous continuum in which every nondegenerate subcontinuum is an arc is a solenoid (or circle). A solenoid is also indecomposable.

XIII.19.5.30. Solenoids arise naturally as attractors of important nonlinear dynamical systems ().

Knaster's Bucket-Handle

This is a "poor man's solenoid," somewhat easier to visualize and with similar topological properties, at least locally. It is perhaps the simplest example of an indecomposable continuum. It can be constructed as an intersection (see Figure XIII.46), but has a simpler direct definition:

XIII.19.5.31. Definition. The *Knaster bucket-handle* is the union of the following closed half-circles in $\mathbb{R}^2$:

All half-circles in the upper half-plane with center $\left(\frac{1}{2}, 0\right)$ with endpoints in the Cantor set K.

All half-circles in the lower half-plane with center $\left(\frac{5}{2 \cdot 3^n}, 0\right)$ $(n \geq 1)$ passing through a point of $K \cap \left[\frac{2}{3^n}, \frac{1}{3^{n-1}}\right]$.

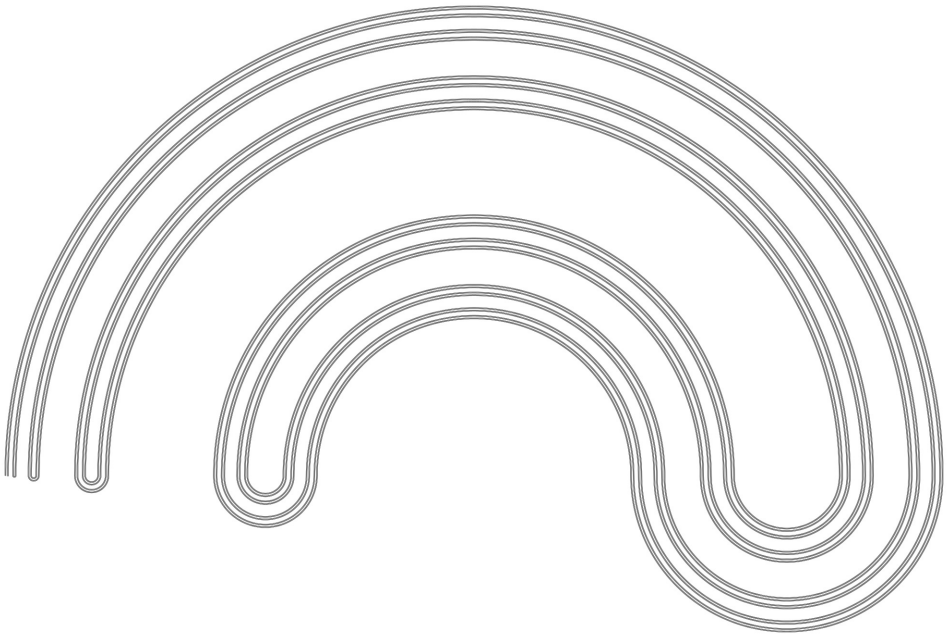

Figure XIII.45: The Knaster bucket-handle

See Figure XIII.45 (from http://upload.wikimedia.org/wikipedia/commons/thumb/3/30/The_Knaster_%22bucket-handle%22_continuum.svg/2000px-The_Knaster_%22bucket-handle%22_continuum.svg.png).

It can be shown that the Knaster bucket-handle is indecomposable (cf. [**?**, 48,V]): although it is connected, it has uncountably many path components (composants), one an injective continuous image of $[0, +\infty)$ and the rest injective continuous images of $\mathbb{R}$. A proper subcontinuum cannot contain any entire path component, so its intersection with any path component is an arc; it follows that it must be contained in a path component, i.e. the complement of any proper subcontinuum is dense.

It turns out there is no Borel subset containing exactly one point from each path component (cf. [**?**]).

There are numerous variations of the construction, with slightly different properties. All these can be described as inverse limits of intervals; see XIII.14.4.18.

Attractors called "horseshoes" () are types of Knaster bucket-handles.

Here is a construction as an intersection, from http://upload.wikimedia.org/wikipedia/commons/thumb/9/98/ContinuBJK.svg/2000px-ContinuBJK.svg.png.

Figure XIII.46: Four steps in the intersection construction of the Knaster bucket-handle

The Pseudo-Arc

XIII.19.5.32. The construction of a pseudo-arc is somewhat involved.

We first need the notion of a *crooked* path. Let R be a (solid) rectangle, subdivided into a strip $R_1, \ldots, R_m$ of subrectangles, a a point in the interior of R_1, and b a point in the interior of R_m:

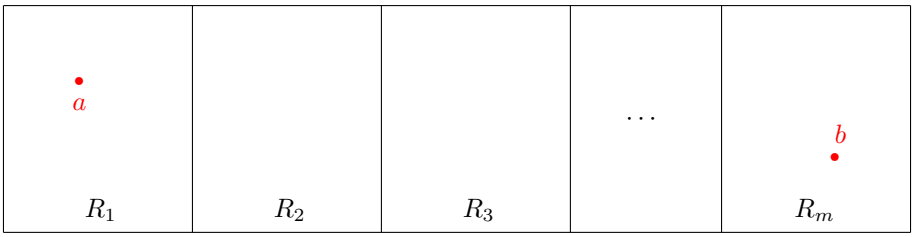

Figure XIII.47: Strip Subdivision of a Rectangle

A path γ from a to b within R is *crooked* with respect to $R_1, \ldots, R_m$ if it has the following property: whenever $t_1, t_2 \in [0,1]$, $t_1 < t_2$, $\gamma(t_1) \in R_i$, and $\gamma(t_2) \in R_j$ with $|i-j| > 2$, there are s_1, s_2 with $t_1 < s_1 < s_2 < t_2$ and

if $i < j$, then $\gamma(s_1) \in R_{j-1}$ and $\gamma(s_2) \in R_{i+1}$

if $j < i$, then $\gamma(s_1) \in R_{j+1}$ and $\gamma(s_2) \in R_{i-1}$.

Instead of a rectangle divided into subrectangles, a chain () of closed balls can be used. A crooked path is defined in the same way.

Thus, for example, if $m = 4$, a crooked path from a to b must first go to R_3, then back to R_2, and then to R_4. So the simplest crooked path looks like this:

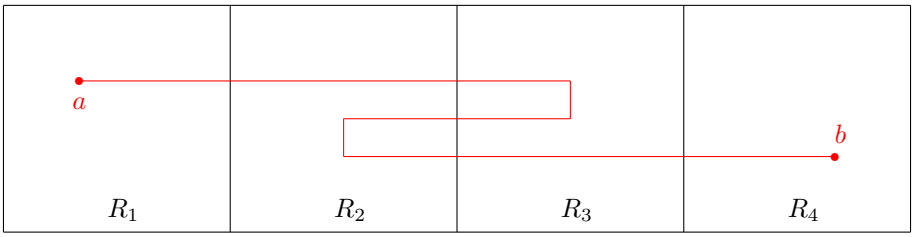

Figure XIII.48: Crooked Path of Length 4

Crooked paths rapidly become more complex as m increases (if $\ell(m)$ is the number of horizontal segments in a minimal crooked path of length m, for $m \geq 4$ we have the recursive formula

$$\ell(m) = 2\ell(m-1) + \ell(m-2)$$

with $\ell(2) = \ell(3) = 1$). For example, if $m = 5$, a crooked path from a to b must first go to R_3, then back to R_2, then R_4, then R_2, then R_4, then R_3, and finally R_5:

A crooked path from a to b in general consists of a crooked path from a to a point in R_{m-1}, followed by a crooked path from that point to a point in R_2, followed by a crooked path from that point to b. Thus

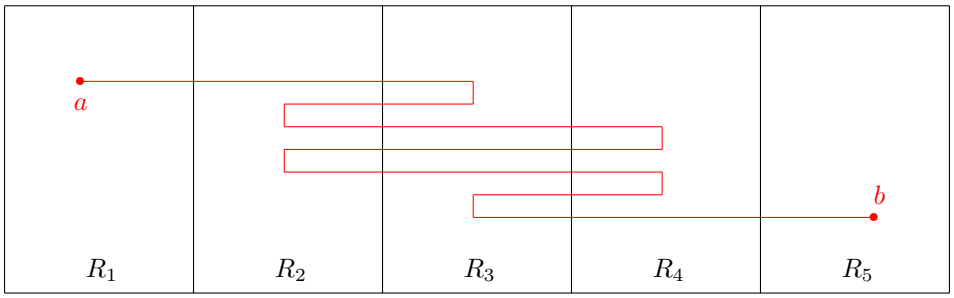

Figure XIII.49: Crooked Path of Length 5

the picture on [HY88, p. 142] is not correct: an actual crooked path is far more complicated (there would be 14,398,739,476,117,879 $\approx 1.4 \times 10^{16}$ horizontal segments for a minimal crooked path of length 45).

To construct a pseudo-arc, fix two points a and b in $\mathbb{R}^2$, and then:

(1) Let X_1 be a narrow (solid) rectangle of width < 1, containing a and b in its interior, and subdivide X_1 into a strip of subrectangles $R_{1,1}, \ldots, R_{1,k_1}$, each of diameter ≤ 1, with a in the interior of $R_{1,1}$ and b in the interior of R_{1,k_1}. Alternatively, let X_1 be the union of a chain of closed balls from a to b.

(2) Take a path from a to b in X_1 which is simple (does not cross itself) and crooked for the $R_{1,j}$.

(3) Fatten up the path within X_1 into a thin strip X_2 homeomorphic to a (solid) rectangle, and subdivide X_2 into a strip of subsets $R_{2,1}, \ldots, R_{2,k_2}$ homeomorphic to subrectangles, of diameter $\leq \frac{1}{2}$, with a in the interior of $R_{2,1}$ and b in the interior of R_{2,k_2}. Alternatively, cover the path with a chain of closed balls, and let X_2 be the union.

(4) Take a simple path from a to b in X_2 which is crooked for the $R_{2,j}$, and iterate the process.

Let $X = \cap_{n=1}^{\infty} X_n$. Then X is a compact subset of $\mathbb{R}^2$ containing a and b. Since each X_n is homeomorphic to a (solid) rectangle, it is connected; thus X is connected by XIII.13.3.6.. X is called a *pseudo-arc*.

A pseudo-arc is compact and connected (a *continuum*), and topologically one-dimensional. It is an *indecomposable continuum*: it cannot be written as a union of two proper subcontinua. In this respect it is enormously different from an ordinary arc. In fact, a pseudo-arc is a *hereditarily indecomposable continuum*: every subcontinuum is also indecomposable. Actually, every subcontinuum of the pseudo-arc with more than one point is homeomorphic to the whole pseudo-arc (an ordinary arc has this property too). And unlike an ordinary arc which has endpoints topologically different from the other points of the arc, a pseudo-arc is *homogeneous*: for any points p and q, there is a homeomorphism of the pseudo-arc to itself sending p to q. These properties are proved in [Bin48], where it is also shown that the pseudo-arc is the *unique* homogeneous hereditarily indecomposable continuum, and also [Bin51a] the unique chainable () hereditarily indecomposable continuum. In particular, up to homeomorphism the pseudo-arc does not depend on the details of the choice of the X_n, so it makes sense topologically to refer to *the* pseudo-arc. The pseudo-arc can be constructed as an inverse limit of intervals (XIII.14.4.18.(ii)).

There is no nonconstant continuous function from an ordinary arc into a pseudo-arc; thus the path components of a pseudo-arc are singletons, i.e. the pseudo-arc is connected but totally path-disconnected.

XIII.19.5.33. Pseudo-arcs may seem pathological, but "almost every" continuum in $\mathbb{R}^2$ is a pseudo-arc [Bin51a], in the sense that if the set $\mathcal{C}$ of continua in $\mathbb{R}^2$ is given the Hausdorff metric () making it into a locally compact metrizable space, the set of continua which are not pseudo-arcs is meager ().

See http://topology.auburn.edu/pm/pseudodraw.pdf for an interesting discussion of the pseudo-arc, including the difficulties inherent in trying to draw a picture of it.

XIII.19.5.34. There is also a similar *pseudo-circle*, described in [Bin51a], whose complement is homeomorphic to the complement of a circle (a bounded component homeomorphic to a disk and an unbounded one). The pseudo-circle is also a hereditarily indecomposable continuum (every proper subcontinuum is a point or a pseudo-arc), and there is also a uniqueness statement up to homeomorphism for pseudo-circles. However, the pseudo-circle is not homogeneous ([**?**], [**?**]). This is a little counterintuitive, since an ordinary circle is homogeneous and an ordinary arc is not; the situation is reversed in the pseudo case. The homogeneity/nonhomogeneity of these spaces is a very subtle matter. There is another similar continuum in the plane, called a *circle of pseudo-arcs* [BJ59], which separates the plane like a circle and is homogeneous (but not indecomposable). There are in fact $2^{\aleph_0}$ topologically distinct hereditarily indecomposable continua in the plane [Bin51a] (there are also hereditarily indecomposable continua of every dimension; cf. [Bin51b], [Kel42]).

There are bizarre plane continua which look nothing like a pseudo-arc: an example is given in [AC59], also constructed as an intersection (or inverse limit), with the property that no two proper subcontinua (containing more than one point) are homeomorphic. In fact, since this continuum has $2^{\aleph_0}$ distinct infinite subcontinua, there are $2^{\aleph_0}$ such continua in the plane, no two of which are homeomorphic. Such a continuum can contain neither an arc nor a pseudo-arc (and hence cannot contain any of the other examples of this section), has empty interior and is topologically one-dimensional, and is totally inhomogeneous (XIII.19.6.11.). Such a space is not indecomposable; in fact, it contains no indecomposable subcontinuum of more than one point.

The Lakes of Wada

XIII.19.5.35. This subset of $\mathbb{R}^2$, first described by K. Yoneyama [] and credited by him to T. Wada, is constructed as an intersection. The pun name "lakes of Wada" may have been first used in [HY88]. A somewhat similar example was previously described by Brouwer [].

A tropical island X_0 named Wada is surrounded by blue ocean. There are two lakes on the island, one with green water and one with brown, with no islands (i.e. the lakes are homeomorphic to open disks). At the first step, canals are dug from the ocean so that every spot of land is within 1 km of blue water. Call the remaining land X_1. In the second step, canals are dug from the green lake to within 1/2 km of every spot of land, so that the green lake plus canals is still homeomorphic to an (open) disk. Call the remaining land X_2. In the third step, canals are dug from the brown lake to within 1/4 km of every spot of land. In the fourth step, the ocean is used again, and then the green lake, then the brown, repeated cyclically. Call the remaining land X after infinitely many steps, i.e. $X = \cap_{n=1}^{\infty} X_n$. X is called the *Land of Wada*.

The construction can (in principle) clearly be continued indefinitely, since each X_n is homeomorphic to a large closed disk with two small open disks removed from its interior (with the boundaries of the three disks pairwise disjoint). At the end, each lake is still homeomorphic to an open disk, and the ocean to the complement in $\mathbb{R}^2$ of a closed disk (if the construction is done on a 2-sphere such as the surface of the earth instead of $\mathbb{R}^2$, the ocean is also an open disk). However, the boundary of each of these three disjoint connected open subsets of $\mathbb{R}^2$ is the set X: every point of X is arbitrarily close to blue, green, and brown water. The set X is compact and connected, and has empty interior (it is topologically one-dimensional, and

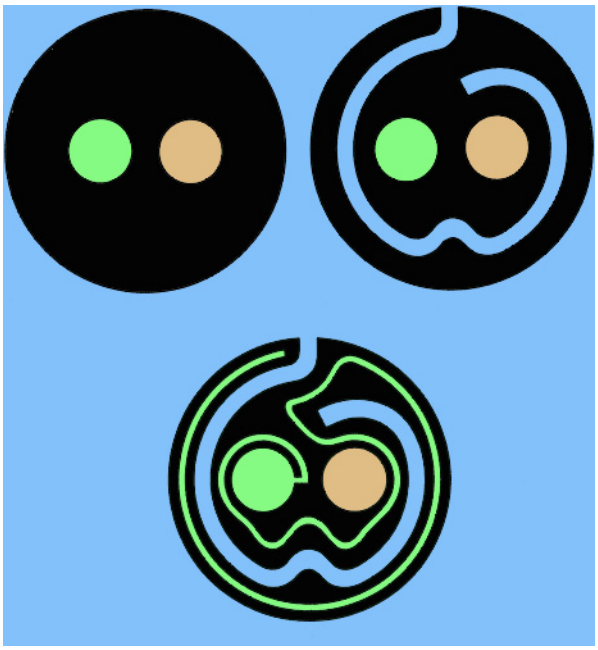

Figure XIII.50: Two steps in the construction of the Lakes of Wada

topologically similar to a pseudo-arc). It is unclear to what extent the homeomorphism type of X depends on the details of the construction of the canals.

Instead of two lakes, we can start with n lakes and end up with $n+1$ disjoint connected open sets in $\mathbb{R}^2$ whose common boundary is the same connected compact set X. With care, the construction can even be done with countably many initial lakes. Thus, if n is any natural number or $\aleph_0$, there are n disjoint open subsets of the 2-sphere, each homeomorphic to an open disk, with dense union, which share a common boundary.

Basins of attraction for nonlinear systems frequently resemble lakes of Wada. These basins of attraction are called *Wada basins*.

The lakes of Wada show again (cf. XIII.19.5.7.) that care must be exercised in formulating the Four-Color Theorem.

Nontrivial Embeddings

There are classes of examples of subsets of $\mathbb{R}^3$ (or $\mathbb{R}^n$) in which the subset itself is a familiar or nicely behaved one, but is embedded in Euclidean space in an unusual or strange way. There are two general subtypes: "tame" embeddings which are locally nice (e.g. smooth embeddings of manifolds), and "wild" embeddings which are not locally nice.

Knots

This is the simplest instance of interesting tame embeddings, consisting of topological circles embedded in $\mathbb{R}^3$ in a nontrivial way.

XIII.19.5.36. DEFINITION. A *knot* is a smooth embedding of S^1 into $\mathbb{R}^3$.

Knot theory is a fascinating and active branch of modern topology; see Figure XIII.51, from http://www.math.unl.edu/~mbrittenham2/ldt/table9.gif, for some examples of knots (some of the pictures are of *links*, made up of more than one circle), and Figure XIII.52 for a nice depiction of the simplest nontrivial knot, the trefoil knot (in a mathematical knot, the blue tube has no thickness). There are many other knot images and animations on the internet. See e.g. [] for more information on knot theory.

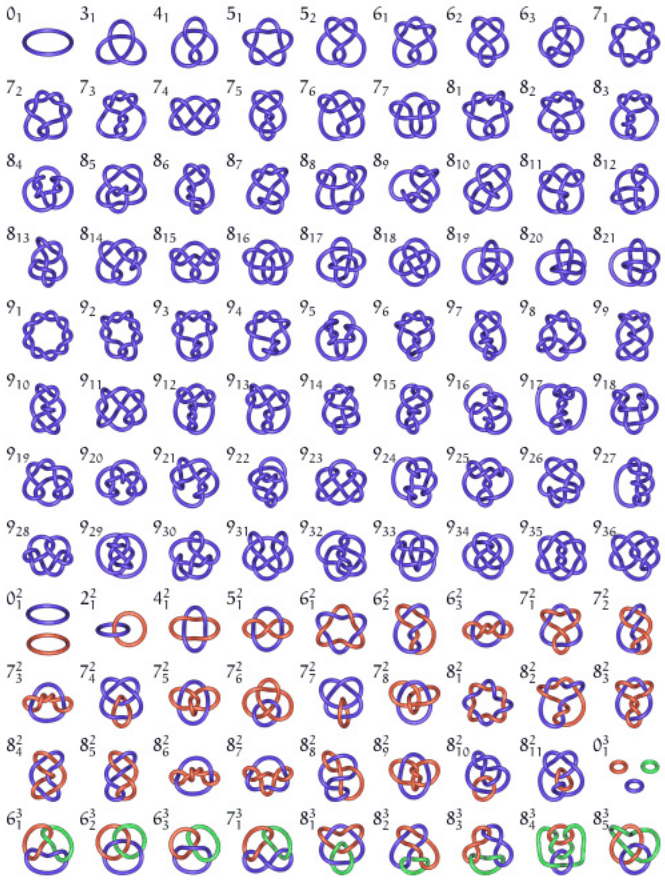

Figure XIII.51: Some Knots and Links

Figure XIII.52: A Trefoil Knot. Artwork by Jim Belk

Higher-Dimensional Knots

XIII.19.5.37. One might also wonder about subsets of $\mathbb{R}^n$ (or S^n) homeomorphic to S^m for $1 < m < n-1$. Such subsets always have connected complements, but the ways they can be embedded (even leaving out "wild" embeddings, e.g. restricting to smooth or piecewise-linear embeddings) are very complicated.

Wild Arcs

XIII.19.5.38. An *arc* in a topological space X is a copy of $[0,1]$ in X (a subspace of X homeomorphic to $[0,1]$). Even an arc in $\mathbb{R}^3$ can be wildly embedded. The simplest and best-known example is due to Fox and Artin [FA48] (Figure XIII.53, from http://www.sciencedirect.com/science/article/pii/S0960077901002429, originally from [HY88]):

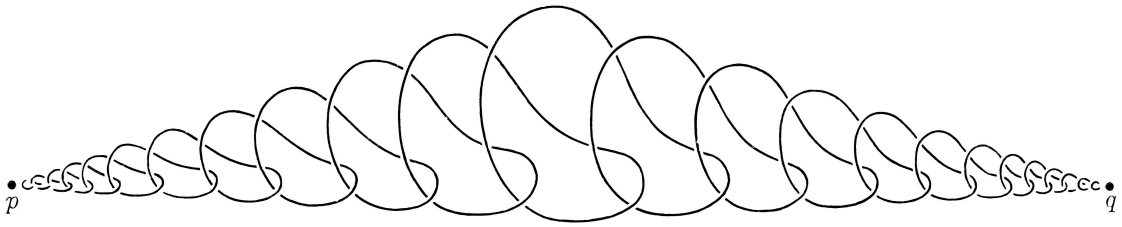

Figure XIII.53: The Fox-Artin Wild Arc

This embedding is wild at the two endpoints. The complement of the arc is not simply connected.

XIII.19.5.39. By successively replacing small subarcs of this arc with a small copy of the whole wild arc, a sequence of embeddings of $[0,1]$ into $\mathbb{R}^3$ can be obtained which are wild at many points. If done carefully, this sequence of embeddings can be made to converge uniformly on $[0,1]$ to an embedding (arc) which is wild at every point.

See [Bor47] for a different kind of pathological arc in $\mathbb{R}^3$.

Alexander's Horned Sphere

XIII.19.5.40. The Alexander horned sphere is a subset of $\mathbb{R}^3$ homeomorphic to S^2 whose exterior is not homeomorphic to the exterior of the unit sphere in $\mathbb{R}^3$ (it is not simply connected ()). The union of the horned sphere and its interior is homeomorphic to B^3, and the interior is homeomorphic to the open unit ball. By extending the horns into the ball instead of outside, a homeomorph of S^2 in $\mathbb{R}^3$ can be made whose interior is not topologically a ball, and by making horns both inside and outside both the interior and exterior can be made pathological.

There are many pictures and animations of the horned sphere on the internet (Figure XIII.55 is from http://conan777.files.wordpress.com/2010/04/hornedsphere3.jpg), although I still think the best picture is the classic one in [HY88] (Figure XIII.54, from http://www.sciencedirect.com/science/article/pii/S0960077901002429). For a beautiful animation of the Alexander Horned Sphere, see https://www.youtube.com/watch?v=Pe2mnrLUYFU.

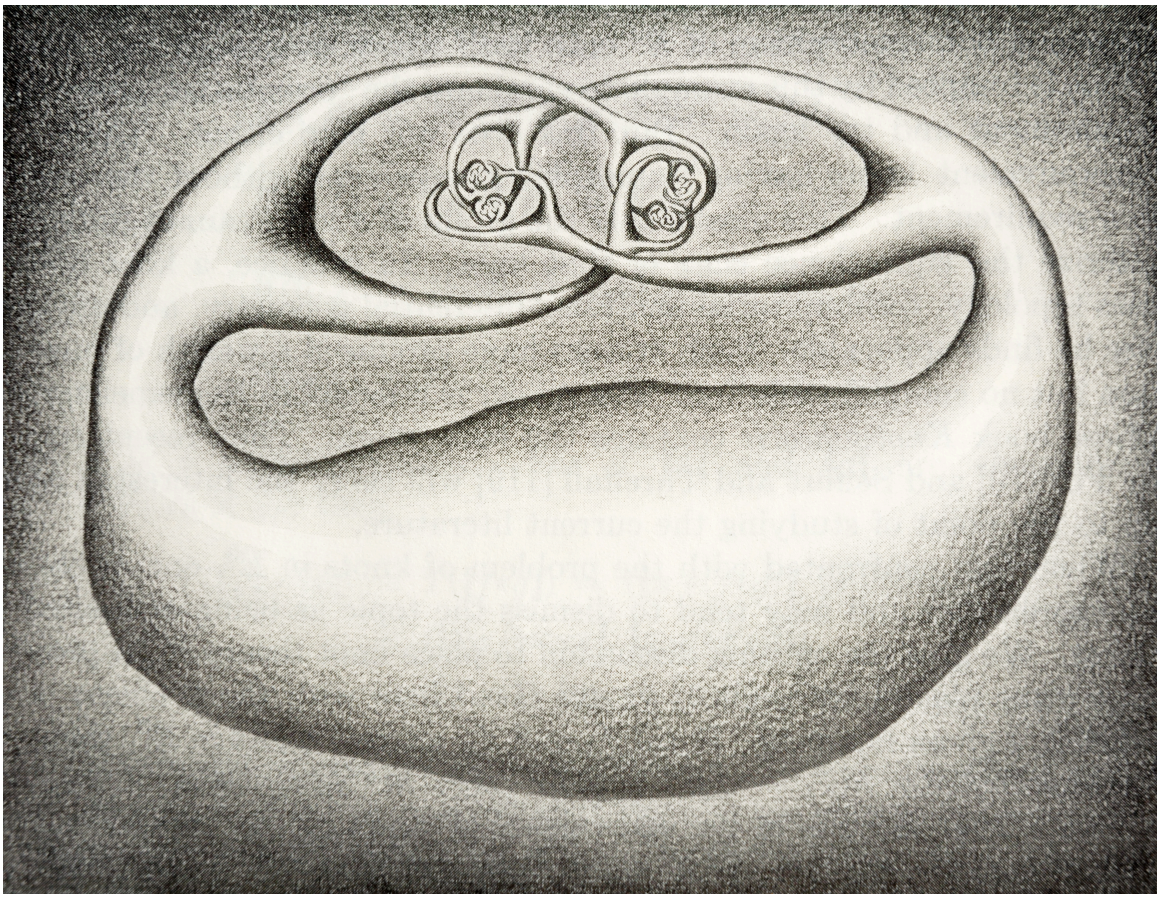

Figure XIII.54: The Alexander Horned Sphere

XIII.19.5.41. The Alexander Horned Sphere is wild at a Cantor set of points. By successively adding small pairs of horns densely, a sequence of embeddings of S^2 into $\mathbb{R}^3$ can be obtained which converges uniformly to an embedding which is wild at every point (cf. XIII.19.5.39.). The horns can be added outside, inside, or both inside and outside.

XIII.19.5.42. There are other rather different wild embeddings of S^2 into $\mathbb{R}^3$. A simple one is to fatten up the Fox-Artin wild arc (Figure XIII.53) into a tube tapering to a point at the ends. A variation, also discussed in [FA48], is shown in Figure XIII.56, from [GH78] (the knots repeat and approach p, q, r, s). See also [Rus73]. Actually, the first wild sphere was obtained by L. Antoine (who was blind!) [**?**], who also constructed Antoine's necklace (XIII.19.5.43.).

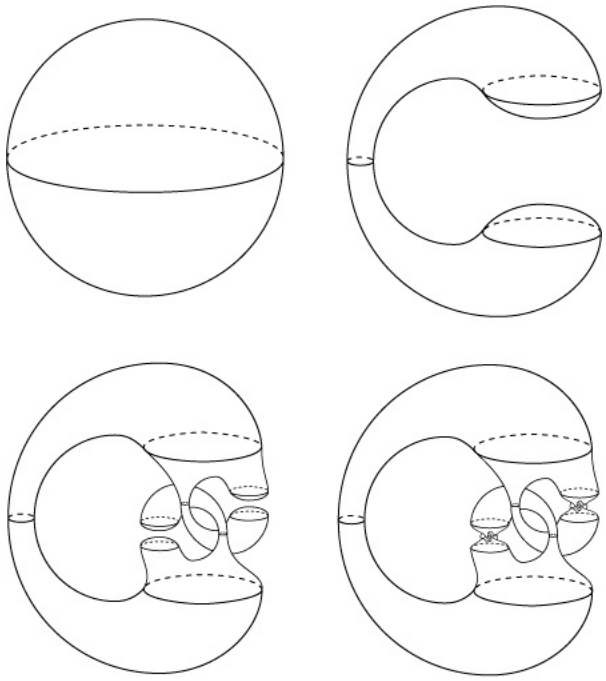

Figure XIII.55: Construction of an Alexander horned sphere

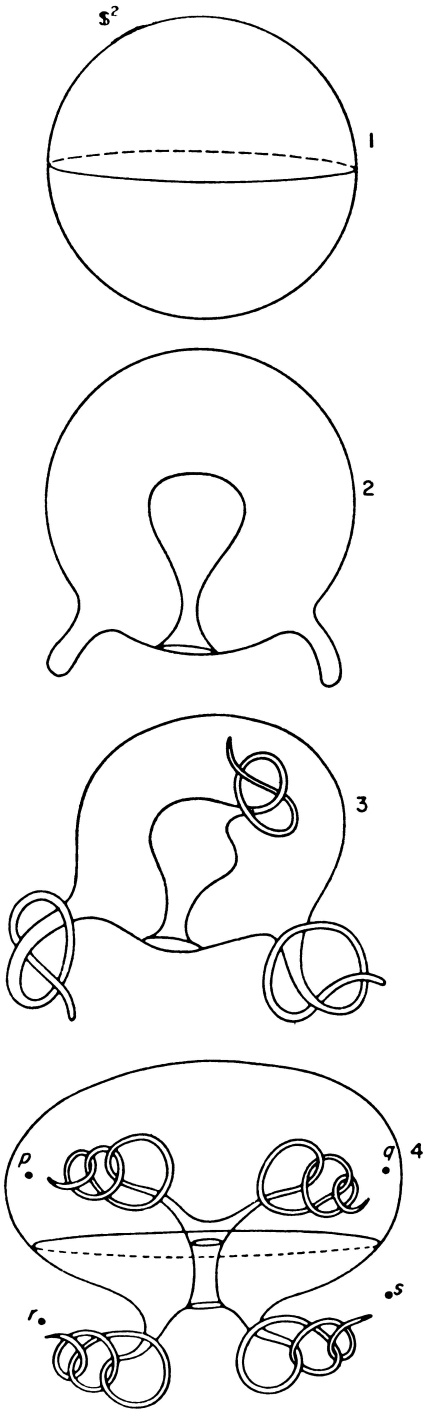

Figure XIII.56: A Few Steps in the Construction of a Wild Sphere

Antoine's Necklace

XIII.19.5.43. This is another subset of $\mathbb{R}^3$ defined by an intersection, a Cantor set wildly embedded in $\mathbb{R}^3$. Begin with a solid torus X_1 in $\mathbb{R}^3$. Inside take a chain X_2 of smaller interlocked solid tori as in Figure XIII.57 (the number of interlocked tori is unimportant as long as it is at least three, although the final embedding of the Cantor set depends on the number of tori at each stage [She68]):

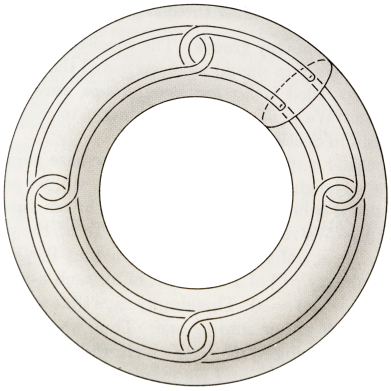

Figure XIII.57: First step in the construction of Antoine's Necklace

Inside each of these smaller solid tori put a similar chain of even smaller interlocked solid tori, and iterate in such a way as to make the diameters of the solid tori at the n'th stage X_n go to zero as $n \to \infty$. The intersection X is *Antoine's Necklace*.

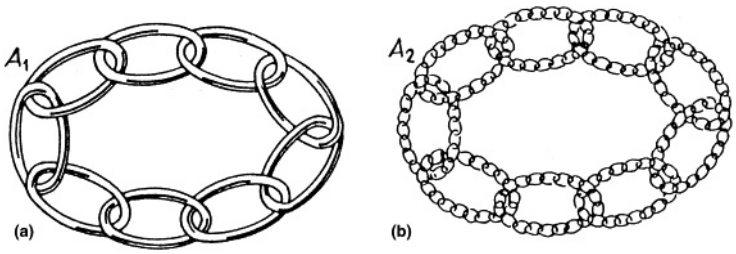

Figure XIII.58: Two steps in the construction of Antoine's Necklace

Figure XIII.59 shows three stages of the construction.

The connected components of X are contained in the connected components of X_n for each n; since the diameters of these connected components approach zero as $n \to \infty$, the connected components of X have diameter zero, i.e. are single points. Thus X is totally disconnected. However, it is clear that X can have no isolated points, since every point of X is arbitrarily close to points from different components of X_n for large enough n. Thus X is homeomorphic to the Cantor set K ().

However, the complement of X in $\mathbb{R}^3$ is not simply connected. If γ is a loop around the "hole" in X_1, then γ cannot be shrunk to a point in the complement of X_n for any n (this seems "obvious", but some

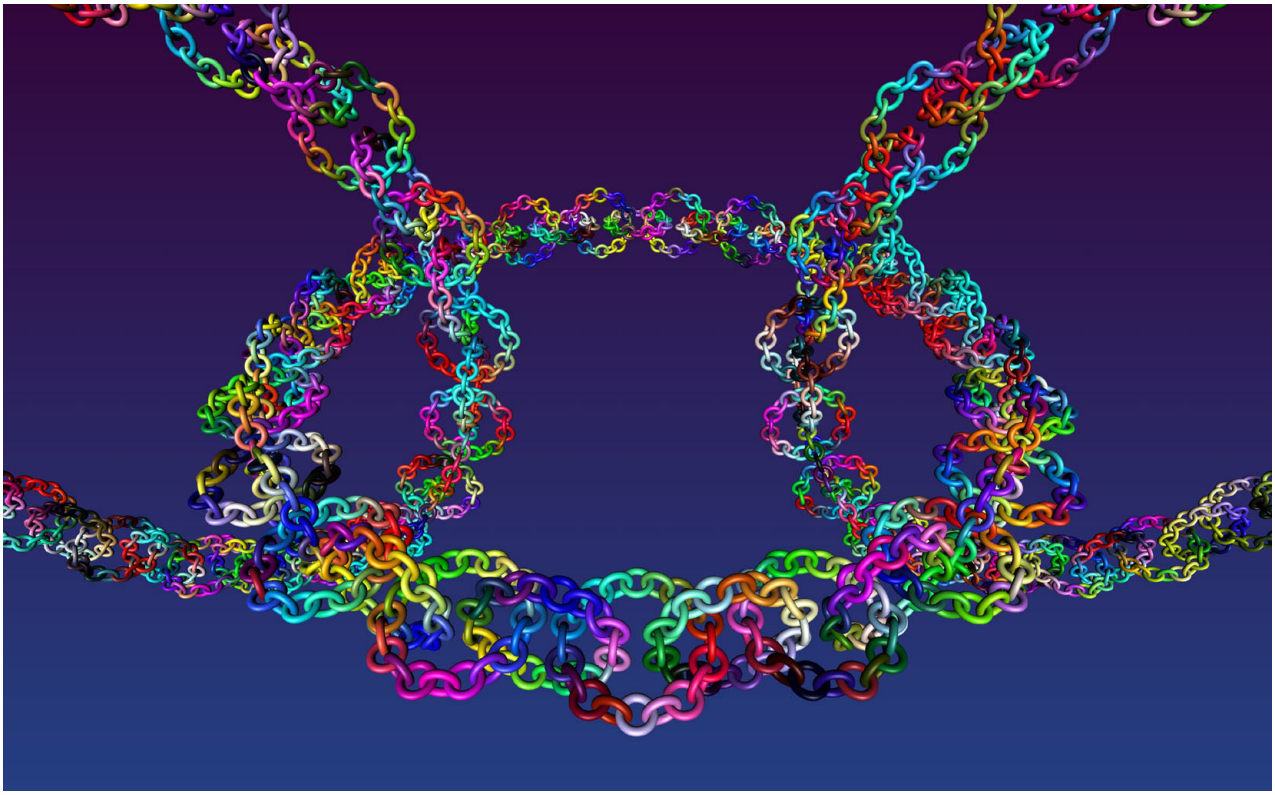

Figure XIII.59: Three steps in the construction of Antoine's Necklace

nontrivial topology is needed to prove it). If it could be shrunk to a point in the complement of X, the homotopy would trace out a continuous image of a disk, a compact set Y in $\mathbb{R}^3$. This set would be disjoint from X_n for sufficiently large n by a simple compactness argument (the complements of the X_n give an open cover of Y). Thus γ could be shrunk to a point in the complement of some X_n, a contradiction.

So X is embedded in $\mathbb{R}^3$ in a very different way than the ordinary Cantor set, regarded as a subset of the x-axis in $\mathbb{R}^3$. The construction and its variations are described in [BM88], where the set is described as a necklace that "cannot fall apart" despite having no string.

It also follows from results in [BM88] that any uncountable compact space which can be embedded in a surface in $\mathbb{R}^3$ (e.g. any uncountable compact subset of $\mathbb{R}^2$) can be embedded in $\mathbb{R}^3$ in uncountably many essentially different ways.

It is known that any subset Z of $\mathbb{R}^2$ homeomorphic to the ordinary Cantor set K (sitting in the x-axis) is embedded in the same way as K: there is a homeomorphism of $\mathbb{R}^2$ onto itself carrying Z onto K [CV98]. Compare with XVII.6.9.3..

See [Rus92] for some generalizations of Antoine's necklace and wild embeddings of spheres in $\mathbb{R}^n$. See also Exercise XIII.19.6.4..

Other Examples

XIII.19.5.44. These examples only scratch the surface of the possibilities. Many other examples can be found in books like [SS95], [Bor67], [Edg08], and [Fal14].

When noncompact subsets of Euclidean space are considered, the possibilities become far greater and more bizarre. For example:

XIII.19.5.45. PROPOSITION. [Kur66, p. 263] Up to homeomorphism, there are $2^{2^{\aleph_0}}$ distinct subsets of $\mathbb{R}$, or of any separable metric space of cardinality $2^{\aleph_0}$.

PROOF: If A is a subset of $\mathbb{R}$, then A is separable (in the relative topology). There are only $2^{\aleph_0}$ continuous functions from any separable space to $\mathbb{R}$, since such a function is completely determined by its values on a countable dense set. Thus there can only be $2^{\aleph_0}$ subsets of $\mathbb{R}$ homeomorphic to A. Since there are $2^{2^{\aleph_0}}$ subsets of $\mathbb{R}$, there must be $2^{2^{\aleph_0}}$ homeomorphism classes. 👍

Since there are only $2^{\aleph_0}$ Borel sets in $\mathbb{R}$ (), "most" of these sets are not even homeomorphic to Borel sets. (Actually, any subset of $\mathbb{R}$ homeomorphic to a Borel set is a Borel set (XIII.10.3.8.).)

XIII.19.6. Exercises

XIII.19.6.1. Let $\boldsymbol{k}$ and $X_{\boldsymbol{k}}$ be as in XIII.19.5.1.. Suppose $\boldsymbol{k}'$ is another sequence of natural numbers and $\phi : X_{\boldsymbol{k}} \to X_{\boldsymbol{k}'}$ is a homeomorphism.

(a) For various points p in $X_{\boldsymbol{k}}$, consider the number and homeomorphism type of connected components of $X_{\boldsymbol{k}} \setminus \{p\}$. Observe that this data must be the same for $X_{\boldsymbol{k}'} \setminus \{\phi(p)\}$.

(b) Use (a) to show that necessarily $\phi\left(\left(\frac{1}{n}, 0\right)\right) = \left(\frac{1}{n}, 0\right)$ for all n.

(c) Conclude that $\boldsymbol{k} = \boldsymbol{k}'$.

(d) If the sequences $\boldsymbol{k}$ and $\boldsymbol{k}'$ are strictly increasing and distinct, there is a simpler proof that $X_{\boldsymbol{k}}$ and $X_{\boldsymbol{k}'}$ are not homeomorphic, since for each $n \geq 2$ there is a unique point $p \in X_{\boldsymbol{k}}$ such that $X_{\boldsymbol{k}} \setminus \{p\}$ has exactly $k_n + 2$ components. Show that there are $2^{\aleph_0}$ such sequences [they are in one-one correspondence with the infinite subsets of $\mathbb{N}$].

XIII.19.6.2. This problem is an elaboration of XIII.19.5.4.. Recall the notation of (). For a compact space X, let X_∞ be the stable perfect subset (K in the case $X = X_{\boldsymbol{m}}$ for some $\boldsymbol{m}$), $S^{(k)}(X)$ the set of isolated points of the k'th derived set $X^{(k)}$, and

$$B^{(k)}(X) = \left[\overline{S^{(k)}(X)} \setminus S^{(k)}(X)\right] \cap X_\infty \ .$$

A homeomorphism from X to a space Y must send X_∞ to Y_∞ and $B^{(k)}(X)$ to $B^{(k)}(Y)$ for each k. Show that $B^{(k)}(X_{\boldsymbol{m}}) \neq B^{(k+1)}(X_{\boldsymbol{m}})$ if and only if $k = m_n$ for some n. Conclude that the $X_{\boldsymbol{m}}$ are mutually nonhomeomorphic for distinct $\boldsymbol{m}$.

XIII.19.6.3. (a) Let X be a compact connected subset of $\mathbb{R}^2$. Show that if $\mathbb{R}^2 \setminus X$ is connected, it is homeomorphic to $\mathbb{R}^2 \setminus \{0\}$. [Use XIII.23.10.1., and show the boundary there can be taken to be a single curve.] Contrast with XIII.20.5.14..

(b) Show more generally that if X and Y are compact subsets of $\mathbb{R}^2$ such that $U = \mathbb{R}^2 \setminus X$ and $V = \mathbb{R}^2 \setminus Y$ are connected, then U and V are homeomorphic if and only if the component spaces X_c and Y_c (XIII.13.9.15.) are homeomorphic. This generalizes both (a) and XIII.20.5.14..

(c) Let X be a compact connected subset of $\mathbb{R}^2$. Show that the unbounded component of $\mathbb{R}^2 \setminus X$ is homeomorphic to $\mathbb{R}^2 \setminus \{0\}$, and that each bounded component is homeomorphic to an open disk. [For the unbounded component, apply (a) to the union of X and the bounded components of $\mathbb{R}^2 \setminus X$. For bounded components, invert in a small circle within the component.] Make an analogous statement about complements of compact connected subsets of S^2. Compare with XII.8.6.6..

These results are special to $\mathbb{R}^2$ (analogous results hold more simply in $\mathbb{R}^1$): several examples from this section show that nothing like this holds in $\mathbb{R}^3$.

XIII.19.6.4. Modify the construction of Antoine's Necklace as follows.

(a) Consider the following linked set of solid tori (picture from [Gar01]; the surfaces should not touch):

Figure XIII.60: Variation of Borromean Rings

The number n of solid tori is not important as long as it is at least 3 (although, as with Antoine's Necklace, the number probably affects the final embedding); the case $n = 3$ is the usual Borromean Rings (Figure XIII.51 6_2^3). Show that the entire set of tori is linked nontrivially, that any two of the solid tori are not linked, and that if any one of the tori is removed the remaining ones are unlinked.

(b) Replace each of these solid tori by a set of smaller solid tori contained in it, linked in the same way. Iterate the construction so that the diameters of the solid tori go to zero, and take the intersection X.

(c) Show that X is homeomorphic to the Cantor set.

(d) Show that the complement of X is not simply connected; thus X is nontrivially (wildly) embedded in $\mathbb{R}^3$.

(e) If T is one of the solid tori in the construction, then $X \cap T$ is a clopen set in X. Show that every clopen set in X is a finite disjoint union of such sets.

(f) Two disjoint compact subsets A and B of $\mathbb{R}^n$ are *unlinked* (or *separated by spheres*) if there is a homeomorphism of $\mathbb{R}^n$ sending A and B into disjoint open balls. Show that if A and B are disjoint clopen sets in X, then there is a partition of A into clopen sets C and D such that $\{B, C, D\}$ are pairwise unlinked in $\mathbb{R}^3$. Conclude that X is not embedded in $\mathbb{R}^3$ in the same way as Antoine's Necklace (any version).

(g) What happens if we use other linkings of the embedded solid tori at each stage, and perhaps vary the linkings from stage to stage? We could, for example, at infinitely many stages knot the solid tori, or replace each solid torus with a thinner solid torus wrapping twice around inside it as in the construction of the solenoid (Figure XIII.44). See Figure XIII.61 (from T. Gray, *The Elements*), and [She68], [Sko86], and [SS13], and the references therein.

Figure XIII.61: Another link which can be iterated.

XIII.19.6.5. Knotted Solenoids. Let S be a solenoid (XIII.19.5.16.).

(a) By construction, S is a subset of a solid torus T. If K is a knot, fatten up K into a solid torus T_K and let ϕ be a homeomorphism of T onto T_K. Let $S_K = \phi(S)$. S_K can be regarded as a knotted version of S. Show that if K_1 and K_2 are knots, show that S_{K_1} and S_{K_2} are embedded in $\mathbb{R}^3$ in the same way if and only if $K_1 \cong K_2$.

(b) If K is a knot, then K can be embedded nontrivially in a solid torus with winding number greater than 1 (write the knot as the closure of a braid; cf. ()). By fattening up K inside the solid torus, we obtain a

knotted solid torus. Another knot can be embedded in this in the same way. Iterating this construction and taking an intersection, an "infinitely knotted" solenoid is obtained. Classify the solenoid obtained via the winding numbers and show that any solenoid can be embedded in $\mathbb{R}^3$ in $2^{\aleph_0}$ essentially different ways.

XIII.19.6.6. (a) Let S be a solenoid embedded in $\mathbb{R}^3$ in the standard (unknotted) way, with $G = \pi^1(S)$ the corresponding subgroup of $\mathbb{Q}$. Show that the fundamental group of $\mathbb{R}^3 \setminus S$ is G. Note that $\mathbb{R}^3 \setminus S$ is a connected open subset of $\mathbb{R}^3$, hence a connected 3-manifold.

(b) Compute the fundamental groups of the complements of the knotted solenoids of XIII.19.6.5., which are also connected 3-manifolds.

XIII.19.6.7. Let G be any countable group. Show that there is a connected open subset of $\mathbb{R}^5$ (hence a connected 5-manifold) with fundamental group G. [See http://mathoverflow.net/questions/192230/is-there-a-manifold-with-fundamental-group-mathbbq for an outline of the construction.] Conversely, the fundamental group of any manifold is countable ().

XIII.19.6.8. **The Whitehead Continuum and the Whitehead Manifold.** [**?**] Here is an interesting construction reminiscent of the construction of solenoids. Let T_0 be a solid (unknotted) torus in $\mathbb{R}^3$, and T_1 a thinner solid torus embedded in T_0 as in Figure XIII.62.

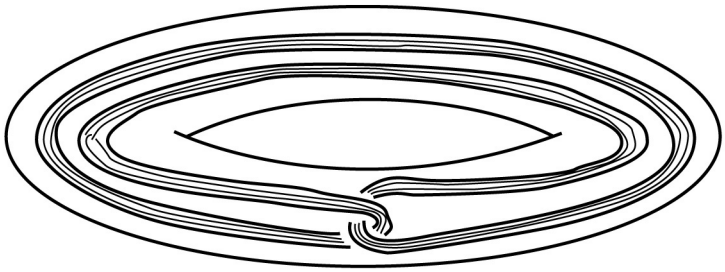

Figure XIII.62: First two steps for the Whitehead continuum

For each k let T_{k+1} be a thin solid torus embedded in T_k in the same way. Note that each T_k is unknotted in $\mathbb{R}^3$.

Let $W = \cap_{k=1}^{\infty} T_k$. Since each T_k is compact and connected, W is also compact and connected. W is called the *Whitehead continuum* (the exact space depends on the details of the construction).

(a) If L is a meridian circle for T_0, show that

(i) L and the longitude axis circle of T_1 form a nontrivial link in $\mathbb{R}^3$, called the *Whitehead link* (XIII.63).

(ii) L is not null-homotopic in $T_0 \setminus T_1$ (or even in $\mathbb{R}^3 \setminus T_1$).

(iii) L is null-homotopic in $S^3 \setminus T_1$, where S^3 is the one-point compactification of $\mathbb{R}^3$.

(b) Discuss other properties of W. Is it path-connected? Simply connected?

Figure XIII.63: The Whitehead link

(c) The complement of W is more interesting. Regard the construction as being done in the one-point compactification S^3 of $\mathbb{R}^3$, and let $E = S^3 \setminus W$. The complement of a solid torus in S^3 is another solid torus; thus E is an increasing union of solid tori. Show that each is embedded in the next as T_1 is embedded in T_0. Show that E is a connected, noncompact 3-manifold, and that E is simply connected [use (a)(iii).] Conclude from () that E is contractible (or give a direct argument). E is called the *Whitehead manifold*. (Unlike for W, up to homeomorphism E does not depend on the details of the construction.)

(d) Show that no neighborhood of ∞ in the one-point compactification $E^\dagger$ of E is simply connected [$E^\dagger$ is homeomorphic to the quotient S^3/W of S^3 obtained by collapsing W to a point. Use (a)(ii).] Thus $E^\dagger$ is not a manifold. Conclude that E is not homeomorphic to $\mathbb{R}^3$.

(e) Show that $E \times \mathbb{R}$ is homeomorphic to $\mathbb{R}^4$, as is $(\mathbb{R}^3/W) \times \mathbb{R}$. (However, contrary to statements in some references like [CWY10], $(S^3/W) \times \mathbb{R} = E^\dagger \times \mathbb{R}$ is not homeomorphic to $\mathbb{R}^4$ since it has two ends and is not contractible.)

(f) If p is a point of W, then $E \subseteq S^3 \setminus \{p\} \cong \mathbb{R}^3$, and thus E is homeomorphic to an open subset of $\mathbb{R}^3$.

(g) Some more properties of E: E is the union of two open subsets, each homeomorphic to $\mathbb{R}^3$, whose intersection is also homeomorphic to $\mathbb{R}^3$ [Gab11]; E does not have any orientation-reversing diffeomorphism [AW07]; E does not admit a complete metric with strictly positive scalar curvature [CWY10], unlike $\mathbb{R}^3$, which does have such a metric, e.g. by identifying it with

$$\{(x, y, z, w) : w = x^2 + y^2 + z^2\} \subseteq \mathbb{R}^4 \ .$$

(h) Let $\boldsymbol{n} = (n_1, n_2, \dots)$ be a sequence in $\mathbb{N}$. Vary the construction of W and E by wrapping T_k around T_{k-1} n_k times before linking as in Figure XIII.62. Let $W_{\boldsymbol{n}}$ be the intersection and $E_{\boldsymbol{n}} = S^3 \setminus W_{\boldsymbol{n}}$. (Thus the Whitehead continuum is $W_{\boldsymbol{n}}$ where $n_k = 1$ for all k.) Show that $W_{\boldsymbol{n}}$ and $E_{\boldsymbol{n}}$ have the same properties as before. Show that $2^{\aleph_0}$ distinct homeomorphism classes of $E_{\boldsymbol{n}}$ are obtained. Thus there are $2^{\aleph_0}$ topologically distinct contractible open subsets of $\mathbb{R}^3$. See [McM62] for details.

In contrast, every simply connected open subset (in particular, every contractible open subset) of $\mathbb{R}^2$ is homeomorphic to $\mathbb{R}^2$ (). In fact, the only simply connected 2-manifolds are $\mathbb{R}^2$ and S^2.

Not every contractible 3-manifold is of the form of (h); cf. [McM62], [TW97]. There does not appear to be any reasonable classification of contractible 3-manifolds. The already known existence of exotic contractible 3-manifolds seems to have been overlooked in [BT82, p. 147].

XIII.19.6.9. The House with Two Rooms. Let X be the subset of $\mathbb{R}^3$ pictured in Figure XIII.64 (from [Hat02]).

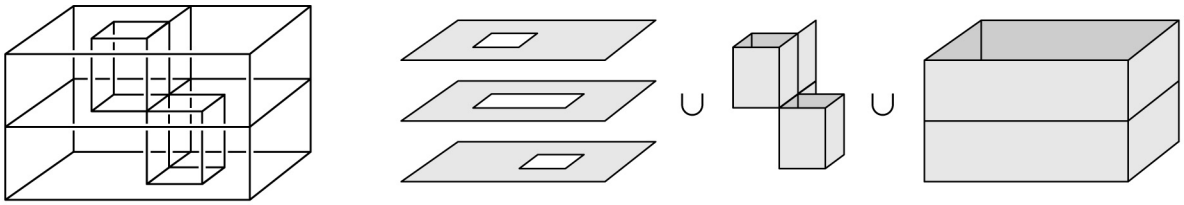

Figure XIII.64: The House With Two Rooms

(a) X is a finite union of planar rectangles, and thus is a two-dimensional (compact) polyhedron in $\mathbb{R}^3$.

(b) Let Y be the rectangular solid in $\mathbb{R}^3$ generated by X (convex hull of X). Show that there is a deformation retraction of Y onto X. [Push down the upper hole and expand the indentation to fill the bottom room, and similarly push up the lower hole.] Conclude () that X is an absolute retract, and in particular is contractible.

(c) Consider the loop in X which is the perimeter of the hole in the upper surface. Show how to contract this loop to a point in X.

(d) Describe an explicit contraction of X. (This is not easy! See e.g. https://sketchesoftopology.wordpress.com/2010/06/23/the-deformation-retraction-of-bings-house/.)

This example is due to Bing [Bin64]. There are several slight variations in various references, all of which have the same essential features.

XIII.19.6.10. The Rational Ruler. Construct a subset X of the closed unit square $[0,1]^2 \subseteq \mathbb{R}^2$ as follows. Begin with the horizontal segment $[0,1]$ on the x-axis, and for each $r \in \mathbb{Q} \cap [0,1]$, $r = \frac{p}{q}$ in lowest terms, add the closed vertical segment between $(r,0)$ and $\left(r, \frac{1}{q}\right)$.

(a) Show that X is a compact subset of $\mathbb{R}^2$.

(b) Construct a retraction of $[0,1]^2$ onto X as follows. Set

$$X_n = X \cup \left\{(x,y) : 0 \leq x \leq 1, 0 \leq y \leq \frac{1}{n}\right\}$$

(note that $X = \cap_n X_n$) and construct a uniformly convergent sequence of retractions from $[0,1]^2$ onto the X_n. Conclude () that X is an absolute retract.

XIII.19.6.11. Say a topological space X is *totally inhomogeneous* if the only homeomorphism from X to X is the identity. Construct $2^{\aleph_0}$ pairwise nonhomeomorphic totally inhomogeneous dendrites in $\mathbb{R}^2$ as follows. Let $(k_1, k_2, \dots)$ be a sequence of distinct natural numbers. As in the construction of the rational ruler (XIII.19.6.10.), begin with $[0,1]$ on the x-axis, and at the n'th rational in $(0,1)$ add k_n whiskers of length $\frac{1}{n}$ (no whiskers at 0 or 1). Replace each whisker by a small copy of the whole set, and iterate. If done carefully, a sequence of retractions from a containing disk can be made to converge uniformly.

XIII.19.6.12. ([Lub53]; cf. [Bor67, p. 150-151]) Let $n \in \mathbb{N}$. Adapt the Lakes of Wada construction to construct in $\mathbb{R}^3$ a connected two-dimensional absolute neighborhood retract X_n such that the complement of X is dense in $\mathbb{R}^3$ and has exactly n components, the boundary of each of which is X. (X thus has a locally nice structure, a least in a homotopy sense, unlike the examples in $\mathbb{R}^2$ like the Lakes of Wada which necessarily are locally quite pathological [**?**].)

XIII.19.6.13. Show that there is no reasonable analog of the four-color theorem in $\mathbb{R}^3$, even for polyhedra. [Lay n boards with rectangular cross-section side-by-side on the xy-plane in $\mathbb{R}^3$ with long dimension parallel to the x-axis, and on top of them lay n boards with long dimension parallel to the y-axis. Glue the k'th horizontal board to the k'th vertical board to make a single cross-shaped polyhedron for each k. See http://demonstrations.wolfram.com/AnInfinitelyColorableSetOf3DRegions/. Another more informal argument I heard somewhere: "Imagine a bowl of spaghetti where every noodle touches all the others."] There are meaningful higher-dimensional analogs of the graph-theoretic versions of the four-color theorem, however.

XIII.19.6.14. The Hahn-Mazurkiewicz Theorem says that a Hausdorff topological space is a continuous image of $[0,1]$ if and only if it is compact, metrizable, connected, and locally connected (and thus automatically path-connected and locally path-connected). Thus the Sierpiński gasket, Sierpiński carpet, and Menger sponge are all continuous images of $[0,1]$. Find explicit continuous surjections. [The construction of a space-filling curve () may provide some insight.]

XIII.19.6.15. **The Infinite Comb.** Consider the compact subset of $\mathbb{R}^2$ consisting of the line segments from 0 to 1 on the x and y axes and the vertical segments from 0 to 1 with x-coordinate $\frac{1}{n}$ for each n (the exact location of the x-coordinates of the vertical segments are unimportant as long as they form a sequence of numbers in $(0,1]$ converging to 0). See Figure XIII.65.

(a) Show that the infinite comb is contractible.

(b) Show that the infinite comb is not locally connected at points on the positive y-axis. Thus it is not strongly contractible to any of these points. It is strongly contractible to any other point.

(c) Figures XIII.66 and XIII.67 show a number of variations of the infinite comb. Which of these are contractible? Which are strongly contractible, to which points? Which pairs of these are homeomorphic? (The first space in XIII.66 is called *Zeno's maze* in [Pug15], but I have not found this name in other references.) Show that all have trivial fundamental group, i.e. are simply connected.

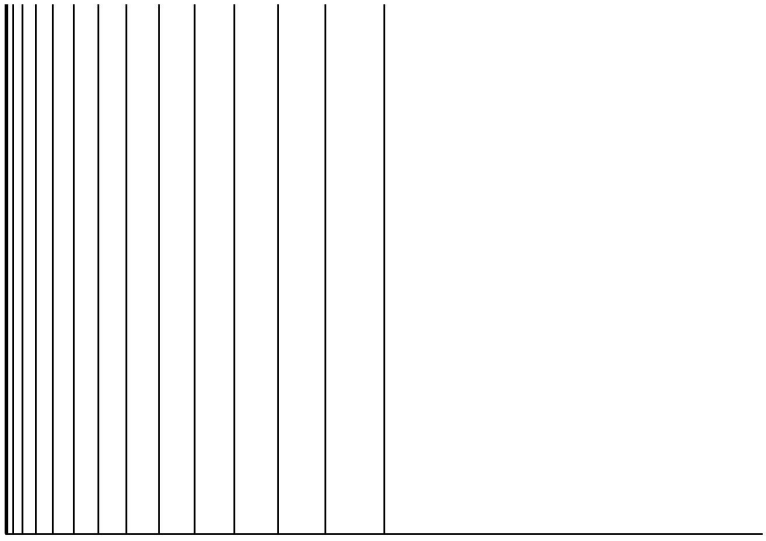

Figure XIII.65: The Infinite Comb

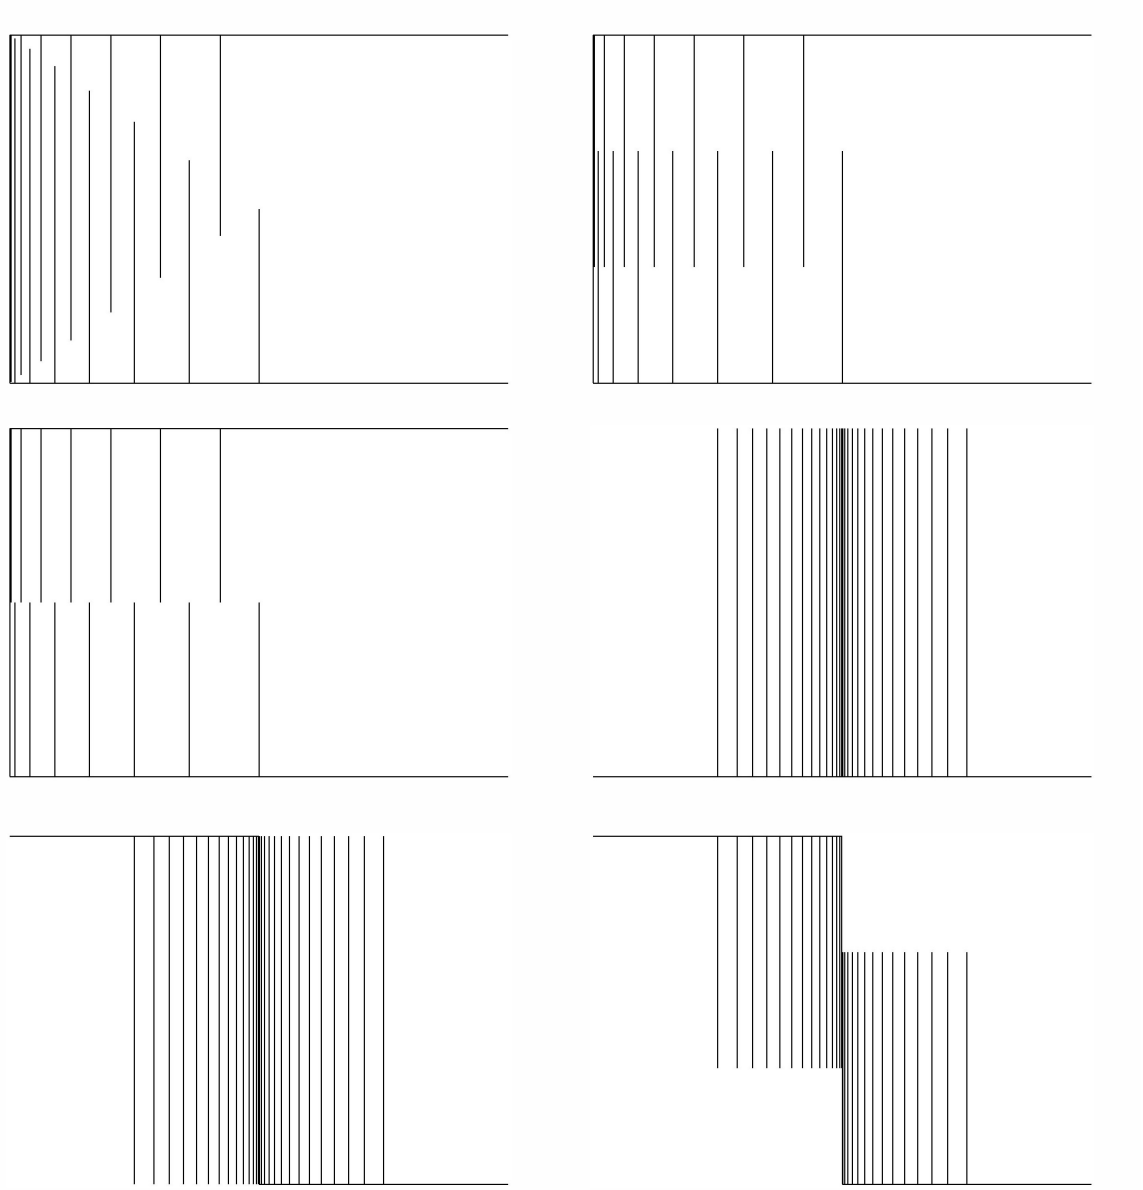

Figure XIII.66: Infinite Comb Variations I

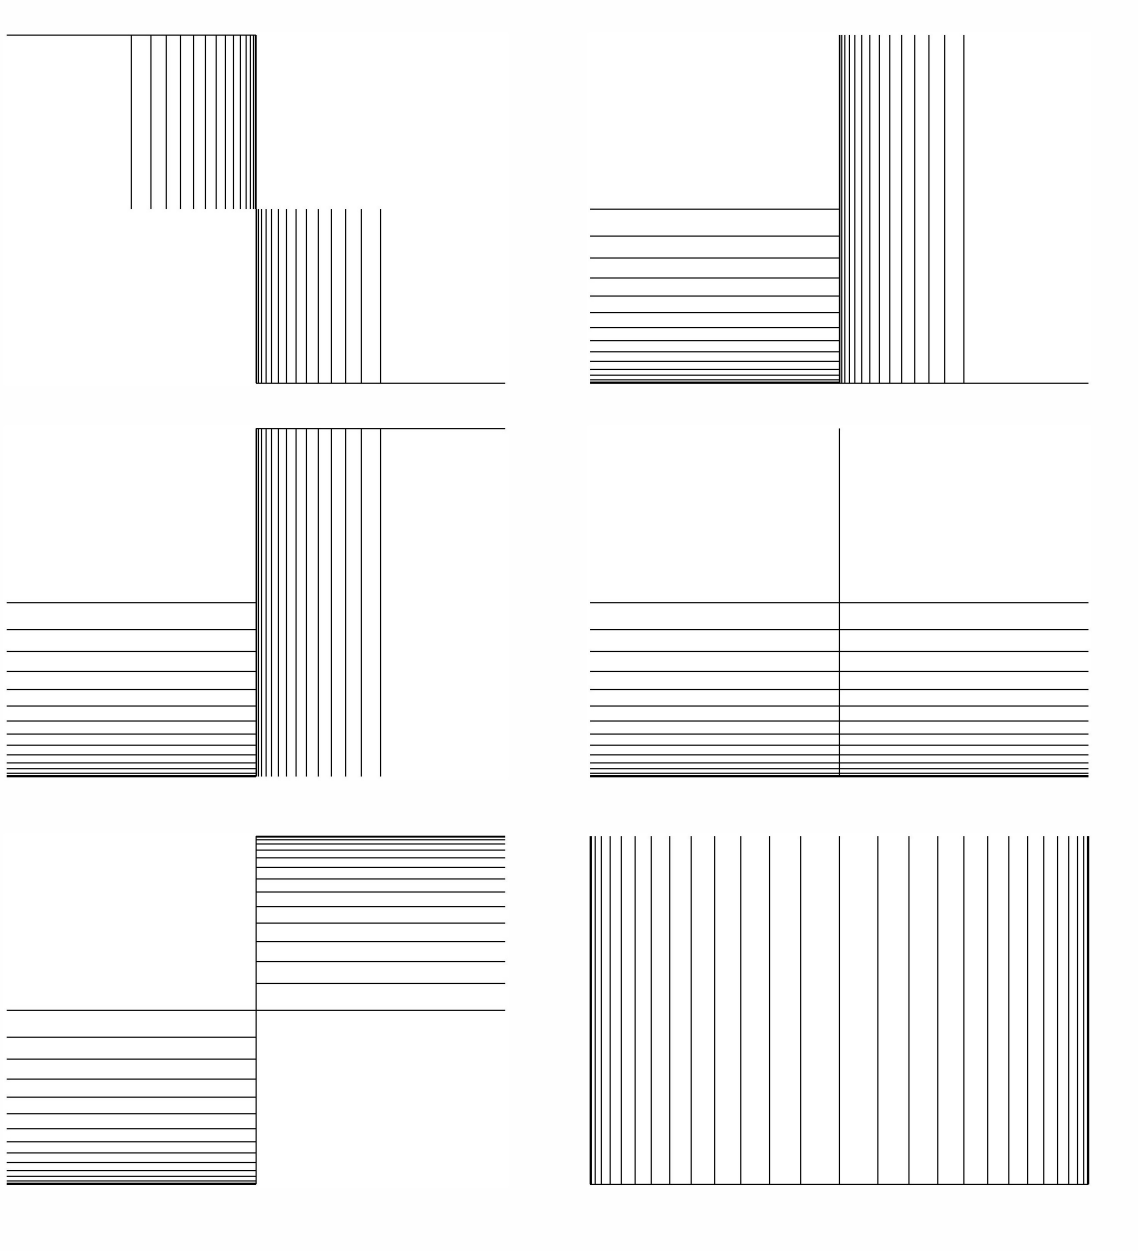

Figure XIII.67: Infinite Comb Variations II

XIII.19.6.16. The Infinite Ladder. A variation of the infinite comb is to add the horizontal segment from 0 to 1 with y-coordinate 1 (Figure XIII.68). This space is somewhat similar to the Hawaiian Earring, but with a crucial difference: show that the fundamental group is countable.

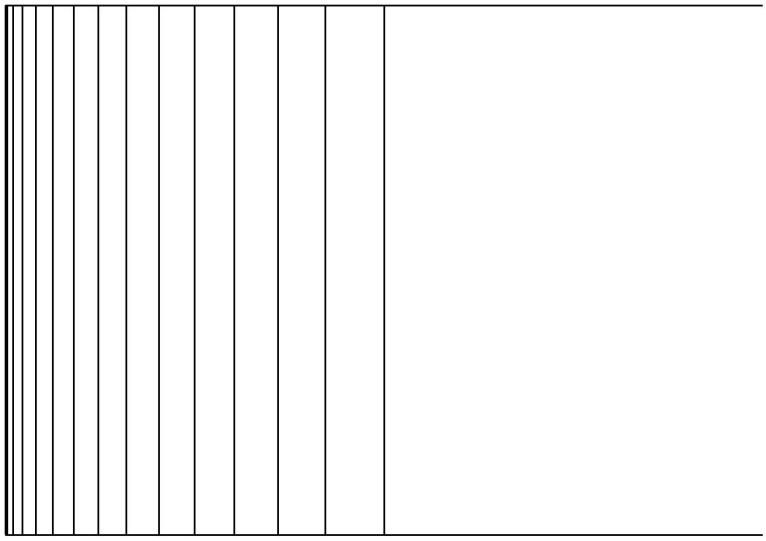

Figure XIII.68: The Infinite Ladder

XIII.20. Manifolds

There are two types of mathematical objects commonly called manifolds: *topological manifolds* and *differentiable*, or *smooth, manifolds* (there are also *PL manifolds*, which are something in between). There is also a notion of "manifold with boundary," both topological and smooth. The term "manifold" is also used in a few other related and even entirely unrelated senses in parts of mathematics. One must be aware of context whenever the term "manifold" is used. Smooth manifolds are special types of topological manifolds with specified extra structure (smooth manifolds come in a number of flavors). Both types of manifolds occur in analysis. In this section, we describe the basics of both theories; each theory is very extensive and goes far beyond what we do here.

XIII.20.1. Topological Manifolds

Topological manifolds are generalizations of curves and surfaces. The property of a curve or surface we use is that near each point, a small piece of the curve or surface looks like an open ball in Euclidean space (of dimension 1 or 2 respectively). Our generalization will allow for higher-dimensional objects also, and will be intrinsic, not requiring our space to be embedded in a Euclidean space.

XIII.20.1.1. Definition. A topological space X is *locally Euclidean* if every point $p \in X$ has an open neighborhood which is homeomorphic to an open ball in $\mathbb{R}^n$ for some $n \geq 0$ (which may vary from point to point), where $\mathbb{R}^0$ is a single point. Such a neighborhood is called a *coordinate patch* and a homeomorphism with an open ball in $\mathbb{R}^n$ is a *coordinate chart*, and the n is called the *local dimension* of X at p. X is *n-dimensional* if it is has the same local dimension n at every point.

Roughly speaking, a topological manifold will just be a topological space which is locally Euclidean. But it turns out we should make a few additional technical restrictions to rule out pathologies that can occur in bizarre examples.

XIII.20.1.2. Some initial remarks about the definition:

(i) The local dimension is well defined by the Invariance of Domain Theorem ().

(ii) All points within a coordinate patch have the same local dimension; thus the local dimension is locally constant (justifying the terminology "local dimension.") Hence the local dimension is constant on components of X (). In particular, a connected locally Euclidean space has the same local dimension at every point.

(iii) An n-dimensional metrizable locally Euclidean topological space has topological dimension n (), so the terminology "n-dimensional" is consistent. The topological dimension of a general metrizable locally Euclidean space is the maximum or supremum of the local dimensions at all points. (This can fail in the nonmetrizable case, cf. [Fed95].)

(iv) Since an open ball in $\mathbb{R}^n$ is first countable, even second countable, a locally Euclidean space is first countable. But it need not be second countable (XIII.20.1.9., XIII.20.5.5.). A locally Euclidean space is locally second countable (XIII.1.3.7.).

(v) Since open balls in $\mathbb{R}^n$ are locally compact, a (Hausdorff) locally Euclidean space is locally compact () and hence completely regular ().

(vi) Since an open ball in $\mathbb{R}^n$ is path-connected, a locally Euclidean space is locally path-connected; hence the components and path components coincide and are clopen sets ().

(vii) An open ball in $\mathbb{R}^n$ is homeomorphic to $\mathbb{R}^n$. Thus the definition can be equivalently rephrased: X is locally Euclidean if every point $p \in X$ has an open neighborhood which is homeomorphic to $\mathbb{R}^n$ for some n. This is the form given in many references. However, it seems preferable to write the definition as we have, since in most examples there are more natural homeomorphisms of point neighborhoods with open balls in $\mathbb{R}^n$ than with $\mathbb{R}^n$ itself. For example, it is immediate from our definition that any open set in $\mathbb{R}^n$ is locally Euclidean (in the relative topology).

(viii) Since an open ball in $\mathbb{R}^n$ is T_1 (even T_2), a locally Euclidean topological space is locally T_1 (even locally T_2), hence T_1 (XIII.7.3.5.). But it need not be Hausdorff (XIII.20.1.3.(v)). This is one of the pathologies we want to exclude in the definition of a topological manifold.

XIII.20.1.3. Examples. (i) Any open set in $\mathbb{R}^n$ is an n-dimensional locally Euclidean space with the relative topology.

(ii) A curve in $\mathbb{R}^n$ is a 1-dimensional locally Euclidean space (with the relative topology), provided it has no endpoints and does not cross or loop back onto itself (more precisely, if it is homeomorphic to an open interval or a circle, or a separated disjoint union of such curves). A simple curve (arc) with endpoints is an example of a manifold with boundary (). "Curves" such as a figure 8, a figure 6, or a "Warsaw circle" (XIII.19.5.6.) are not locally Euclidean and are not manifolds with boundary.

(iii) A surface in $\mathbb{R}^3$ is a 2-dimensional locally Euclidean space with the same restrictions as in (ii), which are more complicated to state precisely. Examples include a sphere, torus, a cylinder without its end circles, or a Möbius strip without its edge. A cylinder with end circles included, or a Möbius strip with its edge included, is a manifold with boundary.

(iv) The unit sphere in $\mathbb{R}^{n+1}$ is an n-dimensional locally Euclidean space for any n. The closed unit ball is not locally Euclidean, but is a manifold with boundary.

(v) A locally Euclidean space need not be Hausdorff. Here is the standard example. Let X be $\mathbb{R} \cup \{0'\}$, with the topology consisting of all open subsets of $\mathbb{R}$ and all sets consisting of $0'$ along with an open neighborhood or deleted open neighborhood of 0. Since $\mathbb{R}$ is an open subset of X, every point of $\mathbb{R}$ has a locally Euclidean neighborhood; and $0'$ does also, e.g. $\{0'\} \cup (\mathbb{R} \setminus \{0\})$. Thus X is locally Euclidean (and 1-dimensional). But 0 and $0'$ do not have disjoint neighborhoods. See Exercise XIII.20.5.15. for a more interesting example.

There are far more complicated examples; see Exercises XIII.20.5.5. and XIII.20.5.8..

XIII.20.1.4. Theorem. Let M be a topological space which is Hausdorff, locally compact, and locally second countable, in which every component is open (e.g. Hausdorff and locally Euclidean). The following are equivalent:

(i) M is paracompact.

(ii) M is metrizable.

(iii) Every component of M is Lindelöf.

(iv) Every component of M is σ-compact.

(v) Every component of M is second countable.

(vi) Every component of M is a Polish space.

The following are equivalent, and imply (i)–(vi):

(vii) M is Lindelöf.

(viii) M is σ-compact.

(ix) M is second countable.

(x) M is a Polish space.

If M satisfies (i)–(vi), then M satisfies (vii)–(x) if and only if M has only countably many components. In particular, if M is connected, then (i)–(x) are equivalent.

PROOF: Since the components of M are clopen (), obviously (vii)–(x) each imply that M has only countably components; and if M has only countably components, then (vii) $\iff$ (iii), (viii) $\iff$ (iv), (ix) $\iff$ (v), and (x) $\iff$ (vi). So we need only prove that (i)–(vi) are equivalent.

Since M is locally compact, (iii) $\iff$ (iv) by XIII.11.8.11., and by XIII.11.8.13., (v) and (vi) are equivalent and imply (iv) and that every component of M is metrizable. Since the components of M are clopen, M is metrizable if and only if each component is metrizable (), so (v) $\Rightarrow$ (ii). (ii) $\Rightarrow$ (i) by XIII.11.10.4.. M is paracompact if and only if each component of M is paracompact (XIII.11.10.10.), and if a component is paracompact it is σ-compact by XIII.11.10.20.. Thus (i) $\Rightarrow$ (iv). And since M is locally second countable, (iii) $\Rightarrow$ (v) by XIII.1.3.8.. 👍

XIII.20.1.5. There are connected Hausdorff locally Euclidean topological spaces not satisfying the conditions of Theorem XIII.20.1.4.. Such a space can be normal (Exercise XIII.20.5.5.) or nonnormal (Exercises XIII.20.5.8.–XIII.20.5.9.). Separability is also not equivalent to the conditions of the theorem; such examples can be separable (Exercise XIII.20.5.9.) or nonseparable (Exercises XIII.20.5.5. and XIII.20.5.8.). Conditions (vii)–(x) imply separability, and are equivalent to separability in the presence of (i)-(vi).

XIII.20.1.6. There is no universal consensus on the proper definition of a topological manifold. All of the following are reasonable candidates which have in fact all appeared in various references. They are arranged roughly, but not exactly, in increasingly restrictive order. Throughout, X denotes a topological space. ✋

(i) X is locally Euclidean.

(ii) X is Hausdorff and locally Euclidean.

(iii) X is Hausdorff, locally Euclidean, and satisfies conditions (i)–(vi) of XIII.20.1.4..

(iv) X is Hausdorff, locally Euclidean, and satisfies conditions (i)–(x) of XIII.20.1.4..

(i)′ X is locally Euclidean and has constant local dimension.

(ii)′ X is Hausdorff, locally Euclidean, and has constant local dimension.

(iii)′ X is Hausdorff, locally Euclidean, satisfies conditions (i)–(vi) of XIII.20.1.4., and has constant local dimension.

(iv)′ X is Hausdorff, locally Euclidean, satisfies conditions (i)–(x) of XIII.20.1.4., and has constant local dimension.

(i)″ X is connected and locally Euclidean.

(ii)″ X is Hausdorff, connected, and locally Euclidean.

(iii)″ X is Hausdorff, connected, locally Euclidean, and satisfies conditions (i)–(vi) of XIII.20.1.4..

(iv)″ X is Hausdorff, connected, locally Euclidean, and satisfies conditions (i)–(x) of XIII.20.1.4..

(Note that (iii)″ and (iv)″ are identical.)

We will take (iii) as our definition, which is probably the most common choice. Reasonable arguments can be made for all of the versions (although the arguments for (i)–(i)″ are weak; manifolds should at least be Hausdorff). Almost all spaces arising in practice which one would want to call manifolds satisfy (iv)″ or at least (iv)′. However, almost all properties of such spaces hold equally well for ones satisfying (iii), with identical proofs; practically all interesting things about manifolds happen separately in each component, so it doesn't really matter how many components there are as long as each individual component is well behaved. Definition (iii) can also be given very cleanly:

XIII.20.1.7. Definition. A topological space X is a *(topological) manifold* if it is metrizable and locally Euclidean.

A space satisfying (iv)″ is then just a connected manifold, one satisfying (iv) is a separable manifold, and one satisfying (iii)′ is an n-dimensional manifold (usually just called an n-manifold) for some n. It seems rather artificial to allow manifolds with nonconstant local dimension, and they rarely arise in practice; we can restrict to the constant local dimension case by just using the term "n-manifold".

XIII.20.1.8. A compact Hausdorff locally Euclidean space automatically satisfies (viii), hence (i)–(x), and in particular is a manifold.

XIII.20.1.9. The case $n = 0$ is allowed in the definition of a manifold. A 0-manifold is just a set with the discrete topology.

XIII.20.2. Topological Manifolds With Boundary

We would like to extend the notion of manifold to include such examples as curves with endpoints, surfaces with boundary curves, and closed balls in $\mathbb{R}^n$. These will be examples of "manifolds with boundary."

The basic tool is the notion of a half-space:

XIII.20.2.1. Definition. The *n-dimensional half-space* ($n \geq 1$) is the subset

$$\mathbb{H}^n = \{(x_1, \ldots, x_n) \in \mathbb{R}^n : x_n \geq 0\}$$

with the relative topology from $\mathbb{R}^n$. Its boundary $\partial\mathbb{H}^n$ is the set of n-tuples with last coordinate zero. We also define $\mathbb{H}^0$ to be a single point, with $\partial\mathbb{H}^0 = \emptyset$.

XIII.20.2.2. DEFINITION. A *(topological) manifold with boundary* is a metrizable space X in which every point has an open neighborhood homeomorphic to an open set in $\mathbb{H}^n$ for some $n \geq 0$ (which may vary from point to point.) Such an open set is called a *coordinate patch*, and the homeomorphism is called a *coordinate chart*. If the n is constant, X is called an *n-manifold with boundary*. A point of X with a neighborhood homeomorphic to $\mathbb{R}^n$ (or to an open set in $\mathbb{R}^n$) is called an *interior point* of X, and a point which maps to a point in $\partial\mathbb{H}^n$ under a coordinate chart is called a *boundary point* of X. Denote by ∂X the set of boundary points of X, called the *boundary* of X.

Note that the use of "interior point" and "boundary point" here is not the same as the general use in topology: such points may not be interior or boundary points respectively in the topological sense. Indeed, since a manifold with boundary is not naturally embedded as a subset of a larger topological space, topological interior and boundary do not really even make sense.

XIII.20.2.3. Just as with manifolds, manifolds with boundary are locally compact and locally path-connected, and the components and path components coincide and are clopen subsets. Each component is second countable and σ-compact, and a Polish space.

XIII.20.2.4. EXAMPLES. (i) $\mathbb{H}^n$ is an n-manifold with boundary. The boundary points are the points of $\partial\mathbb{H}^n$.

(ii) Any (topological) manifold X is a manifold with boundary, with $\partial X = \emptyset$. (So the term "manifold with boundary" does not imply that the boundary is nonempty.)

(iii) Since $\mathbb{H}^1$ is a ray, a closed or half-open interval I in $\mathbb{R}$ is a 1-manifold with boundary ∂I consisting of the endpoint(s). In fact, a complete list (up to homeomorphism) of connected 1-manifolds with boundary is: an open interval, a half-open interval, a closed interval, and a circle.

(iv) A closed disk D in $\mathbb{R}^2$ is a 2-manifold with boundary, with ∂D the boundary circle. More generally, a closed ball in $\mathbb{R}^n$ is an n-manifold with boundary.

(v) A Möbius strip M is a 2-manifold with boundary, with ∂M a circle.

(vi) A figure 8 or figure 6 is not a manifold with boundary, since in each case there is one point which does not have any neighborhood homeomorphic to an open set in $\mathbb{H}^1$ (or $\mathbb{H}^n$ for any n).

(vii) An open disk with a relatively open subset of the bounding circle added (i.e. a relatively open subset of a closed disk) is a manifold with boundary; more generally, an open subset of any manifold with boundary is a manifold with boundary. But an open disk with a subset of the bounding circle added which is not relatively open is not a manifold with boundary, although this is not entirely obvious.

The next result may seem obvious, but a rigorous proof is rather involved on one point.

XIII.20.2.5. THEOREM. Let X be an n-manifold with boundary. Then

(i) The interior and the boundary of X are disjoint. ∂X is closed in X, and the set of interior points is dense and open.

(ii) The interior of X is an n-manifold, and ∂X (if nonempty) is an $(n-1)$-manifold.

It is obvious that the set of interior points is dense and open, and that the interior is an n-manifold. (Under any coordinate chart, points going to a point of $\mathbb{H}^n \setminus \partial\mathbb{H}^n$ are interior points.) The issue in proving

that the interior and boundary are disjoint is to show that a point of $\partial\mathbb{H}^n$ does not have an open neighborhood in $\mathbb{H}^n$ homeomorphic to an open set in $\mathbb{R}^n$ (or in $\mathbb{R}^m$ for any m). This is nontrivial to prove directly, but is an immediate consequence of the Invariance of Domain Theorem (). The simplest direct proof, which uses some algebraic topology, is that a point of $\partial\mathbb{H}^n$ has a deleted neighborhood in $\mathbb{H}^n$ which is contractible, while no point of $\mathbb{R}^n$ has a contractible deleted neighborhood. It follows from the disjointness that ∂X is closed. Showing that ∂X is an $(n-1)$-manifold is straightforward, since the points of ∂X in a coordinate patch around a point of ∂X form a set homeomorphic to a relatively open set in $\partial\mathbb{H}^n$, which is homeomorphic to $\mathbb{R}^{n-1}$.

XIII.20.2.6. Convention: In geometry/topology, the term "manifold" is often used to mean "manifold with boundary" (with, of course, the possibility that the boundary is empty). In particular, the term "compact manifold" normally means "manifold with boundary which is compact" (i.e. the whole space is compact, not just the boundary). To refer to a manifold in the sense of XIII.20.1.7. which is compact, the term *closed manifold* (which has no real logical meaning) is normally used. The term *open manifold* is also sometimes used to mean a manifold which is noncompact and has empty boundary. The same conventions are used for smooth manifolds.

In some references, a manifold with empty boundary is called *unbounded*. However, this term seems much too fraught with potential misinterpretation to be appropriate, especially in an analysis book. I also have a very hard time calling a circle or sphere "unbounded."

In this book, we will strive for minimum ambiguity at the possible cost of excessive pedantry on these terms: we will always use the phrase "manifold with boundary" when a boundary is allowed, and we will avoid using "compact manifold", writing "compact manifold with boundary" if a boundary is allowed and "closed manifold" otherwise. (There is still some ambiguity: is a "closed submanifold" of a manifold a submanifold which is a closed subset of the manifold, or a submanifold which is compact? We will be explicit about which is meant when this occurs.) And we will not use the term "unbounded" in the context of manifolds, except when they are explicit subsets of Euclidean space, where the term "unbounded" has its usual meaning for subsets (i.e. not contained in a ball of finite radius). We will avoid the term "open manifold."

XIII.20.3. New Manifolds From Old

XIII.20.4. Classification of Topological Manifolds

Number of Manifolds

XIII.20.4.1. How many topologically distinct topological manifolds (with or without boundary) are there? Since according to our definition any discrete space is a manifold, the question is meaningless; we should restrict to connected manifolds, or at least to manifolds with only countably many components, i.e. separable manifolds.

Any separable manifold with boundary is a Polish space, and there are $2^{\aleph_0}$ topologically distinct Polish spaces (), so there are at most $2^{\aleph_0}$ topologically distinct separable manifolds with boundary. On the other hand, if $n > 1$ there are $2^{\aleph_0}$ topologically distinct connected open subsets of $\mathbb{R}^n$ (XIII.20.5.14.), each of which is a separable connected n-manifold, so up to homeomorphism there are exactly $2^{\aleph_0}$ separable manifolds, and exactly $2^{\aleph_0}$ separable manifolds with boundary. The same is true if "separable" is replaced by "connected."

There are $2^{2^{\aleph_0}}$ topologically distinct 2-dimensional connected Hausdorff locally Euclidean spaces, both with and without boundary (Exercise XIII.20.5.10.).

The question is more interesting and difficult in the compact case (a compact manifold with boundary is automatically separable). In fact:

XIII.20.4.2. THEOREM. There are only countably many homeomorphism classes of compact manifolds with boundary.

For each $n > 1$, there are infinitely many topologically distinct connected closed n-manifolds (). See [CK70] for a proof of XIII.20.4.2..

XIII.20.5. Exercises

XIII.20.5.1. (a) Show that an open set in a locally Euclidean space is locally Euclidean in the relative topology. Show that an open set in a topological manifold is a topological manifold in the relative topology.

(b) Show that a finite cartesian product of locally Euclidean spaces is locally Euclidean. Show that a finite cartesian product of topological manifolds is a topological manifold. What about products of topological manifolds with boundary? [Consider $\mathbb{H}^n \times \mathbb{H}^m$.]

XIII.20.5.2. Let X be a locally Euclidean space, and U and V open subsets of X. Suppose ϕ is a homeomorphism from U to V. Let X/ϕ be the topological space obtained from X by identifying U and V via ϕ, with the quotient topology.

(a) Show that X/ϕ is locally Euclidean.

(b) Show that the example of XIII.20.1.3.(v) is obtained this way by letting X be two disjoint copies of $\mathbb{R}$ and U and V the two copies of $\mathbb{R} \setminus \{0\}$.

(c) Under what conditions will X/ϕ be Hausdorff?

(d) Construct a circle from $\mathbb{R}$ by this method, and a Möbius strip from $\mathbb{R}^2$.

(e) Generalize to a family of open subsets $\{U_i : i \in I\}$, with specified homeomorphisms ϕ_i of U_i with a fixed space U_0.

XIII.20.5.3. Let X and Y be topological manifolds with boundary. Let ϕ be a homeomorphism from ∂X to ∂Y (existence of such a ϕ entails that X and Y have the same dimension, at least locally), and $X \cup_\phi Y$ the topological space obtained from the disjoint union of X and Y by identifying ∂X and ∂Y by ϕ. (We say X and Y are *glued* along the boundary via ϕ).

(a) Show that $X \cup_\phi Y$ is a topological manifold.

(b) What manifold results from gluing two disks along the boundary, which is a circle? What if one or both disks are replaced by a Möbius strip, whose boundary is also a circle?

(c) The boundary of a cylinder is two disjoint circles. What if two cylinders are glued together along the boundary circles? Does the resulting manifold depend on the homeomorphisms chosen?

(d) Show that if X and Y are smooth manifolds with boundary, and ϕ is a diffeomorphism, then $X \cup_\phi Y$ is a smooth manifold.

XIII.20.5.4. Show that $[0,1) \times (0,1)$, $[0,1) \times [0,1)$, $[0,1) \times [0,1]$, and a closed disk with a single boundary point removed are all homeomorphic to $\mathbb{H}^2$ and hence are topological 2-manifolds with boundary.

XIII.20.5.5. The Long Line. Denote by ω_1 the ordered set of ordinals less than the first uncountable ordinal (). Give $L_0 := \omega_1 \times [0,1)$ the lexicographic ordering, and the order topology (). L_0 is called the *long ray*.

(a) If $a, b \in L_0$, $a < b$, then the interval $[a,b]$ is homeomorphic to a closed bounded interval in $\mathbb{R}$. [Use the fact that any countable successor ordinal is order-isomorphic to a closed subset of $[0,1]$ ().] Hence the open interval (a,b) is homeomorphic to $\mathbb{R}$. Show that L_0 is order-complete and that it has no countable cofinal subset. Show that L_0 is countably compact and sequentially compact, and that every real-valued continuous function on L_0 is eventually constant.

(b) L_0 is not locally Euclidean since it has an endpoint (smallest point). If this is removed, a 1-dimensional locally Euclidean space L_+ is obtained which is called the *open long ray* or *half-long line*. L_+ is normal, even completely normal (and in particular Hausdorff), as is any space with the order topology (XIII.16.1.1.), and is connected since it is order-complete. L_+ has a countable coinitial set but no countable cofinal set.

(c) Show that the open cover $\{(a,b) : a, b \in L_+, a < b\}$ of L_0 has no locally finite refinement. Thus L_+ is not paracompact. Show directly that L_+ does not satisfy any of the other conditions of XIII.20.1.4.. L_+ is also not separable. L_+ is not countably compact or sequentially compact.

(d) Let $-L_0$ be a copy of L_0 with ordering reversed, and L be the union of $-L_0$ and L_0 with the endpoint of $-L_0$ identified with the initial point of L_0, with the order topology (the points of $-L_0$ smaller than the points of L_0). Then L is a 1-dimensional locally Euclidean space which is connected and normal, with neither a countable coinitial set nor a countable cofinal set, does not satisfy any of the conditions of XIII.20.1.4., and is not separable. L is called the *long line*. If $a, b \in L$, $a < b$, then the subset $[a,b]$ of L is homeomorphic to $[0,1]$, and (a,b) is homeomorphic to $\mathbb{R}$. Show that L is countably compact and sequentially compact, and that every real-valued continuous function on L is eventually constant in each direction.

Note that terminology in references is inconsistent: some authors call L_0 or L_+ the "long line."

(e) Show that L, L_+, and L_0 are not contractible.

(f) Show that if M is a connected 1-dimensional Hausdorff locally Euclidean space, then M is homeomorphic to exactly one of the following: $\mathbb{R}$, L, L_+, or a circle S^1.

XIII.20.5.6. Let L and L_0 be as in XIII.20.5.5.. Show that the Stone-Čech compactification () of L_0 coincides with the one-point compactification (). Show that the Stone-Čech compactification of L consists of adding two points to L, one at each "end."

XIII.20.5.7. [**?**, Appendix A] Consider the following Cartesian products of the spaces from XIII.20.5.5.(f):

$L \times L$, the *big plane.*

$L \times L_+$, the *big half-plane.*

$L_+ \times L_+$, the *big quadrant.*

$L \times \mathbb{R}$, the *wide plane* or *long strip.*

$L_+ \times \mathbb{R}$, the *half-long strip.*

$L \times S^1$, the *long cylinder.*

$L_+ \times S^1$, the *half-long cylinder.*

(a) Show that each is a connected 2-dimensional Hausdorff locally Euclidean space not satisfying the conditions of XIII.20.1.4..

(b) There are four obvious copies of L in $L \times L$, the "x-axis", the "y-axis", and the "diagonals." Show that the diagonals are embedded differently than the axes. [Show that any copy of ω_1 in $L \times L$ which hits the x-axis in uncountably many points has only countably many points off the x-axis, but this is false for the diagonals.] The same is true in $L_0 \times L_0$, where L_0 is the long ray (there is only one diagonal here). Use this to show that that no two of the above spaces are homeomorphic (it is hardest to distinguish between the big half-plane, the big quadrant, and the half-long strip; cf. XIII.20.5.4.). [For another approach, use (e).]

(c) Identify the initial circle of $L_0 \times S^1$ to a point. Show that a sequentially compact connected 2-dimensional Hausdorff locally Euclidean space is obtained not satisfying the conditions of XIII.20.1.4., sometimes called the *big disk*. Show that the big disk is not homeomorphic to any of the spaces of (a) (it is hardest to distinguish it from the big plane).

(d) Let E be the "octant" $\{(x, y) \in L_0 \times L_0 : y \leq x\}$. E has two edges, the x-axis A and the diagonal D. Let σ be a finite or infinite sequence of A's and D's. Let M_σ be the space obtained from the finite disjoint union of E's, the same number as the number of terms in σ, by taking the n'th term of σ as the first edge of the n'th copy of E and the other edge as the second edge, and identifying the first edge of the $(n+1)$'st copy of E with the second edge of the n'th copy. Then delete the first edge of the first copy of E and, if σ is finite, the second edge of the last copy. As a variation if σ is finite, identify the second edge of the last copy of E with the initial edge of the first copy to obtain a space M'_σ. All these spaces are connected 2-dimensional locally Euclidean Hausdorff spaces, and the M'_σ are sequentially compact. Show that all M_σ and M'_σ are mutually nonhomeomorphic, except that if σ is finite, σ can be replaced by its complementary sequence obtained by interchanging A's and D's and reversing order, and in the case of M'_σ, σ can be cyclically permuted. We have:

> The big plane is M'_σ, where $\sigma = (A, D, A, D, A, D, A, D)$ or (D, A, D, A, D, A, D, A).
>
> The big half-plane is M_σ, where $\sigma = (A, D, A, D)$.
>
> The big quadrant is M_σ, where $\sigma = (A, D)$.

The big disk can be regarded as M'_σ, where σ is the empty sequence. The "open octant" is the space M_σ, where $\sigma = (A)$ or (D). The M'_σ construction works even for infinite sequences, even (countably) transfinitely [Nyi84].

(e) Describe the Stone-Čech compactification of each of the above spaces.

XIII.20.5.8. The Prüfer Manifold. This is an example of a 2-dimensional connected locally Euclidean space not satisfying the conditions of XIII.20.1.4..

This space was first described by T. Radó in 1925 [], and credited to his teacher, H. Prüfer. We describe a version of the construction from [**?**]; see also [**?**, Appendix A]. There are actually two rather different spaces constructed this way; only the first, described in this problem, is called the "Prüfer manifold," and the second, described in Exercise XIII.20.5.9., is a variation of a space (called the *Moore manifold*) constructed by R. L. Moore []. See [Roy88, p. 208-209] for a description of Moore's construction. To add to the terminological confusion, all these spaces are examples of a class of spaces called *Moore spaces*. A variation of the Prüfer manifold is described in [CV98, p. 268-272].

Although these examples are customarily called "manifolds", they are not manifolds according to the definition in this book since they are not metrizable (in fact, not even normal).

Begin with an uncountable collection $\{\mathbb{R}^2_a : a \in \mathbb{R}\}$ of copies of the plane, and an additional copy $\mathbb{R}^2_+$ of the open upper half plane. Take the separated union U of the $\mathbb{R}^2_a$ and $\mathbb{R}^2_+$; then U is a 2-manifold. Identify the open upper half plane of each $\mathbb{R}^2_a$ with $\mathbb{R}^2_+$ by

$$(x, y) \in \mathbb{R}^2_a \ (y > 0) \iff (xy + a, y) \in \mathbb{R}^2_+$$

and let P be the quotient space. P is called the *Prüfer manifold*.

(a) Show that P is a connected 2-dimensional locally Euclidean space (cf. Exercise XIII.20.5.2.(a)).

(b) Show that P is Hausdorff (cf. Exercise XIII.20.5.2.(c)).

(c) Let Z be the union of the copies of the x-axis in $\mathbb{R}^2_a$ for all a. Show that in the relative topology Z is a separated union of uncountably many copies of $\mathbb{R}$: the x-axis of each $\mathbb{R}^2_a$ is clopen in Z. Thus Z and hence P is not second countable, so P does not satisfy the conditions of XIII.20.1.4..

(d) Let A be the subset of Z consisting of the points on the x-axis of $\mathbb{R}^2_a$ for a rational, and $B = Z \setminus A$ the set of points on the x-axis of $\mathbb{R}^2_a$ for a irrational. Then A and B are disjoint closed subsets of P. Use the Baire Category Theorem () to prove that A and B do not have disjoint neighborhoods in P. Thus P is not normal.

(e) Show that P is not separable. [Consider points in the open lower half-spaces of the $\mathbb{R}^2_a$.]

(f) Show that P is contractible (cf. [**?**, Appendix A]).

XIII.20.5.9. This problem is a continuation of XIII.20.5.8..

(a) Let P_0 be the union of Z and the upper half plane of P (i.e. the image of $\mathbb{R}^2_+$ in P). Then P_0 is a "2-dimensional locally Euclidean space with boundary." P_0 is connected and separable since $\mathbb{R}^2_+$ is dense in P_0, but $\partial P_0 = Z$ consists of a separated union of uncountably many copies of $\mathbb{R}$.

(b) Let Q be obtained by gluing two copies of P_0 along the boundary. Then Q is a 2-dimensional connected Hausdorff locally Euclidean space which is separable but does not satisfy the conditions of XIII.20.1.4..

(c) Q can alternately be constructed from P by identifying for each a the open lower half plane of $\mathbb{R}^2_a$ with a new copy $\mathbb{R}^2_-$ of the open lower half plane by

$$(x, y) \in \mathbb{R}^2_a \ (y < 0) \iff (xy + a, y) \in \mathbb{R}^2_-$$

and taking the quotient topology.

(d) The closed subsets A and B of Z in XIII.20.5.8.(d) also do not have disjoint neighborhoods in Q, so Q is not normal.

(e) Q is not simply connected: the fundamental group of Q is quite complicated (uncountable).

(f) Another example can be constructed from P_0 by identifying, for each a, the positive and negative x-axes of $\mathbb{R}^2_a$ by folding over at 0. A separable locally Euclidean space M is obtained. This is the *Moore manifold*. The Moore manifold is contractible (), hence simply connected.

XIII.20.5.10. If $A \subseteq \mathbb{R}$, modify the construction of P, P_0, Q, and M by attaching $\mathbb{R}^2_a$ if and only if $a \in A$. Call the resulting spaces P_A, P^0_A, Q_A, M_A.

(a) Show that if A is countable, P_A and M_A are homeomorphic to $\mathbb{R}^2$. If $card(A) = n$, $1 \leq n \leq \aleph_0$, Q_A is homeomorphic to a plane with a discrete set of points of cardinality $n - 1$ removed (where $\aleph_0 - 1 = \aleph_0$).

(b) [Bla] Show that if A is a subset of $\mathbb{R}$, there at most $2^{\aleph_0}$ subsets B of $\mathbb{R}$ such that the spaces P_A^0 and P_B^0 are homeomorphic. [Regard all the P_B^0 as subsets of P_0. A homeomorphism from P_A^0 to P_B^0 can be regarded as a continuous function from P_A^0 to P_0. But since P_A^0 is separable and P_0 has cardinality $2^{\aleph_0}$, there are only $2^{\aleph_0}$ continuous functions from P_A^0 to P_0. cf. XIII.19.5.45..] So there are $2^{2^{\aleph_0}}$ topologically distinct P_A^0. Show similarly that there are $2^{2^{\aleph_0}}$ topologically distinct M_A. The P_A^0 and M_A are all separable and contractible. There are also $2^{2^{\aleph_0}}$ topologically distinct P_A and Q_A. The M_A and P_A constructions can be combined into a unified family.

A family of $2^{2^{\aleph_0}}$ mutually nonhomeomorphic simply connected 2-dimensional Hausdorff locally Euclidean spaces, as well as a family of $2^{\aleph_1}$ mutually nonhomeomorphic sequentially compact simply connected 2-dimensional Hausdorff locally Euclidean spaces (the maximum number possible), is constructed in [Nyi84], which is a thorough study of nonmetrizable "manifolds." However, these examples are not separable or contractible.

XIII.20.5.11. (a) A compact Hausdorff locally Euclidean space is metrizable, hence a manifold (XIII.20.1.4.).

(b) If X is Hausdorff and locally Euclidean, it is locally compact, hence has a one-point compactification $X^\dagger$. If X is nonmetrizable, then $X^\dagger$ is not locally Euclidean at infinity, and hence the point at infinity is topologically different from all other points. (Actually $X^\dagger$ is rarely locally Euclidean at infinity even if X is metrizable, hence a manifold.)

(c) If X and Y are nonmetrizable Hausdorff locally Euclidean spaces and $X^\dagger$ and $Y^\dagger$ are homeomorphic, then X and Y are homeomorphic.

(d) For $A \subseteq \mathbb{R}$, let M_A be the space of XIII.20.5.10.. Then there are $2^{2^{\aleph_0}}$ topologically distinct spaces among the $(M_A)^\dagger$. Each of these is a separable connected (even path-connected) compact Hausdorff space.

XIII.20.5.12. ([Kne60]; cf. [Spi79, p. 643]) Construct a three-dimensional version of Q by taking a copy $\mathbb{R}^3_a$ for each $a \in \mathbb{R}$, and identifying $(x, y, z) \in \mathbb{R}^3_a$, $y \neq 0$, with the point in a fixed copy of $\mathbb{R}^3$ with coordinates $(a + yx, y, z + a)$ if $y > 0$ and $(a + yx, y, z - a)$ if $y < 0$.

(a) Show that the quotient Q^3 is a connected separable Hausdorff locally Euclidean space with local dimension 3.

(b) Show that the surfaces $z = c$ give a foliation () of Q^3 with only one leaf, which is two-dimensional. Thus there is a stronger topology on Q^3 under which it is a connected Hausdorff locally Euclidean space of local dimension 2 (not separable).

(c) For an arbitrary subset A of $\mathbb{R}$, similarly construct Q^3_A. Show there are $2^{2^{\aleph_0}}$ distinct homeomorphism classes. Describe Q^3_A if A is finite or countable. There is still a similar foliation of Q^3_A, but it has multiple leaves in general.

XIII.20.5.13. [Spi79, Problem A-8] Show that a connected Hausdorff locally Euclidean space which is not a single point has cardinality $2^{\aleph_0}$.

XIII.20.5.14. [Spi79, Problem 1-24] (a) Let X and Y be totally disconnected closed subsets of $\mathbb{R}^2$. Show that if $\mathbb{R}^2 \setminus X$ and $\mathbb{R}^2 \setminus Y$ are homeomorphic, then X and Y are homeomorphic. [See XIII.19.6.3..]

(b) Conclude from XIII.19.5.4. that there are $2^{\aleph_0}$ topologically distinct connected open subsets of $\mathbb{R}^2$. [Note that if A is any proper subset of the x-axis in $\mathbb{R}^2$, then $\mathbb{R}^2 \setminus A$ is path-connected.]

(c) There are also $2^{\aleph_0}$ topologically distinct connected relatively open subsets of the closed unit disk in $\mathbb{R}^2$, each containing the entire boundary circle.

(d) Show that these spaces remain topologically distinct even if the Cartesian product with $\mathbb{R}^m$ for any m is taken. Thus there are $2^{\aleph_0}$ topologically distinct connected open sets in $\mathbb{R}^n$ for any $n > 1$; in fact, see XIII.19.6.6.–XIII.19.6.8.(h). (There is only one nonempty connected open set in $\mathbb{R}$ up to homeomorphism, and only countably many open sets in $\mathbb{R}$ in all up to homeomorphism, since every open set is a countable disjoint union of open intervals ().)

XIII.20.5.15. [Hat02, 1.3.25] **An Interesting Non-Hausdorff Locally Euclidean Space.** Let T be the invertible linear transformation on $\mathbb{R}^2$ given by $T(x, y) = (2x, y/2)$. Define an equivalence relation on $E = \mathbb{R}^2 \setminus \{0\}$ by $\boldsymbol{v} \sim \boldsymbol{w}$ if $T^n \boldsymbol{v} = \boldsymbol{w}$ for some $n \in \mathbb{Z}$. Let M be the quotient of E by this equivalence relation, and $\pi : E \to M$ the quotient map.

(a) Show that each equivalence class is closed and discrete in E, and that M is T_1 and second countable.

(b) Show that M is the disjoint union of four cylinders C_1, C_2, C_3, C_4, each homeomorphic to $S^1 \times \mathbb{R}_+$, where C_j is the image of the open j'th quadrant in E, and four circles X_+, X_-, Y_+, Y_-, where X_+ is the image of the positive x-axis, X_- the image of the negative x-axis, and $Y_\pm$ the images of the positive and negative y-axis. $C_1 - C_4$ are open in M and $X_\pm, Y_\pm$ are closed in M. The "horizontal" circle in C_j at height $|r|$ is the image of the part of the hyperbola $xy = r$ in the j'th quadrant.

(c) The set $\{(x, y) : 1 \leq x < 2\}$ maps one-one onto $C_1 \cup X_+ \cup C_4$ under π, and the image in M is open and homeomorphic to $S^1 \times \mathbb{R}$. Similarly, $\{(x, y) : -2 \leq x < -1\}$ maps one-one onto $C_2 \cup X_- \cup C_3$, $\{(x, y) : 1 \leq y < 2\}$ maps one-one onto $C_1 \cup Y_+ \cup C_2$ and $\{(x, y) : -2 \leq y < -1\}$ maps one-one onto $C_3 \cup Y_- \cup C_4$. These cylinders are open in M. Conclude that M is locally Euclidean.

(d) The closure of C_1 is $C_1 \cup X_+ \cup Y_+$. Show that if $p \in X_+$ and $q \in Y_+$, then p and q do not have disjoint neighborhoods. Thus M is not Hausdorff. Similarly, points in $X_\pm$ and $Y_\pm$ do not have disjoint neighborhoods. (However, X_+ and X_- have disjoint neighborhoods, as do Y_+ and Y_-.) Describe the closure of $C_2 - C_4$.

(d) Let S be the image of a vertical line segment $\{(x, y) : x = x_0, 0 < y \leq y_0\}$. Show that the closure of S consists of S, one point of X_+, and all of Y_+. Find a sequence in S which converges to a point in X_+ and has every point of Y_+ as a cluster point, and a subsequence which converges to any arbitrarily given point of Y_+. Do the same for other vertical and horizontal line segments.

(e) Show that π is a covering map () from E to M.

(f) Let N be the space obtained from M by additionally identifying diametrically opposed points of E (N is the quotient of E by the action of the subgroup G of $SL_2(\mathbb{R})$ generated by T and $-I$, which is isomorphic to $\mathbb{Z} \times \mathbb{Z}_2$). Then N consists of two open cylinders C_+ (the image of C_1 and C_3) and C_- (the image of C_2 and C_4), and two closed circles X (the image of X_+ and X_-) and Y (the image of Y_+ and Y_-). $C_+ \cup X \cup C_-$ and $C_+ \cup Y \cup C_-$ are open subsets of N homeomorphic to $S^1 \times \mathbb{R}$; thus N is a cylinder $S^1 \times \mathbb{R}$ with the circle $S^1 \times \{0\}$ "doubled." If C_+ is identified with $S^1 \times \mathbb{R}_+$ by taking the images of the hyperbolas $xy = r$ as horizontal circles and images of rays from the origin as vertical lines (one only needs rays of slope between $1/2$ and 2), then points of X are obtained by approaching 0 along the image of a vertical ray in the right half-plane, i.e. a line spiraling around the cylinder at a certain rate, and points of Y are obtained by approaching along the image of a horizontal ray, i.e. a line spiraling around the cylinder at the same rate but in the opposite direction. The quotient map from E to N is also a covering map, i.e. G acts properly discontinuously on E ().

XIII.20.5.16. Show that a metrizable topological space X is a manifold with boundary if and only if every point of X has a closed neighborhood homeomorphic to a closed ball in a Euclidean space.

XIII.21. The Brouwer Fixed-Point Theorem

The Brouwer Fixed-Point Theorem, in its various equivalent formulations, is arguably the most important fact about the topology of Euclidean space (although the Heine-Borel Theorem () is arguably more fundamental), and indeed one of the most important results in all of topology. It essentially makes possible notions of "higher-order connectedness." Among other things, the entire subject of algebraic topology is at least implicitly based on this result. A coherent theory of dimension for topological spaces, and many applications in analysis, also depend on this theorem.

XIII.21.1. Statements of the Results

XIII.21.1.1. We use the following notation. Let B^n be the closed unit ball and S^{n-1} the closed unit sphere in $\mathbb{R}^n$, i.e.

$$B^n = \{\boldsymbol{x} \in \mathbb{R}^n : \|\boldsymbol{x}\| \leq 1\}$$
$$S^{n-1} = \{\boldsymbol{x} \in \mathbb{R}^n : \|\boldsymbol{x}\| = 1\} \ .$$

In writing these, we implicitly assume $n \in \mathbb{N}$ (although they also make sense if $n = 0$: B^0 is a single point and $S^{-1} = \emptyset$). The term "map" will mean "continuous function."

XIII.21.1.2. Theorem. [Brouwer Fixed-Point Theorem] Every continuous function $f : B^n \to B^n$ has a fixed point, i.e. there is a point $\boldsymbol{x} \in B^n$ with $f(\boldsymbol{x}) = \boldsymbol{x}$.

XIII.21.1.3. Theorem. [No-Retraction Theorem] There is no retraction from B^n to S^{n-1}.

XIII.21.1.4. Theorem. [No-Contraction Theorem] The sphere S^{n-1} is not contractible, i.e. the identity map on S^{n-1} is not homotopic to a constant map.

XIII.21.1.5. We will show by elementary arguments that these three statements are equivalent. Thus to prove all the theorems it suffices to prove any one of them. We will also obtain some additional equivalent formulations of the theorem.

XIII.21.1.6. If $n = 1$, the statements are quite simple. $B^1 = [-1, 1]$ and $S^0 = \{-1, 1\}$. Thus the Brouwer Fixed-Point Theorem for $n = 1$ is (), essentially the Intermediate Value Theorem of calculus. The No-Retraction Theorem is also the Intermediate Value Theorem, or the fact that a connected space cannot be mapped continuously onto a disconnected space. The No-Contraction Theorem is obvious, since S^0 is not even connected (cf. ()).

If $n = 2$, the statements are also fairly elementary to prove; see XIII.21.2.. But if $n \geq 3$, all (known) proofs are fairly involved and/or use considerable machinery of some sort. There are many quite varied proofs known, and which one is the "best" is a quite subjective matter.

To prove that XIII.21.1.2.–XIII.21.1.4. are equivalent, it is convenient to show the negations of the statements are equivalent (although this seems a little perverse, since the ultimate result is that these statements are all false):

XIII.21.1.7. THEOREM. Let $n \in \mathbb{N}$. The following statements are equivalent:

(i) There is a continuous function $f : B^n \to B^n$ with no fixed point.

(ii) There is a retraction $r : B^n \to S^{n-1}$.

(iii) S^{n-1} is contractible.

XIII.21.1.8. To prove (ii) $\Rightarrow$ (iii), note that there is a contraction of B^n. The simplest one is given by the function $g(t, \boldsymbol{x}) = t\boldsymbol{x}$ for $0 \leq t \leq 1$, $\boldsymbol{x} \in B^n$. If there were a retraction $r : B^n \to S^{n-1}$, the function $h(t, \boldsymbol{x}) = r(t\boldsymbol{x})$ $(0 \leq t \leq 1,\ \boldsymbol{x} \in S^{n-1})$ would give a contraction of S^{n-1} (to the point $\boldsymbol{x}_0 = r(\mathbf{0})$). [Note that essentially the same argument shows that if X is a contractible space and r is a retraction of X onto a subspace Y, then Y is also contractible.]

XIII.21.1.9. For the converse (iii) $\Rightarrow$ (ii), suppose $h : [0, 1] \times S^{n-1} \to S^{n-1}$ is a contraction of S^{n-1} with $h(1, \boldsymbol{x}) = \boldsymbol{x}$ for all $\boldsymbol{x} \in S^{n-1}$ and $h(0, \boldsymbol{x}) = \boldsymbol{x}_0$ for all $\boldsymbol{x} \in S^{n-1}$, where $\boldsymbol{x}_0$ is a fixed element of S^{n-1}. Define $r : B^n \to S^{n-1}$ by $r(\boldsymbol{x}) = h\left(\|\boldsymbol{x}\|, \frac{\boldsymbol{x}}{\|\boldsymbol{x}\|}\right)$ for $\boldsymbol{x} \neq \mathbf{0}$ and $r(\mathbf{0}) = \boldsymbol{x}_0$. It is easily checked that r is continuous (only continuity at $\mathbf{0}$ is an issue), and is therefore a retraction from B^n to S^{n-1}.

Thus XIII.21.1.7. (ii) and (iii) are equivalent.

XIII.21.1.10. To prove (ii) $\Rightarrow$ (i), let r be a retraction of B^n to S^{n-1}. Then the map $f : B^n \to B^n$ defined by $f(\boldsymbol{x}) = -r(\boldsymbol{x})$ has no fixed point.

XIII.21.1.11. The proof of (i) $\Rightarrow$ (ii) is the hardest to write carefully, but the argument is geometrically simple and appealing. Suppose $f : B^n \to B^n$ has no fixed point. For each $\boldsymbol{x} \in B^n$, the line segment from $f(\boldsymbol{x})$ to $\boldsymbol{x}$ is nontrivial, and can be extended until it hits S^{n-1} in a point we call $r(\boldsymbol{x})$:

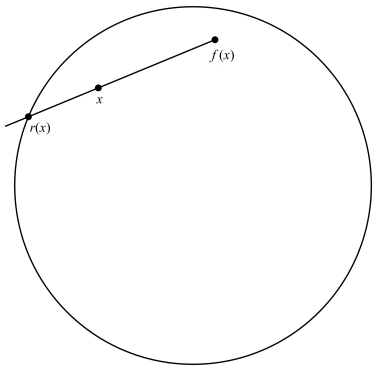

Figure XIII.69: Definition of the retraction

The function thus defined will be a retraction from B^n to S^{n-1}.

The only issue is whether r is continuous. This is geometrically plausible, and can be established carefully as follows. The vector $r(\boldsymbol{x})$ is of the form $f(\boldsymbol{x}) + t(\boldsymbol{x} - f(\boldsymbol{x}))$ for some $t \geq 1$. We can determine t explicitly using inner products and the quadratic formula:

$$\langle f(\boldsymbol{x}) + t(\boldsymbol{x} - f(\boldsymbol{x})), f(\boldsymbol{x}) + t(\boldsymbol{x} - f(\boldsymbol{x}))\rangle = 1$$

$$\langle f(\boldsymbol{x}), f(\boldsymbol{x})\rangle + 2t\langle \boldsymbol{x} - f(\boldsymbol{x}), f(\boldsymbol{x})\rangle + t^2\langle \boldsymbol{x} - f(\boldsymbol{x}), \boldsymbol{x} - f(\boldsymbol{x})\rangle - 1 = 0$$

$$\|\boldsymbol{x} - f(\boldsymbol{x})\|^2 t^2 - 2\langle f(\boldsymbol{x}) - \boldsymbol{x}, f(\boldsymbol{x})\rangle t + (\|f(\boldsymbol{x})\|^2 - 1) = 0$$

$$t = \frac{\langle f(\boldsymbol{x}) - \boldsymbol{x}, f(\boldsymbol{x})\rangle + \sqrt{\langle f(\boldsymbol{x}) - \boldsymbol{x}, f(\boldsymbol{x})\rangle^2 + \|\boldsymbol{x} - f(\boldsymbol{x})\|^2(1 - \|f(\boldsymbol{x})\|^2)}}{\|\boldsymbol{x} - f(\boldsymbol{x})\|^2}$$

which is a continuous function of $\boldsymbol{x}$ since the denominator is never zero.

This completes the proof of XIII.21.1.7..

Essential Maps

XIII.21.1.12. If X is a topological space of "dimension" less than n (we have not yet carefully defined what this means), and f is a map from X into $\mathbb{R}^n$ (or B^n), the range of f should be a set of dimension $< n$ and should thus have dense complement; so it should be possible to perturb f to a uniformly close function g such that the range of g does not include some specified point, e.g. the origin. Actually, the existence of such pathological functions as space-filling curves () casts doubt on the intuition behind this argument, but it turns out rather remarkably that the conclusion is correct.

Another argument leading to the conclusion is that a system of n equations in fewer than n variables "usually" does not have a solution. In special cases there might happen to be a solution, but it should be possible to perturb such a system to a "nearby" system with no solution. On the other hand, it is essentially the content of the Inverse Function Theorem () that if we have a "smooth" system of n equations in n variables which has a locally unique solution, then any "nearby" smooth system also has a (locally unique) solution.

XIII.21.1.13. Definition. Let X be a topological space. A map (continuous function) $f : X \to B^n$ is *inessential* if for every $\epsilon > 0$ there is a map $g : X \to B^n$ with $\|f - g\|_\infty = \sup\{\|f(x) - g(x)\| : x \in X\} < \epsilon$ and with $\mathbf{0} \notin g(X)$. A map f from X to B^n is *essential* if it is not inessential, i.e. every map sufficiently uniformly close to f has $\mathbf{0}$ in the range.

XIII.21.1.14. This use of the term *essential* is somewhat nonstandard, although it is used in a similar sense in [Pea75]. In topology, it is usually said that a map $f : X \to Y$ is essential if it is not homotopic to a constant map. Thus any map from a topological space to a contractible space such as B^n would be inessential. We will use the term in our sense only in relation to maps into B^n.

XIII.21.1.15. The definition of an essential map makes use of the standard metric on B^n. But the definition would be unchanged if any other metric giving the standard topology were used instead, since any two metrics giving the same compact topology are uniformly equivalent (). Thus the property of being essential or inessential is a purely topological property.

We then obtain another statement equivalent to the Brouwer Fixed-Point Theorem:

XIII.21.1.16. THEOREM. The identity map from B^n to B^n is essential.

XIII.21.1.17. To prove that this statement is equivalent to the No-Retraction Theorem, and thus to the Brouwer Fixed-Point Theorem, suppose that the identity map f on B^n is inessential, and fix $g : B^n \to B^n$ with $\|f - g\| < \frac{1}{2}$ and $g(\boldsymbol{x}) \neq \mathbf{0}$ for all $\boldsymbol{x} \in B^n$. We will gradually modify g on the annulus $\{\boldsymbol{x} \in B^n : \frac{1}{2} \leq \|\boldsymbol{x}\| \leq 1\}$ to a function $h : B^n \to B^n$ with $h(\boldsymbol{x}) \neq \mathbf{0}$ for all $\boldsymbol{x} \in B^n$ and $h(\boldsymbol{x}) = \boldsymbol{x}$ for $\boldsymbol{x} \in S^{n-1}$. We will take $h(\boldsymbol{x})$ to be a point on the line segment between $\boldsymbol{x}$ and $g(\boldsymbol{x})$, closer to $\boldsymbol{x}$ as $\|\boldsymbol{x}\|$ approaches 1. The precise formula is

$$h(\boldsymbol{x}) = \begin{cases} g(\boldsymbol{x}) & \text{if} \quad \|\boldsymbol{x}\| \leq \frac{1}{2} \\ (2\|\boldsymbol{x}\| - 1)\boldsymbol{x} + (2 - 2\|\boldsymbol{x}\|)g(\boldsymbol{x}) & \text{if} \quad \frac{1}{2} \leq \|\boldsymbol{x}\| \leq 1 \end{cases} .$$

It is clear that h is a continuous function from B^n to B^n and that $h(\boldsymbol{x}) = \boldsymbol{x}$ if $\|\boldsymbol{x}\| = 1$. To show that $h(\boldsymbol{x}) \neq \mathbf{0}$ for all $\boldsymbol{x}$, it suffices to note that if $\|\boldsymbol{x}\| \geq \frac{1}{2}$, then $\mathbf{0}$ is not on the line segment between $\boldsymbol{x}$ and $g(\boldsymbol{x})$ since $\|\boldsymbol{x} - g(\boldsymbol{x})\| < \frac{1}{2}$.

There is a retraction r from $B^n \setminus \{\mathbf{0}\}$ to S^{n-1}, e.g. radial projection; the map $r \circ h$ would then be a retraction from B^n to S^{n-1}. Thus by the No-Retraction Theorem, f cannot be inessential.

Conversely, suppose there is a retraction r from B^n to S^{n-1}. By scaling, for any $\epsilon > 0$ there is a retraction r_ϵ from $B^n_\epsilon = \{\boldsymbol{x} \in \mathbb{R}^n : \|\boldsymbol{x}\| \leq \epsilon\}$ onto $S^{n-1}_\epsilon = \{\boldsymbol{x} \in \mathbb{R}^n : \|\boldsymbol{x}\| = \epsilon\}$. Define $g_\epsilon : B^n \to B^n$ by

$$g_\epsilon(\boldsymbol{x}) = \begin{cases} r_\epsilon(\boldsymbol{x}) & \text{if} \quad \|\boldsymbol{x}\| \leq \epsilon \\ \boldsymbol{x} & \text{if} \quad \epsilon \leq \|\boldsymbol{x}\| \leq 1 \end{cases} .$$

Then $\|f - g_\epsilon\| \leq 2\epsilon$ and $g_\epsilon(\boldsymbol{x}) \neq \mathbf{0}$ for all $\boldsymbol{x} \in B^n$, so f is inessential. Thus XIII.21.1.16. implies the No-Retraction Theorem.

Partitions and the Lebesgue Covering Theorem

XIII.21.1.18. We now discuss two more equivalent versions of the Brouwer Fixed-Point Theorem. The statements are slightly more technical, and are phrased in terms of the n-cube

$$I^n = [-1, 1]^n = \{(x_1, \ldots, x_n) : -1 \leq x_k \leq 1\}$$

which is obviously homeomorphic to B^n. We will let A_k and B_k $(1 \leq k \leq n)$ be the opposite k-faces of I^n:

$$A_k = \{(x_1, \ldots, x_n) \in I^n : x_k = -1\}$$

$$B_k = \{(x_1, \ldots, x_n) \in I^n : x_k = 1\}$$

which are obviously disjoint closed subsets of I^n. The union of all the A_k and B_k is the boundary ∂I^n of I^n, which is homeomorphic to S^{n-1}.

Recall the definition of a partition (XIII.7.6.4.).

XIII.21.1.19. THEOREM. [FACE PARTITION THEOREM] For $1 \leq k \leq n$, let P_k be a partition between A_k and B_k in I^n. Then

$$P_1 \cap \cdots \cap P_n \neq \emptyset .$$

XIII.21.1.20. We show that the Face Partition Theorem for $n \in \mathbb{N}$ is equivalent to the No-Retraction Theorem for the same n, and hence to the Brouwer Fixed-Point Theorem. It is again convenient to prove that the negations of the statements are equivalent.

Suppose there is a retraction r from I^n to ∂I^n. Let $(r_1, \ldots, r_n)$ be the coordinate functions of r, and set

$$P_k = r_k^{-1}(\{0\})$$

$$U_k = r_k^{-1}([-1, 0))$$

$$V_k = r_k^{-1}((0, 1])$$

Then P_k is a partition between A_k and B_k for each k, and clearly $P_1 \cap \cdots \cap P_n = \emptyset$, so the statement of the Face Partition Theorem is false.

Conversely, let P_k be a partition between A_k and B_k for each k, with associated open sets U_k containing A_k and V_k containing B_k, such that $P_1 \cap \cdots \cap P_n = \emptyset$. For each k, define $f_k : I^n \to [-1, 1]$ by

$$f_k(\boldsymbol{x}) = \begin{cases} \frac{\rho(\boldsymbol{x}, P_k)}{\rho(\boldsymbol{x}, P_k) + \rho(\boldsymbol{x}, A_k)} & \text{if} \quad \boldsymbol{x} \in U_k \\ 0 & \text{if} \quad \boldsymbol{x} \in P_k \\ -\frac{\rho(\boldsymbol{x}, P_k)}{\rho(\boldsymbol{x}, P_k) + \rho(\boldsymbol{x}, B_k)} & \text{if} \quad \boldsymbol{x} \in V_k \end{cases}$$

where ρ is the standard metric on I^n. Then f_k is continuous. If $f : I^n \to I^n$ is the function with coordinate functions $(f_1, \ldots, f_n)$, then $f(\boldsymbol{x}) \neq \mathbf{0}$ for all $\boldsymbol{x} \in I^n$. Let r be a retraction of $I^n \setminus \{\mathbf{0}\}$ onto ∂I^n, and let $g = r \circ f$. It is easy to check that $g(A_k) \subseteq B_k$ and $g(B_k) \subseteq A_k$. It follows that g cannot have a fixed point, so the statement of the Brouwer Fixed-Point Theorem is false.

XIII.21.1.21. Theorem. [Lebesgue Covering Theorem] Let $\mathcal{F}$ be a finite collection of closed sets covering I^n, with the property that no $F \in \mathcal{F}$ meets both A_k and B_k for any k. Then there are distinct $F_1, \ldots, F_{n+1}$ in $\mathcal{F}$ with

$$F_1 \cap \cdots \cap F_{n+1} \neq \emptyset$$

(i.e. $\mathcal{F}$ has order $\geq n$ ()).

XIII.21.1.22. It is easy to show that the Lebesgue Covering Theorem implies the Brouwer Fixed-Point Theorem. Again we show the contrapositive. Suppose r is a retraction of I^n onto ∂I^n. Let

$$\mathcal{F} = \{r^{-1}(A_k), r^{-1}(B_k) : 1 \leq k \leq n\}$$

which is a finite cover of I^n by $2n$ sets satisfying the hypotheses of the Lebesgue Covering Theorem, but no $n + 1$ of the sets can have nonempty intersection.

To show the Face Partition Theorem, and hence the Brouwer Fixed-Point Theorem, implies the Lebesgue Covering Theorem is more complicated, and requires a lemma (cf. [Eng95, Lemma 1.2.9]):

XIII.21.1.23. LEMMA. Let X be a metrizable space, or more generally a completely normal space (), and E a closed subset of X. Let Y and Z be disjoint closed subsets of X. Let $\tilde{P}$ be a partition between $Y \cap E$ and $Z \cap E$ in E. Then there is a partition P between Y and Z in X with $P \cap E \subseteq \tilde{P}$.

PROOF: There are relatively open subsets $\tilde{U}$, $\tilde{V}$ of E such that $Y \cap E \subseteq \tilde{U}$, $Z \cap E \subseteq \tilde{V}$, $\tilde{U} \cap \tilde{V} = \emptyset$, and $E \setminus (\tilde{U} \cup \tilde{V}) = \tilde{P}$. The closure of $Z \cup \tilde{V}$ (in X) is $Z \cup [\tilde{V}]^-$, and $Y \cap [\tilde{V}]^- = (Y \cap E) \cap [\tilde{V}]^- = \emptyset$ since $[\tilde{V}]^- \subseteq E$ because E is closed, and $Y \cap E \subseteq \tilde{U}$, which is relatively open in E. Thus Y is disjoint from the closure of $Z \cup \tilde{V}$. We also have that $\tilde{U}$ is disjoint from both Z and $[\tilde{V}]^-$. So $Y \cup \tilde{U}$ is disjoint from the closure of $Z \cup \tilde{V}$. By a symmetric argument $Z \cup \tilde{V}$ is disjoint from the closure of $Y \cup \tilde{U}$. Thus by () there are disjoint open sets U and V in X with $Y \cup \tilde{U} \subseteq U$ and $Z \cup \tilde{V} \subseteq V$. Set $P = X \setminus (U \cup V)$. Then P is a partition between Y and Z in X, and $P \cap E$ is disjoint from both $\tilde{U}$ and $\tilde{V}$, i.e. $P \cap E \subseteq \tilde{P}$. 👍

XIII.21.1.24. We now show that the Face Partition Theorem for an $n \in \mathbb{N}$ implies the Lebesgue Covering Theorem for the same n (cf. [Eng95, Theorem 1.8.15]). Let $\mathcal{F}$ be a finite collection of closed subsets of I^n satisfying the hypotheses of the Lebesgue Covering Theorem. For $1 \leq k \leq n$ set

$$\mathcal{F}_k = \{F \in \mathcal{F} : A_k \cap F \neq \emptyset\}$$

$$\mathcal{E}_1 = \mathcal{F}_1, \quad \mathcal{E}_{k+1} = \mathcal{F}_{k+1} \setminus (\mathcal{E}_1 \cup \cdots \cup \mathcal{E}_k) \text{ for } 1 \leq k \leq n$$

$$E_k = \cup\{F : F \in \mathcal{E}_k\} \text{ for } 1 \leq k \leq n+1 \ .$$

Then the E_k are closed, and we have

$$A_k \subseteq I^n \setminus (E_{k+1} \cup \cdots \cup E_{n+1})$$

$$B_k \subseteq I^n \setminus E_k \ .$$

Set $\tilde{P}_0 = I^n$, and for $1 \leq k \leq n$ set

$$\tilde{P}_k = E_1 \cap \cdots \cap E_k \cap (E_{k+1} \cup \cdots \cup E_{n+1})$$

$$\tilde{U}_k = \tilde{P}_{k-1} \setminus (E_{k+1} \cup \cdots \cup E_{n+1})$$

$$\tilde{V}_k = \tilde{P}_{k-1} \setminus (E_1 \cap \cdots \cap E_k) \ .$$

Then, for $1 \leq k \leq n$, $\tilde{P}_k$ is closed, $\tilde{P}_k \subseteq \tilde{P}_{k-1}$, $A_k \cap \tilde{P}_{k-1} \subseteq \tilde{U}_k$, $B_k \cap \tilde{P}_{k-1} \subseteq \tilde{V}_k$, $\tilde{U}_k \cap \tilde{V}_k = \emptyset$, and

$$\tilde{P}_{k-1} \setminus (\tilde{U}_k \cup \tilde{V}_k) = \tilde{P}_{k-1} \cap \tilde{P}_k = \tilde{P}_k$$

so $\tilde{P}_k$ is a partition between $A_k \cap \tilde{P}_{k-1}$ and $B_k \cap \tilde{P}_{k-1}$ in $\tilde{P}_{k-1}$. Apply Lemma XIII.21.1.23. successively to obtain for each k a partition P_k between A and B in I^n with $P_k \cap \tilde{P}_{k-1} \subseteq \tilde{P}_k$. Thus by the Face Partition Theorem

$$\emptyset \neq P_1 \cap \cdots \cap P_n \subseteq \tilde{P}_n = E_1 \cap \cdots \cap E_{n+1}.$$

If $\boldsymbol{x} \in E_1 \cap \cdots \cap E_{n+1}$, then for $1 \leq k \leq n+1$ there is an $F_k \in \mathcal{E}_k$ with $\boldsymbol{x} \in F_k \subseteq E_k$; then $F_1 \cap \cdots \cap F_{n+1} \neq \emptyset$, and the F_k are all distinct since each $F \in \mathcal{F}$ is in exactly one $\mathcal{E}_k$.

XIII.21.1.25. The Face Partition Theorem and the Lebesgue Covering Theorem are versions of the statements $ind(\mathbb{R}^n) = n$ () and $dim(\mathbb{R}^n) = n$ () respectively; cf. [Eng95].

XIII.21.2. The Case $n = 2$

The Brouwer Fixed-Point Theorem for $n = 2$ is not as easy as the case $n = 1$ (XIII.21.1.6.), but is relatively simple.

XIII.21.2.1. The argument uses the map $p : \mathbb{R} \to S^1$ defined by

$$p(t) = (\cos 2\pi t, \sin 2\pi t) \ .$$

This map is surjective, but far from injective; however, if $s_0 \in \mathbb{R}$ and $\boldsymbol{z}_0 = p(s_0) \in S^1$, the restriction of p to the open interval $\left(s_0 - \frac{1}{2}, s_0 + \frac{1}{2}\right)$ is a homeomorphism from $\left(s_0 - \frac{1}{2}, s_0 + \frac{1}{2}\right)$ onto $S^1 \setminus \{-\boldsymbol{z}_0\}$. We will write $p_{s_0}^{-1}$ for the inverse map from $S^1 \setminus \{-\boldsymbol{z}_0\}$ onto $\left(s_0 - \frac{1}{2}, s_0 + \frac{1}{2}\right)$.

XIII.21.2.2. Lemma. [Path-Lifting Lemma] Let $\gamma : [0,1] \to S^1$ be a path (continuous function), with $\gamma(0) = \boldsymbol{z}_0$. If $s_0 \in \mathbb{R}$ is fixed with $p(s_0) = \boldsymbol{z}_0$, then there is a unique path $\tilde{\gamma} : [0,1] \to \mathbb{R}$ with $\tilde{\gamma}(0) = s_0$ and $\gamma = p \circ \tilde{\gamma}$.

Proof: A partition $\mathcal{P} = \{0 = t_0, t_1, \ldots, t_n = 1\}$ of $[0,1]$ will be called *sufficiently fine* if, for each k, $\|\gamma(t) - \gamma(s)\| < 2$ for all $t, s \in [t_{k-1}, t_k]$. There is a sufficiently fine partition since γ is uniformly continuous (). Suppose $\mathcal{P}$ is a sufficiently fine partition. There is a unique path $\beta : [0, t_1] \to \mathbb{R}$ with $\beta(0) = s_0$ and $\gamma|_{[0,t_1]} = p \circ \beta$, namely $\beta(t) = p_{s_0}^{-1}(\gamma(t))$ for $0 \le t \le t_1$ [to show uniqueness, note that the range of β must be contained in a connected subset of $p^{-1}(\gamma([0,t_1])) \subseteq p^{-1}(S^1 \setminus \{-\boldsymbol{z}_0\})$, so $\beta([0,t_1]) \subseteq \left(s_0 - \frac{1}{2}, s_0 + \frac{1}{2}\right)$.] In particular, $s_1 = \beta(t_1)$ is uniquely determined by γ and the choice of s_0. Define $\tilde{\gamma}(t)$ for $t \in [0,t_1]$ to be $\beta(t)$.

Now let $\boldsymbol{z}_1 = p(s_1) = \gamma(t_1)$, and repeat the construction to define $\tilde{\gamma}$ on $[t_1, t_2]$, and inductively extend to all of $[0,1]$. We then have $\tilde{\gamma}(0) = s_0$ and $\gamma = p \circ \tilde{\gamma}$.

To show uniqueness, suppose $\bar{\gamma}$ is another lift of γ, i.e. $\bar{\gamma}(0) = s_0$ and $\gamma = p \circ \bar{\gamma}$ (e.g. $\bar{\gamma}$ could be a lift defined by the same process using a different sufficiently fine partition). By the uniqueness shown above, we must have $\bar{\gamma} = \tilde{\gamma}$ on $[0,t_1]$, then on $[t_1,t_2]$, and ultimately on all of $[0,1]$. 👍

XIII.21.2.3. The lift $\tilde{\gamma}$ depends on the choice of s_0. But if the s_0 is changed, necessarily by addition of an integer n, then the lift is simply translated by n (the translation by n is obviously a lift with the right properties, so must be the unique one).

XIII.21.2.4. We will want a similar result for homotopies, i.e. maps from $[0,1]^2$ to S^1. If h is a map from $[0,1]^2$ to S^1, and $\boldsymbol{z}_0 = h(\mathbf{0})$, and $s_0 \in \mathbb{R}$ with $p(s_0) = \boldsymbol{z}_0$, then by XIII.21.2.2. there is a unique lifting $\tilde{h} : [0,1]^2 \to \mathbb{R}$ with $\tilde{h}(\mathbf{0}) = s_0$ which is continuous on each line segment in $[0,1]^2$ beginning at $\mathbf{0}$, defined for each $\boldsymbol{x} \in [0,1]^2$ by lifting the path $\gamma(t) = h(t\boldsymbol{x})$. However, it is not obvious that this map is continuous on $[0,1]^2$ (this is roughly the same question as whether the same value for $\tilde{h}(\boldsymbol{x})$ is obtained by lifting any other path in $[0,1]^2$ from $\mathbf{0}$ to $\boldsymbol{x}$). The lifted map $\tilde{h}$ is continuous in a neighborhood of $\mathbf{0}$ since all the lifts are done using $p_{s_0}^{-1}$, which is continuous; it is possible, but tricky, to expand successively through larger regions to the whole square (cf. ()).

We will take an alternate approach, first due to A. W. Tucker [Tuc46] (cf. [Spa81]).

XIII.21.2.5. There is a "multiplication" in S^1: if $\boldsymbol{z} = (\cos 2\pi t, \sin 2\pi t)$, write z symbolically as $e^{2\pi it}$ (this is actually more than symbolic; cf. ()). The t is not unique, but for a given $\boldsymbol{z}$ any two such t differ by an integer. If $\boldsymbol{w} = e^{2\pi is}$, define $\boldsymbol{zw} = e^{2\pi i(t+s)}$. Although t and s are only determined up to adding an integer, and thus $t+s$ is only determined up to an integer, the point $e^{2\pi i(t+s)}$ is well defined in S^1. This multiplication is associative and commutative. The point $\mathbf{1} = (1,0) = p(0)$ is an identity for this multiplication, and the point $\boldsymbol{z}^{-1} = e^{-2\pi it}$ is an inverse for $\boldsymbol{z} = e^{2\pi it}$. Multiplication is continuous as a function from $S^1 \times S^1$ to S^1, inversion (which geometrically is just reflection across the x-axis) is also continuous, and p has the property that $p(t+s) = p(t)p(s)$ for any $t, s \in \mathbb{R}$ (p is a *homomorphism*).

XIII.21.2.6. Now suppose $h : [0,1]^2 \to S^1$ is a continuous function, with $h(\mathbf{0}) = \boldsymbol{z}_0$, and $s_0 \in \mathbb{R}$ with $p(s_0) = \boldsymbol{z}_0$. By uniform continuity there is an $\epsilon > 0$ such that $\|h(\boldsymbol{x}) - h(\boldsymbol{y})\| < 2$ whenever $\boldsymbol{x}, \boldsymbol{y} \in [0,1]^2$ and $\|\boldsymbol{x} - \boldsymbol{y}\| < \epsilon$. Fix $n \in \mathbb{N}$ with $n > \frac{\sqrt{2}}{\epsilon}$; then $\frac{\|\boldsymbol{x}\|}{n} < \epsilon$ for all $\boldsymbol{x} \in [0,1]^2$. For $\boldsymbol{x} \in [0,1]^2$ and $1 \le k \le n$, define

$$g_k(\boldsymbol{x}) = h\left(\frac{k}{n}\boldsymbol{x}\right) h\left(\frac{k-1}{n}\boldsymbol{x}\right)^{-1} .$$

Then g_k is a continuous function from $[0,1]^2$ to S^1, and

$$h(\boldsymbol{x}) = \boldsymbol{z}_0 g_1(\boldsymbol{x}) g_2(\boldsymbol{x}) \cdots g_n(\boldsymbol{x}) .$$

The range of g_k is contained in $S^1 \setminus \{-\mathbf{1}\}$: since $\left\|\frac{k}{n}\boldsymbol{x} - \frac{k-1}{n}\boldsymbol{x}\right\| < \epsilon$,

$$\left\| h\left(\frac{k}{n}\boldsymbol{x}\right) - h\left(\frac{k-1}{n}\boldsymbol{x}\right)\right\| = \left\| h\left(\frac{k}{n}\boldsymbol{x}\right) h\left(\frac{k-1}{n}\boldsymbol{x}\right)^{-1} - \mathbf{1}\right\| < 2 .$$

So there is a lift $\tilde{g}_k : [0,1]^2 \to \mathbb{R}$ defined by

$$\tilde{g}_k(x) = p_0^{-1}(g_k(\boldsymbol{x}))$$

which is continuous. Set

$$\tilde{h}(\boldsymbol{x}) = s_0 + \tilde{g}_1(\boldsymbol{x}) + \cdots + \tilde{g}_n(\boldsymbol{x}) .$$

then $\tilde{h}$ is a finite sum of continuous functions, hence continuous, and is a lift of h. By the uniqueness described in XIII.21.2.4., this is the unique continuous lift of h with $h(\mathbf{0}) = s_0$. Thus we have proved:

XIII.21.2.7. Lemma. [Homotopy Lifting Lemma] Let $h : [0,1]^2 \to S^1$ be a continuous function, with $h(\mathbf{0}) = \boldsymbol{z}_0$, and $s_0 \in \mathbb{R}$ with $p(s_0) = \boldsymbol{z}_0$. Then there is a unique continuous function $\tilde{h} : [0,1]^2 \to \mathbb{R}$ such that $\tilde{h}(\mathbf{0}) = s_0$ and $h = p \circ \tilde{h}$.

Note that the proof actually shows that the same is true for functions from $[0,1]^n$ to S^1 for any n.

XIII.21.2.8. A *loop* in S^1 is a path $\gamma : [0,1] \to S^1$ with $\gamma(1) = \gamma(0)$. A loop in S^1 is effectively the same thing as a continuous function from S^1 to S^1: the restriction q of p to $[0,1)$ is a bijection, and although the inverse map q^{-1} is not continuous, if γ is a loop in S^1 the map $f = \gamma \circ q^{-1}$ is a continuous function from S^1 to S^1, and conversely if $f : S^1 \to S^1$ is continuous, $\gamma = f \circ q$ (extended by setting $\gamma(1) = \gamma(0)$) is a loop in S^1.

XIII.21.2.9. If γ is a loop in S^1 with $\gamma(0) = \gamma(1) = \boldsymbol{z}_0$, and $s_0 \in \mathbb{R}$ with $p(s_0) = \boldsymbol{z}_0$, and $\tilde{\gamma}$ is the lift of γ to $\mathbb{R}$, then it is *not* generally true that $\tilde{\gamma}(1) = \tilde{\gamma}(0)$. But $\tilde{\gamma}(1) - \tilde{\gamma}(0)$ is an integer which does not depend on the choice of s_0 by XIII.21.2.3., called the *index* or *degree* of γ. Thus each continuous function from S^1 to S^1 has a well-defined index.

XIII.21.2.10. PROPOSITION. Homotopic maps from S^1 to S^1 have the same index.

PROOF: Let f_0 and f_1 be homotopic maps from S^1 to S^1 via maps f_s, and γ_s the loop corresponding to f_s. Then $h(t, s) = \gamma_s(t)$ is a continuous map from $[0, 1]^2$ to S^1. Take a lift $\tilde{h}$ of h to a continuous function from $[0, 1]^2$ to $\mathbb{R}$ (XIII.21.2.7.); then

$$\phi(s) = \tilde{h}(1, s) - \tilde{h}(0, s)$$

is the index of f_s, and is a continuous function of s. Since it takes only integer values, it must be constant, i.e. the index of f_0 equals the index of f_1. 👍

XIII.21.2.11. THEOREM. The circle S^1 is not contractible; thus the Brouwer Fixed-Point Theorem holds for $n = 2$.

PROOF: The identity map on S^1 has index 1, and a constant map has index 0, so they cannot be homotopic. 👍

XIII.21.2.12. The converse of XIII.21.2.10. is true (): maps from S^1 to S^1 with the same index are homotopic; so we get a parametrization of the homotopy classes of maps from S^1 to S^1. It is easy to get a loop with arbitrary index: set $\gamma_n(t) = p(nt)$. Thus the index map from homotopy classes of maps to $\mathbb{Z}$ is a bijection. This set of homotopy classes can be made into a group (the *fundamental group*) $\pi_1(S^1)$ via concatenation, and $\pi_1(S^1) \cong \mathbb{Z}$. See () for the general theory of fundamental groups.

XIII.21.2.13. The map $p : \mathbb{R} \to S^1$ is called the *universal covering map*, and $\mathbb{R}$ is the universal cover of S^1. See () for the general theory of covering maps.

XIII.21.3. The General Case

If $n \geq 3$, the Brouwer Fixed-Point Theorem for n is more difficult than for $n = 2$ since there is no map from $\mathbb{R}^{n-1}$ onto S^{n-1} analogous to the map p (S^{n-1} is simply connected ()). So one must proceed differently. One method of proof amounts to again defining a degree (index) which is an integer for every map from S^{n-1} to S^{n-1}, and proving that homotopic maps have the same degree, and that the identity map has degree 1 and a constant map has degree 0.

The proof must have a combinatorial component of some sort. The standard argument requires working with triangulations () and can be phrased in several ways which are all more or less equivalent:

(1) The most direct argument involves a combinatorial result called *Sperner's Lemma*. See e.g. (), (), [Spa81, p. 151], ... for expositions of this argument.

(2) One can develop abstract homology theory up through the Mayer-Vietoris sequence, and use this sequence to give a proof of the degree formula and therefore the No-Retraction Theorem by induction. See e.g. (), (), (), ... for this approach.

(3) The homology argument of (2) can be written out directly in the case of spheres without explicit use of the term "homology." See [Dug78] or () for this approach.

The Sperner's Lemma argument actually proves the following more general result (cf. [Spa81, p. 151]):

XIII.21.3.1. THEOREM. Let X be a compact manifold with boundary which can be triangulated (e.g. a smooth compact manifold with boundary). Then there is no retraction of X onto ∂X.

As a variation of this result, the following version follows immediately from the Brouwer Fixed-Point Theorem:

XIII.21.3.2. THEOREM. Let U be a bounded open set in $\mathbb{R}^n$. Then there is no retraction from $\bar{U}$ onto ∂U.

PROOF: Suppose r is a retraction of $\bar{U}$ onto ∂U. Fix $\boldsymbol{a} \in U$, and m so that $B = \bar{B}_m(\boldsymbol{a})$ contains $\bar{U}$. Let s be radial retraction of $B \setminus \{\boldsymbol{a}\}$ onto $\partial B \cong S^{n-1}$. Define, for $\boldsymbol{x} \in B$,

$$f(\boldsymbol{x}) = \begin{cases} s(r(\boldsymbol{x})) & \text{if} \quad \boldsymbol{x} \in \bar{U} \\ s(\boldsymbol{x}) & \text{if} \quad \boldsymbol{x} \in B \setminus \bar{U} \end{cases} .$$

It is easy to check that f is continuous, since $\partial(B \setminus \bar{U}) \subseteq \partial U \cup \partial B$. Then f is a retraction of B onto ∂B, contradicting the No-Retraction Theorem. 👍

XIII.21.3.3. This result can fail if U is not bounded, e.g. if U is the open upper half-plane in $\mathbb{R}^2$.

XIII.21.3.4. We will not give a direct proof of the Brouwer Fixed-Point Theorem for $n \geq 3$. We will deduce the theorem from some analysis results, including Sard's Theorem and the Implicit Function Theorem ().

XIII.21.4. Exercises

XIII.21.4.1. **Fundamental Theorem of Algebra.** Here is a winding-number proof of the Fundamental Theorem of Algebra (XII.1.4.2., XII.9.9.3., XII.9.9.4.); cf. [vM89]. Suppose

$$f(z) = a_0 + a_1 z + \cdots + a_n z^n$$

is a nonconstant polynomial of degree n (i.e. $a_n \neq 0$) with complex coefficients, with no roots in $\mathbb{C}$. Then $a_0 \neq 0$.

(a) Set

$$g(z) = a_0 z^n + a_1 z^{n-1} + \cdots + a_{n-1} z + a_n \ .$$

Show that $g(z) = z^n f\left(\frac{1}{z}\right)$ for $z \neq 0$ and $g(0) = a_n$. Thus g also has no roots in $\mathbb{C}$.
(b) Let r be radial retraction of $\mathbb{C} \setminus \{0\}$ onto S^1, and define $h : [0,1] \times S^1 \to S^1$ by

$$h(t,z) = r\left(\frac{f(tz)}{g\left(\frac{t}{z}\right)}\right) \ .$$

Show that h is a homotopy between a constant function and $\phi(z) = z^n$, a contradiction since $n > 0$.

XIII.21.5. Proof of the No-Retraction Theorem

In this section, we give two nice analysis proofs of the No-Retraction Theorem, which give a proof of the general Brouwer Fixed-Point Theorem. The first proof was found by MILNOR [Mil78] and simplified by ROGERS [Rog80]. The second proof is due to HIRSCH [Hir94].

We first reduce the problem to the smooth case. For the first proof, we will only need the following result (and not even all of it) for $\mathcal{C}^1$, but it is no harder to prove for $\mathcal{C}^\infty$, and the second proof needs the $\mathcal{C}^\infty$ result. We use the notation B^n for the closed unit ball in $\mathbb{R}^n$, S^{n-1} its boundary, the $(n-1)$-sphere, and $\mathbb{D}^n$ the open unit ball in $\mathbb{R}^n$.

XIII.21.5.1. LEMMA. If there is a (continuous) retraction of B^n onto S^{n-1}, then there is a $\mathcal{C}^\infty$ retraction. In fact, there is a C^∞ retraction which is radial projection on a neighborhood of S^{n-1}.

PROOF: Let s be a retraction. Since B^n is compact, s is uniformly continuous, so there is a δ, $0 < \delta < \frac{1}{4}$, such that $\|s(\boldsymbol{x}) - s(\boldsymbol{y})\| < \frac{1}{4}$ whenever $\boldsymbol{x}, \boldsymbol{y} \in B^n$ and $\|\boldsymbol{x} - \boldsymbol{y}\| < \delta$. Then if $\boldsymbol{x} \in B^n$ and $\|\boldsymbol{x}\| > 1 - \delta$, we have

$$\begin{aligned}\|s(\boldsymbol{x}) - \boldsymbol{x}\| &\le \left\|s(\boldsymbol{x}) - s\left(\frac{\boldsymbol{x}}{\|\boldsymbol{x}\|}\right)\right\| + \left\|s\left(\frac{\boldsymbol{x}}{\|\boldsymbol{x}\|}\right) - \boldsymbol{x}\right\| \\ &= \left\|s(\boldsymbol{x}) - \frac{\boldsymbol{x}}{\|\boldsymbol{x}\|}\right\| + \left\|\frac{\boldsymbol{x}}{\|\boldsymbol{x}\|} - \boldsymbol{x}\right\| < \frac{1}{4} + \delta < \frac{1}{2}\ .\end{aligned}$$

By the General Weierstrass Approximation Theorem (XX.10.3.3.), or (), there is a $\mathcal{C}^\infty$ function $f : B^n \to \mathbb{R}^n$ (in fact the coordinate functions can be polynomials) with $\|f - s\|_\infty < \frac{1}{4}$. Then, for $\boldsymbol{x} \in B^n$, $\|\boldsymbol{x}\| > 1 - \delta$, we have

$$\|f(\boldsymbol{x}) - \boldsymbol{x}\| \le \|f(\boldsymbol{x}) - s(\boldsymbol{x})\| + \|s(\boldsymbol{x}) - \boldsymbol{x}\| < \frac{1}{4} + \frac{1}{2} = \frac{3}{4}\ .$$

Let h be a $\mathcal{C}^\infty$ function from $[0,1]$ to $[0,1]$ which is identically 0 on $[0, 1-\delta]$ and identically 1 on $\left[1 - \frac{\delta}{2}, 1\right]$ (). For $\boldsymbol{x} \in B^n$, define

$$g(\boldsymbol{x}) = h(\|\boldsymbol{x}\|)\boldsymbol{x} + (1 - h(\|\boldsymbol{x}\|)f(\boldsymbol{x})\ .$$

Then g is $\mathcal{C}^\infty$, $g(\boldsymbol{x}) = \boldsymbol{x}$ if $\|x\| \ge 1 - \frac{\delta}{2}$, and $g(\boldsymbol{x}) = f(\boldsymbol{x})$ if $\|x\| \le 1 - \delta$.

If $\|x\| \le 1 - \delta$, we have $\|g(\boldsymbol{x}) - s(\boldsymbol{x})\| = \|f(\boldsymbol{x}) - s(\boldsymbol{x})\| < \frac{1}{4}$, and since $\|s(\boldsymbol{x})\| = 1$, we have $\|g(\boldsymbol{x})\| > \frac{3}{4}$, and in particular $g(\boldsymbol{x}) \ne \boldsymbol{0}$. And if $\|x\| > 1 - \delta$, then $g(\boldsymbol{x})$ lies on the line segment between $\boldsymbol{x}$ and $f(\boldsymbol{x})$; since

$$\|f(\boldsymbol{x}) - \boldsymbol{x}\| < \frac{3}{4} < 1 - \delta < \|\boldsymbol{x}\|$$

we again have that $g(\boldsymbol{x}) \ne \boldsymbol{0}$. Thus

$$r(\boldsymbol{x}) = \frac{g(\boldsymbol{x})}{\|g(\boldsymbol{x})\|}$$

is a $\mathcal{C}^\infty$ retraction of B^n onto S^{n-1} (note that $\phi(\boldsymbol{x}) = \|\boldsymbol{x}\|$ is $\mathcal{C}^\infty$ on $\mathbb{R}^n \setminus \{\boldsymbol{0}\}$). We have $r(\boldsymbol{x}) = \frac{\boldsymbol{x}}{\|\boldsymbol{x}\|}$ if $\|\boldsymbol{x}\| \ge 1 - \frac{\delta}{2}$. 👍

Thus the No-Retraction Theorem reduces to:

XIII.21.5.2. THEOREM. Let $n \in \mathbb{N}$. Then there is no $\mathcal{C}^\infty$ retraction from B^n to S^{n-1} which is radial projection on a neighborhood of S^{n-1}.

The First Proof

XIII.21.5.3. To prove the theorem, suppose r is a $\mathcal{C}^1$ retraction. Set $g(\boldsymbol{x}) = r(\boldsymbol{x}) - \boldsymbol{x}$ and, for $0 \leq t \leq 1$ set

$$f_t(\boldsymbol{x}) = (1-t)\boldsymbol{x} + tr(\boldsymbol{x}) = \boldsymbol{x} + tg(\boldsymbol{x})$$

for $\boldsymbol{x} \in B^n$. Then g and each f_t is C^1, $f_t(\boldsymbol{x}) \in B^n$ for all t and $\boldsymbol{x} \in B^n$, and $f_t(\boldsymbol{x}) = \boldsymbol{x}$ for all t and $\boldsymbol{x} \in S^{n-1}$.

Since B^n is compact, Dg is bounded on B^n, and hence there is a constant $K(>0)$ such that

$$\|g(\boldsymbol{x}) - g(\boldsymbol{y})\| \leq K\|\boldsymbol{x} - \boldsymbol{y}\|$$

for all $\boldsymbol{x}, \boldsymbol{y} \in B^n$. If $0 \leq t < \frac{1}{K}$ and $\boldsymbol{x}, \boldsymbol{y} \in B^n$ with $f_t(\boldsymbol{x}) = f_t(\boldsymbol{y})$, then

$$\boldsymbol{x} - \boldsymbol{y} = t(g(\boldsymbol{x}) - g(\boldsymbol{y}))$$

$$\|\boldsymbol{x} - \boldsymbol{y}\| = t\|g(\boldsymbol{x}) - g(\boldsymbol{y})\| \leq Kt\|\boldsymbol{x} - \boldsymbol{y}\|$$

and since $Kt < 1$, $\boldsymbol{x} = \boldsymbol{y}$. Thus f_t is one-to-one if $0 \leq t < \frac{1}{K}$.

We have $Df_t(\boldsymbol{x}) = I + tDg(\boldsymbol{x})$ for all t and $\boldsymbol{x}$. Since Dg is bounded on B^n, there is a constant $t_0 > 0$, which we may take to be $< \frac{1}{K}$, such that $Det(Df_t(\boldsymbol{x})) > 0$ for all t, $0 \leq t \leq t_0$, and all $\boldsymbol{x} \in B^n$.

By the Inverse Function Theorem, f_t is an injective open mapping on $\mathbb{D}^n$ for $0 \leq t \leq t_0$. Let $U_t = f_t(\mathbb{D}^n)$; then U_t is an open set in $\mathbb{R}^n$ contained in B^n, hence $U_t \subseteq \mathbb{D}^n$.

XIII.21.5.4. LEMMA. Let f be a continuous function from B^n to B^n. Suppose $f(S^{n-1}) \subseteq S^{n-1}$ and that $f|_{\mathbb{D}^n}$ is an open mapping (as a map to $\mathbb{R}^n$). Then f maps $\mathbb{D}^n$ onto $\mathbb{D}^n$ and B^n onto B^n.

PROOF: Since f is an open mapping on $\mathbb{D}^n$, we have $f(\mathbb{D}^n) \subseteq \mathbb{D}^n$. If $f(\mathbb{D}^n)$ is a proper subset of $\mathbb{D}^n$, there is a $\boldsymbol{y} \in \mathbb{D}^n$ which is in $\overline{f(\mathbb{D}^n)} \setminus f(\mathbb{D}^n)$. But $f(B^n)$ is a compact set containing $f(\mathbb{D}^n)$, so $\boldsymbol{y} \in f(B^n)$, and hence $\boldsymbol{y} = f(\boldsymbol{x})$ for some $\boldsymbol{x} \in B^n \setminus \mathbb{D}^n = S^{n-1}$. But $f(S^{n-1}) \subseteq S^{n-1}$, a contradiction. Thus $f(\mathbb{D}^n) = \mathbb{D}^n$. Then $f(B^n)$ is a closed set containing $\mathbb{D}^n$, so $f(B^n) = B^n$.

XIII.21.5.5. Continuing with the proof of the theorem, we conclude from the lemma that $U_t = \mathbb{D}^n$ and $f_t(B^n) = B^n$ for $0 \leq t \leq t_0$.

Now consider the function

$$\phi(t) = \int_{B^n} Det(Df_t(\boldsymbol{x}))\, d\boldsymbol{x} = \int_{B^n} Det(I + tDg(\boldsymbol{x}))\, d\boldsymbol{x}\ .$$

This $\phi(t)$ is a polynomial (of degree $\leq n$) in t. If $0 \leq t \leq t_0$, then f_t is a $\mathcal{C}^1$ diffeomorphism from B^n to itself, and thus by the change-of-variables theorem () we have $\phi(t) = Vol(B^n)$ for $0 \leq t \leq t_0$. Thus ϕ is constant on $[0, t_0]$, and therefore constant everywhere, and nonzero.

However, f_1 maps B^n into S^{n-1} and thus has rank $\leq n-1$ at every point, so $Det(Df_1(\boldsymbol{x}))$ is zero for all $\boldsymbol{x}$, and hence $\phi(1) = 0$, a contradiction.

This completes the proof of Theorem XIII.21.5.2..

The Second Proof

The second proof is much shorter (given XIII.21.5.1.), but uses Sard's Theorem, and thus is not as elementary as the first proof.

XIII.21.5.6. Let r be a C^∞ retraction from B^n to S^{n-1} which is radial projection on a neighborhood of S^{n-1}. By Sard's Theorem (the version in XIII.23.6.3. suffices), there is a regular value $\boldsymbol{y} \in S^{n-1}$ (in fact a dense set of regular values, but we only need one!) Let $X = r^{-1}(\{\boldsymbol{y}\})$. Then X consists of regular points of r, hence is a one-dimensional compact manifold with boundary consisting of a radial line segment in from $\boldsymbol{y}$ and possibly some additional points in $\mathbb{D}^n$ (cf. VIII.5.8.1.), and $X \cap \mathbb{D}^n$ is a manifold without boundary, i.e. $\partial X = \{\boldsymbol{y}\}$. But a compact 1-manifold with boundary is a finite separated union of copies of $[0,1]$ and S^1, and thus has an *even* number of boundary points, a contradiction.

This completes the proof of Theorem XIII.21.5.2.. 

XIII.21.6. The Fixed-Point Theorem for Cubes

From the Brouwer Fixed-Point Theorem we can deduce that a continuous function from any cube to itself has a fixed point.

XIII.21.6.1. DEFINITION. Let X be a topological space. Then X has the *fixed-point property* if every map (continuous function) ϕ from X to X has a fixed point (i.e. there is an $x \in X$ with $\phi(x) = x$).

This definition is mostly useful only for compact Hausdorff spaces; it is difficult for a space which is not a compact Hausdorff space to have the fixed-point property. It is rare even for compact metrizable spaces: for example, a two-point space or circle does not have the property.

XIII.21.6.2. Recall that a *cube* is a product $[0,1]^I$ of copies of $[0,1]$, where I is an index set. If I is a finite set with n elements, $[0,1]^I$ is homeomorphic to B^n, hence has the fixed-point property by the Brouwer Fixed-Point Theorem.

XIII.21.6.3. THEOREM. Every cube has the fixed-point property.

PROOF: Let $X = [0,1]^I$ be a cube. For each finite set $F \subseteq I$, let X_F be the subset of X for which all coordinates not in F are 0. Then $X_F \cong [0,1]^F$. The X_F form a directed set of subspaces of X whose union is dense.

Let $\phi : X \to X$ be a map. For each finite $F \subseteq I$, define $\phi_F : X_F \to X_F$ by $\phi_F(x) = \pi_F(\phi(x))$, where π_F is the projection from X to X_F (setting coordinates outside F to 0). Since X_F has the fixed-point property, ϕ_F has a fixed point; let x_F be a fixed point of ϕ_F for each finite F.

Then (x_F) is a net in X, indexed by finite subsets of I directed by inclusion. Since X is compact, this net has a convergent subnet $(x_j)_{j \in J}$, where each x_j is x_{F_j} for some finite $F_j \subseteq I$. Say $x_j \to x \in X$. Then $\phi(x_j) \to \phi(x)$ since ϕ is continuous.

Fix a coordinate $i \in I$. Then $i \in F_j$ for all sufficiently large j. Let $\pi_i : X \to [0,1]$ be the i'th coordinate function (projection onto the i'th coordinate). Then $\pi_i(x_j) \to \pi_i(x)$ and $\pi_i(\phi(x_j)) \to \pi_i(\phi(x))$. If j is large enough that $i \in F_j$, then $\pi_i(\phi(x_j)) = \pi_i(\phi_{F_j}(x_j))$ by definition of ϕ_{F_j}; thus $\pi_i(\phi_{F_j}(x_j)) \to \pi_i(\phi(x))$. But $\phi_{F_j}(x_j) = x_j$ for all j; thus $\pi_i(x_j) \to \pi_i(\phi(x))$. So $\pi_i(\phi(x)) = \pi_i(x)$. This is true for all $i \in I$, so $\phi(x) = x$, i.e. x is a fixed point of ϕ. 👍

XIII.21.6.4. The AC is needed at several points in this proof. But the full force of the AC is not needed for any particular I; if I is countable (Hilbert cube) only the Countable AC is needed.

XIII.21.6.5. There is a generalization, the Schauder Fixed-Point Theorem ().

XIII.22. Topological Dimension Theory

It has been a long and occasionally painful process to give a good definition of the "dimension" of a topological space. There are many reasonable definitions of dimension, and it is a remarkable and significant fact that they all give the same numerical value for "reasonable" topological spaces, including separable metrizable spaces. In this section, we describe some of the principal definitions and their properties. Although we give definitions applicable to all topological spaces, we will concentrate on their properties only in the separable metrizable case.

One obvious property any reasonable dimension theory must have is that the dimension of $\mathbb{R}^n$ should be n. This is true for all the definitions of dimension we will consider, but it is surprisingly hard to prove for most of them.

Some standard references for Dimension Theory are [Men28], [HW41], [Nag65], [Nag70], [AP73], [Pea75], [Eng95]. The first is mainly just of historical value today, but the others are worth reading for content, especially the last. Of course, newer references contain more complete results.

XIII.22.1. Essential Dimension

XIII.22.1.1. Definition. Let X be a topological space. The *essential dimension* $ed(X)$ of X is the largest n such that there is an essential map () from X to B^n. We say $ed(X) = \infty$ if there is an essential map from X to B^n for all n, and $ed(X) = 0$ if every map from X to $B^1 = [-1, 1]$ is inessential. Set $ed(\emptyset) = -1$.

The relevance of this definition is the following result, which is essentially equivalent to the Brouwer Fixed-Point Theorem:

XIII.22.1.2. Theorem. We have $ed(\mathbb{R}^n) = ed(B^n) = ed(S^n) = n$.

See XIII.22.1.5. for a more general result.

The next fact also justifies the form of the definition.

XIII.22.1.3. Proposition. Let X be a topological space. If there is an essential map from X to B^n, then there is an essential map from X to B^m for any $m < n$.

Proof: Let $f : X \to B^n$ be an essential map, with coordinate functions $(f_1, \ldots, f_n)$. Fix $m < n$, and define $\tilde{f} : X \to B^m$ by

$$\tilde{f}(x) = (f_1(x), \ldots, f_m(x)) \ .$$

Suppose $\tilde{f}$ is inessential. For $\epsilon > 0$, let $\tilde{g} : X \to B^m$ with $\|\tilde{g} - \tilde{f}\|_\infty < \epsilon$ and $\mathbf{0} \notin \tilde{g}(X)$. Let $(g_1, \ldots, g_m)$ be the coordinate functions of $\tilde{g}$. Define $g : X \to \mathbb{R}^n$ by

$$g(x) = (g_1(x), \ldots, g_m(x), f_{m+1}(x), \ldots, f_n(x)) \ .$$

Then $\|g - f\|_\infty < \epsilon$ and $\mathbf{0} \notin g(X)$. The function g does not necessarily map X into B^n, but we can retract the part that does not: define h by

$$h(x) = \begin{cases} g(x) & \text{if} \quad \|g(x)\| \leq 1 \\ \frac{g(x)}{\|g(x)\|} & \text{if} \quad \|g(x)\| > 1 \end{cases} \ .$$

Then h is a map from X to B^n, $\|h-f\|_\infty < \epsilon$, and $\mathbf{0} \notin h(X)$. Since $\epsilon > 0$ is arbitrary, this contradicts that f is essential. Thus $\tilde{f}$ is essential. 👍

XIII.22.1.4. PROPOSITION. Let X be a topological space, and $f : X \to B^n$ a map. Then f is essential if and only if there is an $\alpha > 0$ such that for every $g : X \to B^n$ sufficiently uniformly close to f, $g(X)$ contains the ball B^n_α of radius α around $\mathbf{0}$.

PROOF: It is obvious that any f with this property is essential. Conversely, suppose f is essential. Fix $0 < \epsilon < 1$ for which there is no h with $\|f-h\|_\infty < \epsilon$ and $0 \notin h(X)$. Let $g : X \to B^n$ with $\|g-f\| < \frac{\epsilon}{2}$, and suppose there is an $\boldsymbol{x}_0$ with $\|\boldsymbol{x}_0\| < \frac{\epsilon}{2}$ and $\boldsymbol{x}_0 \notin g(X)$. Define $h : B^n \to B^n$ by

$$h(\boldsymbol{x}) = \begin{cases} \boldsymbol{x} - \boldsymbol{x}_0 & \text{if} \quad \|\boldsymbol{x}-\boldsymbol{x}_0\| \leq 1 \\ \frac{\boldsymbol{x}-\boldsymbol{x}_0}{\|\boldsymbol{x}-\boldsymbol{x}_0\|} & \text{if} \quad \|\boldsymbol{x}-\boldsymbol{x}_0\| > 1 \end{cases} .$$

Then $h(\boldsymbol{x}_0) = \mathbf{0}$, and $\boldsymbol{x}_0$ is the only $\boldsymbol{x}$ with $h(\boldsymbol{x}) = 0$; and $\|h-\iota\|_\infty < \frac{\epsilon}{2}$, where ι is the identity map on B^n, so $\|h \circ g - f\|_\infty < \epsilon$ and $\mathbf{0} \notin h \circ g(X)$, a contradiction. 👍

We now prove a general result that includes XIII.22.1.2..

XIII.22.1.5. THEOREM. Let X be a smooth n-manifold with boundary. Then $ed(X) = n$.

PROOF: X contains a closed subset Y homeomorphic to B^n, and there is a retraction r from X onto Y (this requires the Tietze Extension Theorem () in general, but if $X = B^n$, $\mathbb{R}^n$, or S^n, such a Y and r can be given explicitly without resort to the Tietze Extension Theorem). Let f be a homeomorphism from Y onto B^n. Then f is an essential map by XIII.21.1.16., so $f \circ r$ is an essential map from X to B^n [if g approximates $f \circ r$, and ι is the embedding of Y into X, then $g \circ \iota$ approximates $f \circ r \circ \iota = f$] and $ed(X) \geq n$.

On the other hand, suppose $m > n$ and f is a map from X to B^m. To show that f is inessential, it suffices to show that the restriction of f to each component of X is inessential, since the components are clopen and f can be modified independently on each component. Thus we may assume X is connected, and in particular second countable. Then f can be arbitrarily closely approximated by a smooth function g, and by () the range of g has dense complement. Thus f is inessential by XIII.22.1.4. and $ed(X) < m$. 👍

XIII.22.1.6. The smooth structure was used only to prove $ed(X) \leq n$; the first half of the proof applies to any topological n-manifold with boundary (and in fact to any normal topological space X containing a copy of B_n) to give $ed(X) \geq n$. Note that the conclusion is purely topological, and the smooth structure is used only to give a simple way of approximating continuous functions by continuous functions whose range is "small." The result also holds for manifolds which do not have differentiable structures, but requires a different proof in this case (Exercise XIII.22.8.4.). An alternate proof that $ed(B^n) \leq n$ can be given using XIII.22.4.13. and Exercise XIII.22.8.3..

XIII.22.1.7. COROLLARY. Let X be a smooth n-manifold with boundary, and Y a smooth m-manifold with boundary. If $n \neq m$, then X and Y are not homeomorphic. In particular, if $n \neq m$, $\mathbb{R}^n$ is not homeomorphic to $\mathbb{R}^m$, or to any open subset of $\mathbb{R}^m$.

Extending Maps to Spheres

Essential dimension can be characterized also by an extension property for maps to spheres:

XIII.22.1.8. THEOREM. Let X be a completely regular space. Then $ed(X) \leq n$ if and only if, whenever Y is a closed subset of X and $f : Y \to S^n$ is continuous, then f extends to a continuous map $g : X \to S_n$.

PROOF: Suppose $ed(X) \leq n$, Y is a closed subspace of X, and $f : Y \to S^n$. Regard f as a map from Y to B^{n+1}. By the Tietze Extension Theorem (), f extends to a map h from X to B^{n+1}. Then h is inessential, so by an argument almost identical to the proof of (), there is a $\phi : B^{n+1} \to B^{n+1}$ which is the identity on a neighborhood of S^n and for which $\tilde{h} = \phi \circ h$ satisfies $\mathbf{0} \notin \tilde{h}(X)$. Then $h|_Y = \tilde{h}|_Y$, so $\tilde{h}$ is also an extension of f. If r is the radial retraction of $B^{n+1} \setminus \{\mathbf{0}\}$ onto S^n, then $g = r \circ \tilde{h}$ is an extension of f to $g : X \to S^n$.

Conversely, suppose X has the extension property, and suppose $f : X \to B^{n+1}$. Fix $\epsilon > 0$, and let $Y = f^{-1}(S^n_\epsilon)$ (where $S^n_\epsilon = \{\boldsymbol{x} \in B^{n+1} : \|\boldsymbol{x}\| = \epsilon\}$). Then Y is a closed subset of X, so $f|_Y$ extends to a map h from X to S^n_ϵ. Define $g : X \to B^{n+1}$ by

$$g(x) = \begin{cases} h(x) & \text{if} \quad \|f(x)\| \leq \epsilon \\ f(x) & \text{if} \quad \|f(x)\| \geq \epsilon \end{cases} .$$

Then g is continuous, $\|g - f\|_\infty \leq 2\epsilon$, and $\mathbf{0} \notin g(X)$. Thus f is inessential and $ed(X) \leq n$. 👍

A trick gives the following interesting and useful variant:

XIII.22.1.9. COROLLARY. Let X be a normal space, Y a closed subspace, and $f : Y \to S^n$ a map. If $ed(X \setminus Y) \leq n$, then f extends to a map from X to S^n.

PROOF: By (), f extends to a neighborhood U of Y in X. Since X is normal, there is a neighborhood V of Y in X with $\bar{V} \subseteq U$. Thus f extends to $\tilde{f} : \bar{V} \to S^n$. Then $Z = (X \setminus Y) \cap \bar{V}$ is a closed subspace of $X \setminus Y$, and $g = \tilde{f}|_Z$ is a map from Z to S^n. By XIII.22.1.8., g extends to $\tilde{g} : X \setminus Y \to S^n$. Then $\tilde{f}$ and $\tilde{g}$ define a map from X to S^n extending f. 👍

Essential Dimension of Subspaces

XIII.22.1.10. If X is a topological space and Y is a subspace of X, one would expect that $ed(Y) \leq ed(X)$. However, this turns out to be false in general, even if X is a compact Hausdorff space (). The problem is that a map from Y to B^n need not extend to X in general. It is true in general that $ed(Y) \leq ed(X)$ if X is separable and metrizable (). And if Y is closed, it is always true, and an immediate consequence of XIII.22.1.8.:

XIII.22.1.11. COROLLARY. Let X be a completely regular space, and Y a closed subspace of X. Then $ed(Y) \leq ed(X)$.

PROOF: Suppose $ed(X) = n$. Let Z be a closed subset of Y, and $f : Z \to S^n$ a map. Then Z is closed in X, so by XIII.22.1.8. f extends to a map $g : X \to S^n$. Then $g|_Y$ is an extension of f to Y. Thus $ed(Y) \leq n$ by the other direction of XIII.22.1.8.. 👍

XIII.22.1.12. PROPOSITION. Let X be a completely regular space. Then $ed(X) = ed(\beta X)$, where βX is the Stone-Čech compactification () of X.

PROOF: Let f be a map from X to B^n, and $\bar{f}$ its extension to βX. If $g : X \to B^n$, then $\|\bar{g} - \bar{f}\|_\infty = \|g - f\|_\infty$; thus if f is essential, $\bar{f}$ is also essential. On the other hand, if f is inessential, then for every $\epsilon > 0$ there is a $g : X \to B^n$ with $\|g - f\|_\infty < \epsilon$ and $g(X)$ bounded away from $\mathbf{0}$ (XIII.22.1.4.); thus $\mathbf{0} \notin \bar{g}(\beta X)$, so $\bar{f}$ is also inessential. 👍

Essential Dimension of Subspaces of $\mathbb{R}^n$

XIII.22.1.13. THEOREM. Let X be a subset of $\mathbb{R}^n$. Then $ed(X) \leq n$, and $ed(X) = n$ if and only if X has nonempty interior.

XIII.22.2. Invariance of Domain

We can now prove Brouwer's Invariance of Domain Theorem:

XIII.22.2.1. THEOREM. [INVARIANCE OF DOMAIN] Let U be a nonempty open subset of $\mathbb{R}^n$, and f a one-to-one continuous function from U to $\mathbb{R}^m$. Then

(i) $m \geq n$.

(ii) If $m = n$, then $f(V)$ is open in $\mathbb{R}^n$ for every open subset V of U (in particular, $f(U)$ is open in $\mathbb{R}^n$), i.e. f is an open mapping and a homeomorphism onto its range.

This will be a consequence of the following:

XIII.22.2.2. THEOREM. Let X be a subset of $\mathbb{R}^n$, and f a one-to-one continuous function from X onto a subset Y of $\mathbb{R}^n$. If $\boldsymbol{x}$ is an interior point of X, then $f(\boldsymbol{x})$ is an interior point of Y.

XIII.22.2.3. A point $\boldsymbol{x} \in X$ is an interior point of X if and only if it is an interior point of a compact subset of X: if $\boldsymbol{x}$ is an interior point of X, then $\boldsymbol{x}$ is an interior point of a sufficiently small closed ball around $\boldsymbol{x}$ which is contained in X, and the converse is obvious. Thus it suffices to prove XIII.22.2.2. for X compact. And in this case, the map f is automatically a homeomorphism.

Thus it suffices to prove that interior points of a compact subset X of $\mathbb{R}^n$ can be characterized topologically, which is the substance of the next result:

XIII.22.2.4. LEMMA. Let X be a compact subset of $\mathbb{R}^n$, and $\boldsymbol{x} \in X$. Then $\boldsymbol{x} \in \partial X$ if and only if, whenever U is a neighborhood of $\boldsymbol{x}$ in X, there is an open neighborhood V of $\boldsymbol{x}$ in X contained in U such that every map from $X \setminus V$ to S^{n-1} extends to a map from X to S^{n-1}.

PROOF: Suppose $\boldsymbol{x} \in \partial X$, and U is a neighborhood of $\boldsymbol{x}$ in X. Then there is an open ball W around $\boldsymbol{x}$ in $\mathbb{R}^n$ such that $\bar{W} \cap X \subseteq U$. Set $V = W \cap X$. Let f be a map from $X \setminus V$ to S^{n-1}. Then ∂W is homeomorphic to S^{n-1}, and $X \setminus V$ is compact and hence closed in $(X \setminus V) \cup \partial W$. The complement $Z = [(X \setminus V) \cup \partial W] \setminus (X \setminus V)$ is an open subset of ∂W, hence an $(n-1)$-manifold with a smooth structure, and thus $ed(Z) = n - 1$ by XIII.22.1.5. (only the "easy" part $ed(Z) \leq n - 1$ is needed). So by XIII.22.1.9. f extends to a map $\tilde{f}$ from $(X \setminus V) \cup \partial W$ to S^{n-1}. Since $\boldsymbol{x} \in \partial X$, there is an $\boldsymbol{x}_0 \in W$ with $\boldsymbol{x}_0 \notin X$, and there is a retraction r from $\bar{W} \setminus \{\boldsymbol{x}_0\}$ to ∂W. Define $g : X \to S^{n-1}$ by

$$g(\boldsymbol{y}) = \begin{cases} \tilde{f}(r(\boldsymbol{y})) & \text{if} \quad \boldsymbol{y} \in V \\ f(\boldsymbol{y}) & \text{if} \quad \boldsymbol{y} \in X \setminus V \end{cases} .$$

Then $g : X \to S^{n-1}$ is an extension of f to X.

Conversely, suppose $\boldsymbol{x}$ is an interior point of X, and ϵ is small enough that the closed ball B of radius ϵ around $\boldsymbol{x}$ is contained in X. Let U be the open ball of radius ϵ centered at $\boldsymbol{x}$; then $\partial U = \partial B$ is homeomorphic to S^{n-1}, and $X \setminus U$ can be radially projected onto ∂U. Call this map f. If V is any neighborhood of $\boldsymbol{x}$ contained in U, then f can be extended to a map from $X \setminus V$ to ∂W using radial projection from $\boldsymbol{x}$. But f cannot be extended to a map g from X to ∂U, since the restriction of g to B would be a retraction of B onto ∂B. 👍

XIII.22.3. Other Dimension Functions

For analysis purposes, essential dimension seems to be the most useful dimension function on spaces. However, it is not commonly used by topologists. There are three standard dimension functions used by topologists: small inductive dimension, large inductive dimension, and covering dimension.

Small Inductive Dimension

XIII.22.3.1. Small inductive dimension *ind* is the earliest and probably still the most-used dimension function on spaces. The definition is motivated by the idea that the boundary of a "nice" region of $\mathbb{R}^n$ should have dimension $n - 1$. The definition is (surprise!) an inductive one: we successively define what it means for a space to have dimension $\leq n$.

XIII.22.3.2. DEFINITION. Let X be a topological space. Then

(i) $ind(X) = -1$ if and only if $X = \emptyset$.

(ii) $ind(X) \leq n$ if and only if, whenever $x \in X$ and U is an open neighborhood of x in X, there is an open neighborhood V of x contained in U with $ind(\partial V) \leq n - 1$.

(iii) $ind(X) = n$ if $ind(X) \leq n$ and it is false that $ind(X) \leq n - 1$.

(iv) $ind(X) = \infty$ if for every n it is false that $ind(X) \leq n$.

XIII.22.3.3. Thus, for example, a topological space X satisfies $ind(X) = 0$ if and only if it is nonempty and, for each $x \in X$ and each open neighborhood U of x, there is an open neighborhood V of x contained in U with $\partial V = \emptyset$. But a subset of X has empty boundary if and only if it is clopen; so $ind(X) = 0$ if and only if for each $x \in X$ and each open neighborhood U of x, there is a clopen neighborhood V of x contained in U, i.e. if and only if X is nonempty and there is a base for the topology of X consisting of clopen sets. (Thus if X is T_0 and $ind(X) = 0$, X must be completely regular.)

XIII.22.3.4. PROPOSITION. Let X be a regular topological space. Then $ind(X) \leq n$ if and only if, whenever A is a closed set in X and $x \in X \setminus A$, there is a partition P between $\{x\}$ and A with $ind(P) \leq n-1$.

PROOF: There is an open neighborhood U of x with $\bar{U} \subseteq X \setminus A$. There is an open neighborhood V of x contained in U with $ind(\partial V) \leq n - 1$. Then $P = \partial V$ is a partition between $\{x\}$ and A. 👍

XIII.22.3.5. PROPOSITION. Let X be a topological n-manifold with boundary ($n \geq 1$). Then $1 \leq ind(X) \leq n$. In particular, if X is a topological 1-manifold with boundary, then $ind(X) = 1$. So $ind(\mathbb{R}) = ind([0, 1]) = ind(S^1) = 1$.

PROOF: By induction on n. If $n = 1$, a point of X has arbitrarily small neighborhoods whose boundary consists of either one or two points, hence of inductive dimension 0. Thus $ind(X) \leq 1$. But X is locally connected and thus $ind(X) = 0$ is false. And if X is an $(n+1)$-manifold with boundary, each point of X has arbitrarily small neighborhoods whose boundary is homeomorphic to either S^n or B^n, hence with inductive dimension $\leq n$; thus $ind(X) \leq n + 1$. Also, $ind(X) = 0$ is false for the same reason as before. 👍

XIII.22.3.6. In fact, if X is a topological n-manifold with boundary, then $ind(X) = n$, but it is much harder to prove equality, even if $X = B^n$ or $X = \mathbb{R}^n$. Actually, it is hard to prove that there is any topological space X with $ind(X) > 1$.

One simple but important property of small inductive dimension is monotonicity:

XIII.22.3.7. PROPOSITION. Let X be a topological space, and Y a subspace of X. Then $ind(Y) \leq ind(X)$.

PROOF: By induction on $n = ind(X)$. If $n = -1$ there is nothing to prove. Suppose the result is true whenever $ind(X) \leq n$. If $ind(X) \leq n + 1$ and $Y \subseteq X$, and $y \in Y$, let U be an open neighborhood of y in Y. Then there is an open neighborhood $\tilde{U}$ of y in X with $U = \tilde{U} \cap Y$. There is an open neighborhood $\tilde{V}$ of y in X with $\tilde{V} \subseteq \tilde{U}$ and $ind(\partial_X \tilde{V}) \leq n$. Set $V = \tilde{V} \cap Y$; then V is an open neighborhood of y in Y with $V \subseteq U$. We have $\partial_Y V \subseteq \partial_X \tilde{V}$ (), so by the inductive hypothesis $ind(\partial_Y V) \leq n$. Thus $ind(Y) \leq n + 1$. 👍

XIII.22.3.8. Small inductive dimension is a good notion for separable metrizable spaces, but turns out to have pathological properties outside this class and is regarded by topologists as of little use or interest for more general spaces.

Large Inductive Dimension

The small inductive dimension is strictly a local concept. There is a technical variation, called the *large inductive dimension* (Ind), which is more of a global condition.

XIII.22.3.9. DEFINITION. Let X be a topological space. Then

(i) $Ind(X) = -1$ if and only if $X = \emptyset$.

(ii) $Ind(X) \leq n$ if and only if, whenever Y is a closed subset of X and U is an open neighborhood of Y in X, there is an open neighborhood V of Y contained in U with $Ind(\partial V) \leq n - 1$.

(iii) $Ind(X) = n$ if $Ind(X) \leq n$ and it is false that $Ind(X) \leq n - 1$.

(iv) $Ind(X) = \infty$ if for every n it is false that $Ind(X) \leq n$.

XIII.22.3.10. PROPOSITION. Let X be a normal topological space. Then $Ind(X) \leq n$ if and only if, whenever A and B are disjoint closed sets in X, there is a partition P between A and B with $Ind(P) \leq n-1$.

The proof is nearly identical to the proof of XIII.22.3.4..

XIII.22.3.11. PROPOSITION. Let X be a T_1 topological space. Then $ind(X) \leq Ind(X)$.

PROOF: It is easily proved by induction that if $Ind(X) \leq n$, then $ind(X) \leq n$. 👍

XIII.22.3.12. THEOREM. If X and Y are metrizable, then

$$Ind(X \times Y) \leq Ind(X) + Ind(Y) \ .$$

Equality does not hold in general. For example, the space X of () satisfies $Ind(X) = 1$ and $Ind(X \times X) = 1$ also, since $X \times X$ is homeomorphic to X. (This space is separable metrizable, so $ind(X) = Ind(X) = dim(X)$.) There are compact metrizable spaces for which equality fails []. It is unknown whether equality can fail for ANR's; for well-behaved ANR's equality does hold [Bor36].

The inequality holds in somewhat greater generality, but does not even hold for all compact Hausdorff spaces: there are compact Hausdorff spaces X and Y with $Ind(X) = 1$, $Ind(Y) = 2$, and $Ind(X \times Y) = 4$ [Fil72]. Compare with XIII.22.3.40..

Sum and Decomposition Theorems

We now obtain some moderately complicated but crucial results about dimensions of unions, and decompositions into sets of smaller dimension.

It is clear that if X is a union of two subspaces of dimension n, then the dimension of X might be larger than n: for example, $\mathbb{R}$ can be decomposed into the rational and irrational numbers, each of which has dimension 0. There is only an inequality in general (). In fact, any sufficiently nice space of dimension n can be written as a union of $n + 1$ subspaces of dimension 0 (). But if the space is nice and the subspaces are closed, the dimension of the union does not grow, even with countably many subspaces:

XIII.22.3.13. THEOREM. [SUM THEOREM FOR IND] Let X be a separable metrizable space. If $X = \cup_{j=1}^{\infty} X_j$, with each X_j closed in X and $ind(X_j) \leq n$ for all j, then $ind(X) = Ind(X) \leq n$.

The name "Sum Theorem," which has become standard, comes from the practice in older references on set theory and topology to use *sum* as a synonym for *union*. Similarly, *product* was used to mean *intersection*.

To prove this theorem, we first prove a zero-dimensional version for Ind which is valid in much greater generality:

XIII.22.3.14. THEOREM. Let X be a normal space. If $X = \cup_{j=1}^{\infty} X_j$, with each X_j closed in X and $Ind(X_j) = 0$ for all j, then $Ind(X) = 0$.

Before proving XIII.22.3.13., we need two lemmas, the first of which includes a useful construction:

XIII.22.3.15. LEMMA. Let X be a topological space and $\mathcal{V}$ a base for the topology of X (consisting of open sets). Set

$$Y = \bigcup_{V \in \mathcal{V}} \partial V$$

and $Z = X \setminus Y$. Then $ind(Z) \leq 0$.

PROOF: Let $z \in Z$ and U an open neighborhood of z in Z. Then there is an open set W in X with $U = W \cap Z$. There is a $V \in \mathcal{V}$ with $z \in V$ and $V \subseteq U$. Since $\partial V \subseteq Y$, we have that $V \cap Z = \bar{V} \cap Z$, so $V \cap Z$ is relatively clopen in Z and $z \in V \cap Z \subseteq U$. 👍

The second lemma is a variant of XIII.21.1.23. (cf. [Eng95, 1.2.9]).

XIII.22.3.16. LEMMA. Let X be a metrizable space, or more generally a completely normal space (), and Z a subspace of Z with $Ind(Z) = 0$. If A and B are disjoint closed subsets of X, then there are open sets V_1, V_2 in X with $A \subseteq V_1$, $B \subseteq V_2$, $V_1 \cap V_2 = \emptyset$, and

$$[X \setminus (V_1 \cup V_2)] \cap Z = \emptyset \ .$$

PROOF: Let V_1' and V_2' be open neighborhoods of A and B whose closures are disjoint. Let U_1 be a relatively clopen subset of Z containing $\bar{V}_1' \cap Z$ (all closures are closures in X) and disjoint from $\bar{V}_2 \cap Z$, and $U_2 = Z \setminus U_1$. Note that V_1' is disjoint from U_2 and hence from $\bar{U}_2$ since V_1' is open; thus $A \cap \bar{U}_2 = \emptyset$. Similarly, $B \cap \bar{U}_1 = \emptyset$.

Since $\bar{U}_1 \cap Z = U_1$ and $\bar{U}_2 \cap Z = U_2$, the sets U_1 and U_2 are completely separated in X, and hence the sets $A \cup U_1$ and $B \cup U_2$ are also completely separated in X. Thus they have disjoint neighborhoods V_1 and V_2 in X. Since $Z \subseteq V_1 \cup V_2$, $[X \setminus (V_1 \cup V_2)] \cap Z = \emptyset$. 👍

We now give the proof of XIII.22.3.13..

PROOF: By induction on n. The case $n = 0$ follows immediately from XIII.22.3.14. and the fact that if Y is a T_0 Lindelöf space with $ind(Y) = 0$, then $Ind(Y) = 0$ (XIII.13.6.5. and the proof of XIII.13.6.7.((iv) $\Rightarrow$ (iii))). Now suppose $n > 0$ and the statement holds for $n-1$ (including the statement that $ind(Y) = Ind(Y)$

if $ind(Y) \leq n-1$). There is a countable base $\mathcal{V}$ for the topology of X consisting of open sets V with $ind(\partial V) \leq n-1$. Set

$$Y = \bigcup_{V \in \mathcal{V}} \partial V$$

and $Z = X \setminus Y$. Then $ind(Z) \leq 0$ by Lemma XIII.22.3.15., so $Ind(Z) \leq 0$ since Z is Lindelöf. We have that $ind(Y) \leq n-1$ by the inductive assumption. Let A and B be disjoint closed subsets of X. By Lemma XIII.22.3.16. there are disjoint neighborhoods V_1 and V_2 of A and B with $Z \subseteq V_1 \cup V_2$. Hence $P = X \setminus (V_1 \cup V_2)$ is a partition between A and B. Since $P \subseteq Y$, $ind(P) \leq n-1$, so $Ind(P) \leq n-1$ by the inductive assumption. Thus $Ind(X) \leq n$ by XIII.22.3.10.. So we have for this n that if each X_k satisfies $ind(X_k) \leq n$, then $Ind(X) \leq n$. In particular, if $ind(X) = n$, set $X_k = X$ for all k to conclude that $Ind(X) \leq n$. Since $ind(X) \leq Ind(X)$ (XIII.22.3.11.), we have $Ind(X) = n$. 👍

We now obtain some corollaries of XIII.22.3.13..

XIII.22.3.17. Corollary. Let X be a separable metrizable space. Then $ind(X) = Ind(X)$.

XIII.22.3.18. Corollary. If X is a countable regular space, then $Ind(X) = ind(X) = dim(X) = 0$.

Proof: A countable topological space is Lindelöf, so a countable regular space is normal. Each singleton set $\{x\}$ has $Ind(\{x\}) = 0$, thus $Ind(X) = 0$. We then have $ind(X) = 0$, so $dim(X) = 0$ by XIII.13.6.7.((iii) $\Rightarrow$ (iv)). 👍

The regularity assumption is necessary: there exist connected countable Hausdorff spaces ().

XIII.22.3.19. Corollary. [First Decomposition Theorem] Let X be a separable metrizable space, and $n \geq 0$. If $ind(X) = n$, then X can be written as a disjoint union $Y \cup Z$, where $ind(Y) = n-1$ and $ind(Z) = 0$. Conversely, if X can be so written, then $n-1 \leq ind(X) \leq n$.

Proof: Since $ind(X) = n$, there is an $x \in X$ and an open neighborhood U of X such that no open neighborhood V of x contained in U has $ind(\partial V) \leq n-2$. There is a countable base V for X with $ind(\partial V) \leq n-1$ for all $V \in \mathcal{V}$. Set

$$Y = \bigcup_{V \in \mathcal{V}} \partial V$$

and $Z = X \setminus Y$. Then $ind(Z) \leq 0$ by Lemma XIII.22.3.15.. We have $ind(Y) \leq n-1$ by XIII.22.3.13.. But if $V \in \mathcal{V}$ with $x \in V \subseteq U$, then $ind(\partial V) = n-1$, so $ind(Y) = n-1$ by XIII.22.3.7.. Thus $Z \neq \emptyset$, i.e. $ind(Z) = 0$.

For the converse, suppose $X = Y \cup Z$, where $ind(Y) = n-1$ and $ind(Z) = 0$. Then $ind(X) \geq n-1$ by XIII.22.3.7.. Let $x \in X$ and U an open neighborhood of x. Then by Lemma XIII.22.3.16. there are disjoint neighborhoods V_1 of x and V_2 of $X \setminus U$ such that $Z \subseteq V_1 \cup V_2$. Then $\partial V_1 \subseteq Y$, so $ind(\partial V_1) \leq n-1$; and $V_1 \subseteq U$. Thus $ind(X) \leq n$. 👍

Applying this result repeatedly, we obtain:

XIII.22.3.20. Corollary. [Second Decomposition Theorem] Let X be a separable metrizable space. Then $ind(X) \leq n$ if and only if X can be written as a disjoint union of $n+1$ subspaces $X_1, \ldots, X_{n+1}$ with $ind(X_k) \leq 0$ for all k. If $ind(X) = n$, then X can be so written with $ind(X_k) = 0$ for all k.

XIII.22.3.21. Large Inductive Dimension Ind, unlike ind, is not monotone: if Y is a subspace of X, it is not necessarily true that $Ind(Y) \leq Ind(X)$ (). But it is true if Y is closed in X: the proof is an easy induction similar to the proof of XIII.22.3.7..

Covering Dimension

This is perhaps the most generally useful notion of dimension. The idea is due to Lebesgue, but the actual definition was given by Čech.

XIII.22.3.22. The idea behind covering dimension is that $\mathbb{R}$ can be covered with small open intervals in such a way that only consecutive intervals overlap, i.e. no three of the intervals have nonempty intersection; however, since it is connected, it cannot be covered by pairwise disjoint bounded open intervals. Similarly, $\mathbb{R}^2$ can be covered by small open sets in such a way that no four of the sets have nonempty intersection (e.g. tile the plane with hexagons, or consider a brick wall, and slightly expand the tiles or bricks to open sets), but it appears that in any covering by bounded open sets at least three of the sets must have a nonempty intersection (although this turns out to be not so easy to prove). It is a little harder, but possible, to cover $\mathbb{R}^3$ with small open sets in such a way that no five of the sets have nonempty intersection (try it!), but in any open cover by bounded sets at least four of the sets must have nonempty intersection.

XIII.22.3.23. Definition. Let X be a topological space, and $\mathcal{U} = \{U_i : i \in I\}$ an open cover of X. Then $\mathcal{U}$ has *order* $\leq n$ if, whenever $i_1, \ldots, i_{n+2}$ are distinct elements of I, then

$$U_{i_1} \cap \cdots \cap U_{i_{n+2}} = \emptyset$$

(i.e. every point of X is contained in at most $n+1$ of the sets). $\mathcal{U}$ has *order* n if it has order $\leq n$ but not order $\leq n-1$, i.e. there are distinct $i_1, \ldots, i_{n+1}$ in I such that

$$U_{i_1} \cap \cdots \cap U_{i_{n+1}} \neq \emptyset \ .$$

XIII.22.3.24. Definition. Let X be a nonempty topological space. The *covering dimension* $dim(X)$ of X is $\leq n$ if every finite open cover of X has a refinement of order $\leq n$. Say $dim(X) = n$ if $dim(X) \leq n$ and it is false that $dim(X) \leq n-1$. If $dim(X) \leq n$ is false for all n, then $dim(X) = \infty$. Set $dim(\emptyset) = -1$.

XIII.22.3.25. Most, but not all, authors use $dim(X)$ to denote covering dimension, as we will; the notation $cov(X)$ is also sometimes used. But in some references such as [HW41], $dim(X)$ means something else ($ind(X)$ in [HW41]); some references on geometric measure theory such as [Edg98] use $dim(X)$ to denote the Hausdorff dimension of a metric space X (a metric, but not a topological, invariant ()).

XIII.22.3.26. An open cover $\mathcal{V}$ of a topological space X is order zero if and only if X is nonempty and $\mathcal{V}$ is a partition of X into clopen sets. Thus $dim(X) = 0$ if and only if X is nonempty and every finite open cover of X has a refinement consisting of a partition of X into clopen sets.

XIII.22.3.27. Proposition. Let X be a topological space. If $dim(X) = 0$, then $Ind(X) = 0$. If X is normal and $Ind(X) = 0$, then $dim(X) = 0$.

Proof: Suppose $dim(X) = 0$, Y is a closed subspace of X, and U is an open neighborhood of Y. The open cover $\{U, Y^c\}$ of X has a refinement $\{W_i\}$ consisting of clopen sets. Let V be the union of the W_i contained in U; then V is open. The complement V^c is a union of W_i's contained in Y^c, hence also open. So V is clopen, $V \subseteq U$, and $V^c \subseteq Y^c$, so $Y \subseteq V \subseteq U$. Thus $Ind(X) = 0$.

Conversely, suppose X is normal and $Ind(X) = 0$. Let $\mathcal{U} = \{U_1, \ldots, U_n\}$ be a finite open cover of X. By XIII.7.6.8., $\mathcal{U}$ has a closed shrinking $\{E_1, \ldots, E_n\}$. Since $Ind(X) = 0$, for each k there is a clopen set W_k with $E_k \subseteq W_k \subseteq U_k$. Thus $\{W_1, \ldots, W_n\}$ is an open cover of X. Inductively define

$$V_k = W_k \setminus \bigcup_{j<k} W_j \ .$$

Then the V_k are pairwise disjoint clopen sets with $V_k \subseteq U_k$ for each k. If $p \in X$, let k be the first index for which $p \in W_k$; then $p \in V_k$. So $\{V_1, \ldots, V_n\}$ is a partition of X into clopen sets which refines $\mathcal{U}$. Thus $dim(X) = 0$. 👍

The normality hypothesis can be eliminated using XIII.22.3.33. (XIII.22.3.34.), i.e. for any topological space X, $dim(X) = 0$ if and only if $Ind(X) = 0$. A refinement of the second half of the argument (cf. [Pea75,]) gives a partial inductive characterization of dim similar to the definition of Ind:

XIII.22.3.28. Theorem. Let X be a normal topological space, and $n \in \mathbb{N} \cup \{0\}$. Then $dim(X) \leq n$ if, whenever Y is a closed subspace of X and U an open neighborhood of Y, there is an open neighborhood V of Y contained in U with $dim(\partial V) \leq n - 1$.

An inductive argument then shows:

XIII.22.3.29. Corollary. Let X be a normal topological space. Then $dim(X) \leq Ind(X)$.

XIII.22.3.30. Note that the result XIII.22.3.28. is "if," not "if and only if" (it is "if and only if" if $n = 0$). We can have $dim(X) < Ind(X)$, even for compact Hausdorff spaces (). If X is metrizable, then $dim(X) = Ind(X)$ (). There is no relation between $dim(X)$ and $ind(X)$ for general normal spaces (), but see XIII.22.4.4.; and it follows from XIII.22.3.27. and XIII.22.3.11. that if X is T_1 and $dim(X) = 0$, then $ind(X) = 0$.

XIII.22.3.31. Covering dimension can be alternately be defined using open shrinkings (XIII.7.6.7.), a special kind of refinement. A refinement $\mathcal{V}$ of an open cover $\mathcal{U} = \{U_i : i \in I\}$ can be converted to an open shrinking using consolidation. A *consolidation* of $\mathcal{V}$ under $\mathcal{U}$ consists of, for each $V \in \mathcal{V}$, choosing an $i \in I$ with $V \subseteq U_i$ and calling this i $k(V)$. Then for each i set $W_i = \cup\{V \in \mathcal{V} : k(V) = i\}$. Then W_i is an open set contained in U_i for each i, and $\mathcal{W} = \{W_i : i \in I\}$ is an open cover of X since each $V \in \mathcal{V}$ is contained in some W_i. Thus $\mathcal{W}$ is an open shrinking of $\mathcal{U}$. If $\mathcal{U}$ is a finite open cover, then $\mathcal{W}$ is also a finite cover.

A consolidation of $\mathcal{V}$ under $\mathcal{U}$ is highly nonunique in general, and requires the AC to define.

It is easy to check that if $\mathcal{V}$ has order $\leq n$, then any consolidation of $\mathcal{V}$ under another open cover $\mathcal{U}$ also has order $\leq n$. Thus we obtain:

XIII.22.3.32. Proposition. Let X be a topological space, and $n \geq 0$. The following are equivalent:

(i) $dim(X) \leq n$.

(ii) Every finite open cover of X has a finite refinement of order $\leq n$.

(iii) Every finite open cover of X has an open shrinking of order $\leq n$.

The following sharpening is useful:

XIII.22.3.33. Theorem. Let X be a topological space, and $n \geq 0$. Then $dim(X) \leq n$ if and only if, whenever $\mathcal{U} = \{U_1, \ldots, U_{n+2}\}$ is an open cover of X with $n+2$ elements, there is an open shrinking of $\mathcal{U}$ of order $\leq n$.

Proof: If $dim(X) \leq n$, the condition trivially follows. Conversely, suppose $dim(X) > n$, and let $\mathcal{V} = \{V_1, \ldots, V_m\}$ be a finite open cover of X with no refinement of order $\leq n$ (so $m \geq n+2$). If $i_1, \ldots, i_k$ are distinct natural numbers $\leq m$, with $V_{i_1} \cap \cdots \cap V_{i_k} \neq \emptyset$, and $\mathcal{W} = \{W_1, \ldots, W_m\}$ is an open shrinking of $\mathcal{V}$ with $W_{i_1} \cap \cdots \cap W_{i_k} = \emptyset$, replace $\mathcal{V}$ by $\mathcal{W}$. Doing this process successively for each such $i_1, \ldots, i_k$ (there are only finitely many such sets), we may assume $\mathcal{V}$ has the property that whenever $i_1, \ldots, i_k \leq m$ and $V_{i_1} \cap \cdots \cap V_{i_k} \neq \emptyset$, and $\mathcal{W} = \{W_1, \ldots, W_m\}$ is an open shrinking of $\mathcal{V}$, then $W_{i_1} \cap \cdots \cap W_{i_k} \neq \emptyset$.

The reduction does not change the fact that the order of $\mathcal{V}$ is at least $n+1$, so reordering $\mathcal{V}$ if necessary we may assume $\cap_{j=1}^{n+2} V_j \neq \emptyset$. Now set $U_j = V_j$ if $1 \leq j \leq n+1$ and $U_{n+2} = \cup_{j=n+2}^{m} V_j$. If $\mathcal{W} = \{W_1, \ldots, W_{n+2}\}$ is an open shrinking of $\mathcal{U}$, then

$$\{W_1, \ldots, W_{n+1}, W_{n+2} \cap V_{n+2}, \ldots, W_{n+2} \cap V_m\}$$

is an open shrinking of $\mathcal{V}$, and hence

$$\emptyset \neq \left(\cap_{j=1}^{n+1} W_j\right) \cap (W_{n+2} \cap V_{n+2}) \subseteq \cap_{j=1}^{n+2} W_j \ .$$

An application removes the normality hypothesis from XIII.22.3.27.:

XIII.22.3.34. PROPOSITION. Let X be a topological space. If $Ind(X) = 0$, then $dim(X) = 0$. Thus $Ind(X) = 0$ if and only if $dim(X) = 0$.

PROOF: If $dim(X) = 0$, then $Ind(X) = 0$ by XIII.22.3.27.. Conversely, suppose $Ind(X) = 0$. By XIII.22.3.33., to show that $dim(X) = 0$ it suffices to show that if $\{U, V\}$ is an open cover of X, there is a refinement $\{W, W^c\}$ of $\{U, V\}$ of order 0, i.e. a clopen set W with $V^c \subseteq W \subseteq U$. But this follows immediately from the definition that $Ind(X) = 0$ since V^c is a closed set and U is an open neighborhood of V^c. 👍

There is a locally compact Hausdorff space X with $ind(X) = 0$ but $dim(X) > 0$ and $Ind(X) > 0$ (XIII.11.14.8.).

Here is another simple consequence:

XIII.22.3.35. COROLLARY. Let X be a normal space. If $card(X) < 2^{\aleph_0}$, then $dim(X) = 0$.

PROOF: Let $\{U, V\}$ be an open cover of X. Then U^c and V^c are disjoint closed sets in X, so by Urysohn's Lemma there is a continuous function $f : X \to [0, 1]$ with $f = 0$ on U^c and $f = 1$ on V^c. Then $f(X)$ is a subset of $[0, 1]$ of cardinality $< 2^{\aleph_0}$, so cannot contain any interval; thus there is an $r \in (0, 1) \setminus f(X)$. The sets $Z = \{x \in X : f(x) > r\}$ and $W = \{x \in X : f(x) < r\}$ form a partition of X into clopen sets, with $Z \subseteq U$ and $W \subseteq V$. Thus $dim(X) = 0$. 👍

XIII.22.3.36. PROPOSITION. Let X be a normal space, and $n \geq 0$. If, for every pair A, B of disjoint closed sets of X there is a partition P between A and B with $dim(P) \leq n - 1$, then $dim(X) \leq n$. 3.1.27

XIII.22.3.37. Why finite open covers, and not general open covers? Mainly, the theory just turns out to work well this way. But note that any open cover of finite order is locally finite, and there are spaces, even normal spaces, with open covers which have no locally finite (even no point-finite) refinements (XIII.11.14.12.). But for paracompact spaces, there is no difference:

XIII.22.3.38. THEOREM. [DOWKER'S THEOREM] Let X be a topological space with $dim(X) \leq n$, and $\mathcal{U}$ a locally finite open cover of X. Then $\mathcal{U}$ has a refinement of order $\leq n$.

XIII.22.3.39. COROLLARY. Let X be a paracompact space. The following are equivalent:

(i) $dim(X) \leq n$.

(ii) Every finite open cover of X has a shrinking of order $\leq n$.

(iii) Every open cover of X has a refinement of order $\leq n$.

(iv) Every open cover of X has an open shrinking of order $\leq n$.

XIII.22.3.40. THEOREM. [Hem46] Let X and Y be compact Hausdorff spaces. Then $dim(X \times Y) \leq dim(X) + dim(Y)$.

Compare with XIII.22.3.12..

XIII.22.3.41. Covering dimension is not well behaved for spaces which are not normal. There is a technical variation which works somewhat better for completely regular spaces (dimension theory is of almost no use or interest for spaces which are not at least completely regular). Recall that a set U in a topological space X is a *cozero set* if there is a continuous function $f : X \to \mathbb{R}$ with $U = \{x \in X : f(x) \neq 0\}$. A cozero set is an open F_σ; if X is normal, the converse is also true. Some references use the term *functionally open* for cozero sets.

XIII.22.3.42. DEFINITION. Let X be a topological space. Then $zdim(X) \leq n$ if every finite open cover of X by cozero sets has a finite refinement by cozero sets which is of order $\leq n$.

XIII.22.3.43. There is no obvious relation between $dim(X)$ and $zdim(X)$ for general (even completely regular) spaces X. The two can differ: the spaces of XIII.11.14.7. and XIII.11.14.8. have $zdim$ 0, but $dim > 0$ since they are not normal. It is possible that $zdim(X) \leq dim(X)$ for all completely regular X, although this is not obvious (since $zdim(X) = dim(\beta X)$ for every completely regular X, this is equivalent to the question whether $dim(\beta X) \leq dim(X)$ for every completely regular X). But every open cover of a normal space has a shrinking consisting of cozero sets (Exercise XIII.22.8.2.); hence if X is normal, $zdim(X) = dim(X)$. Some authors define the covering dimension of a space X to be $zdim(X)$, and $zdim$ is written ∂im in some references.

Nuclear Dimension

There is an interesting characterization of covering dimension for spaces, which has an important generalization to C*-algebras (cf. [**?**]). This characterization was implicit in [HW41] (it can be easily proved from XIII.22.3.20.), but was apparently not explicitly described until [KW04]. In honor of the authors who described it and the applications to the classification of C*-algebras, we call this *nuclear dimension*. This notion has close connections to the Besicovitch Covering Theorem ().

XIII.22.3.44. DEFINITION. Let X be a topological space. An open cover $\mathcal{U}$ of X is *n-decomposable* if $\mathcal{U}$ is a disjoint union $\mathcal{U} = \mathcal{U}_1 \cup \cdots \cup \mathcal{U}_{n+1}$ of $n+1$ subcollections, each of which consists of pairwise disjoint sets.

XIII.22.3.45. DEFINITION. A topological space X has *nuclear dimension* $\leq n$ if every finite open cover of X has an n-decomposable refinement. The *nuclear dimension* $dim_{nuc}(X)$ is the smallest n such that X has nuclear dimension $\leq n$ ($dim_{nuc}(X) = \infty$ if there is no such n).

XIII.22.3.46. It is obvious that an n-decomposable open cover has order $\leq n$. The converse is false: consider a cover of a circle by three arcs. (A cover is 0-decomposable if and only if it has order zero, i.e. consists of a partition into clopen subsets.) Thus $dim(X) \leq dim_{nuc}(X)$ for any X.

However, we do have:

XIII.22.3.47. PROPOSITION. Let X be a normal topological space, and $0 \leq n < \infty$. Then every open cover of X of order n has an n-decomposable refinement.

PROOF: Let $\mathcal{V}$ be an open cover of X of order n. Since $\mathcal{V}$ is locally finite, there is a partition of unity $\{f_i\}$ subordinate to $\mathcal{V}$ (), which defines a continuous function ϕ from X to $|K|$ for a simplicial complex K of dimension $\leq n$ (). Let K' be the barycentric subdivision of K. Then each vertex σ of K' is the barycenter of a unique simplex Δ_σ of K; let $d(\sigma) \in \{0, \ldots, n\}$ be the dimension of Δ_σ.

Since $|K'|$ can be identified with $|K|$, ϕ may be regarded as a map from X to $|K'|$. For each vertex σ of K', let U_σ be the preimage under ϕ of the star of σ, the points of $|K'|$ whose σ-coordinate is positive. Then $\mathcal{U} = \{U_\sigma\}$ is an open cover of X which refines $\mathcal{V}$. For each k, $0 \leq k \leq n$, let

$$\mathcal{U}_k = \{U_\sigma : d(\sigma) = k\} \ .$$

Then $\mathcal{U}$ is the disjoint union of the $\mathcal{U}_k$. If σ, τ are vertices of K' with $d(\sigma) = d(\tau) = k$, then σ and τ are the barycenters of distinct k-simplexes in K, so the stars of σ and τ are disjoint, and thus U_σ and U_τ are disjoint. So $\mathcal{U}$ is n-decomposable. If $\mathcal{V}$ is finite, K (hence K') is finite, so $\mathcal{U}$ is also finite. 👍

XIII.22.3.48. COROLLARY. Let X be a normal topological space. Then $dim(X) = dim_{nuc}(X)$.

XIII.22.3.49. Actually, $dim_{nuc}(X) = zdim(X)$ for any completely regular space ().

Partition Dimension

In analogy with the Lebesgue Covering Theorem (), we make another definition:

XIII.22.3.50. DEFINITION. Let X be a nonempty topological space. The *partition dimension* $pd(X)$ is the smallest $n \geq 0$ such that, whenever $(A_1, B_1), \ldots, (A_{n+1}, B_{n+1})$ are $n+1$ pairs of disjoint closed sets in X, there are partitions P_k of (A_k, B_k) for $1 \leq k \leq n+1$ with $P_1 \cap \cdots \cap P_{n+1} = \emptyset$. If there is no such n, set $pd(X) = \infty$. Set $pd(\emptyset) = -1$.

XIII.22.3.51. If X is a topological space, then $pd(X) \leq n$ if and only if, whenever $(A_1, B_1), \ldots, (A_{n+1}, B_{n+1})$ are $n+1$ pairs of disjoint closed sets in X, there are partitions P_k of (A_k, B_k) for $1 \leq k \leq n+1$ with $P_1 \cap \cdots \cap P_{n+1} = \emptyset$. If X is normal and this condition holds for one n, it holds for all larger n (and if the condition holds for some n, then X is normal). The Lebesgue Covering Theorem implies that $pd(B_n) \geq n$.

Decomposition Dimension

We define one more notion of dimension:

XIII.22.3.52. DEFINITION. Let X be a nonempty topological space. The *decomposition dimension* $dd(X)$ is the smallest n such that X can be written

$$X = X_1 \cup \cdots \cup X_{n+1}$$

where $ind(X_k) \leq 0$ for $1 \leq k \leq n+1$. If there is no such n, then $dd(X) = \infty$. Set $dd(\emptyset) = -1$.

XIII.22.3.53. The Second Decomposition Theorem (XIII.22.3.20.) says that $dd(X) = ind(X)$ for any separable metrizable X.

Local Dimensions

There have been (at least) two rather different local dimensions defined in the literature, with the second having some variations. The first was introduced by MENGER [Men28] and used in [HW41]. We use the nonstandard notation *lind* for this version to distinguish it from the second version.

XIII.22.3.54. DEFINITION. If X is a topological space and $x \in X$, define $lind_x(X)$ inductively: $lind_x(X) \leq n$ if and only if, whenever U is an open neighborhood of x in X, there is an open neighborhood V of x contained in U with $ind(\partial V) \leq n-1$. Define $lind_x(X)$ to be the smallest n such that $lind_x(X) \leq n$. If there is no such n, set $lind_x(X) = \infty$.

XIII.22.3.55. We clearly have $lind_x(X) \leq ind(X)$ for each x, and by definition $ind(X) = \sup_{x\in X} lind_x(X)$.

The second type of local dimension was defined by DOWKER [**?**] and used e.g. in [Pea75]. We give the definition using *dim*; any of the other standard dimension theories can be used in its place. We restrict to regular spaces, where the definition is more natural due to the following result:

XIII.22.3.56. PROPOSITION. Let X be a regular topological space, and $x \in X$. Then the following numbers coincide:

n_1, the smallest $n \in \{0\} \cup \mathbb{N} \cup \{\infty\}$ such that there is an open neighborhood U of x with $dim(\bar{U}) \leq n$.

n_2, the smallest $n \in \{0\} \cup \mathbb{N} \cup \{\infty\}$ such that there is a closed neighborhood U of x with $dim(U) \leq n$.

n_3, the smallest $n \in \{0\} \cup \mathbb{N} \cup \{\infty\}$ such that there is a neighborhood U of x with $dim(U) \leq n$.

The same result holds if *dim* is replaced by *ind* or *Ind*.

PROOF: Trivially $n_3 \leq n_2 \leq n_1$. Let U be a neighborhood of x with $dim(U) = n_3$. Then U contains an open neighborhood V of x, and V contains an open neighborhood W of x with $\bar{W} \subseteq V$ (). Since $\bar{W}$ is a closed subset of U, by () we have

$$n_1 \leq dim(\bar{W}) \leq dim(U) = n_3 \ .$$

XIII.22.3.57. DEFINITION. Let X be a regular topological space, and $x \in X$. The local dimension $dim_x(X)$ of X at x is the common value of the three numbers in XIII.22.3.56.. (If X is not regular, it is customary to define $dim_x(X)$ to be n_1.) Similarly define ind_x and $Ind_x(X)$. Define

$$loc\, dim(X) = \sup_{x\in X} dim_x(X)$$
$$loc\, ind(X) = \sup_{x\in X} ind_x(X)$$
$$loc\, Ind(X) = \sup_{x\in X} Ind_x(X) \ .$$

XIII.22.3.58. We clearly have $dim_x(X) \leq dim(X)$, $ind_x(X) \leq ind(X)$, and $Ind_x(X) \leq Ind(X)$ for any X and x; thus $loc\,dim(X) \leq dim(X)$, $loc\,ind(X) \leq ind(X)$, $loc\,Ind(X) \leq Ind(X)$ for any X.

If X is T_1, then $ind(Y) \leq Ind(Y)$ for any subspace Y of X, so $ind_x(X) \leq Ind_x(X)$ for any $x \in X$ and hence $loc\,ind(X) \leq loc\,Ind(X)$. Similarly, if X is normal, then any closed subset Y of X is normal, so $dim(Y) \leq Ind(Y)$; thus $dim_x(X) \leq Ind_x(X)$ for any $x \in X$ and hence $loc\,dim(X) \leq loc\,Ind(X)$.

XIII.22.3.59. PROPOSITION. Let X be a topological space. Then $loc\,ind(X) = ind(X)$.

PROOF: We have $loc\,ind(X) \leq ind(X)$. For the reverse inequality, set $loc\,ind(X) = n$. Let $x \in X$ and let U be an open neighborhood of X with $ind(\bar{U}) = n$. Let V be an open neighborhood of x. Then $U \cap V$ is an open neighborhood of X contained in U. Since $ind(\bar{U}) = n$, there is a relatively open neighborhood W of x contained in $U \cap V$ with $ind(\partial_{\bar{U}} W) \leq n - 1$. But since $U \cap V$ is open in X, so is W, and since $W \subseteq U$, $\partial_{\bar{U}} W = \partial_X W$. Since $W \subseteq V$ and $ind(\partial_X W) \leq n - 1$, and $x \in X$ is arbitrary, $ind(X) \leq n$. 👍

XIII.22.3.60. Thus $loc\,ind$ is of little or no interest. However, $loc\,dim$ can differ from dim, and $loc\,Ind$ from Ind, so they are of some interest. The most dramatic example is that, under some set-theoretic assumptions such as the Continuum Hypothesis or the Diamond Principle, for any $n \geq 4$ a normal locally Euclidean space X can be constructed in which each point has an open neighborhood homeomorphic to $\mathbb{R}^n$ (X is a "nonmetrizable n-manifold"), so $ind(X) = loc\,dim(X) = loc\,Ind(X) = n$, but for which $dim(X)$ and $Ind(X)$ are greater than n. See [Fed98] (which contains a detailed survey of the history of dimension theory). Other examples show that the failure of equality for general compact Hausdorff spaces does not depend on additional set-theoretic assumptions.

XIII.22.3.61. COROLLARY. If X is T_1, then $ind(X) \leq loc\,Ind(X)$.

To compare and contrast the approaches to local dimension of MENGER and DOWKER:

XIII.22.3.62. PROPOSITION. Let X be a regular topological space, and $x \in X$. Then $lind_x(X) \leq ind_x(X)$.

PROOF: Set $ind_x(X) = n$. Let U be an open neighborhood of X with $ind(\bar{U}) = in$. Then there is an open neighborhood V of x with $\bar{V} \subseteq U$. Since $ind(\bar{U}) = n$, there is a relatively open neighborhood W of x contained in V with $ind(\partial_{\bar{U}} W) \leq n-1$. But since V is open in X, so is W, and since $\bar{V} \subseteq U$, $\partial_{\bar{U}} W = \partial_X W$. Thus $lind_x(X) \leq n$. 👍

For regular spaces X, this gives another proof that $loc\,ind(X) = ind(X)$:

$$ind(X) = \sup_{x \in X} lind_x(X) \leq \sup_{x \in X} ind_x(X) = loc\,ind(X) \leq ind(X) \ .$$

This also implies that if X is regular and $ind(X) < \infty$, then $lind_x(X) = ind_x(X) = ind(X)$ for at least one $x \in X$. But not necessarily for all x:

XIII.22.3.63. EXAMPLE. The local dimensions $lind_x$ and ind_x can differ dramatically at some points, even in nice spaces. Let X be the one-point compactification of the separated union of $[0,1]^n$ for all n. Then X is a compact metrizable space. If p is the point at infinity, then $lind_p(X) = 0$ since there is a local base at p of clopen sets; but $ind(U) = \infty$ for any neighborhood U of p, so $ind_p(X) = \infty$.

The set of x for which $lind_x(X) = ind(X)$ is interesting to consider, and is the primary interest of MENGER'S approach; cf. Exercise XIII.22.8.5..

XIII.22.3.64. REMARK. If X is a topological space, we can also define

n_4, the smallest $n \in \{0\} \cup \mathbb{N} \cup \{\infty\}$ such that there is an open neighborhood U of x with $dim(U) \leq n$.

If X is regular, $n_4 \geq n_3 = dim_x(X)$, but they are not obviously equal since dim is not monotone in general. Similarly, if Ind is used in place of dim, we obtain that $n_4 \geq Ind_x(X)$. If X is totally normal (e.g. if X is metrizable), then $n_4 = dim_x(X)$ or $n_4 = Ind_x(X)$, as the case may be, for any $x \in X$.

XIII.22.4. Comparing the Dimensions

All the dimensions defined so far agree for separable metric spaces:

XIII.22.4.1. THEOREM. Let X be a topological space which is separable and metrizable (equivalently, second countable and regular). Then $ind(X) = Ind(X) = dim(X) = ed(X) = pd(X) = dd(X)$.

This result not only confirms that for "nice" spaces there is an unambiguous notion of topological dimension, but is also useful since some properties of dimension are proved easily for some of the dimension functions and not so easily for others. Proofs of the theorem can be found in [HW41] and [Eng95].

For general spaces, even for metrizable spaces or compact Hausdorff spaces, the dimension functions do not always agree. We state without proof some of the principal relations between them; see e.g. [HW41], [Pea75], [Eng95].

XIII.22.4.2. THEOREM. ([Kat52], [Mor54b]) If X is a metrizable space (not necessarily separable), then $Ind(X) = dim(X)$.

XIII.22.4.3. There is a completely metrizable space X with $ind(X) = 0$ and $Ind(X) = dim(X) = 1$ [Roy68]. There are first countable compact Hausdorff spaces X with $ind(X) < Ind(X)$ ([Fil69], [Pas70]). More examples can be found in [Nag70] and [Pea75].

XIII.22.4.4. THEOREM. [?] If X is a compact Hausdorff space, then $dim(X) \leq ind(X)$.

The result extends to strongly paracompact spaces, and in particular to Lindelöf spaces, but not even to completely metrizable spaces as ROY'S example shows. There is a compact Hausdorff space X with $dim(X) < ind(X)$ ([Lun49]; cf. [Eng95, 3.1.31]).

XIII.22.4.5. THEOREM. [Ale47] If X is completely regular, then $ed(X) = zdim(X)$. If X is normal, then $ed(X) = dim(X)$.

The next result is a corollary of XIII.22.3.7. and XIII.22.4.1.:

XIII.22.4.6. COROLLARY. Let X be a separable metrizable space and Y a subset of X. Then $dim(Y) \leq dim(X)$.

XIII.22.4.7. There is an example of a compact Hausdorff space X and a normal subspace Y such that $dim(X) = Ind(X) = 0$ and $dim(Y) = Ind(Y) = 1$ ([Dow55]; cf. [Eng95, 2.2.11], [GJ76, 16M]).

For separable metrizable spaces, we obtain a strengthening of XIII.22.3.29.:

XIII.22.4.8. PROPOSITION. Let X be a separable metrizable space (or, more generally, a completely normal hereditarily Lindelöf space). Then $dim(X) \leq dd(X) (= ind(X))$.

PROOF: Suppose $dd(X) \leq n$, i.e. $X = X_1 \cup \cdots \cup X_{n+1}$ with $ind(X_k) \leq 0$ for all k. Let $\mathcal{U} = \{U_1, \ldots, U_m\}$ be a finite open cover of X. For each k, we have $dim(X_k) \leq 0$ (), so the cover $\{U_1 \cap X_k, \ldots, U_m \cap X_k\}$ of X_k has a shrinking $\{F_1, \ldots, F_m\}$ consisting of relatively clopen subsets of X_k. Since X is completely normal, there are disjoint open neighborhoods $\{V_{1,k}, \ldots, V_{m,k}\}$ of $F_1, \ldots, F_m$ in X. Consider the open cover $\mathcal{W}$ of X consisting of all sets of the form $U_j \cap V_{j,k}$. Then $\mathcal{W}$ refines $\mathcal{U}$, and has order $\leq n$ since for any $n+2$ distinct sets $U_{j_i} \cap V_{j_i,k_i}$ in $\mathcal{W}$ there must be some k with $k_i = k$ for two distinct i. Thus $dim(X) \leq n$. 👍

This result also follows from XIII.22.3.29. and the fact that $dd(X) = ind(X) = Ind(X)$ for separable metrizable spaces (XIII.22.3.17., XIII.22.3.53.), but this requires the Sum Theorem for ind; the inequality $dim(X) \leq dd(X)$ for separable metrizable spaces does not require the Sum Theorem.

XIII.22.4.9. PROPOSITION. Let X be a normal topological space. Then $pd(X) \leq dim(X)$.

PROOF: Suppose $dim(X) \leq n$, and let $\{(A_1, B_1), \ldots, (A_{n+1}, B_{n+1})\}$ be a set of $n+1$ pairs of disjoint closed subsets of X. Then the open cover

$$\left\{ X \setminus A_1,\ \ldots\ ,\ X \setminus A_{n+1},\ X \setminus \left(\bigcup_{k=1}^{n+1} B_k \right) \right\}$$

has a shrinking $\mathcal{V} = \{V_1, \ldots, V_{n+2}\}$ of order $\leq n$. Let $\{F_1, \ldots, F_{n+2}\}$ be a closed shrinking of $\mathcal{V}$. For $1 \leq k \leq n+1$ define

$$\tilde{A}_k = A_k \cup (F_{n+2} \setminus V_k), \quad \tilde{B}_k = B_k \cup F_k\ .$$

Since $A_k \cap F_k = \emptyset$ and $B_k \cap F_{n+2} = \emptyset$ for each k, we have $\tilde{A}_k \cap \tilde{B}_k = \emptyset$. Also,

$$\bigcup_{k=1}^{n+1} F_k \subseteq \bigcup_{k=1}^{n+1} \tilde{B}_k\ .$$

We have that

$$F_{n+2} \cap \left(\bigcap_{k=1}^{n+1} V_k \right) \subseteq V_{n+2} \cap \left(\bigcap_{k=1}^{n+1} V_k \right) = \emptyset$$

since $\mathcal{V}$ has order $\leq n$. Thus $F_{n+2} \subseteq \cup_{k=1}^{n+1} \tilde{A}_k$. Since $\cup_{k=1}^{n+2} F_k = X$, we have

$$\bigcup_{k=1}^{n+1} (\tilde{A}_k \cup \tilde{B}_k) = X \ .$$

Let P_k be a partition between $\tilde{A}_k$ and $\tilde{B}_k$ for each k. Then P_k is a partition between A_k and B_k, and $\cap_{k=1}^{n+1} P_k = \emptyset$ since it is disjoint from $\cup_{k=1}^{n+1} (\tilde{A}_k \cup \tilde{B}_k) = X$. 👍

XIII.22.4.10. PROPOSITION. Let X be a normal space. Then $dim(X) = pd(X)$.

PROOF: Because of XIII.22.4.9., we need to show that $dim(X) \leq pd(X)$. Assume $pd(X) \leq n$, and let $\mathcal{U} = \{U_1, \ldots, U_{n+2}\}$ be an open cover of X. There is a closed shrinking $\{A_1, \ldots, A_{n+2}\}$ of $\mathcal{U}$. Set $B_k = X \backslash U_k$. Then $\{(A_1, B_1), \ldots, (A_{n+1}, B_{n+1})\}$ is a family of pairs of disjoint closed sets in X, so there are partitions P_k between A_k and B_k for $1 \leq k \leq n+1$ with $\cap_{k=1}^{n+1} P_k = \emptyset$, i.e. for each $k \leq n+1$ there are disjoint open sets V_k, W_k containing A_k and B_k respectively with

$$\bigcap_{k=1}^{n+1} X \setminus (V_k \cup W_k) = \emptyset \ .$$

Set

$$V_{n+2} = U_{n+2} \cap \left(\bigcup_{k=1}^{n+1} W_k \right) \ .$$

Then $V_k \subseteq U_k$ for all k, and

$$\begin{aligned}
\bigcup_{k=1}^{n+2} V_k &= \left(\bigcup_{k=1}^{n+1} V_k \right) \cup \left(U_{n+2} \cap \left[\bigcup_{k=1}^{n+1} W_k \right] \right) \\
&= \left(\bigcup_{k=1}^{n+1} V_k \cup U_{n+2} \right) \cap \left(\left[\bigcup_{k=1}^{n+1} V_k \right] \cup \left[\bigcup_{k=1}^{n+1} W_k \right] \right) \\
&= \left(\bigcup_{k=1}^{n+1} V_k \cup U_{n+2} \right) \cap X = \bigcup_{k=1}^{n+1} V_k \cup U_{n+2} \supseteq \bigcup_{k=1}^{n+2} A_k = X
\end{aligned}$$

so $\mathcal{V} = \{V_1, \ldots, V_{n+2}\}$ is a shrinking of $\mathcal{U}$. We also have

$$\begin{aligned}
\bigcap_{k=1}^{n+2} V_k &= \left(\bigcap_{k=1}^{n+1} V_k \right) \cap \left(U_{n+2} \cap \left[\bigcup_{k=1}^{n+1} W_k \right] \right) \\
&\subseteq \left(\bigcap_{k=1}^{n+1} V_k \right) \cap \left(\bigcup_{k=1}^{n+1} W_k \right) = \emptyset
\end{aligned}$$

so $\mathcal{V}$ has order $\leq n$. By XIII.22.3.33., $dim(X) \leq n$. 👍

XIII.22.4.11. PROPOSITION. Let X be a completely regular space. Then $pd(X) \leq ed(X)$.

PROOF: We will use XIII.22.1.8.. Suppose $ed(X) \leq n$, and let $(A_1, B_1), \ldots, (A_{n+1}, B_{n+1})$ be $n+1$ pairs of disjoint closed sets in X. Let Y be the union of all the A_k and B_k. Then Y is a closed subset of X. For each k, $1 \leq k \leq n+1$, set $f_k(x) = 0$ if $x \in A_k$ and $f_k(x) = 1$ if $x \in B_k$. If $f = (f_1, \ldots, f_{n+1})$, then f is a map from Y to $\partial I^{n+1} \cong S^n$. By XIII.22.1.8., f extends to a map g from X to ∂I^{n+1}. Let g_k $(1 \leq k \leq n+1)$ be the k'th coordinate function of g; then g_k extends f_k to X. Set $P_k = g_k^{-1}(1/2)$. Then P_k is a partition between A_k and B_k, and $P_1 \cap \cdots P_{k+1} = \emptyset$ since $\left(\frac{1}{2}, \ldots, \frac{1}{2}\right) \notin \partial I^{n+1}$. Thus $pd(X) \leq n$. 👍

XIII.22.4.12. PROPOSITION. Let X be a normal space. Then $ed(X) = pd(X)$.

PROOF: We need only show $ed(X) \leq pd(X)$. We again use XIII.22.1.8.. Suppose $pd(X) \leq n$, Y is a closed subset of X, and f is a map from Y to ∂I^{n+1}. For $1 \leq k \leq n+1$, let A_k [resp. B_k] be the set of $x \in X$ such that the k'th coordinate of $f(x)$ is 0 [resp. 1]. Then there are partitions P_k between A_k and B_k for each k, with $\cap_{k=1}^{n+1} P_k = \emptyset$ since $pd(X) \leq n$, i.e. for each $k \leq n+1$ there are disjoint open sets V_k, W_k containing A_k and B_k respectively with

$$\bigcap_{k=1}^{n+1} X \setminus (V_k \cup W_k) = \emptyset \ .$$

Let $\{U_1, \ldots, U_{n+1}\}$ be a swelling of $\{P_1, \ldots, P_{n+1}\}$ (XIII.7.6.11.), so $P_k \subseteq U_k$ and $\cap_{k=1}^{n+1} U_k = \emptyset$. Then $V_k \cup P_k$ and $W_k \cup P_k$ are closed in X, hence normal, so by Urysohn's Lemma there is a map $\phi_k : V_k \cup P_k \to \left[0, \frac{1}{2}\right]$ with $\phi_k(V_k \setminus U_k) = \{0\}$ and $\phi_k(P_k) = \left\{\frac{1}{2}\right\}$, and a map $\psi_k : W_k \cup P_k \to \left[\frac{1}{2}, 1\right]$ with $\psi_k(P_k) = \left\{\frac{1}{2}\right\}$ and $\psi_k(W_k \setminus U_k) = \{1\}$. Then ϕ_k and ψ_k define a map f_k from X to $[0,1]$ since they agree on the closed set $P_k = (V_k \cup P_k) \cap (W_k \cup P_k)$. We have $g_k(A_k) = \{0\}$ and $g_k(B_k) = \{1\}$. The g_k define a map $g : X \to I^n$. Since $g_k^{-1}\left(\left\{\frac{1}{2}\right\}\right) \subseteq U_k$ for each k and $\cap_{k=1}^{n+1} U_k = \emptyset$, g never takes the value $p = \left(\frac{1}{2}, \ldots, \frac{1}{2}\right)$. If r is a retraction from $I^n \setminus \{p\}$ to ∂I^n, then $r \circ g$ is an extension of f to X. 👍

Combining XIII.22.4.12. with XIII.22.4.10., we obtain:

XIII.22.4.13. COROLLARY. Let X be a normal space. Then $dim(X) = pd(X) = ed(X)$.

XIII.22.4.14. In fact, by an extension of the same methods it can be shown that $ed(X) = zdim(X)$ for any completely regular X ().

The hardest of the inequalities in XIII.22.4.1. is that $ind(X) \leq dim(X)$. We now work on this.

XIII.22.4.15. We have $Ind(X) \leq dim(X)$ (and hence $Ind(X) = dim(X)$ by XIII.22.3.29.) if X is metrizable.

Summary

We summarize the inequalities for the various dimension functions we have considered (except dd). To simplify to the only cases of substantial interest, we will only consider *normal* spaces.

XIII.22.4.16. If X is a normal topological space, then

$$ind(X) \leq loc\, Ind(X) \leq Ind(X)$$

$$loc\, dim(X) \leq dim(X) \leq Ind(X)$$

$$ed(X) = pd(X) = dim(X) \ .$$

Examples show that there are no further inequalities among $ind(X)$, $Ind(X)$, $dim(X)$, $loc\, Ind(X)$, $loc\, dim(X)$, $ed(X)$, and $pd(X)$ for general normal X.

If X is a compact Hausdorff space, then we have

$$loc\, dim(X) = dim(X) \leq ind(X) \leq loc\, Ind(X) = Ind(X)$$

$$ed(X) = pd(X) = dim(X) \ .$$

Examples show that there are no further inequalities among $ind(X)$, $Ind(X)$, $dim(X)$, $loc\, Ind(X)$, $loc\, dim(X)$, $ed(X)$, and $pd(X)$ for general compact Hausdorff X.

If X is a metrizable topological space, then we have

$$ind(X) \leq loc\, Ind(X) = loc\, dim(X) = dim(X) = Ind(X) = ed(X) = pd(X) \ .$$

If X is separable and metrizable (equivalently, second countable and regular), then $ind(X)$ is equal to the others. Examples show that $ind(X)$ can be less than the others for general metrizable X.

XIII.22.5. More Dimension Theories

Analytic Dimension

XIII.22.5.1. Let X be a completely regular topological space. We will give a characterization due to Katětov of $zdim(X)$ in terms of the ring (algebra) $BC_{\mathbb{R}}(X)$ of bounded real-valued continuous functions on X. (This ring is denoted $C^*(X)$ in many references such as [GJ76], which is a thorough study of topology via these rings. We have adopted different notation since $C^*(X)$ is too easily confused with C*-algebra notation.) $BC_{\mathbb{R}}(X)$ has a norm

$$\|f\| = \sup_{x \in X} |f(x)|$$

under which it is a real Banach space. The norm is determined by the algebraic structure since it can be defined using the order structure, and a function is nonnegative if and only if it is a square. Note that every subring of $BC_{\mathbb{R}}(X)$ containing the constant functions is a subalgebra (all subrings we consider will contain the constant functions).

XIII.22.5.2. If X is compact, or more generally countably compact, then $BC_{\mathbb{R}}(X) = C_{\mathbb{R}}(X)$, the set of all real-valued continuous functions on X [if $f : X \to \mathbb{R}$ is continuous, then $\{f^{-1}((-n, n)) : n \in \mathbb{N}\}$ is a countable open cover of X which has a finite subcover]. A space X with $BC_{\mathbb{R}}(X) = C_{\mathbb{R}}(X)$ is called *pseudocompact*; there exist pseudocompact spaces which are not countably compact, but every normal pseudocompact space is countably compact [GJ76, 3D]. In general, we have a natural identification $BC_{\mathbb{R}}(X) \cong C_{\mathbb{R}}(\beta X)$, where βX is the Stone-Čech compactification of X ().

XIII.22.5.3. The idea behind KATĚTOV'S characterization is that if X is a compact subset of $\mathbb{R}^n$, then polynomials in the coordinate functions are dense in $C_{\mathbb{R}}(X)$, i.e. $C_{\mathbb{R}}(X)$ has a dense unital subalgebra generated by n elements (the coordinate functions). This turns out to be the minimum number of generators of a dense unital subalgebra if $dim(X) = n$, e.g. if X has nonempty interior.

XIII.22.5.4. Simply taking the minimum number of generators of a dense unital subalgebra does not work as a satisfactory notion of dimension for a general X, however. For one thing, $BC_{\mathbb{R}}(X)$ can easily be nonseparable, and will be if βX is not metrizable, e.g. if X is not compact; then even no countably generated subalgebra can be dense. And the wrong answer is obtained even for a space as simple as a circle S^1: the minimum number of generators of a dense unital subalgebra of $C_{\mathbb{R}}(S^1)$ is two, since no real-valued continuous function on S^1 separates points.

The key trick is to consider analytic subrings:

XIII.22.5.5. DEFINITION. Let X be a completely regular space. An *analytic subring* of $BC_{\mathbb{R}}(X)$ is a closed unital subalgebra A with the property that if $f^2 \in A$, then $f \in A$. The smallest analytic subring containing a set $\mathcal{F}$ of functions is called the *analytic subring generated by* $\mathcal{F}$.

Note that any intersection of analytic subrings is an analytic subring, so there is always a smallest analytic subring containing any given set of functions.

XIII.22.5.6. EXAMPLES. (i) The example of the unit circle $S^1 = \{(x, y) \in \mathbb{R}^2 : x^2 + y^2 = 1\}$ nicely illustrates the idea. Let $f(x, y) = x$. Then the unital subalgebra generated by f is not dense in $C_{\mathbb{R}}(S^1)$. However, if A is the analytic subring of $C_{\mathbb{R}}(S^1)$ generated by f, then A contains $g = 1 - f^2$. We have $g(x, y) = 1 - x^2 = y^2$. Thus A also contains $h(x, y) = y$ since $g = h^2$, and it follows from the Stone-Weierstrass Theorem () that A is all of $C_{\mathbb{R}}(S^1)$. Thus $C_{\mathbb{R}}(S^1)$ is generated as an analytic subring by one function, i.e. "S^1 is one-dimensional."

(ii) Let X be compact. Consider the analytic subring A generated by the empty set, i.e. the smallest analytic subring of $C_{\mathbb{R}}(X)$. Then A contains the constant function 1 by definition, so it also contains every function taking exactly the values ± 1, and thus the indicator function of every clopen subset of X. So all continuous functions with finite range are in A. A is just the closure of this set, i.e. A is the closed subalgebra of $C_{\mathbb{R}}(X)$ generated by the indicator functions of clopen sets in X. So A is all of $C_{\mathbb{R}}(X)$ if and only if X is totally disconnected, i.e. zero-dimensional ().

XIII.22.5.7. If $\mathcal{F}$ is a subset of $BC_{\mathbb{R}}(X)$, a subset Y of X is a *stationary set* for $\mathcal{F}$ if every $f \in \mathcal{F}$ is constant on Y. If Y is a stationary set for $\mathcal{F}$, so is $\bar{Y}$, so we need consider only closed stationary sets. Of course, each singleton is a stationary set, and the converse is true if and only if $\mathcal{F}$ separates points of X. The Stone-Weierstrass Theorem can be rephrased:

XIII.22.5.8. THEOREM. Let X be a compact Hausdorff space, and $\mathcal{F}$ a subset of $C_{\mathbb{R}}(X)$. Then the closed unital subalgebra of $C_{\mathbb{R}}(X)$ generated by $\mathcal{F}$ consists of all functions in $C_{\mathbb{R}}(X)$ which are constant on each stationary set of $\mathcal{F}$.

A variation of this, due to KATĚTOV, is the key result:

XIII.22.5.9. THEOREM. Let X be a compact Hausdorff space, and $\mathcal{F}$ a subset of $C_{\mathbb{R}}(X)$. Then the analytic subring of $C_{\mathbb{R}}(X)$ generated by $\mathcal{F}$ consists of all functions in $C_{\mathbb{R}}(X)$ which are constant on each connected stationary set of $\mathcal{F}$.

One can restrict attention to maximal connected stationary sets: every connected stationary set is contained in a maximal connected stationary set (XIII.13.3.2.), which is automatically closed (XIII.13.1.9.).

XIII.22.5.10. We can provisionally define the analytic dimension of X to be the smallest n such that $BC_{\mathbb{R}}(X)$ is generated as an analytic subring by n elements. This is a good definition if $BC_{\mathbb{R}}(X)$ is separable, which occurs if and only if X is compact and metrizable (). In general, we make the following definition:

XIII.22.5.11. DEFINITION. Let X be a completely regular space. The *analytic dimension* $ad(X)$ is the smallest n, $0 \leq n \leq \aleph_0$, such that every countably generated (i.e. separable) closed subalgebra of $BC_{\mathbb{R}}(X)$ is contained in an analytic subring generated by n elements.

The analytic dimension $ad(X)$ is the smallest n such that every finite subset of $BC_{\mathbb{R}}(X)$ is contained in an analytic subring generated by n elements. If X is compact and metrizable, then $ad(X)$ is the smallest n such that $BC_{\mathbb{R}}(X)$ is generated as an analytic subring by n elements. Note that the analytic subring generated by even finitely many elements need not be separable: if X is the product of uncountably many two-point spaces, then X is compact and zero-dimensional, and the analytic subring of $C_{\mathbb{R}}(X)$ generated by $\emptyset$ is all of $C_{\mathbb{R}}(X)$, which is nonseparable since X is not metrizable.

The main theorem of KATĚTOV is:

XIII.22.5.12. THEOREM. Let X be a completely regular space. Then $ad(X) = zdim(X)$. Thus, if X is normal, $ad(X) = dim(X)$.

See [GJ76] for a complete discussion and proof, which is fairly involved. Since $ad(X)$ is transparently equal to $ad(\beta X)$ for any X, we obtain:

XIII.22.5.13. COROLLARY. Let X be a completely regular space. Then $zdim(X) = zdim(\beta X) = dim(\beta X)$. If X is normal, then $dim(X) = dim(\beta X)$.

The corollary can be proved directly without introducing analytic dimension (cf. XIII.22.1.12., XIII.22.4.5.; [GJ76, 16.11]).

Affine Dimension

Homological Dimension

XIII.22.5.14. There are important metric notions of dimension which are not topological invariants, such as Hausdorff dimension, packing dimension, and Assouad dimension ().

XIII.22.6. Embedding in Euclidean Space

In this subsection, we prove two important theorems about embedding of topological spaces in Euclidean space.

If X is a topological space of dimension n, we want to embed X in $\mathbb{R}^p$ for some p which is a function of n. Of course, for X to embed in any Euclidean space it is necessary that X be separable and metrizable, so we make an assumption that all spaces in this section are separable and metrizable. Thus all standard dimension functions agree on such an X, so "dimension n" is unambiguous.

XIII.22.6.1. THEOREM. Let X be a subset of $\mathbb{R}^n$. Then X has dimension n if and only if the interior of X is nonempty, i.e. if and only if X contains a nonempty open set in $\mathbb{R}^n$.

The proof is deferred to XIII.22.6.14..

XIII.22.6.2. If a (separable metrizable) space X has dimension n, it cannot be embedded in $\mathbb{R}^n$ in general (consider a circle). It cannot even generally be embedded in $\mathbb{R}^{n+1}$: a graph cannot always be embedded in $\mathbb{R}^2$, and the projective plane and the Klein bottle are closed 2-manifolds which cannot be embedded in $\mathbb{R}^3$. The n-skeleton of a $2n+2$-simplex cannot be embedded in $\mathbb{R}^{2n}$ []. The best which can be done in general is the following:

XIII.22.6.3. THEOREM. Let X be a separable metrizable space with $dim(X) \leq n$. Then X embeds in $\mathbb{I}^{2n+1}$. In fact, every continuous function from X to $\mathbb{I}^{2n+1}$ is a uniform limit of embeddings.

To prove XIII.22.6.3. (and in fact to prove a slightly better result), we introduce notation for some useful subsets of $\mathbb{R}^n$:

XIII.22.6.4. DEFINITION. Let $0 \leq n \leq m$. Then

$\mathfrak{P}_n^m$ is the set of points in $\mathbb{R}^m$ with precisely n rational coordinates.

$\mathfrak{M}_n^m$ is the set of points in $\mathbb{R}^m$ with at most n rational coordinates.

$\mathfrak{L}_n^m$ is the set of points in $\mathbb{R}^m$ with at least n rational coordinates.

$\mathfrak{N}_n = \mathfrak{M}_n^{2n+1}$ is the *Nöbeling universal space of dimension n*.

Note that $\mathfrak{M}_n^m \cup \mathfrak{L}_n^m = \mathbb{R}^m$ and $\mathfrak{M}_n^m \cap \mathfrak{L}_n^m = \mathfrak{P}_n^m$ for any n and m.

XIII.22.6.5. PROPOSITION. For any $0 \leq n \leq m$, $dim(\mathfrak{P}_n^m) = 0$, $dim(\mathfrak{M}_n^m) = n$, $dim(\mathfrak{L}_n^m) = m - n$, $dim(\mathfrak{N}_n) = n$.

PROOF: $\mathfrak{P}_n^m$ is a countable union of (relatively) closed subsets where n specified coordinates are specified fixed rational numbers and the other $m-n$ coordinates are irrational. Such a set is homeomorphic to $\mathbb{J}^{m-n}$, which has dimension 0. Thus $dim(\mathfrak{P}_n^m) = 0$ by the Sum Theorem (the zero-dimensional version XIII.22.3.14. suffices).

The observations

$$\mathfrak{M}_n^m = \mathfrak{P}_0^m \cup \mathfrak{P}_1^m \cup \cdots \cup \mathfrak{P}_n^m$$
$$\mathfrak{L}_n^m = \mathfrak{P}_n^m \cup \mathfrak{P}_{n+1}^m \cup \cdots \cup \mathfrak{P}_m^m$$

and the Sum Theorem imply that $dim(\mathfrak{M}_n^m) \leq n$ and $dim(\mathfrak{L}_n^m) \leq m-n$. But $\mathfrak{M}_n^m$ contains a subspace homeomorphic to $\mathbb{R}^n$ (say the set of all points with the first $m-n$ coordinates π), and $\mathfrak{L}_n^m$ similarly contains a copy of $\mathbb{R}^{m-n}$, so $dim(\mathfrak{M}_n^m) \geq n$ and $dim(\mathfrak{L}_n^m) \geq m-n$ by XIII.22.3.7.. 👍

The theorem we will prove is:

XIII.22.6.6. THEOREM. Let X be a separable metrizable space of dimension $\leq n$. Then there is an embedding $f : X \to \mathfrak{N}_n$ such that the closure of $f(X)$ in $\mathfrak{N}_n$ is compact. In fact, any bounded continuous function from X to $\mathbb{R}^{2n+1}$ can be uniformly approximated arbitrarily closely by such a function.

This result justifies the name "Nöbeling universal space." Theorem XIII.22.6.3. is an immediate corollary. Another important corollary is:

XIII.22.6.7. COROLLARY. Let X be a separable metrizable space of dimension n. Then X has a metrizable compactification of dimension n. In fact, there is a compact subset K_n of $\mathbb{R}^{2n+1}$ with $dim(K_n) = n$ such that every separable metrizable space of dimension $\leq n$ embeds in K_n.

PROOF: There is an embedding $f : \mathfrak{N}_n \to \mathfrak{N}_n$ such that $K_n = \overline{f(\mathfrak{N}_n)}$ is a compact subset of $\mathfrak{N}_n$. 👍

Actually, the Menger Universal Space M_n^{2n+1} is such a space (XIII.19.5.15.).

XIII.22.6.8. The strategy of the proof of XIII.22.6.6. will be to show that the set E of embeddings of X into $\mathfrak{N}_n$ such that the closure of $f(X)$ in $\mathfrak{N}_n$ is compact is a countable intersection of dense open sets in $BC(X, \mathbb{R}^{2n+1})$. The theorem will then follow from the Baire Category Theorem ().

We fix a totally bounded metric ρ on X. There is such a metric since X embeds in the Hilbert cube (). There is thus for each m a finite open cover $\mathcal{U}_m$ of X by open balls of diameter $\leq 1/m$; $\cup_m \mathcal{U}_m$ is a base for the topology of X, and in fact any finite open cover of X is refined by one of the U_m (). By passing to a subsequence, we may assume $\mathcal{U}_{m+1}$ refines U_m for each m.

Let $\mathcal{F}$ be the set of all tuples of the form

$$\mathcal{F} = \{(i_1, \ldots, i_{n+1}; q_1, \ldots, q_{n+1}) : 1 \leq i_1 < i_2 < \cdots < i_{n+1} \leq 2n+1,\ q_k \in \mathbb{Q}\}\ .$$

Then $\mathcal{F}$ is countable. For each $F \in \mathcal{F}$, define

$$L_F = \{(x_1, \ldots, x_{2n+1}) \in \mathbb{R}^{2n+1} : x_{i_k} = q_k \text{ for } 1 \leq k \leq n+1\}\ .$$

Then L_F is a hyperplane in $\mathbb{R}^{2n+1}$ of dimension n, $L_F \cap \mathfrak{N}_n = \emptyset$, and

$$\bigcup_{F \in \mathcal{F}} L_F = \mathfrak{L}_{n+1}^{2n+1} = \mathbb{R}^{2n+1} \setminus \mathfrak{N}_n\ .$$

For each $F \in \mathcal{F}$ and $m \in \mathbb{N}$, let $W_{F,m}$ be the set of all $f \in BC(X, \mathbb{R}^{2n+1})$ such that $\overline{f(X)}$ is disjoint from L_F and f is an $\mathcal{U}_m$-map, i.e. for every $y \in \overline{f(X)}$ there is an open neighborhood V of y such that $f^{-1}(V) \subseteq U$ for some $U \in \mathcal{U}_m$. We will show that $W_{F,m}$ is a dense open set in $BC(X, \mathbb{R}^{2n+1})$. This will prove the theorem since

$$E = \bigcap_{F,m} W_{F,m} \ .$$

XIII.22.6.9. To show that $W_{F,m}$ is open in $BC(X, \mathbb{R}^{2n+1})$, fix $f \in W_{F,m}$. Since $\overline{f(X)}$ is compact and disjoint from L_F, the distance from $\overline{f(X)}$ to L_F is a positive number η. For each $y \in \overline{f(X)}$, there is an open neighborhood V_y in $\mathbb{R}^{2n+1}$ such that $f^{-1}(V_y)$ is contained in some $U \in \mathcal{U}_m$. Let γ be the Lebesgue number of the cover $\mathcal{V} = \{V_y : y \in \overline{f(X)}\}$ of $\overline{f(X)}$, i.e. if B is a ball of radius $\leq \gamma$ in $\mathbb{R}^n$ intersecting $\overline{f(X)}$, then $B \subseteq V_y$ for some $y \in \overline{f(X)}$, and thus $f^{-1}(B)$ is contained in some $U \in \mathcal{U}_m$.

Set $\delta = \min(\gamma/3, \eta/2)$. If $g \in BC(X, \mathbb{R}^{2n+1})$ with $\|f - g\| < \delta$, then for any $x \in X$ and $a \in L_F$ we have

$$\|g(x) - a\| \geq \|f(x) - a\| - \|f(x) - g(x)\| > \frac{\eta}{2}$$

so $\overline{g(X)} \cap L_f = \emptyset$.

Let $y \in \overline{g(X)}$. There is a $z \in X$ with $\|y - g(z)\| < \delta$. If B is the open ball of radius δ around y, and $x \in g^{-1}(B)$, then

$$\|g(x) - f(z)\| \leq \|g(x) - g(z)\| + \|g(z) - f(z)\| < 3\delta \leq \gamma$$

since $g(x)$ and $g(z)$ are both in B and $\|f - g\| < \delta$. Thus $g(x)$ is in the open ball C around $f(z)$ of radius γ, i.e. $g^{-1}(B) \subseteq f^{-1}(C)$, which is contained in some $U \in \mathcal{U}_m$. Thus $g \in W_{F,m}$. So $W_{F,m}$ is open.

Showing that $W_{F,m}$ is dense in $BC(X, \mathbb{R}^{2n+1})$ takes more work. We need to approximate using vectors in general position.

XIII.22.6.10. Proposition. If S is a finite union of affine subspaces of $\mathbb{R}^n$ of dimension $\leq n-1$, then the complement of S is dense (and open) in $\mathbb{R}^n$.

Proof: The complement of an affine subspace of $\mathbb{R}^n$ of dimension $\leq n-1$ is dense and open, and in any topological space a finite intersection of dense open sets is dense and open. 👍

In fact, by the Baire Category Theorem, a countable union of affine subspaces of $\mathbb{R}^n$ of dimension $\leq n-1$ has dense (but usually not open) complement. This also follows from the Sum Theorem XIII.22.3.13..

XIII.22.6.11. Corollary. If $G = \{\boldsymbol{x}_1, \ldots, \boldsymbol{x}_p\}$ is a subset of $\mathbb{R}^n$ in general position (), $\boldsymbol{y} \in \mathbb{R}^n$, and $\epsilon > 0$, then there is an $\boldsymbol{x}_{p+1} \in \mathbb{R}^n$ with $\|\boldsymbol{y} - \boldsymbol{x}_{p+1}\| < \epsilon$ and $\{\boldsymbol{x}_1, \ldots, \boldsymbol{x}_p, \boldsymbol{x}_{p+1}\}$ in general position.

Proof: If $\{\boldsymbol{x}_{i_1}, \ldots, \boldsymbol{x}_{i_r}\}$ is a subset of G with $r \leq n$, and $\boldsymbol{x} \in \mathbb{R}^n$, then $\{\boldsymbol{x}_{i_1}, \ldots, \boldsymbol{x}_{i_r}, \boldsymbol{x}\}$ span an r-dimensional affine subspace if and only if $\boldsymbol{x}$ is not in the $(r-1)$-dimensional affine subspace spanned by $\{\boldsymbol{x}_{i_1}, \ldots, \boldsymbol{x}_{i_r}\}$. So we need only choose $\boldsymbol{x}_{p+1}$ to not be in any of these finitely many affine subspaces. 👍

Applying this result repeatedly, we obtain:

XIII.22.6.12. COROLLARY. If $\{\boldsymbol{x}_1, \ldots, \boldsymbol{x}_p\}$ is a subset of $\mathbb{R}^n$ in general position, $\boldsymbol{y}_1, \ldots, \boldsymbol{y}_q \in \mathbb{R}^n$, and $\epsilon > 0$, then there are $\boldsymbol{x}_{p+1}, \ldots, \boldsymbol{x}_{p+q} \in \mathbb{R}^n$ such that $\|\boldsymbol{x}_{p+k} - \boldsymbol{y}_k\| < \epsilon$ for $1 \leq k \leq q$ and $\{\boldsymbol{x}_1, \ldots, \boldsymbol{x}_{p+q}\}$ is in general position.

In fact, if $\{\boldsymbol{x}_1, \ldots, \boldsymbol{x}_p\}$ is in general position, $(\boldsymbol{y}_k)$ is any sequence in $\mathbb{R}^n$, and (ϵ_k) is any sequence of positive numbers, there is a sequence $(\boldsymbol{x}_{p+k})$ in $\mathbb{R}^n$ such that $\|\boldsymbol{x}_{p+k} - \boldsymbol{y}_k\| < \epsilon_k$ for every k and the infinite set $\{\boldsymbol{x}_1, \ldots, \boldsymbol{x}_p, \boldsymbol{x}_{p+1}, \ldots\}$ is in general position.

XIII.22.6.13. Now fix F and m, and let $f \in BC(X, \mathbb{R}^{2n+1})$ and $\epsilon > 0$. Let $\{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_n\}$ be a set of points in general position spanning L_F as an affine subspace. Cover $\overline{f(X)}$ by finitely many open balls of diameter $\leq \frac{\epsilon}{2}$; by increasing m if necessary, we may assume $\mathcal{U}_m$ refines the cover of X consisting of inverse images of these balls, i.e. that the diameter of $f(U)$ is less than $\frac{\epsilon}{2}$ for all $U \in \mathcal{U}_m$. Let

$$\mathcal{V} = \{V_1, \ldots, V_q\}$$

be a shrinking of $\mathcal{U}_m$ of order $\leq n$. For each k, $1 \leq k \leq q$, fix $z_k \in V_k$. Choose $\boldsymbol{x}_{n+1}, \ldots, \boldsymbol{x}_{n+q} \in \mathbb{R}^{2n+1}$ such that $\|\boldsymbol{x}_{n+k} - f(z_k)\| < \frac{\epsilon}{2}$ for each k and $\{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{n+q}\}$ is in general position.

Let $\{h_k : 1 \leq k \leq q\}$ be a partition of unity on X subordinate to $\mathcal{V}$, e.g. the standard partition of unity from ρ (). For $x \in X$, set

$$g(x) = \sum_{k=1}^{q} h_k(x)\boldsymbol{x}_{n+k} \ .$$

We claim $g \in W_{F,m}$ and $\|f - g\| \leq \epsilon$. If $x \in X$, then for each k for which $h_k(x) > 0$, we have $x \in V_k$, so $\|f(x) - f(z_k)\| < \frac{\epsilon}{2}$ and thus $\|f(x) - \boldsymbol{x}_{n+k}\| < \epsilon$. We thus have

$$\|f(x) - g(x)\| = \left\| \sum_{k=1}^{q} h_k(x)f(x) - \sum_{k=1}^{q} h_k(x)\boldsymbol{x}_{n+k} \right\|$$

$$= \left\| \sum_{k=1}^{q} h_k(x)[f(x) - \boldsymbol{x}_{n+k}] \right\| \leq \sum_{k=1}^{q} h_k(x)\|f(x) - \boldsymbol{x}_{n+k}\| < \sum_{k=1}^{q} \epsilon h_k(x) = \epsilon$$

so $\|f - g\| < \epsilon$.

To show $g \in W_{F,m}$, we first show $\overline{g(X)} \cap L_F = \emptyset$. If $x \in X$, then since $\mathcal{V}$ has order $\leq n$, $g(x)$ is a convex combination of at most $n+1$ of the $\boldsymbol{x}_{n+k}$, say $\boldsymbol{x}_{n+i_0}, \ldots, \boldsymbol{x}_{n+i_n}$. Since

$$\{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_n, \boldsymbol{x}_{n+i_0}, \ldots, \boldsymbol{x}_{n+i_n}\}$$

is a set of at most $2n+2$ vectors in $\mathbb{R}^{2n+1}$ which is in general position, it is affinely independent; thus the affine subspaces generated by $\{\boldsymbol{x}_0, \ldots, \boldsymbol{x}_n\}$ (which is L_F) and $\{\boldsymbol{x}_{n+i_0}, \ldots, \boldsymbol{x}_{i_n}\}$ do not intersect (). In particular, the convex hull of $\{\boldsymbol{x}_{n+i_0}, \ldots, \boldsymbol{x}_{i_n}\}$ (which is a simplex) does not intersect L_F. There are finitely many such simplexes as x ranges over X; the union of these simplexes is a compact subset (polyhedron) P of $\mathbb{R}^{2n+1}$ containing $g(X)$ which does not meet L_F. Thus $\overline{g(X)}$ does not meet L_F.

If $\boldsymbol{y} \in P$, let $\phi_k(\boldsymbol{y})$ be the barycentric coordinate of $\boldsymbol{y}$ with respect to $\boldsymbol{x}_{n+k}$ (). Then ϕ_k is a continuous function from P to $[0,1]$, and $h_k = \phi_k \circ g$. If $\boldsymbol{y} \in \overline{g(X)}$, then since the $\phi_k(\boldsymbol{y})$ sum to 1, there is a k with $\phi_k(\boldsymbol{y}) > 0$. Fix such a k, and let $Z = \{\boldsymbol{z} \in P : \phi_k(\boldsymbol{z}) > 0\}$. Then Z is a neighborhood of $\boldsymbol{y}$, and $g^{-1}(Z) \subseteq V_k$. Thus $g \in W_{F,m}$.

This completes the proof of Theorem XIII.22.6.6.. 

XIII.22.6.14. We now turn to the proof of Theorem XIII.22.6.1.. If X contains an open subset of $\mathbb{R}^n$, it obviously has dimension n. The proof of the converse involves a somewhat delicate construction, and uses the following functions. If $\boldsymbol{a} \in \mathbb{R}^n$ and $\epsilon > 0$, let $h_{\boldsymbol{a},\epsilon}$ be the function from $\mathbb{R}^n \setminus \{\boldsymbol{a}\}$ to $\mathbb{R}^n$ which moves each point of $\mathbb{R}^n \setminus \{\boldsymbol{a}\}$ radially away from $\boldsymbol{a}$ a distance ϵ. This function has the following properties for all $\boldsymbol{x}, \boldsymbol{y} \in \mathbb{R}^n \setminus \{\boldsymbol{a}\}$, as is easily verified:

(i) $h_{\boldsymbol{a},\epsilon}$ is a homeomorphism from $\mathbb{R}^n \setminus \{\boldsymbol{a}\}$ onto $\mathbb{R}^n \setminus \bar{B}_\epsilon(\boldsymbol{a})$.

(ii) $\|h_{\boldsymbol{a},\epsilon}(\boldsymbol{x}) - \boldsymbol{x}\| = \epsilon$.

(iii) $\|\boldsymbol{x} - \boldsymbol{y}\| \leq \|h_{\boldsymbol{a},\epsilon}(\boldsymbol{x}) - h_{\boldsymbol{a},\epsilon}(\boldsymbol{y})\| \leq \|\boldsymbol{x} - \boldsymbol{y}\| + 2\epsilon$.

We will actually prove the following stronger result:

XIII.22.6.15. THEOREM. Let X be a subset of $\mathbb{R}^n$ with empty interior. Then X is homeomorphic to a subset Y of $\mathbb{R}^n$ with $\bar{Y} \subseteq \mathfrak{M}^n_{n-1}$. In particular, Y is nowhere dense in $\mathbb{R}^n$ and $dim(Y) = dim(X) \leq n - 1$.

PROOF: By XIII.22.2.2., any subset of $\mathbb{R}^n$ homeomorphic to X has empty interior. The complement of $\mathfrak{M}^n_{n-1}$ in $\mathbb{R}^n$ is the set of points with all rational coordinates, hence is countable. Let $\{\boldsymbol{a}_k : k \in \mathbb{N}\}$ be an enumeration of this complement. Set $Y_1 = X$, and inductively define a sequence Y_k of subsets of $\mathbb{R}^n$ and homeomorphisms $h_k : Y_k \to Y_{k+1}$ as follows. Y_k has empty interior, so there is a $\boldsymbol{b}_k \in \mathbb{R}^n \setminus Y_k$ with

$$\|\boldsymbol{b}_k - \boldsymbol{a}_k\| < \frac{3^{-k}}{4} .$$

Define h_k to be the restriction of $h_{\boldsymbol{b}_k,3^{-k}}$ to Y_k, and $Y_{k+1} = h_k(Y_k)$. We have

$$\|h_k(\boldsymbol{y}) - \boldsymbol{a}_k\| \geq \|h_k(\boldsymbol{y}) - \boldsymbol{b}_k\| - \|\boldsymbol{b}_k - \boldsymbol{a}_k\| > 3^{-k} - \frac{3^{-k}}{4} = \frac{3^{-k+1}}{4}$$

for all $\boldsymbol{y} \in Y_k$.

For each k set $f_k = h_k \circ \cdots \circ h_1$. Then f_k is a homeomorphism from X onto Y_{k+1}. By XIII.22.6.14.(ii) and the triangle inequality we have, for $j < k$ and $\boldsymbol{x} \in X$,

$$\|f_k(\boldsymbol{x}) - f_j(\boldsymbol{x})\| \leq \sum_{m=j+1}^{k} 3^{-m} < \sum_{m=j+1}^{\infty} 3^{-m} = \frac{3^{-j}}{2} .$$

Thus the f_k form a uniform Cauchy sequence and converge uniformly to a continuous function $f : X \to \mathbb{R}^n$. Set $Y = f(X)$. For $\boldsymbol{x}, \boldsymbol{z} \in X$, we have $\|f(\boldsymbol{x}) - f(\boldsymbol{z})\| \geq \|\boldsymbol{x} - \boldsymbol{z}\|$ by XIII.22.6.14.(iii), so f is injective and $f^{-1}|_Y$ is a contraction, hence continuous; thus f is a homeomorphism from X onto Y.

For any k we have, for any $\boldsymbol{x} \in X$,

$$\|f(\boldsymbol{x}) - f_k(\boldsymbol{x})\| \leq \frac{3^{-k}}{2}$$

and hence

$$\|f(\boldsymbol{x}) - \boldsymbol{a}_k\| \geq \|f_k(\boldsymbol{x}) - \boldsymbol{a}_k\| - \|f(\boldsymbol{x}) - f_k(\boldsymbol{x})\| > \frac{3^{-k+1}}{4} - \frac{3^{-k}}{2} = \frac{3^{-k}}{4} .$$

Thus $\boldsymbol{a}_k$ is not in $\bar{Y}$, i.e. $\bar{Y} \subseteq \mathfrak{M}^n_{n-1}$. 👍

XIII.22.7. Infinite-Dimensional Spaces

XIII.22.7.1. A topological space can be infinite-dimensional in any of the above senses. There are in fact examples of (normal) spaces which are infinite-dimensional in some senses but not others. For separable metrizable spaces the notion of infinite-dimensionality is unambiguous.

XIII.22.7.2. There are degrees of infinite-dimensionality, however. One might expect, for example, that $[0,1]^\kappa$ should be "κ-dimensional." A more important distinction, however, at least for metrizable spaces, is between "countable-dimensional" and "uncountable-dimensional" spaces:

XIII.22.7.3. DEFINITION. Let X be a topological space. Then X is *countable-dimensional* if it is a countable union of finite-dimensional subspaces. X is *countably infinite-dimensional* if it is countable-dimensional but not finite-dimensional.

This definition can be made for any of the dimension functions; we will be imprecise as to the meaning of "finite-dimensional" but note this is well-defined for separable metrizable spaces.

XIII.22.7.4. By (), a normal space X is countable-dimensional (in the sense of Ind) if and only if it can be written as a countable union of subspaces X_n with $Ind(X_n) = 0$ for all n. X is countably infinite-dimensional if and only if it can be written as a countable union of zero-dimensional subspaces, but not as a finite union of zero-dimensional subspaces.

XIII.22.7.5. It is easy to give examples of countably infinite-dimensional separable metrizable spaces: the disjoint union $\sqcup_n [0,1]^n$ works. For a compact metrizable example, take the one-point compactification of the disjoint union, or the infinite join if a connected compact metrizable example is desired. It is only slightly harder to string together the cubes to get a compact AR which is countably infinite-dimensional.

Another distinction comes from considering a strengthening of the partition dimension concept:

XIII.22.7.6. DEFINITION. Let X be a normal topological space. Then X is *strongly infinite-dimensional* if there is a sequence of pairs (A_k, B_k) of disjoint closed sets in X such that, if P_k is any partition between A_k and B_k for each k, then $\cap_{k=1}^\infty P_k \neq \emptyset$.

X is *weakly infinite-dimensional* if $pd(X) = \infty$ but X is not strongly infinite-dimensional, i.e. for every sequence of pairs (A_k, B_k) of disjoint closed sets in X, there are partitions P_k such that $\cap_{k=1}^\infty P_k = \emptyset$, but for each n there are pairs $(A_1, B_1), \ldots, (A_n, B_n)$ such that, if P_k is any partition between A_k and B_k for each k, then $\cap_{k=1}^n P_k \neq \emptyset$.

XIII.22.7.7. PROPOSITION. Every countably infinite-dimensional completely normal space is weakly infinite-dimensional.

PROOF: This is a simple adaptation of (). Write $X = \cup_{n=1}^\infty X_n$, where X_n is zero-dimensional. If $\{(A_n, B_n) : n \in \mathbb{N}\}$ is a sequence of pairs of disjoint closed sets in X, then by XIII.22.3.16. there is for each n a partition P_n between A_n and B_n with $P_n \cap X_n = \emptyset$. Then $\cap_{n=1}^\infty P_n = \emptyset$. 👍

On the contrary, we have:

XIII.22.7.8. THEOREM. The Hilbert cube $\mathbb{H}$ is strongly infinite-dimensional.

PROOF: (cf. [HW41, p. 49]) In $\mathbb{H} = [0,1]^{\mathbb{N}}$, let A_k be the set of all points with k'th coordinate 0, and B_k the set of points with k'th coordinate 1. Then A_k and B_k are disjoint closed sets in X. Suppose P_k is a partition between A_k and B_k for each k. For each n let $f_n : [0,1]^n \to \mathbb{H}$ be defined by

$$f_n(x_1, \dots, x_n) = (x_1, \dots, x_n, 0, 0, \dots) \ .$$

Fix n. If $\tilde{A}_k = f_n^{-1}(A_k)$, $\tilde{B}_k = f_n^{-1}(B_k)$, $\tilde{P}_k = f_n^{-1}(P_k)$ for $1 \leq k \leq n$, then $\tilde{A}_k$ and $\tilde{B}_k$ are just the opposite k-faces of $[0,1]^n$, and $\tilde{P}_k$ is a partition in $[0,1]^n$ between $\tilde{A}_k$ and $\tilde{B}_k$, so by the Face Partition Theorem (XIII.21.1.19.), $\cap_{k=1}^n \tilde{P}_k \neq \emptyset$; thus $\cap_{k=1}^n P_k \neq \emptyset$ in X. This is true for all n, so the P_k have the Finite Intersection Property, and thus $\cap_{k=1}^\infty P_k \neq \emptyset$ since the P_k are compact. 👍

XIII.22.7.9. COROLLARY. The Hilbert cube is not countable-dimensional.

Since the Hilbert cube is separable and metrizable, it is unambiguous what dimension function we use.

XIII.22.7.10. It is thus highly questionable whether we should say that $dim\left([0,1]^{\aleph_0}\right) = \aleph_0$.

There is a theory of transfinite dimension for (some) countable-dimensional spaces (Exercise XIII.22.8.9.).

XIII.22.7.11. There are many pathologies in infinite-dimensional spaces. For example, if X is n-dimensional for finite n, then X has closed subspaces of dimension k for all $0 \leq k \leq n$ (cf. the proof of XIII.22.3.19.). But there are examples of an infinite-dimensional compact metrizable space X such that every subspace of X is either zero-dimensional or infinite-dimensional (such a space is called *hereditarily infinite-dimensional*). Using the CH, an X can be constructed with the property that every uncountable subspace is infinite-dimensional (the CH is necessary; existence of such a space cannot be proved in ZFC, cf. XIII.22.3.35.). Note that every (regular) space has zero-dimensional subspaces, e.g. any countable subspace (XIII.22.3.18.).

Examples of the following types of spaces (and many more) can be found in [vM89]:

A weakly infinite-dimensional compact space which is not countable-dimensional.

A strongly infinite-dimensional compact space which is hereditarily infinite-dimensional.

A strongly infinite-dimensional totally disconnected space (XIII.22.8.7.; there can be no such compact example by XIII.13.6.7.).

All these examples are separable and metrizable.

XIII.22.7.12. Until quite recently, the structure theory of infinite-dimensional spaces lagged far behind that of finite-dimensional spaces. But there has been a lot of recent progress. See [vM01] and [Eng95] for more details.

XIII.22.8. Exercises

XIII.22.8.1. (a) Show that if X is T_1 and $dim(X) = 0$, then $ind(X) = 0$. [If U is an open neighborhood of a point p, consider the open cover $\{U, X \setminus \{p\}\}$ of X.]

(b) If X is the Sierpiński space, show that $dim(X)$ and $Ind(X)$ are vacuously 0, but $ind(X) = 1$ (XIII.13.9.1.).

XIII.22.8.2. Let X be a normal space.

(a) Use XIII.7.6.8. and Urysohn's Lemma to show that any open cover $\mathcal{U}$ of X has an open shrinking consisting of cozero sets.

(b) Show that $zdim(X) = dim(X)$.

XIII.22.8.3. [vM89] This problem gives a direct proof that $pd(B^n) \leq n$ (cf. XIII.22.1.5., XIII.22.4.13.); we actually show that if X is any compact subset of $\mathbb{R}^n$, then $pd(X) \leq n$.

(a) Show that if D is a dense subset of $\mathbb{R}$, and

$$D^{(n)} = \{(x_1, \ldots, x_n) \in \mathbb{R}^n : x_k \in D \text{ for at least one } k\}$$

and if A and B are disjoint compact subsets of $\mathbb{R}^n$, then there is a partition between A and B in $\mathbb{R}^n$ contained in $D^{(n)}$. [Cover A with finitely many open rectangular solids which are products of intervals with endpoints in D, whose closures are disjoint from B.]

(b) Show that if $(A_1, B_1), \ldots, (A_{n+1}, B_{n+1})$ are $n+1$ pairs of disjoint closed sets in X, then there are partitions P_k between A_k and B_k in X with $\cap_{k=1}^{n+1} P_k = \emptyset$. [Let $D_1, \ldots, D_{n+1}$ be $n+1$ disjoint dense subsets of $\mathbb{R}$, and choose $P_k \subseteq D_k^{(n)}$.]

XIII.22.8.4. Show that every topological n-manifold X with boundary has $dim(X) = n$. [Write each component of X as a countable union of subsets homeomorphic to B_n, and apply **??**.]

XIII.22.8.5. (a) [Men28] Let X be a separable metrizable space of dimension n. The *dimensional kernel* of X is

$$DK(X) = \{x \in X : lind_x(X) = n\} .$$

Show that $DK(X)$ is an F_σ and $ind(DK(X)) \geq n-1$. [Write the complement as a union of a set of dimension $\leq n-2$ and a set of dimension 0. Use the Sum Theorem and the argument of XIII.22.3.15..] Of course, $ind(DK(X)) \leq n$ by XIII.22.3.7.. For "most" X, $ind(DK(X)) = n$.

(b) X is *weakly n-dimensional* if $ind(DK(X)) = n-1$. Show that the space of () is weakly 1-dimensional.

For every n there exist weakly n-dimensional spaces. A compact metrizable space cannot be weakly n-dimensional; in fact, a weakly n-dimensional space cannot contain a compact subset of dimension n [HW41, p. 95].

XIII.22.8.6. Let X be a topological space and Y a (nonempty) subspace of X.

(a) Show that $ind(Y) = 0$ if and only if there is a base $\mathcal{B}$ for the topology of X such that $Y \cap \partial U = \emptyset$ for all $U \in \mathcal{B}$.

(b) Apply XIII.1.2.10. to show that if X is second countable and $ind(Y) = 0$, there is a countable base $\mathcal{B}$ for the topology of X such that $Y \cap \partial U = \emptyset$ for all $U \in \mathcal{B}$.

(c) Show that if X is second countable and $ind(Y) = 0$, then there is a G_δ subset Y_δ of X with $Y \subseteq Y_\delta$ and $ind(Y_\delta) = 0$. [Consider $X \setminus \cup_{U \in \mathcal{B}} \partial U$, where $\mathcal{B}$ is a countable base as in (b); cf. XIII.22.3.15..]

(d) Using the Second Decomposition Theorem XIII.22.3.20., prove the *Extension Theorem*: if X is second countable, $Y \subseteq X$, and $ind(Y) = n$, then there is a G_δ subset Y_δ of X with $Y \subseteq Y_\delta$ and $ind(Y_\delta) = n$.

XIII.22.8.7. ([?]; cf. [Eng95, 1.4.F]) Let K be the Cantor set, and $n \in \mathbb{N} \cup \{\infty\}$. Set $X = [0,1]^n$. Let $\mathcal{G}$ be the set of G_δ's in $K \times X$. Then $card(\mathcal{G}) = 2^{\aleph_0}$. Let ϕ be a bijection from K to $\mathcal{G}$. Fix a point $x_0 \in X$, and define a function $f : K \to X$ by choosing $f(t)$ to be a point such that $(t, f(t)) \notin \phi(t)$ if there is such a point and $f(t) = x_0$ otherwise. Let $Y = \{(t, f(t)) : t \in K\} \subseteq K \times X$ be the graph of f; give Y the subspace topology.

(a) Show that projection onto the first coordinate is an injective continuous function from Y onto K. Thus Y is totally disconnected. (So Y may be thought of as K with a topology stronger than the usual topology.)

(b) If G is a G_δ in $K \times X$ containing Y, then $G = \phi(t)$ for some $t \in K$, and hence G contains $\{t\} \times X$. Conclude that $ind(G) = n$.

(c) Apply the Extension Theorem (XIII.22.8.6.(d)) to conclude that $ind(Y) = n$.

Note that Y is separable and metrizable, so all dimension functions coincide on Y. This argument uses the AC.

XIII.22.8.8. Increasing and Decreasing Dimensions. Prove the following theorem:

THEOREM. (AC) Let $d \in \mathbb{N}$, and let X be a separable metrizable space of dimension d. Then for any $n \in \mathbb{N} \cup \{\infty\}$ there is a separable metrizable space Y_n of dimension n and a continuous bijection $\phi_n : Y \to X$. Thus for any such n there is a stronger separable metrizable topology on X of dimension n. The same holds if $dim(X) = 0$ and $card(X) = 2^{\aleph_0}$. Thus continuous bijections can raise or lower dimension arbitrarily, even for separable metrizable spaces.

(a) A separable metrizable space of cardinality less than $2^{\aleph_0}$ has dimension 0 (XIII.22.3.35.). Thus, if $d > 0$, X has cardinality $2^{\aleph_0}$ (XIII.7.10.6.(c)).

(b) If $0 \leq n < d$, write X as a disjoint union $X_1 \cup \cdots \cup X_{d+1}$, where each X_k has dimension 0 (XIII.22.3.20.). Expand the topology on X by making $X_1, \ldots, X_{d-n}$ clopen. This can be done concretely by taking the following subspace of $X \times \{0, 1, \ldots, d-n\}$:

$$Y_n = \{(x,0) : x \in \cup_{k>d-n} X_k\} \cup \bigcup_{1 \leq k \leq d-n} \{(x,k) : x \in X_k\} .$$

Use XIII.22.3.20. to show that $ind(Y_n) = n$.

If $X = \mathbb{R}$ and $n = 0$, we can take $[(\mathbb{R} \setminus \mathbb{Q}) \times \{0\}] \cup [\mathbb{Q} \times \{1\}] \subseteq \mathbb{R}^2$, the graph of $\chi_{\mathbb{Q}}$. One can also obtain such a topology by expanding the usual topology by making each rational number an isolated point (cf. XIII.11.14.8., which is not quite the same). This space can be realized as the following subspace of $\mathbb{R}^2$:

$$\{(x,0) : x \in \mathbb{R} \setminus \mathbb{Q}\} \cup \left\{ \left(r, \frac{1}{q} \right) : r = \frac{p}{q} \in \mathbb{Q} \right\}$$

where $\frac{p}{q}$ is in lowest terms and $q > 0$ (writing $0 = \frac{0}{1}$). This is the graph of the "Thomae function" which is continuous at the irrationals and discontinuous at the rationals. Actually the graph of any function with a dense set of jump discontinuities would do.

(c) For the case $n > d$, note that in XIII.22.8.7. K and X can be replaced in the construction by any separable metrizable spaces of cardinality $2^{\aleph_0}$. If we use $[0,1]^n$, the space Y will satisfy $n \leq ind(Y) \leq d + n$. If $ind(Y) > n$, reduce it to n using (b).

In particular, for any $n \in \mathbb{N} \cup \{\infty\}$ there is a separable metrizable topology $\mathcal{T}_n$ on $\mathbb{R}$, or $[0,1]$, stronger than the usual topology, with $dim(\mathbb{R}, \mathcal{T}_n) = n$. [In this case the Y has dimension exactly n: note that Y cannot contain any nonempty open set in $\mathbb{R} \times \mathbb{R}^n \cong \mathbb{R}^{n+1}$ by Invariance of Domain, and apply XIII.22.6.1..]

XIII.22.8.9. [] Extend the definitions of ind and Ind transfinitely: if α is an ordinal, then $ind(X) \leq \alpha$ if and only if, whenever $x \in X$ and U is an open neighborhood of x in X, there is an open neighborhood V of x contained in U with $ind(\partial V) < \alpha$, and similarly for Ind.

(a) If X is a T_1 space, and $Ind(X)$ is defined, then $ind(X)$ is defined and $ind(X) \leq Ind(X)$.

(b) If X is a separable metrizable space, and $ind(X)$ is defined, then X is countable-dimensional. Thus $ind(X)$ is not defined even for every compact metrizable space; in particular, $ind(\mathbb{H})$ is not defined. If X is compact, metrizable, and countable-dimensional, then $ind(X)$ and $Ind(X)$ are defined.

(c) If X is a separable metrizable space, and $ind(X)$ is defined, then $ind(X)$ is a countable ordinal.

(d) For every countable ordinal α, there are compact metrizable spaces X_α and Y_α with $ind(X_\alpha) = \alpha$ and $Ind(Y_\alpha) = \alpha$. There are compact metrizable spaces X with $\omega < ind(X) < Ind(X)$.

(e) If $ind_x(X)$ is finite for every $x \in X$, then $ind(X) \leq \omega$. The converse is false, even for compact metrizable X. Define a transfinite version of local dimension ind_x, and show that $ind(X) = \sup_{x \in X} ind_x(X)$ for any X.

XIII.22.8.10. Let X be a topological space.

DEFINITION. A *block decomposition* of X is a locally finite cover $\mathcal{F} = \{F_i\}$ of X by blocks (), where $F_i = \bar{U}_i$ for a pairwise disjoint set $\{U_i\}$ of open sets in X.

In some references, a block decomposition is called a *canonical covering* (perhaps since blocks are sometimes called canonically closed sets), but this is poor terminology since there is nothing canonical about a block decomposition.

(a) Show that if $\mathcal{F} = \{F_i\}$ is a block decomposition of X, then for $i \neq j$ the interiors of F_i and F_j are disjoint, i.e. F_i and F_j intersect only along their boundaries. Thus in the definition we may take the U_i to be the interiors of the F_i.

(b) If $\mathcal{F} = \{F_i\}$ and $\mathcal{G} = \{G_j\}$ are block decompositions of X, and whenever $F_i^o \cap G_j^o \neq \emptyset$ we set H_{ij} to be the closure of $F_i^o \cap G_j^o$, show that the H_{ij} form a block decomposition of X refining both $\mathcal{F}$ and $\mathcal{G}$.

(c) If $\mathcal{F} = \{F_i\}$ and $\mathcal{G} = \{G_j\}$ are block decompositions of X and $\mathcal{G}$ refines $\mathcal{F}$, then each G_j is contained in a unique F_i and each F_i is the union of the G_j contained in it.

XIII.22.8.11. Approximation Dimension. [Pon63]; cf. [Pea75] Here is an approach to dimension closer to the earlier intuitive ones. Let X be a (Hausdorff) topological space.

DEFINITION. If $X = \emptyset$, set $\delta(X) = -1$. If X is nonempty, $\delta(X)$ is the smallest n such that X has a directed regular () family $\mathcal{F}_\lambda$ of block decompositions, each of order $\leq n$, and $\delta(X) = \infty$ if there is no such n.

If $X = \emptyset$, set $\Delta(X) = -1$. If X is nonempty, $\Delta(X)$ is the smallest n such that X has a directed fine () family $\mathcal{F}_\lambda$ of block decompositions, each of order $\leq n$, and $\Delta(X) = \infty$ if there is no such n.

The functions $\delta(X)$ and $\Delta(X)$ are called the *approximation dimension* and *cofinal approximation dimension* of X respectively. We have $\delta(X) \leq \Delta(X)$ by (); $\delta(X) = \infty$ if X is not regular, and $\Delta(X) = \infty$ if X is not paracompact ().

(a) Show that for any (Hausdorff) space X, $\delta(X) = 0$ if and only if $ind(X) = 0$, and that the following are equivalent:

(i) $\Delta(X) = 0$.

(ii) X is paracompact and $dim(X) = 0$.

(iii) Every open cover of X has a refinement consisting of a partition into clopen sets (X is *perfectly zero-dimensional*).

(b) Show that if X is a topological space and $n \in \mathbb{N} \cup \{0\}$, then $\delta(X) \leq n$ if and only if there is a space Z with $ind(Z) = 0$ and a continuous closed surjective map $f : Z \to X$ such that $|f^{-1}(\{x\})| \leq n + 1$ for all $x \in X$.

(c) Show that if X is a regular space and $n \in \mathbb{N} \cup \{0\}$, then $\Delta(X) \leq n$ if and only if there is a perfectly zero-dimensional space Z and a continuous closed surjective map $f : Z \to X$ such that $|f^{-1}(\{x\})| \leq n + 1$ for all $x \in X$.

(d) Show that $ind(X) \leq \delta(X)$ for any topological space X, and $Ind(X) \leq \Delta(X)$ for any regular space X.

(e) Show that if X is metrizable, then $\Delta(X) = dim(X) = Ind(X)$. If X is separable and metrizable, then $\delta(X) = ind(X) = dim(X) = Ind(X) = \Delta(X)$, i.e. δ and Δ coincide with all other dimension functions we have considered.

XIII.22.8.12. (a) Let X be a normal space, and A a closed subspace. Use XIII.22.1.8. to prove that

$$dim(X) \leq \max(dim(A), dim(X \setminus A)) \ .$$

(b) Conclude that if X is separable metric and A is a closed subspace, then

$$dim(X) = \max(dim(A), dim(X \setminus A)) \ .$$

[Use that $ind = dim$ for separable metric spaces, and conclude the opposite inequality from XIII.22.3.7..]

(c) Conclude that if X and Y are separable metric, A is a closed subspace of X, and f a quotient mapping from A to a subset of Y, then the adjunction space $X \cup_f Y$ () satisfies

$$dim(X \cup_f Y) = \max(dim(Y), dim(X \setminus A)) \leq \max(dim(X), dim(Y)) \ .$$

In particular, if X is separable metric and CX is the cone over X, then

$$dim(CX) = dim(X \times [0, 1)) \leq dim(X) + 1 \ .$$

(d) Show that if X is normal and A and B are arbitrary subspaces with $X = A \cup B$, then

$$dim(X) \leq dim(A) + dim(B) + 1 \ .$$

Equality can hold (e.g. $\mathbb{R}$ is a union of two zero-dimensional subspaces).

See [Pea75, 5.8] for (a) and [Pea75, 5.11] for (d).

XIII.22.9. Fubini's Differentiation Theorem

Although even uniformly convergent infinite series of functions cannot be differentiated term-by-term in general, there are a few types of series for which term-by-term differentiation is valid. The most notable example is convergent power series (). Another example is convergent series of nondecreasing functions, the topic of this subsection.

The main theorem is due to Fubini. The name "Fubini's Theorem" is, however, normally reserved for another of Fubini's results on interchanging the order of multiple integration (). This result is sometimes called "Fubini's Differentiation Theorem," a name we will use. This theorem can be stated for sequences (as can any result about infinite series, since the theories of sequences and series are formally equivalent), but the hypotheses are clumsy to state in the sequence setting (cf. Exercise XIII.22.10.1.).

XIII.22.9.1. Theorem. [Fubini's Differentiation Theorem] Let $\sum_{k=1}^{\infty} f_k(x)$ be an infinite series of nondecreasing functions on an interval $[a,b]$, converging pointwise to a (nondecreasing) function f. Then

(i) The series converges uniformly to f on $[a,b]$.

(ii) The series $\sum_{k=1}^{\infty} f_k'(x)$ converges pointwise a.e. on $[a,b]$ to $f'(x)$.

In particular, $f_k'(x) \to 0$ for almost all $x \in [a,b]$.

(Conclusion (ii) is the main part of the theorem; (i) is an easy observation.)

Proof: Begin with (i). For any $x \in [a,b]$, we have

$$f(x) = [f(x) - f(a)] + f(a) = \sum_{k=1}^{\infty} [f_k(x) - f_k(a)] + \sum_{k=1}^{\infty} f_k(a)$$

with both series convergent. If $\epsilon > 0$, choose N such that for all $n \geq N$,

$$\left| \sum_{k=n+1}^{\infty} [f_k(b) - f_k(a)] \right| < \frac{\epsilon}{2} \quad \text{and} \quad \left| \sum_{k=n+1}^{\infty} f_k(a) \right| < \frac{\epsilon}{2} .$$

Then, for any $n \geq N$ and any $x \in [a,b]$, we have

$$\left| f(x) - \sum_{k=1}^{n} f_k(x) \right| = \left| \sum_{k=n+1}^{\infty} [f_k(x) - f_k(a)] + \sum_{k=n+1}^{\infty} f_k(a) \right|$$

$$\leq \left| \sum_{k=n+1}^{\infty} [f_k(x) - f_k(a)] \right| + \left| \sum_{k=n+1}^{\infty} f_k(a) \right| \leq \left| \sum_{k=n+1}^{\infty} [f_k(b) - f_k(a)] \right| + \left| \sum_{k=n+1}^{\infty} f_k(a) \right| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon$$

(the middle inequality on the last line holds because f_k is nondecreasing) and thus the series converges uniformly to f on $[a,b]$.

We now turn to (ii). First assume all the f_k are nonnegative. There is a subset A of $[a,b]$ whose complement has measure 0 and such that f and all the f_k are differentiable at all $x \in A$ (). Let $s_n(x) = \sum_{k=1}^{n} f_k(x)$ be the n'th partial sum and $r_n(x) = f(x) - s_n(x) = \sum_{k=n+1}^{\infty} f_k(x)$ the remainder. Then s_n and r_n are nonnegative, nondecreasing, and differentiable on A, with $s_n'(x) \geq 0$ and $r_n'(x) \geq 0$ for all $x \in A$. Since $s_n'(x) \leq s_n'(x) + r_n'(x) = f'(x)$ for all $x \in A$, we have that $\sum_{k=1}^{\infty} f_k'(x)$ converges for all $x \in A$ since it is a nonnegative series with bounded partial sums, and

$$\sum_{k=1}^{\infty} f_k'(x) \leq f'(x)$$

for all $x \in A$.

To show that equality holds a.e. on $[a,b]$, it suffices to find a subsequence (s_{n_j}') which converges to f' a.e. on $[a,b]$. Since $s_n(b) \to f(b)$, for each j there is an $n_j > n_{j-1}$ such that $r_{n_j}(b) = f(b) - s_{n_j}(b) < 2^{-j}$ and hence, for each $x \in [a,b]$, we have

$$0 \leq \sum_{j=1}^{\infty} r_{n_j}(x) \leq \sum_{j=1}^{\infty} r_{n_j}(b) = \sum_{j=1}^{\infty} [f(b) - s_{n_j}(b)] < \infty$$

and thus the series $\sum_{j=1}^{\infty} r_{n_j}(x)$ satisfies the hypotheses in the preceding paragraph, so there is a subset B of $[a,b]$ such that $[a,b] \setminus B$ has measure 0 and

$$0 \leq \sum_{j=1}^{\infty} r_{n_j}'(x) = \sum_{j=1}^{\infty} [f'(x) - s_{n_j}'(x)] < \infty$$

for all $x \in B$. Thus, for every $x \in B$, we have $\lim_{j\to\infty} [f'(x) - s_{n_j}'(x)] = 0$, so

$$\lim_{j\to\infty} s_{n_j}'(x) = f'(x)$$

for almost all $x \in [a,b]$.

Now drop the assumption that the f_k are nonnegative. (The only place this assumption was used was to obtain that the r_n were nonnegative.) Set $g(x) = f(x) - f(a)$ and $g_k(x) = f_k(x) - f_k(a)$ for each k and each $x \in [a,b]$. Then the g_k are nonnegative and nondecreasing, $g' = f'$, $g_k' = f_k'$ for all k, and $g(x) = \sum_{k=1}^{\infty} g_k(x)$ for all k. Thus the previous argument applies to g and the g_k, and shows that

$$f'(x) = g'(x) = \sum_{k=1}^{\infty} g_k'(x) = \sum_{k=1}^{\infty} f_k'(x) \text{ a.e.}$$

XIII.22.10. Exercises

XIII.22.10.1. Give a correct restatement of the Fubini Differentiation Theorem for sequences. Show that the following is *not* a correct statement:

"Let (f_n) be a nondecreasing sequence of nondecreasing functions on an interval $[a,b]$ converging uniformly on $[a,b]$ to a (nondecreasing) function f. Then $f_n' \to f'$ pointwise a.e. on $[a,b]$."

[Consider a strictly increasing sequence (f_n) of nondecreasing step functions converging uniformly to $f(x) = x$ on $[0,1]$. Modify this example to make the f_n continuous by connecting the steps by line segments of large slope. In these examples, there is no $x \in [0,1]$ for which $f_n'(x) \to f'(x)$.]

XIII.22.10.2. Let g be the Cantor function (). Regard g as a function on $\mathbb{R}$ by setting $g(x) = 0$ for $x < 0$ and $g(x) = 1$ for $x > 1$. Then g is nonnegative, continuous, nondecreasing, $g(0) = 0$, $g(1) = 1$, and $g' = 0$ a.e. Let $\{[a_k, b_k] : k \in \mathbb{N}\}$ be an enumeration of the closed bounded intervals with rational endpoints $a_k < b_k$.

(a) For each k let f_k be a scaled copy of g transferred to $[a_k, b_k]$:

$$f_k(x) = 2^{-k} f\left(\frac{x - a_k}{b_k - a_k}\right) .$$

Show that f_k is nonnegative, continuous, nondecreasing, $f_k(x) = 0$ for $x \le a_k$, $f_k(x) = 2^{-k}$ for $x \ge b_k$, and $f_k' = 0$ a.e.

(b) Set $f(x) = \sum_{k=1}^{\infty} f_k(x)$. Show that the series converges uniformly on all of $\mathbb{R}$, and that f is continuous and strictly increasing on $\mathbb{R}$.

(c) Apply XIII.22.9.1. to conclude that $f' = 0$ a.e.

XIII.22.10.3. [Move to section on series of functions]

(a) Let $\{a_k : k \in \mathbb{N}\}$ be an enumeration of $\mathbb{Q} \cap [0,1]$. Show that the infinite series $\sum_{k=1}^{\infty} \frac{3}{k!} \sqrt[3]{x - a_k}$ converges uniformly on $[0,1]$ to a function g which is continuous and strictly increasing.

(b) Let $[a,b]$ be the range of g, and $f = g^{-1} : [a,b] \to [0,1]$. Show that f is continuous, strictly increasing, and that $f' = 0$ on the dense set $g(\mathbb{Q})$.

(c) Show that g is differentiable at every irrational number x in $[0,1]$ and that $g'(x) > 1$. Thus f is differentiable at every point of $[a,b]$ and $0 \le f'(x) < 1$ for all $x \in [a,b]$.

This example is due to D. Pompeiu ([**?**]; cf. [vRS82, 13.3] or [Str81, p. 215-216]). For this f, the set $\{x \in [a,b] : f'(x) = 0\}$, while dense in $[a,b]$, is countable. There are more dramatic examples, e.g. there is a strictly increasing continuous function f on $[a,b]$ such that $f' = 0$ a.e. (Exercise XIII.22.10.2.).

XIII.22.10.4. Let $K \subseteq [0,1]$ be a Cantor set of positive measure, and let g be a nonnegative real-valued continuous function on $[0,1]$ which is zero precisely on K, e.g. $g(x)$ is the distance from x to K. Set

$$f(x) = \int_0^x g(t)\, dt .$$

Then f is strictly increasing on $[0,1]$, differentiable everywhere with $f' = g$ (), i.e. $\mathcal{C}^1$, and $f' = 0$ on a set of positive measure.

XIII.22.10.5. Does there exist a strictly increasing differentiable function f on an interval $[a, b]$ such that the set

$$S = \{x \in [a, b] : f'(x) = 0\}$$

satisfies that $S \cap [c, d]$ has positive measure for all $a \leq c < d \leq b$? (Compare XIII.22.10.3., XIII.22.10.4..)

XIII.22.10.6. Let $f_k(x) = \frac{1}{k} \tan^{-1} kx - \frac{1}{k+1} \tan^{-1}(k+1)x$.

(a) Show that f_k is strictly increasing on $[-1, 1]$.

(b) Show that $\sum_{k=1}^{\infty} f_k(x)$ converges (uniformly) on $[-1, 1]$ to a differentiable function f.

(c) Although f and each f_k are differentiable everywhere, it is not true that $f'(x) = \sum_{k=1}^{\infty} f_k'(x)$ everywhere (we do not have $f'(0) = \sum_{k=1}^{\infty} f_k'(0)$).

XIII.23. Sard's Theorem

Sard's Theorem in its various forms is one of the most remarkable properties of Euclidean space with its differentiable structure, and is perhaps *the* fundamental result of the subject of differential topology.

Consider a smooth map f from $\mathbb{R}^n$ to $\mathbb{R}^m$, or, more generally, from a smooth n-manifold N to a smooth m-manifold M. Then, for any $\boldsymbol{x}_0 \in \mathbb{R}^n$, $Df(\boldsymbol{x}_0)$ is a linear transformation from $\mathbb{R}^n$ to $\mathbb{R}^m$. The point $\boldsymbol{x}_0$ is *singular* if $Df(\boldsymbol{x}_0)$ has rank strictly smaller than m; otherwise, $\boldsymbol{x}_0$ is *regular*. The image in M of the set of singular points of f is called the set of *singular values* of f; a $\boldsymbol{y}_0$ in the range of f which is not a singular value is called a *regular value* of f. (The image of a regular point can be a singular value if it is also the image of a singular point.) The names reflect the fact that f is well-behaved in a neighborhood of a regular point but can be quite pathological near a singular point (cf. ()). Points of M not in the range of f are also (rather perversely) usually called regular values of f. Every critical value of f is a singular value; the converse is not necessarily true if $m > 1$.

Although the set of singular points of f can be a large subset of $\mathbb{R}^n$ (f could even be a constant function!), Sard's Theorem states that the set of singular *values* of f is a "negligibly small" subset of $\mathbb{R}^m$ (or M), in a certain precise sense (measure zero and meager). Thus, in many situations, it can be concluded that "almost all" values of f are regular values; even the existence of one regular value for f can sometimes have important consequences (cf. XIII.21.5.6.).

Sard's Theorem is intuitively quite plausible, and relatively easy to prove, if $n \leq m$, and only quite mild differentiability assumptions on f are needed. In the case $n < m$, where every point of N is a singular point (since the rank of $Df(\boldsymbol{x}_0)$ is always $\leq n$ for any $\boldsymbol{x}_0$), it simply says that the range of f is a "small" subset of M (intuitively it has dimension $\leq n$); although the existence of "space-filling curves" () can shake one's confidence about this, Sard's Theorem in the case $n < m$ says that there can be no smooth space-filling curve or lower-dimensional surface. And in the case $n = m = 1$, the statement says that for a continuously differentiable function, "most" horizontal lines are not tangent to the graph.

In the case $n > m$, or $n = m > 1$, the result is also intuitively plausible: if $\boldsymbol{x}_0$ is a singular point, then near $\boldsymbol{x}_0$ the function f is approximately a linear function whose range is a proper subspace of $\mathbb{R}^m$, and such a subspace is negligibly small in a measure or category sense, and thus a small neighborhood of $\boldsymbol{x}_0$ should have an image of "much smaller" size in $\mathbb{R}^m$. However, this intuitive idea turns out not to be directly translatable into a proof in this case, and is even false in general unless some delicate smoothness conditions are assumed (the underlying intuitive reason for the smoothness conditions is closely related to V.10.7.11.). The fact that the conclusion holds in the case $n > m$ is rather subtle and quite remarkable, and has all sorts of important consequences, e.g. it easily implies the Brouwer Fixed-Point Theorem, which is the most fundamental fact about the topology of Euclidean space, as well as underlying transversality, the fundamental technical tool of differential topology.

Sard's Theorem is often called the *Morse-Sard Theorem* since the case $m = 1$ was proved by A. P. Morse in 1939 [Mor39]; the general theorem was proved by A. Sard in 1942 [Sar42]. Sard, a student of Marston Morse, obtained some of the results independently of A. P. Morse in his Ph.D. dissertation of 1936. Note that A. P. Morse was not the same person as Marston Morse (they were apparently unrelated). Sard states in [Sar42] that Marston Morse previously proved the theorem of A. P. Morse in the cases $n \leq 6$, in part jointly with Sard (unpublished). A closely related result was obtained in [Bro35]. There have been various generalizations and refinements, cf. [Fed69], [Yom83], [Bat93].

XIII.23.1. Sets of Measure Zero

The notion of a set of measure zero is really a concept from measure theory (). But little if any actual measure theory is needed to develop the definition and basic properties needed in this section.

XIII.23.1.1. DEFINITION. A subset $A \subseteq \mathbb{R}^n$ *has measure zero in* $\mathbb{R}^n$ if, for every $\epsilon > 0$, there is a sequence (B_k) of open balls in $\mathbb{R}^n$ such that $A \subseteq \cup_k B_k$ and

$$\sum_{k=1}^{\infty} \rho_k^n < \epsilon$$

where ρ_k is the radius of B_k. We allow empty balls, i.e. open balls of radius 0; thus the collection $\{B_k\}$ may be finite or countably infinite.

Note that up to a constant factor, the sum $\sum_{k=1}^{\infty} \rho_k^n$ is just the sum of the n-dimensional volumes $\sum_{k=1}^{\infty} V_n(B_k)$ of the B_k. By adjusting ϵ, the sum of the volumes can be used instead in the definition.

XIII.23.1.2. We should properly say "A has n-dimensional Lebesgue measure zero" instead of "A has measure zero in $\mathbb{R}^n$." Note that the "*in* $\mathbb{R}^n$" is a crucial part of the terminology: it does not make sense to simply say that a subset of Euclidean space has measure zero without specifying which Euclidean space it is with respect to. For example, the interval $[0, 1]$ does not have measure zero in $\mathbb{R}^1$, but if it is regarded as a segment on the x-axis it does have measure zero in $\mathbb{R}^2$. The term *null set* is often used for a set of measure zero.

XIII.23.1.3. A ball of radius r in $\mathbb{R}^n$ is contained in a cube of side length $2r$ with sides parallel to the coordinate axes; conversely, a cube of side length $2s$ is contained in the ball of radius $s\sqrt{n}$ around its center. So the definition can be equivalently rephrased replacing "open ball" with "open cube" and "radius" with "side length." The cubes can be restricted to ones with sides parallel to the axes, or not.

An open ball intersecting A is contained in an open ball of twice the radius centered at a point of A. Thus all the balls in the definition may be taken with centers in A. The same consideration can be made with cubes.

There is much more flexibility. If B is a ball, there is a ball with rational radius with the same center whose radius is less than twice the radius of B; thus we may restrict to using open balls with rational radius. Similarly, open cubes with rational edges can be used. In a similar manner, we may restrict to using only open balls or cubes whose centers have rational coordinates (and rational radii or sides).

Another especially useful variation is to use open rectangular solids. For if R is an open rectangular solid, R can be covered by a finite number of open cubes whose total volume is less than $2V_n(R)$. Thus we obtain:

XIII.23.1.4. PROPOSITION. Let $A \subset \mathbb{R}^n$. Then A has measure zero in $\mathbb{R}^n$ if and only if, for every $\epsilon > 0$, there is a sequence (R_k) of open rectangular solids in $\mathbb{R}^n$ with $A \subseteq \cup_k R_k$ and

$$\sum_{k=1}^{\infty} V_n(R_k) < \epsilon \ .$$

As before, some of the R_k may be empty, i.e. there may be either a finite or countably infinite number of R_k.

XIII.23.1.5. PROPOSITION. (i) Any subset of a subset of $\mathbb{R}^n$ of measure zero in $\mathbb{R}^n$ has measure zero in $\mathbb{R}^n$.

(ii) A countable union of subsets of $\mathbb{R}^n$ of measure zero in $\mathbb{R}^n$ has measure zero in $\mathbb{R}^n$.

PROOF: Part (i) is obvious. For (ii), let (A_j) be a sequence of subsets of $\mathbb{R}^n$ of measure zero in $\mathbb{R}^n$, and $A = \cup_j A_j$. Let $\epsilon > 0$. For each j let (B_{jk}) be a sequence of open balls in $\mathbb{R}^n$ covering A_j for which the sum of the volumes is less than $2^{-j}\epsilon$. Then the B_{jk} cover A and the sum of the volumes is less than ϵ. 👍

XIII.23.1.6. COROLLARY. Let $A \subseteq \mathbb{R}^n$. Then A has measure zero in $\mathbb{R}^n$ if and only if every $\boldsymbol{x}_0 \in A$ has a neighborhood U such that $A \cap U$ has measure zero in $\mathbb{R}^n$.

PROOF: This is really the Lindelöf property of $\mathbb{R}^n$. If $\boldsymbol{x}_0 \in A$ and U is any neighborhood of $\boldsymbol{x}_0$, then there is a ball V of rational radius, whose center has rational coordinates, with $\boldsymbol{x}_0 \in V \subseteq U$. If $A \cap U$ has measure zero in $\mathbb{R}^n$, so does $A \cap V$. There are only countably many distinct such V, so A is a countable union of sets of measure zero in $\mathbb{R}^n$. The converse is trivial. 👍

XIII.23.1.7. EXAMPLES. (i) Let S be the $(n-1)$-dimensional subspace

$$\{(x_1, \ldots, x_{n-1}, 0) : x_1, \ldots, x_{n-1} \in \mathbb{R}\}$$

of $\mathbb{R}^n$. Then S is a countable union of bounded subsets. Each bounded subset can be contained in a single open rectangular solid whose thickness is so small that its volume is arbitrarily small. Thus S has measure zero in $\mathbb{R}^n$.

(ii) No (nonempty) open rectangle in $\mathbb{R}^n$ can have measure zero in $\mathbb{R}^n$. This fact, while intuitively quite plausible, is somewhat tricky to prove; see (). Since any nonempty open set in $\mathbb{R}^n$ contains an open rectangle, no nonempty open set can have measure zero, i.e. every set of measure zero in $\mathbb{R}^n$ has empty interior.

XIII.23.1.8. PROPOSITION. Let U be a subset of $\mathbb{R}^n$, $\boldsymbol{f} : U \to \mathbb{R}^n$ a Lipschitz function (). If $A \subseteq U$ has measure zero in $\mathbb{R}^n$, so does $\boldsymbol{f}(A)$. In particular, isometries and affine functions preserve sets of measure zero.

PROOF: Suppose $A \subseteq U$ has measure zero in $\mathbb{R}^n$. Let M be the Lipschitz constant of $\boldsymbol{f}$. Let $\epsilon > 0$, and let (B_k) be a sequence of open balls with centers $\boldsymbol{x}_k \in A$ covering A with total volume less than $\frac{\epsilon}{M^n}$. If ρ_k is the radius of B_k, then $\boldsymbol{f}(B_k \cap U)$ is contained in the open ball of radius $M\rho_k$ around $\boldsymbol{f}(\boldsymbol{x}_k)$; thus $\boldsymbol{f}(A)$ is contained in the union of these open balls, which have total volume $< \epsilon$. 👍

XIII.23.1.9. COROLLARY. Let U and V be open subsets of $\mathbb{R}^n$, and $\boldsymbol{f}$ a $(\mathcal{C}^1)$ diffeomorphism from U to V. If $A \subseteq U$, then A has measure zero in $\mathbb{R}^n$ if and only if $\boldsymbol{f}(A)$ does.

PROOF: Every point of U has a compact neighborhood V contained in U, on which $\boldsymbol{f}$ is Lipschitz (); thus if $A \cap V$ has measure zero in $\mathbb{R}^n$, so does $\boldsymbol{f}(A \cap V)$. 👍

XIII.23.1.10. Sets of measure zero are not preserved under homeomorphisms in general (). Thus having measure zero is a metric concept but not a topological concept.

The next result is a special case of Tonelli's Theorem (), needed for the proof of Sard's Theorem. This proof appears in [Ste83, p. 51] and is attributed to H. FURSTENBERG. An F_σ is a countable union of closed sets. Since every closed set in $\mathbb{R}^n$ is a countable union of compact sets, a subset of $\mathbb{R}^n$ is an F_σ if and only if it is σ-compact. Of course, every closed set in $\mathbb{R}^n$ is an F_σ. See ().

XIII.23.1.11. THEOREM. [BABY TONELLI THEOREM] Let K be an F_σ in $\mathbb{R}^n$. Suppose, for each $t \in \mathbb{R}$, we have that

$$K_t := \{(x_1, \ldots, x_{n-1}) : (x_1, \ldots, x_{n-1}, t) \in K\} \subseteq \mathbb{R}^{n-1}$$

has measure zero in $\mathbb{R}^{n-1}$. Then K has measure zero in $\mathbb{R}^n$.

Informally, if each horizontal cross-section of K has $(n-1)$-dimensional measure zero, then K has n-dimensional measure zero.

We need two lemmas for the proof. The first is a variation of () (note that this result is not quite correctly stated in [Ste83]):

XIII.23.1.12. LEMMA. Let $[a, b]$ be a closed bounded interval in $\mathbb{R}$ $c > 0$, and $\mathcal{U}$ a cover of $[a, b]$ by open intervals of length $\leq c$. Then there is a finite subcover $\{I_1, \ldots, I_n\}$ of $\mathcal{U}$ for which

$$\sum_{k=1}^{n} \ell(I_k) \leq 2(b - a + c) \ .$$

PROOF: Since $[a, b]$ is compact there is a finite subcover. Any finite subcover contains a minimal subcover $\mathcal{V}$ (i.e. $\mathcal{V}$ is a cover but no proper subset of $\mathcal{V}$ is a cover). Number the intervals in $\mathcal{V}$ in increasing order of left endpoint (no two can have the same left endpoint by minimality), i.e. $\mathcal{V} = \{I_1, \ldots, I_n\}$ where $I_k = (a_k, b_k)$ with $a_k < a_{k+1}$ for $1 \leq k < n$. These endpoints necessarily satisfy

$$a_1 < a \leq a_2 < b_1 \leq a_3 < b_2 \leq \cdots \leq a_n < b_{n-1} \leq b < b_n$$

(if one of these inequalities is violated, the collection of intervals is not minimal). We then have

$$\sum_{k=1}^{n} \ell(I_k) = \sum_{k=1}^{n} (b_k - a_k) = (a - a_1) + (b - a) + (b_n - b) + \sum_{k=1}^{n-1} (b_k - a_{k+1}) \ .$$

The last sum is the total length of the overlaps of the intervals; since the overlaps are disjoint and contained in $[a, b]$, this total length is $\leq b - a$. Also, $a - a_1 \leq c$ and $b_n - b \leq c$. Thus we have

$$\sum_{k=1}^{n} \ell(I_k) \leq c + (b - a) + c + (b - a) = 2(b - a + c) \ .$$

XIII.23.1.13. LEMMA. Let K be a compact subset of $\mathbb{R}^n \cong \mathbb{R}^{n-1} \times \mathbb{R}$, and $t \in \mathbb{R}$. Set

$$K_t := \{(x_1, \ldots, x_{n-1}) : (x_1, \ldots, x_{n-1}, t) \in K\} \subseteq \mathbb{R}^{n-1} \ .$$

If U is an open set in $\mathbb{R}^{n-1}$ containing K_t, then there is a $\delta > 0$ such that

$$K \cap \left[\mathbb{R}^{n-1} \times (t-\delta, t+\delta)\right] \subseteq U \times (t-\delta, t+\delta) \ .$$

PROOF: Suppose there is no such δ. Then there is a sequence $(\boldsymbol{x}_k, t_k)$ of points of K with $t_k \to t$ and $\boldsymbol{x}_k \notin U$ for all k. Passing to a subsequence, we may assume $(\boldsymbol{x}_k, t_k) \to (\boldsymbol{x}, t) \in K$ for some $\boldsymbol{x}$ by compactness of K. But then $\boldsymbol{x} \in K_t$, and $\boldsymbol{x}_k \to \boldsymbol{x}$ in $\mathbb{R}^{n-1}$, contradicting that U is an open neighborhood of $\boldsymbol{x}$. 👍

XIII.23.1.14. We now prove Theorem XIII.23.1.11.. It suffices to assume that K is compact. Then there is an interval $[a, b]$ such that $K \subseteq \mathbb{R}^{n-1} \times [a, b]$. Fix $\epsilon > 0$. For each $t \in [a, b]$ there is a countable (even finite) collection $\mathcal{R}_t$ of open rectangular solids in $\mathbb{R}^{n-1}$ covering K_t whose total $(n-1)$-dimensional volume is

$$v_t \leq \frac{\epsilon}{2(b-a+1)} \ .$$

Let U_t be the union of the rectangular solids in $\mathcal{R}_t$. By XIII.23.1.13. there is a $\delta_t > 0$ such that

$$K \cap \left[\mathbb{R}^{n-1} \times (t-\delta_t, t+\delta_t)\right] \subseteq U_t \times (t-\delta_t, t+\delta_t) \ .$$

We may assume $\delta_t \leq 1/2$ for all t. The intervals $\{(t-\delta_t, t+\delta_t) : t \in [a, b]\}$ form an open cover of $[a, b]$, so by Lemma XIII.23.1.12. there is a subcover

$$\{(t_1 - \delta_{t_1}, t_1 + \delta_{t_1}), \ldots, (t_m - \delta_{t_m}, t_m + \delta_{t_m})\}$$

whose total length $\sum_{k=1}^m 2\delta_{t_k}$ is $\leq 2(b-a+1)$. If $\mathcal{R}$ is the collection of open rectangular solids of the form

$$R \times (t_k - \delta_{t_k}, t_k + \delta_{t_k})$$

for $R \in \mathcal{R}_{t_k}$, $1 \leq k \leq m$, then the collection $\mathcal{R}$ covers K and the total n-dimensional volume is

$$\sum_{k=1}^m 2\delta_{t_k} v_{t_k} \leq \frac{\epsilon}{2(b-a+1)} \sum_{k=1}^m 2\delta_{t_k} \leq \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, K has measure zero in $\mathbb{R}^n$.
This completes the proof of Theorem XIII.23.1.11.. 👍

XIII.23.1.15. This theorem extends (XVIII.3.1.12.) from F_σ's to a much larger class of subsets of $\mathbb{R}^n$ (Lebesgue measurable subsets), but not to arbitrary subsets. See XVIII.3.3.1..

Sets of Measure Zero in a Manifold

We can extend the notion of subset of measure zero to smooth manifolds:

XIII.23.1.16. Definition. Let M be a $\mathcal{C}^r$ n-manifold ($r \geq 1$). A subset A of M *has measure zero in* M if, for every $x \in A$, there is a coordinate chart (U, ϕ) for M with $x \in U$ such that $\phi(A \cap U)$ has measure zero in $\mathbb{R}^n$.

XIII.23.1.17. It follows easily from XIII.23.1.9. that if $A \subseteq M$ has measure zero in M, and (U, ϕ) is any coordinate chart for M, then $\phi(A \cap U)$ has measure zero in $\mathbb{R}^n$. This could have been taken as the definition of a subset of measure zero, but the condition in XIII.23.1.16. is easier to check.

If M is not second countable, what we have technically defined is a locally null subset of M. (This technicality may be safely ignored as irrelevant in our applications.)

There is no analogous reasonable definition of a subset of measure zero in a topological manifold ().

The next result is a straightforward corollary of XIII.23.1.8.:

XIII.23.1.18. Proposition. Let N and M be $\mathcal{C}^r$ n-manifolds ($r \geq 1$), with N separable, and $f : N \to M$ a $\mathcal{C}^r$ function. If A is a subset of N which has measure zero in N, then $f(A)$ has measure zero in M.

XIII.23.1.19. This result holds also if N is n-dimensional and M is m-dimensional with $n < m$ (), but not necessarily if $m < n$.

XIII.23.2. Statement of Sard's Theorem

XIII.23.2.1. Theorem. [Sard's Theorem] Let N be a separable $\mathcal{C}^r$ n-manifold, and M a $\mathcal{C}^r$ m-manifold, with $r \geq \max(n - m + 1, 1)$, and let $f : N \to M$ be a $\mathcal{C}^r$ function. Then the set of singular values of f is a subset of M of measure zero in M.

XIII.23.2.2. We will prove special cases of the theorem separately before turning to the most general version. The special cases are written separately because the proof simplifies in these cases and sometimes a more general result holds. The cases we discuss are:

(i) $n < m$.

(ii) $n = m = 1$.

(iii) $n = m > 1$.

(iv) $n > m$, r large.

(v) $n > m$, sharp r bound.

Our proof is adapted from [Ste83] and [Hir94].

XIII.23.2.3. The first reduction in all cases is to note that N can be covered by countably many coordinate charts, each of which is contained in the preimage of a coordinate chart in M, and since the union of countably many null sets is a null set and null sets are preserved under diffeomorphisms, it suffices to prove the theorem for $N = \mathbb{R}^n$ and $M = \mathbb{R}^m$. In fact, since N is σ-compact, it suffices to prove the theorem for the set of singular values in the image of an arbitrary compact subset of $\mathbb{R}^n$.

XIII.23.2.4. The restriction that N be separable, i.e. that it has only countably many components, is necessary in general: if N has $2^{\aleph_0}$ components, a function from N to M can be surjective even if it is constant on each component of N; such a function is $\mathcal{C}^\infty$ and has identically zero derivative, and hence every point of M is a singular value.

XIII.23.3. The Case $n < m$

XIII.23.4. The Case $n = m = 1$

XIII.23.4.1. The simplest case is $n = m = 1$. Suppose f is a $\mathcal{C}^1$ function from $\mathbb{R}$ (or an open interval in $\mathbb{R}$) to $\mathbb{R}$. The singular points of f are just the critical numbers (the x_0 for which $f'(x_0) = 0$). It suffices to show that the image of the critical numbers in any closed bounded subinterval of the domain has measure zero in $\mathbb{R}$.

So suppose $[a, b]$ is such an interval. Since f' is continuous on $[a, b]$, it is uniformly continuous there (). Fix $\epsilon > 0$. Then there is a $\delta > 0$ such that $|f'(x) - f'(y)| < \epsilon$ whenever $x, y \in [a, b]$, $|x - y| < \delta$. Partition $[a, b]$ into subintervals $I_k = [x_{k-1}, x_k]$ with $\ell(I_k) = x_k - x_{k-1} < \delta$ for all k. For every I_k containing a singular point of f, we have $|f'(x)| < \epsilon$ for all $x \in I_k$. Thus by the Mean Value Theorem we have $|f(x) - f(y)| < \epsilon\ell(I_k)$ for all $x, y \in I_k$, for any such k. Thus $f(I_k)$ is contained in an interval J_k of length $< \epsilon\ell(I_k)$ for any such k (actually $f(I_k)$ is itself such an interval). Thus the set of singular values of f in $[a, b]$ is contained in a finite number of intervals of total length

$$\sum \ell(J_k) < \sum_{k=1}^{n} \epsilon\ell(I_k) = \epsilon(b - a)$$

and since $\epsilon > 0$ is arbitrary, this set of singular values has measure zero (in fact zero content) in $\mathbb{R}$.

This completes the proof in the case $n = m = 1$. 👍

The $\mathcal{C}^1$ assumption on f can be weakened and even eliminated in this case. The following result is due to Luzin (XIX.5.1.14.); we give an alternate proof due to S. Ivanov (http://mathoverflow.net/questions/113991/counterexample-to-sard-theorem-for-a-not-c1-map/114000#114000):

XIII.23.4.2. Theorem. Let f be a function from $\mathbb{R}$ (or an interval in $\mathbb{R}$) to $\mathbb{R}$. Set

$$\mathcal{C} = \{x \in \mathbb{R} : f'(x) \text{ exists and equals } 0\}$$

and let $\mathcal{S} = f(\mathcal{C})$. Then $\mathcal{S}$ has measure zero in $\mathbb{R}$.

Proof: We will use the Vitali Covering Theorem (). It suffices to show that the part of $\mathcal{C}$ in (a, b) has image of measure zero, for any bounded open interval (a, b) in the domain of f, so we may assume the domain of f is (a, b) and hence that $\mathcal{C}$ has finite outer measure. Fix $\epsilon > 0$. For every $x_0 \in \mathcal{C}$, there is a δ_0 such that $(x_0 - \delta_0, x_0 + \delta_0) \subseteq (a, b)$ and

$$\left|\frac{f(x) - f(x_0)}{x - x_0}\right| < \frac{\epsilon}{5}$$

for all x with $|x - x_0| < \delta_0$. Set

$$\mathcal{I}_{x_0} = \left\{\left(x - \frac{\delta}{5}, x + \frac{\delta}{5}\right) : 0 < \delta \leq \delta_0\right\}$$

and let $\mathcal{I} = \cup_{x_0 \in \mathcal{C}} \mathcal{I}_{x_0}$. Then $\mathcal{I}$ is a Vitali covering of $\mathcal{C}$.

For each $I = \left(x_0 - \frac{\delta}{5}, x_0 + \frac{\delta}{5}\right) \in \mathcal{I}$, let I' be the interval $(x_0 - \delta, x_0 + \delta)$ with the same midpoint as I of five times the length. By () there is a sequence (I_n) of disjoint sets in $\mathcal{I}$ such that the I'_n cover $\mathcal{C}$. If $x \in I'_n$, and x_n is the midpoint of I_n, then

$$|f(x) - f(x_n)| < \frac{\epsilon}{5}|x - x_n| < \frac{\epsilon}{5}\frac{\ell(I'_n)}{2} = \epsilon\frac{\ell(I_n)}{2}$$

and thus, if $x, y \in I'_n$ we have

$$|f(x) - f(y)| \leq |f(x) - f(x_n)| + |f(x_n) - f(y)| < \epsilon\ell(I_n)$$

and so $f(I'_n)$ is contained in an interval J_n of length $\epsilon\ell(I_n)$. The J_n cover $\mathcal{S}$.

Since the I_n are disjoint, we have $\sum_n \ell(I_n) \leq b - a$, so

$$\sum_{n=1}^{\infty} \ell(J_n) = \epsilon \sum_{n=1}^{\infty} \ell(I_n) \leq \epsilon(b - a)$$

and since $\epsilon > 0$ is arbitrary, we have that $\mathcal{S}$ has measure zero in $\mathbb{R}$. 👍

XIII.23.5. The Case $n = m > 1$

XIII.23.6. The Case $n > m$, r Large

We now show that the theorem holds for general n and m if r is sufficiently large. Most importantly, this result applies for all n and m if f is $\mathcal{C}^\infty$. The estimate on the minimum r from this argument is not sharp in general (it is quadratic in $n - m$, not linear). This proof is adapted from [Hir94].

XIII.23.6.1. For $n, m \in \mathbb{N}$, define $s(n, m) \in \mathbb{N}$ as follows:

$$s(n,m) = \begin{cases} 1 & \text{if} \quad n \leq m \\ \frac{(n-m+1)(n-m+2)}{2} & \text{if} \quad n > m \end{cases}.$$

The following properties needed for the proof of the theorem are easily verified:

XIII.23.6.2. Proposition. The numbers $s(n, m)$ have the following properties:

(i) $s(n, m) > \frac{n}{m}$ if $n > m$.

(ii) $s(n, m) - k \geq s(n - 1, m)$ if $1 \leq k \leq \frac{n}{m}$.

(iii) $s(n, m) = s(n - 1, m - 1)$ if $m > 1$.

XIII.23.6.3. Theorem. Let $n, m \in \mathbb{N}$. Then if $r \geq s(n, m)$, N is a separable $\mathcal{C}^r$ manifold, M a $\mathcal{C}^r$ m-manifold, and $f : N \to M$ is a $\mathcal{C}^r$ function, then the set of singular values of f is a subset of M of measure zero in M.

XIII.23.6.4. The proof will be by double induction: induction on m, and for fixed m induction on n. The cases $n \leq m$ have already been proved (), so fix n and m and assume that $n > m$ and that the theorem is proved for $(n-1, m)$, and for $(n-1, m-1)$ if $m > 1$. If Σ is the set of singular points of N, it suffices to show that every $\boldsymbol{x}_0 \in \Sigma$ has a neighborhood U such that $f(\Sigma \cap U)$ has measure 0 in M. Write

$$\Sigma = \Sigma_1 \cup \Sigma_2 \cup \Sigma_3$$

where

Σ_1 is the set of $\boldsymbol{x}_0 \in \Sigma$ for which all partial derivatives of f of orders $\leq \frac{n}{m}$ vanish at $\boldsymbol{x}_0$.

Σ_2 is the set of $\boldsymbol{x}_0 \in \Sigma$ such that the first-order partials of f vanish at $\boldsymbol{x}_0$ but some partial derivative of f of order k, $2 \leq k \leq \frac{n}{m}$, is nonzero at $\boldsymbol{x}_0$.

Σ_3 is the set of $\boldsymbol{x}_0 \in \Sigma$ such that some first-order partial of f is nonzero at $\boldsymbol{x}_0$.

XIII.23.6.5. First suppose $\boldsymbol{x} \in \Sigma_1$.

XIII.23.6.6. Now suppose $\boldsymbol{x}_0 \in \Sigma_2$, $\boldsymbol{y}_0 = f(\boldsymbol{x}_0)$. For each multiindex α of order k, $2 \leq k < \frac{n}{m}$, set

$$g_{\alpha,i} = \frac{\partial^\alpha f_i}{\partial x_\alpha}$$

where f_i is the i'th coordinate function of f. Then $g_{\alpha,i}$ is $\mathcal{C}^q$, where

$$q = r - k \geq s(n,m) - \frac{n}{m} \geq s(n-1,m) \ .$$

For each multiindex α of order k, $2 \leq k < \frac{n}{m}$, and each i and j, let $X_{\alpha,i,j}$ be the set of points $\boldsymbol{x} \in \Sigma_2$ such that $g_{\alpha,i}(\boldsymbol{x}) = 0$ and $\frac{\partial g_{\alpha,i}}{\partial x_j}(\boldsymbol{x}) \neq 0$. Then $\boldsymbol{x}_0 \in X_{\alpha,i,j}$ for some α, i, j.

Fix α, i, j with $\boldsymbol{x}_0 \in X_{\alpha,i,j}$. Then, since $g_{\alpha,i}(\boldsymbol{x}_0) = 0$ and $\frac{\partial g_{\alpha,i}}{\partial x_j}(\boldsymbol{x}_0) \neq 0$, $\boldsymbol{x}_0$ is a regular point of $g_{\alpha,i}$. Thus there is a neighborhood U of $\boldsymbol{x}_0$ such that 0 is a regular value of $h_{\alpha,i} = g_{\alpha,i}|_U$ and therefore $Z_{\alpha,i} = h_{\alpha,i}^{-1}(\{0\})$ is a $\mathcal{C}^q$-submanifold of N of dimension $n-1$ containing $\boldsymbol{x}_0$. Since $q \geq s(n-1,m)$ and $f|_{Z_{\alpha,i}}$ is $\mathcal{C}^q$, the inductive hypothesis applies. Any point of Σ_2 which is in $Z_{\alpha,i}$ is a singular point of $f|_{Z_{\alpha,i}}$ since its differential is zero, so we conclude that the measure of $f(\Sigma_2 \cap Z_{\alpha,i})$ is zero. Since $X_{\alpha,i,j} \cap U \subseteq Z_{\alpha,i}$, we have that the measure of $X_{\alpha,i,j} \cap U$ is zero. There is a neighborhood of $\boldsymbol{x}_0$ in Σ_2 contained in a finite union of such sets for various α, i, j, so we conclude that the measure of $f(\Sigma_2)$ is zero.

XIII.23.6.7. If $m = 1$, $\Sigma_3 = \emptyset$ so the proof is finished. If $m > 1$, suppose $\boldsymbol{x}_0 \in \Sigma_3$, $\boldsymbol{y}_0 = f(\boldsymbol{x}_0)$. By (), there are neighborhoods U of $\boldsymbol{x}_0$ and V of $\boldsymbol{y}_0$, and diffeomorphisms $g : \mathbb{R}^{n-1} \times \mathbb{R} \to U$ and $h : V \to \mathbb{R}^{m-1} \times \mathbb{R}$ with $g(\boldsymbol{0}, 0) = \boldsymbol{x}_0$, $h(\boldsymbol{y}_0) = (\boldsymbol{0}, 0)$, such that $\phi = h \circ f \circ g$ is of the form

$$\phi(\boldsymbol{z}, t) = (\psi(\boldsymbol{z}, t), t)$$

for some $\mathcal{C}^r$-function $\psi : \mathbb{R}^{n-1} \times \mathbb{R} \to \mathbb{R}^{m-1}$. The singular values of f in V are precisely the images under h^{-1} of the singular values of ϕ, so it suffices to show that the set $\mathcal{S}$ of singular values of ϕ has measure 0. Fix t, and let $\omega_t : \mathbb{R}^{n-1} \to \mathbb{R}^{m-1}$ be defined by $\omega_t(\boldsymbol{z}) = \psi(\boldsymbol{z}, t)$. Then ω is $\mathcal{C}^r$, so by the inductive hypothesis

the set S_t of singular values of ω_t has measure 0 in $\mathbb{R}^{m-1}$. We have that $\boldsymbol{z}$ is a singular point of ω_t if and only if (z,t) is a singular point of ϕ, so

$$\mathcal{S} = \{(\boldsymbol{z},t) : t \in \mathbb{R}, \boldsymbol{z} \in S_t\} \ .$$

Thus by the Baby Tonelli Theorem (XIII.23.1.11.) $\mathcal{S}$ has measure zero in $\mathbb{R}^{m-1} \times \mathbb{R}$.

This completes the proof of Theorem XIII.23.6.3.. 👍

XIII.23.7. The Case $n > m$, Sharp r Bound

We now turn to the final and most delicate part of the theorem, establishing the sharp bound on r. It is questionable whether it is worth proving this version, since the softer result XIII.23.6.3. suffices for almost all applications. But the conceptual reason behind the sharp bound on r is important and instructive.

The reason for the sharp bound $r \geq n - m + 1$ is a higher-dimensional version of the following one-dimensional fact (cf. ()):

XIII.23.7.1. PROPOSITION. Let $f : \mathbb{R} \to \mathbb{R}$ be a $\mathcal{C}^r$ function ($r \geq 0$). If f has a nonisolated zero at x_0, then $f(x_0) = f'(x_0) = \cdots = f^{(r)}(x_0) = 0$. It follows that f vanishes at x_0 at least to order r^+, i.e.

$$\lim_{x \to x_0} \frac{f(x)}{(x - x_0)^r} = 0 \ .$$

PROOF: If $r = 0$ there is nothing to prove. If $r \geq 1$, let (x_n) be a sequence of zeroes of f converging to x_0. By Rolle's Theorem, for each n there is a y_n between x_0 and x_n with $f'(y_n) = 0$. We have $y_n \to x_0$ by the Squeeze Theorem, so $f'(x_0) = 0$ since f' is continuous. If $r > 1$, repeat the argument using f' in place of f and the y_n in place of the x_n to conclude that $f''(x_0) = 0$, and continue inductively. The last statement follows from V.10.1.3.. 👍

XIII.23.7.2. This result is sharp. If $f(x) = \frac{|x|}{1+(\log|x|)^2} \sin(\log|x|)$ for $x \neq 0$ and $f(0) = 0$, then f is $\mathcal{C}^1$ and has a nonisolated zero at 0, but vanishes only to order 1^+ at 0. There are similar counterexamples for larger r.

XIII.23.8. The Category Version

The following result is a simple corollary of the measure-theoretic version of Sard's Theorem (cf. [Bro35]).

XIII.23.8.1. THEOREM. Let N be a separable $\mathcal{C}^r$ n-manifold, M a $\mathcal{C}^r$ m-manifold, and $f : N \to M$ a $\mathcal{C}^r$ function, where $r \geq \max(n - m + 1, 1)$. Then the set of singular values of f is a meager set in M.

PROOF: First note that the set of singular points of f is closed in N: it is the set of $\boldsymbol{x}_0 \in N$ such that $Det(Df(\boldsymbol{x}_0)Df(\boldsymbol{x}_0)^t) = 0$ (). Thus, although the set of singular values of f need not be closed in M, it is an F_σ (XIII.11.7.11.), and has measure zero by XIII.23.2.1.; thus it has empty interior (), i.e. its complement in M is a dense G_δ. 👍

XIII.23.8.2. Corollary. Let N be a separable n-manifold, M an m-manifold, and $f : N \to M$ a $\mathcal{C}^1$ function. If $n < m$, then the range of f is a meager subset of M.

XIII.23.8.3. These results apply to the case where N and M are Euclidean spaces. They imply that manifolds of different dimensions cannot be diffeomorphic; in particular, $\mathbb{R}^n$ and $\mathbb{R}^m$ are not diffeomorphic if $n \neq m$ (actually more is true: they cannot even be homeomorphic, cf. ()).

XIII.23.9. Counterexamples

The differentiability restrictions in Sard's theorem are sharp (as long as only $\mathcal{C}^r$ functions are considered for $r \in \mathbb{N}$; some relaxation is possible if more delicate degrees of differentiability are allowed, cf. [Bat93]). Even before any of the publications of A. P. Morse or Sard, H. Whitney [Whi35] described counterexamples to stronger statements.

XIII.23.9.1. Whitney described a (highly nondifferentiable) parametrized curve $\gamma : [0,1] \to \mathbb{R}^2$, with γ injective, such that

$$\lim_{t \to t_0} \frac{|t - t_0|}{\|\gamma(t) - \gamma(t_0)\|} = 0$$

for every $t_0 \in [0,1]$. Then the function $\gamma^{-1} : C = \gamma([0,1]) \to [0,1]$ has "zero derivative" at each point $\boldsymbol{a}$ of C in the sense that

$$\lim_{\boldsymbol{x} \to \boldsymbol{a}} \frac{|\gamma^{-1}(\boldsymbol{x}) - \gamma^{-1}(\boldsymbol{a})|}{\|\boldsymbol{x} - \boldsymbol{a}\|} = 0$$

where the limit is taken within C. By Whitney's Extension Theorem (), γ^{-1} extends to a $\mathcal{C}^1$ function f from $\mathbb{R}^2$ to $\mathbb{R}$; every point of C is a critical point of f, so every number in $[0,1]$ is a critical value.

As described in [Hir94], "This [example] leads to the following paradox: the graph of f is a surface $S \subset \mathbb{R}^3$ on which there is an arc A, at every point of which the surface has a horizontal tangent plane, yet A is not at a constant height. To make this more vivid, imagine that S is a hill and A a path on the hill. The hill is level at every point of the path, yet the path goes up and down." In fact, the path can be made to go monotonically up from bottom to top. We should point out that such a path would not be a very good route to follow to ascend the hill, since it has infinite arc length; in fact, its projection into the xy-plane has positive Lebesgue measure (the curve has Hausdorff dimension 2 and positive 2-dimensional Hausdorff measure). There cannot be a smooth path with this property because of the Chain Rule.

Whitney briefly described a higher-dimensional version, giving a $\mathcal{C}^{n-1}$ function f_n ($n \geq 2$) from $\mathbb{R}^n$ to $\mathbb{R}$ for which the set of critical values contains an interval.

If f_n is such a function, then for any m the function $g_{n,m} : \mathbb{R}^{n+m-1} \to \mathbb{R}^m$ given by

$$g_{n,m}(x_1, \dots, x_n, x_{n+1}, \dots, x_{n+m-1}) = (f_n(x_1, \dots, x_n), x_{n+1}, \dots, x_{n+m-1})$$

is a $\mathcal{C}^{n-1}$ function whose singular values contain an entire rectangle in $\mathbb{R}^m$.

XIII.23.9.2. Here is a simpler example from [Gri85] for the case $n = 2$, $m = 1$.

We need a $\mathcal{C}^1$ function f from $\mathbb{R}$ to $\mathbb{R}$ for which every point of the Cantor set K is a singular value. Here is one construction. Fix γ, $2 < \gamma < 3$, and let $\alpha = (\alpha_1, \alpha_2, \dots)$ with $\alpha_n = \gamma^{-n}$. Construct the Cantor set K_α as in XIII.18.2.1., i.e. subintervals of length γ^{-n} are removed at each step. Let (I_k) be a list of the

removed intervals. Let ϕ be a mesa function () on $[0,1]$ and $\beta = \int_0^1 \phi(t)\,dt$; then $0 < \beta < 1$. If the length of I_k is γ^{-n}, let h_k be a translated and scaled version of ϕ on I_k whose integral is 3^{-n}, i.e. scaled horizontally by γ^{-n} and vertically by $\frac{1}{\beta}\left(\frac{\gamma}{3}\right)^n$. Since

$$\lim_{n\to\infty}\left(\frac{\gamma}{3}\right)^n = 0$$

we have that $\sum_{k=1}^{\infty} h_k$ converges uniformly to a continuous function h. Then $h(t) \geq 0$ for all $t \in \mathbb{R}$ and $h(t) = 0$ for all $t \in K_\alpha$, and for $t < 0$, $t > 1$.

Set $g(x) = \int_{-\infty}^{x} h(t)\,dt$. Then g is a nondecreasing $\mathcal{C}^1$ function on $\mathbb{R}$, $g(x) = 0$ for $x \leq 0$ and $g(x) = 1$ for $x \geq 1$, and $g(x) \in K$ for $x \in K_\alpha$. For each such x, $g'(x) = h(x) = 0$. Thus every point of K is a critical value of g (the converse holds too).

Let $f : \mathbb{R}^2 \to \mathbb{R}$ be defined by $f(x,y) = g(x) + g(y)$. Then f is $\mathcal{C}^1$, and if x and y are in K_α, then $Df(x,y) = 0$. If $z \in [0,2]$, then there are $c, d \in K$ such that $z = c + d$ (Exercise XIII.18.3.1.). There are $x, y \in K_\alpha$ with $g(x) = c$ and $g(y) = d$; so $f(x,y) = z$ and z is a critical value, hence singular value, of f. Thus the set of singular values of f does not have measure zero in $\mathbb{R}$. (Actually $[0,2]$ is the entire range of f, and consists of singular values.)

Note that h is not differentiable everywhere, hence g, and therefore f, are not $\mathcal{C}^2$; of course a $\mathcal{C}^2$ function with this property cannot exist by Sard's Theorem.

XIII.23.10. Applications

XIII.23.10.1. THEOREM. Let X be a compact subset of $\mathbb{R}^n$. Then for any $\epsilon > 0$ there is an open neighborhood U of X in $\mathbb{R}^n$ with $\bar{U}$ compact, such that ∂U is a smooth submanifold of $\mathbb{R}^n$ (i.e. $\bar{U}$ is a compact smooth submanifold with boundary), such that $\rho(\mathbf{y}, X) < \epsilon$ for all $\mathbf{y} \in U$, U contains all $\mathbf{y} \in \mathbb{R}^n$ with $\rho(\mathbf{y}, X) < \frac{\epsilon}{4}$, and, for every $\mathbf{y} \in \partial U$, $\frac{\epsilon}{4} < \rho(\mathbf{y}, X) < \epsilon$.

PROOF: Let $V = \{\mathbf{y} \in \mathbb{R}^n : \rho(\mathbf{y}, X) < \epsilon\}$. Then V is a neighborhood of X in $\mathbb{R}^n$ with compact closure. Define $g : \mathbb{R}^n \to \mathbb{R}$ by $g(\mathbf{y}) = \rho(\mathbf{y}, X)$; then g is continuous. Let f be a C^∞ function from $\mathbb{R}^n$ to $\mathbb{R}$ (e.g. a polynomial in the coordinates) uniformly approximating g within $\frac{\epsilon}{4}$ on $\bar{V}$; there is such an f by the Stone-Weierstrass Theorem (). There is a regular value α for f with $\frac{\epsilon}{2} < \alpha < \frac{3\epsilon}{4}$ by Sard's Theorem. Set

$$U = \{\mathbf{y} \in V : f(\mathbf{y}) < \alpha\}\ .$$

Then U is open. Since for $\mathbf{y} \in \bar{V}$ we have $f(\mathbf{y}) - \frac{\epsilon}{4} < \rho(\mathbf{y}, X) < f(\mathbf{y}) + \frac{\epsilon}{4}$, we have that $\bar{U} \subseteq V$, so

$$\partial U = \{\mathbf{y} \in V : f(y) = \alpha\}$$

is a smooth closed submanifold of $\mathbb{R}^n$, and the desired inequalities follow. 👍

XIII.23.10.2. In fact the $\frac{\epsilon}{4}$ can be replaced by any $\eta < \epsilon$ by a suitable modification of the proof.

XIII.23.10.3. In the case $n = 2$, if X is a compact subset of the plane there is for any $\epsilon > 0$ an ϵ-neighborhood U of X in $\mathbb{R}^2$ whose boundary consists of finitely many disjoint smooth closed curves. (Such a neighborhood is not necessarily homeomorphic to a disjoint union of closed disks, however, e.g. if X is a circle.) See XIII.23.12.3. for a constructive proof not using Sard's Theorem.

XIII.23.11. Refined Versions

Even sharper versions of Sard's Theorem are known, such as:

XIII.23.11.1. THEOREM. [Fed69, 3.4.3] Let $n > k \geq 0$ and $r \geq 1$ be integers, and let f be a $\mathcal{C}^r$ function from an open subset U of $\mathbb{R}^n$ into a normed vector space Y. Set

$$B_k = f(\{\boldsymbol{x} \in U : rank\ Df(\boldsymbol{x}) \leq k\}) \subseteq Y\ .$$

Then

$$\mathscr{H}^{k+\frac{n-k}{r}}(B_k) = 0$$

(where $\mathscr{H}^s$ denotes s-dimensional Hausdorff measure on Y (XVII.6.3.3.).)

Note that the usual form (XIII.23.2.1.) of Sard's Theorem follows from the case $Y = \mathbb{R}^m$, $k = m-1$, $r \geq \max(n-m+1, 1)$ (the set of singular values of f is B_{m-1}, or actually B_k, $k = \min(n, m-1)$).

The result can be rephrased in terms of Hausdorff dimension (XVII.6.3.16.), although the statement is slightly weaker:

XIII.23.11.2. COROLLARY. Let $n > k \geq 0$ and $r \geq 1$ be integers, and let f be a $\mathcal{C}^r$ function from an open subset U of $\mathbb{R}^n$ into a normed vector space Y. Set

$$B_k = f(\{\boldsymbol{x} \in U : rank\ Df(\boldsymbol{x}) \leq k\}) \subseteq Y\ .$$

Then

$$dim_H(B_k) \leq k + \frac{n-k}{r}\ .$$

XIII.23.11.3. COROLLARY. Let f be a $\mathcal{C}^\infty$ function from an open set in $\mathbb{R}^n$ to $\mathbb{R}^m$. If $S \subseteq \mathbb{R}^m$ is the set of singular values of f, then

$$dim_H(S) \leq \min(n, m-1)\ .$$

The case $k = 0$ (the set of critical values) is also interesting:

XIII.23.11.4. COROLLARY. Let f be a $\mathcal{C}^r$ function from an open set in $\mathbb{R}^n$ to a normed vector space Y. If $C \subseteq Y$ is the set of critical values of f, then

$$dim_H(C) \leq \frac{n}{r}\ .$$

If f is $\mathcal{C}^\infty$, then $dim_H(C) = 0$.

XIII.23.11.5. These results extend immediately to the case where X is a separable smooth n-manifold and f a $\mathcal{C}^r$ function from X to a normed vector space Y. Extending to the case where Y is a separable smooth manifold is more difficult because of subtleties in defining Hausdorff measure and Hausdorff dimension for subsets of a manifold (cf. ()).

XIII.23.11.6. There is another fairly recent generalization of XIII.23.2.1.. A function $f : U \subseteq \mathbb{R}^n \to \mathbb{R}^m$ is $\mathcal{C}^{r,1}$ if it is r-times differentiable on U and $D^r f$ is Lipschitz (), and *locally* $\mathcal{C}^{r,1}$ if it is $\mathcal{C}^{r,1}$ in a neighborhood of each point of U. A locally $\mathcal{C}^{r,1}$ function is $(r+1)$-times differentiable a.e. on U, and a $\mathcal{C}^{r+1}$ function is locally $\mathcal{C}^{r,1}$.

XIII.23.11.7. THEOREM. [Bat93] Let N be a separable $\mathcal{C}^r$ n-manifold, and let $f : N \to \mathbb{R}^m$ be a locally $\mathcal{C}^{r-1,1}$ function, with $r \geq \max(n-m+1, 1)$. Then the set of singular values of f is a subset of $\mathbb{R}^m$ of measure zero in $\mathbb{R}^m$.

There is again a slight problem in extending to the case where the target is a manifold, since the definition of locally $\mathcal{C}^{r-1,1}$ must be extended to this case.

XIII.23.12. Exercises

XIII.23.12.1. Carefully justify all the assertions in XIII.23.1.3., i.e. show that adding each of the various restrictions or modifications to the definition does not change the class of null sets.

XIII.23.12.2. Show that if C is any Cantor set in $\mathbb{R}$ of Lebesgue measure 0, there is a $\mathcal{C}^1$ function $f : \mathbb{R} \to \mathbb{R}$ whose set of critical values is C. [Write $C = C_\lambda$ as in XIII.18.2.9., and mimic the argument of XIII.23.9.2., using IV.2.16.2..]

XIII.23.12.3. [?] Give a constructive proof of the case $n = 2$ of XIII.23.10.1., as follows.

(a) Show that the diameter of a regular hexagon of side s is $2s$. [Write the hexagon as a union of six equilateral triangles.]

(b) If X is a compact subset of $\mathbb{R}^2$ and V is an open neighborhood of X, there is a bounded open neighborhood W of X contained in V. Let ϵ be the distance between X and ∂W. Show that $\epsilon > 0$.

(c) Cover the plane with a hexagonal honeycomb with sides of length $s < \frac{\epsilon}{4}$, and let A be the union of all the closed hexagons which are contained in W. Show that X is contained in the interior U of A.

(d) Show that $\partial A = \partial U$ consists of finitely many disjoint simple closed polygonal curves.

(e) If desired, the corners of these boundary curves can be rounded off to give smooth boundary curves.

(f) Try to do the same argument using squares (try staggering the squares so no four edges meet at a point), and try generalizing to $\mathbb{R}^n$.

XIII.23.12.4. [Edg98] Here is another example of how $\mathcal{C}^1$ differs from $\mathcal{C}^2$ and can be pathological. Let f be a strictly increasing singular function from $\mathbb{R}$ to $\mathbb{R}$, i.e. a continuous function with $f' = 0$ a.e. (XIX.2.3.5.(i)), and let g be an antiderivative for f. Then g is $\mathcal{C}^1$. Let γ be the graph of g, a parametrized curve in $\mathbb{R}^2$.

(a) Show that g is a strictly convex function (), and hence γ is a strictly convex $\mathcal{C}^1$ curve.

(b) Show that the curvature of γ () is 0 a.e.

(c) If Pompeiu's example (XIX.2.3.5.(iii)) is used for f, then γ has everywhere defined curvature, which is 0 on a dense set. (But note that γ is not $\mathcal{C}^2$ since γ'' is not continuous.)

XIII.24. Miscellaneous Aspects of Topology

XIII.24.1. The Countable Chain Condition

Various forms of the AC are needed at points of this discussion, so for simplicity we will assume the AC.

XIII.24.1.1. Definition. Let X be a topological space. X has the *Countable Chain Condition (CCC)* if every collection of pairwise disjoint nonempty open sets in X is countable (finite or countably infinite).

XIII.24.1.2. The CCC is a nice condition for a space to have; but the Countable Chain Condition turns out to be logically subtle, and it has been studied by set theorists. It is related to Martin's Axiom (), a weakening of the Continuum Hypothesis. There are spaces, even compact Hausdorff spaces, which do not have the CCC: the simplest example is the one-point compactification of an uncountable discrete space.

XIII.24.1.3. As an example of the logical subtlety, it cannot be proved or disproved in ZFC that a product of two spaces with the CCC has the CCC. This is connected with the question of the existence of a Suslin line ().

There are some things which can be said, such as:

XIII.24.1.4. Proposition. A separable topological space has the CCC.

This is obvious, since every nonempty open set contains points of a dense subset.

XIII.24.1.5. Proposition. Let X and Y be topological spaces. If X has the CCC and there is a surjective map from X to Y, then Y also has the CCC.

Proof: Let $f : X \to Y$ be a surjective map. If $\{V_i : i \in I\}$ is a collection of pairwise disjoint nonempty open sets in Y, then $\{f^{-1}(V_i) : i \in I\}$ is a collection of pairwise disjoint nonempty open sets in X, so I is countable. 👍

XIII.24.1.6. Proposition. Let X be a space with the CCC, and U an open subset. Then U has the CCC in the relative topology.

Proof: Any relatively open set in U is open in X. 👍

What about products of separable spaces? "Small" products are separable, hence have the CCC, but large products are not separable in general. However, an arbitrary product of separable spaces turns out to have the CCC (XIII.24.1.13.). This is rather tricky to prove; we give a proof using an intermediate property from measure theory.

Measurable Separability

XIII.24.1.7. DEFINITION. Let X be a topological space. X is *measurably separable (MS)* if there is a probability measure μ defined on a σ-algebra $\mathcal{A}$ of subsets of X, such that every nonempty open set in X contains a set in $\mathcal{A}$ of strictly positive measure. Such a measure is called a *separating measure* for X.

Note that the open sets in X are not assumed be μ-measurable (i.e. in $\mathcal{A}$).

XIII.24.1.8. PROPOSITION. Every separable topological space is MS.

PROOF: Let X be a separable topological space and (x_n) a dense sequence. Then the purely atomic measure μ supported on the x_n with $\mu(\{x_n\}) = 2^{-n}$ is a separating measure. 👍

XIII.24.1.9. PROPOSITION. Every MS space has the CCC.

PROOF: Let X be an MS space, μ a separating measure on $(X, \mathcal{A})$, and $\{U_i : i \in I\}$ a collection of pairwise disjoint nonempty open sets in X. For each i there is an $A_i \in \mathcal{A}$ with $A_i \subseteq U_i$ and $\mu(A_i) > 0$. A finite measure space cannot have an uncountable family of pairwise disjoint measurable sets of strictly positive measure, so I is countable. 👍

XIII.24.1.10. PROPOSITION. Let X and Y be topological spaces. If X is MS and there is a surjective map from X to Y, then Y is also MS.

PROOF: Let $f : X \to Y$ be a surjective map. If μ is a separating measure on A, defined on $(X, \mathcal{A})$, let $\mathcal{B} = f^{\to}(\mathcal{A})$ (XVI.1.6.6.), and $f_*(\mu)$ the push-forward (XVII.1.6.14.) of μ to $(Y, \mathcal{B})$. Then $f_*(\mu)$ is a separating measure for Y. 👍

XIII.24.1.11. PROPOSITION. Let X be an MS space, and U an open subset. Then U is MS in the relative topology.

PROOF: Let $(X, \mathcal{A}, \mu)$ be a separating measure. Form the restriction $\mu|_U$ of μ to U. Since U might not be μ-measurable, the restriction must be defined as in XVII.1.6.7.. Then $\mu|_U$ is a nonzero finite measure on $(U, \mathcal{A}_U)$. The renormalization to a probability measure is a separating measure for U. 👍

The concept of measurable separability was designed to prove the following theorem:

XIII.24.1.12. THEOREM. An arbitrary product of MS spaces is MS (in the product topology).

PROOF: Let $\{X_i : i \in I\}$ be a set of MS spaces, and for each i let μ_i be a separating measure for X_i, defined on a σ-algebra $\mathcal{A}_i$. Let $X = \prod_i X_i$ and $\mu = \times_i \mu_i$ on the σ-algebra $\mathcal{A} = \otimes_i \mathcal{A}_i$ (). We claim that μ is a separating measure for X.

Let U be a nonempty open set in X. Then there is a finite set $F \subseteq I$ and nonempty open sets V_i in X_i $(i \in F)$ such that

$$\left[\prod_{i\in F} V_i\right] \times \left[\prod_{i\in I\setminus F} X_i\right] \subseteq U \ .$$

For each $i \in F$ there is an $A_i \in \mathcal{A}_i$ with $A_i \subseteq V_i$ and $\mu_i(A_i) > 0$. Set

$$A = \left[\prod_{i\in F} A_i\right] \times \left[\prod_{i\in I\setminus F} X_i\right] \in \mathcal{A} \ .$$

Then $A \subseteq U$ and $\mu(A) = \prod_{i\in F} \mu_i(A_i) > 0$. 👍

Note that if I is large, open sets in X are not in $\mathcal{A}$ in general.

Putting together XIII.24.1.8., XIII.24.1.12., and XIII.24.1.9., we obtain:

XIII.24.1.13. COROLLARY. An arbitrary product of separable topological spaces has the CCC.

XIII.25. Piecewise-Linear Topology

The idea behind piecewise-linear (PL) topology is to reduce the study of the topology of "reasonable" subsets of Euclidean space, and eventually all "reasonable" (e.g. compact metrizable) topological spaces, to the affine structure of $\mathbb{R}^n$. This is clearly possible in principle since the affine structure on $\mathbb{R}^n$ determines its topological structure, and it turns out in practice to be a slick and clever way to express many topological notions in essentially combinatorial language.

PL topology has somewhat passed out of fashion. However, the basic setup (which is all we will do here, what topologists would consider to be "preliminaries") consisting of polyhedra and simplicial complexes and their maps, is material every mathematician should be familiar with.

The standard reference for PL topology is [RS72], on which much of our exposition is based.

XIII.25.1. Polyhedra, Cells, and Simplexes

The term "polyhedron" traditionally refers to a three-dimensional figure made up of a finite number of vertices, edges, and faces; it is the three-dimensional analog of a polygon. We will use the term in a somewhat different sense, applying to objects of arbitrary dimension; thus (most) polyhedra in the traditional sense will be polyhedra in our sense, as will be polygons in the plane, closed intervals, points, and analogous higher-dimensional figures.

There is an ambiguity in the usual use of terms like "polyhedron," "polygon," "triangle," "square," etc.: do we include the "interior" or just the "surface"? Our definition of polyhedron will include both cases, although when a specific polyhedron is considered we must carefully specify which we mean. For example, a solid triangle (homeomorphic to a disk) and a triangle not including the interior (homeomorphic to a circle) will both be polyhedra; the first is a 2-dimensional polyhedron and the second a 1-dimensional polyhedron.

Cells

XIII.25.1.1. Definition. A *cell* in $\mathbb{R}^n$ is a compact convex set with only finitely many extreme points. An extreme point of a cell is called a *vertex* of the cell. (The plural of *vertex* is *vertices*.) The *dimension* of a cell is the dimension of the affine subspace it generates.

XIII.25.1.2. Since a compact convex subset of $\mathbb{R}^n$ is the convex hull of its extreme points (), a cell is precisely the convex hull of a finite set S of points in $\mathbb{R}^n$. (Note, however, that not all the points of S are necessarily vertices of the cell defined by S, although each vertex of the cell is in S.)

XIII.25.1.3. Example. A rectangle (product of intervals) is a cell. A rectangle whose sides all have the same length is called a *cube*.

It is convenient in PL-topology to use the ρ_∞ metric on $\mathbb{R}^n$. The closed balls in this metric are cubes, hence cells. A closed ball in the usual ρ_2 metric, or the ρ_p metric for $1 < p < \infty$, is not a cell except in $\mathbb{R}^1$, since it has infinitely many extreme points.

XIII.25.1.4. If a cell C in $\mathbb{R}^m$ has $n+1$ vertices $\boldsymbol{v}_0, \boldsymbol{v}_1, \ldots, \boldsymbol{v}_n$, then the affine subspace it generates is parallel to the subspace spanned by $\{\boldsymbol{v}_1 - \boldsymbol{v}_0, \ldots, \boldsymbol{v}_n - \boldsymbol{v}_0\}$, hence the dimension of C is the dimension of this subspace, which is $\leq n$. It can be strictly less than n (e.g. for a convex polygon in $\mathbb{R}^2$).

XIII.25.1.5. Recall () that a *face* of a convex set C is a subset F such that, whenever an interior point of a line segment in C is in F, the endpoints of the segment are in F. We have easily from () (or with an elementary proof):

XIII.25.1.6. PROPOSITION. Let C be a cell in $\mathbb{R}^n$, and F a face of C. Then F is also a cell, and the vertices of F are a subset of the vertices of C. The dimension of F is strictly smaller than the dimension of C if F is a proper face of C.

XIII.25.1.7. Not every set of vertices of a cell C determines a face: for example, if C is a (solid) square in $\mathbb{R}^2$, the faces are just the vertices, the edges, and the whole square. Two opposite vertices do not determine a face.

XIII.25.1.8. PROPOSITION. Let C be a cell in $\mathbb{R}^n$ and $\boldsymbol{y} \in C$. Let F_y be the smallest face of C containing $\boldsymbol{y}$. Then F_y is either $\{\boldsymbol{y}\}$ or the union F of all line segments in C containing $\boldsymbol{y}$ in the interior.

PROOF: If F is empty, then $\boldsymbol{y}$ is an extreme point of C and $F_y = \{\boldsymbol{y}\}$. Suppose $F \neq \emptyset$. By definition, any face containing y contains F, so we need only show that F is a face of C. To show F is convex, suppose $\boldsymbol{a}$ and $\boldsymbol{b}$ are in F, and that $\boldsymbol{c}$ is a convex combination of $\boldsymbol{a}$ and $\boldsymbol{b}$. There are line segments $\boldsymbol{ad}$ and $\boldsymbol{be}$ in C containing $\boldsymbol{y}$ in their interior. Let Q be the quadrilateral in the plane generated by $\boldsymbol{bd}$ and $\boldsymbol{be}$ with vertices $\boldsymbol{a}$, $\boldsymbol{b}$, $\boldsymbol{d}$, and $\boldsymbol{e}$; then $Q \subseteq C$ by convexity. Let L be the line through $\boldsymbol{c}$ and $\boldsymbol{y}$. Then $L \cap C$ contains $L \cap Q$, which is a line segment with $\boldsymbol{y}$ in its interior. Thus $\boldsymbol{c} \in F$ and F is convex.

Now suppose $\boldsymbol{a}, \boldsymbol{b} \in C$, and $\boldsymbol{c}$ is a (nontrivial) linear combination of $\boldsymbol{a}$ and $\boldsymbol{b}$ which is in F. Then there is a line segment $\boldsymbol{cd}$ in C containing $\boldsymbol{y}$ in its interior. Let T be the triangle (in the plane generated by $\boldsymbol{ab}$ and $\boldsymbol{cd}$) with vertices $\boldsymbol{a}$, $\boldsymbol{b}$, and $\boldsymbol{d}$; then $T \subseteq C$ by convexity. If L is the line through $\boldsymbol{a}$ and $\boldsymbol{y}$, then $L \cap C$ contains $L \cap T$, which is a line segment containing $\boldsymbol{y}$ in its interior. Thus $\boldsymbol{a} \in F$. Similarly $\boldsymbol{b} \in F$. So F is a face of C. 👍

XIII.25.1.9. If C is a cell in $\mathbb{R}^n$, let $\mathring{C}$ be the set of all points of C not contained in any proper face of C, and $\dot{C}$ the union of the proper faces of C. Then $\mathring{C}$ and $\dot{C}$ are called the *interior* and *boundary* of C respectively (they are the topological interior and topological boundary of C in the affine subspace it generates with the relative topology). The interior $\mathring{C}$ is nonempty: if $\boldsymbol{v}_1, \ldots, \boldsymbol{v}_m$ are the vertices of C, then $\mathring{C}$ contains all points of the form $\sum_{k=1}^m \lambda_k \boldsymbol{v}_k$ where all $\lambda_k > 0$ (and $\sum_{k=1}^m \lambda_k = 1$). In fact, $\mathring{C}$ is precisely this set. $\mathring{C}$ is a relatively open subset of C, and $\dot{C} = C \setminus \mathring{C}$ is compact.

XIII.25.1.10. PROPOSITION. Let C be a cell in $\mathbb{R}^n$, and $f : \mathbb{R}^n \to \mathbb{R}^m$ an affine function. Then $f(C)$ is a cell in $\mathbb{R}^m$.

PROOF: If $\boldsymbol{v}_1, \ldots, \boldsymbol{v}_m$ are the vertices of C, then $f(C)$ is exactly the convex hull of $\{f(\boldsymbol{v}_1), \ldots, f(\boldsymbol{v}_m)\}$, hence a cell. (But $f(\boldsymbol{v}_k)$ is not necessarily a vertex of $f(C)$ for every k.) 👍

XIII.25.1.11. PROPOSITION. Let C be a convex subset of $\mathbb{R}^n$. Then C is a cell if and only if C is a finite intersection of (closed) half-spaces.

One direction of this is proved in XIII.25.1.31., and the converse in Exercise XIII.25.5.1..

Simplexes

XIII.25.1.12. DEFINITION. An *n-simplex* is an n-dimensional cell with exactly $n+1$ extreme points. A *simplex* is an n-simplex for some n.

The plural of *simplex* should properly be *simplices*, but (unlike with *vertex*) the anglicized plural *simplexes* has come into general use.

XIII.25.1.13. PROPOSITION. Let C be a cell in $\mathbb{R}^m$ with vertices $\boldsymbol{v}_0, \dots, v_n$. Then the following are equivalent:

(i) C is an n-simplex.

(ii) The set $\{\boldsymbol{v}_1 - \boldsymbol{v}_0, \dots, \boldsymbol{v}_n - \boldsymbol{v}_0\}$ is linearly independent in $\mathbb{R}^m$.

(iii) Every $\boldsymbol{a} \in C$ can be uniquely written as a convex combination

$$\boldsymbol{a} = \sum_{k=0}^{n} \lambda_k \boldsymbol{v}_k$$

with all $\lambda_k \geq 0$ and $\sum_{k=0}^{n} \lambda_k = 1$.

PROOF: (i) $\iff$ (ii): This follows immediately from XIII.25.1.4., since C is n-dimensional if and only if $\{\boldsymbol{v}_1 - \boldsymbol{v}_0, \dots, \boldsymbol{v}_n - \boldsymbol{v}_0\}$ spans an n-dimensional subset of $\mathbb{R}^m$.
(ii) $\Rightarrow$ (iii): Since C is a cell, every element of C can be written as a convex combination of the $\boldsymbol{v}_k$. So if (iii) is false, there are $(\lambda_0, \dots, \lambda_n) \neq (\mu_0, \dots, \mu_n)$ satisfying the conditions of (iii) with

$$\sum_{k=0}^{n} \lambda_k \boldsymbol{v}_k = \sum_{k=0}^{n} \mu_k \boldsymbol{v}_k$$

$$\boldsymbol{0} = \sum_{k=0}^{n} (\lambda_k - \mu_k)\boldsymbol{v}_k = \sum_{k=1}^{n} (\lambda_k - \mu_k)(\boldsymbol{v}_k - \boldsymbol{v}_0) + \sum_{k=0}^{n} (\lambda_k - \mu_k)\boldsymbol{v}_0 = \sum_{k=1}^{n} (\lambda_k - \mu_k)(\boldsymbol{v}_k - \boldsymbol{v}_0)$$

since $\sum_{k=0}^{n} (\lambda_k - \mu_k) = 0$ because $\sum_{k=0}^{n} \lambda_k = \sum_{k=0}^{n} \mu_k = 1$. So $\{\boldsymbol{v}_1 - \boldsymbol{v}_0, \dots, \boldsymbol{v}_n - \boldsymbol{v}_0\}$ is not linearly independent.
(iii) $\Rightarrow$ (ii): 👍

XIII.25.1.14. If C is a simplex, the numbers λ_k for which $\boldsymbol{a} = \sum_{k=0}^{n} \lambda_k \boldsymbol{v}_k$ are called the *barycentric coordinates* of $\boldsymbol{a}$ in C. These are indexed by the vertices of C, i.e. λ_k is the barycentric coordinate of $\boldsymbol{a}$ with respect to $\boldsymbol{v}_k$ (in C). If C is not a simplex, then barycentric coordinates are not well defined since some points can be written in more than one way as convex combinations of the vertices.

XIII.25.1.15. In $\mathbb{R}^{n+1}$, let Σ_n be the convex hull of the set of standard basis vectors $\{\mathbf{e}_0, \ldots, \mathbf{e}_n\}$ (it is convenient here to index the coordinates from 0 to n rather than from 1 to $n+1$). Then

$$\Sigma_n = \left\{ (\lambda_0, \ldots, \lambda_n) \in \mathbb{R}^{n+1} : \lambda_k \geq 0, \sum_{k=0}^{n} \lambda_k = 1 \right\}$$

is called the *standard n-simplex*. If S is any n-simplex in $\mathbb{R}^m$ with vertices $\boldsymbol{v}_0, \ldots, \boldsymbol{v}_n$, then there is a unique affine map $\phi : \mathbb{R}^{n+1} \to \mathbb{R}^m$ with $\phi(\mathbf{e}_k) = \boldsymbol{v}_k$ for each k, which maps Σ_n homeomorphically onto S. Thus every n-simplex "looks the same" and is affinely homeomorphic to the standard n-simplex.

We sometimes regard the simplex in $\mathbb{R}^n$ with vertices $0, \mathbf{e}_1, \ldots, \mathbf{e}_n$, i.e.

$$\left\{ (\lambda_1, \ldots, \lambda_n) : \lambda_k \geq 0, \sum_{k=1}^{n} \lambda_k \leq 1 \right\}$$

as the standard n-simplex. There is an obvious affine homeomorphism between this simplex and Σ_n.

A 0-simplex is a single point. A 1-simplex is a (closed) line segment. A 2-simplex is a (solid) triangle. A 3-simplex is a (solid) tetrahedron.

XIII.25.1.16. If S is an n-simplex with vertices $\boldsymbol{v}_0, \ldots, \boldsymbol{v}_n$, and $\boldsymbol{w}_0, \ldots, \boldsymbol{w}_n$ are any $n+1$ points in $\mathbb{R}^m$, then there is a unique affine function f from S onto the convex hull of $\{\boldsymbol{w}_0, \ldots, \boldsymbol{w}_n\}$ with $f(\boldsymbol{v}_k) = \boldsymbol{w}_k$ for all k. The obvious formula is

$$f\left(\sum_{k=0}^{n} \lambda_k \boldsymbol{v}_k \right) = \sum_{k=0}^{n} \lambda_k \boldsymbol{w}_k$$

for $\lambda_k \geq 0$, $\sum_{k=0}^{n} \lambda_k = 1$.

XIII.25.1.17. Proposition. Every simplex is a finite intersection of (closed) half-spaces.

Polyhedra

XIII.25.1.18. Definition. A *polyhedron* is a subset of some $\mathbb{R}^n$ which is a finite union of cells.

This is not the way the definition of a polyhedron is usually expressed in PL topology, but is equivalent (in the compact case). The PL definition (XIII.25.1.34.) is hard to motivate geometrically, so we have chosen this alternative definition.

XIII.25.1.19. Definition. Let B be a (usually compact) subset of $\mathbb{R}^n$, and $\boldsymbol{a}$ a point of $\mathbb{R}^n$ not in B. The *join* $\boldsymbol{a}B$ of $\boldsymbol{a}$ and B is the union of all line segments in $\mathbb{R}^n$ between $\boldsymbol{a}$ and a point of B. The join is a *cone* with vertex $\boldsymbol{a}$ and base B if every $\boldsymbol{x} \in \boldsymbol{a}B \setminus \{\boldsymbol{a}\}$ can be uniquely written as $\lambda\boldsymbol{a}(1-\lambda)\boldsymbol{b}$ for some $\boldsymbol{b} \in B$ and $0 \leq \lambda < 1$.

XIII.25.1.20. It is easily seen that $\boldsymbol{a}B$ is a cone if and only if every ray beginning at $\boldsymbol{a}$ intersects B in at most one point. A cone $\boldsymbol{a}B$ is compact if B is compact.

XIII.25.1.21. DEFINITION. Let X be a subset of $\mathbb{R}^n$, $\boldsymbol{a} \in X$, and $\epsilon > 0$. Set

$$N_\epsilon(\boldsymbol{a}, X) = \{\boldsymbol{x} \in X : \rho_\infty(\boldsymbol{a}, \boldsymbol{x}) \leq \epsilon\}$$

$$\dot{N}_\epsilon(\boldsymbol{a}, X) = \{\boldsymbol{x} \in X : \rho_\infty(\boldsymbol{a}, \boldsymbol{x}) = \epsilon\}$$

$$\mathring{N}_\epsilon(\boldsymbol{a}, X) = \{\boldsymbol{x} \in X : \rho_\infty(\boldsymbol{a}, \boldsymbol{x}) < \epsilon\} \ .$$

Then $\mathring{N}_\epsilon(\boldsymbol{a}, X)$ is an open neighborhood of $\boldsymbol{a}$ in X, and $N_\epsilon(\boldsymbol{a}, X)$ is a closed neighborhood of $\boldsymbol{a}$ in X. If $N_\epsilon(\boldsymbol{a}, X)$ is a cone with vertex $\boldsymbol{a}$ and base $\dot{N}_\epsilon(\boldsymbol{a}, X)$, $N_\epsilon(\boldsymbol{a}, X)$ is called the *ϵ-star* of $\boldsymbol{a}$ in X; if not, the ϵ-star of $\boldsymbol{a}$ in X is not defined. X is *locally conical* if for every $\boldsymbol{a} \in X$ there is an ϵ-star of $\boldsymbol{a}$ in X for some $\epsilon > 0$.

The set $N_\epsilon(\boldsymbol{a}, X)$ is the intersection of X with a cube of side 2ϵ centered at $\boldsymbol{a}$, and $\dot{N}_\epsilon(\boldsymbol{a}, X)$ is the intersection of X with the boundary of this cube.

If $\boldsymbol{a}$ has an ϵ-star in X, it also has an ϵ'-star for any $\epsilon' < \epsilon$.

Roughly speaking, a set X in $\mathbb{R}^n$ is locally conical if every point $\boldsymbol{a}$ of X has a neighborhood U in $\mathbb{R}^n$ such that $X \cap U$ is a union of ray segments with endpoint $\boldsymbol{a}$ with lengths bounded away from zero.

XIII.25.1.22. EXAMPLES. (i) Any open set in $\mathbb{R}^n$ is locally conical: if U is open and $\boldsymbol{a} \in U$, then for sufficiently small $\epsilon > 0$ $N_\epsilon(\boldsymbol{a}, U)$ is an entire closed cube centered at $\boldsymbol{a}$.

(ii) Any affine subspace or half-space in $\mathbb{R}^n$ is locally conical: in fact, any point in such a subset has an ϵ-star for every $\epsilon > 0$.

(iii) A polygon in $\mathbb{R}^2$, with or without interior, is locally conical.

(iv) A circle is not locally conical: in fact, no point has an ϵ-star for any $\epsilon > 0$. Similarly, a closed disk is not locally conical.

The important fact justifying our nonstandard definition of polyhedron is:

XIII.25.1.23. THEOREM. Let X be a compact subset of $\mathbb{R}^m$. The following are equivalent:

(i) X is a polyhedron.

(ii) X is a finite union of simplexes.

(iii) X is locally conical.

The theorem will be proved using some lemmas.

XIII.25.1.24. LEMMA. Let $X_1, \ldots, X_n$ be subsets of $\mathbb{R}^m$, $X = \cap_{k=1}^n X_k$, and $\boldsymbol{a} \in X$. If $N_{\epsilon_k}(\boldsymbol{a}, X_k)$ is an ϵ_k-star of $\boldsymbol{a}$ in X_k for each k, and $\epsilon = \min(\epsilon_1, \ldots, \epsilon_n)$, then $N_\epsilon(\boldsymbol{a}, X) = \cap_{k=1}^n N_\epsilon(\boldsymbol{a}, X_k)$ is an ϵ-star of $\boldsymbol{a}$ in X.

PROOF: Obvious from the fact that $N_\epsilon(\boldsymbol{a}, X_k)$ is an ϵ-star of $\boldsymbol{a}$ in X_k for all k. 👍

XIII.25.1.25. COROLLARY. A finite intersection of locally conical subsets of $\mathbb{R}^n$ is locally conical.

XIII.25.1.26. LEMMA. Let $X_1, \ldots, X_n$ be compact locally conical subsets of $\mathbb{R}^m$. Then $X = \cup_{k=1}^n X_k$ is locally conical.

PROOF: Let $\boldsymbol{a} \in X$. By renumbering, suppose $\boldsymbol{a} \in \cap_{k=1}^r X_k$ and $x \notin \cup_{k=r+1}^n X_k$. Let $N_{\epsilon_k}(\boldsymbol{a}, X_k)$ be an ϵ_k-star of $\boldsymbol{a}$ in X_k for $1 \leq k \leq r$. Choose $\epsilon > 0$ so that $\epsilon \leq \epsilon_k$ for $1 \leq k \leq r$ and $\epsilon < \rho_\infty\left(\boldsymbol{a}, \cup_{k=r+1}^n X_k\right)$. Then it is easily checked that $N_\epsilon(\boldsymbol{a}, X)$ is an ϵ-star of $\boldsymbol{a}$ in X. 👍

XIII.25.1.27. LEMMA. Every simplex is locally conical.

PROOF: A half-space is locally conical (XIII.25.1.22.(ii)); thus any simplex is locally conical by XIII.25.1.17. and XIII.25.1.25.. 👍

XIII.25.1.28. LEMMA. Let C be a cell in $\mathbb{R}^n$, and $\boldsymbol{a} \in C$. Then C is the union of cones of the form $\boldsymbol{a}F$, where F is a face of C not containing $\boldsymbol{a}$.

PROOF: Let $\boldsymbol{x} \in C$, $\boldsymbol{x} \neq \boldsymbol{a}$. If R is the ray starting at $\boldsymbol{a}$ through $\boldsymbol{x}$, then $R \cap C$ is a segment from $\boldsymbol{a}$ to a point $\boldsymbol{y}$. The face F_y (XIII.25.1.8.) cannot contain $\boldsymbol{a}$ since there is no line segment in C through $\boldsymbol{a}$ and $\boldsymbol{y}$ containing $\boldsymbol{y}$ in its interior (and $\boldsymbol{y} \neq \boldsymbol{a}$). Thus $\boldsymbol{x}$ is in the union of the sets $\boldsymbol{a}F$. Such a set is a cone, since if a ray from $\boldsymbol{a}$ intersects a face F in points $\boldsymbol{z}$ and $\boldsymbol{z}'$ with $\boldsymbol{z}$ between $\boldsymbol{a}$ and $\boldsymbol{z}'$, by definition of a face F must contain $\boldsymbol{a}$. 👍

PROOF OF XIII.25.1.23.: We have (ii) ⇒ (iii) by XIII.25.1.27. and XIII.25.1.26., and (ii) ⇒ (i) is trivial.

(i) ⇒ (ii): By XIII.25.1.26., it suffices to show that every cell is a finite union of simplexes. We prove this by induction on the dimension of the cell. If C is a cell of dimension ≤ 1, then C is a point or line segment, hence a simplex. Now suppose all cells of dimension $< n$ are unions of simplexes, and let C be a cell of dimension n. If $\boldsymbol{a} \in C$, then by XIII.25.1.28. C is a (finite) union of cones of the form $\boldsymbol{a}F$, where F is a face of C not containing $\boldsymbol{a}$. Each such F is a cell of dimension $< n$, hence a finite union of simplexes $S_1, \ldots, S_r$. Then $\boldsymbol{a}F$ is the union of $\boldsymbol{a}S_1, \ldots, \boldsymbol{a}S_r$, each of which is a simplex by ().

It remains to show (iii) ⇒ (ii). This will be shown by induction on the dimension of the Euclidean space containing the set. A compact locally conical subset of $\mathbb{R}^1$ is a finite union of points and closed line segments, each of which is a simplex. Now suppose all compact locally conical subsets of Euclidean spaces of dimension less than n are finite unions of simplexes. Let X be a compact locally conical subset of $\mathbb{R}^n$. To show that X is a finite union of simplexes, it suffices to show that for every $\boldsymbol{a} \in X$, an ϵ-star of $\boldsymbol{a}$ in X is a finite union of simplexes for some $\epsilon = \epsilon_a$. For then the sets $\mathring{N}_{\epsilon_a}(\boldsymbol{a}, X)$ form an open cover of X which has a finite subcover. So suppose $N_\epsilon(\boldsymbol{a}, X)$ is an ϵ-star. Let F be a proper face of the closed cube $\{\boldsymbol{x} \in \mathbb{R}^n : \rho(\boldsymbol{a}, \boldsymbol{x}) \leq \epsilon\}$. Then F is compact and locally conical, and thus $X \cap F$ is compact and locally conical by XIII.25.1.25.. Since $X \cap F$ is contained in a Euclidean space of dimension less than n, it is a finite union of simplexes. Then $\dot{N}_\epsilon(\boldsymbol{a}, X)$,

which is a finite union of the $X \cap F$, is a finite union of simplexes $S_1, \ldots, S_r$. But then $N_\epsilon(\boldsymbol{a}, X)$ is the union of $\boldsymbol{a}S_1, \ldots, \boldsymbol{a}S_r$, each of which is a simplex by ().

This completes the proof of XIII.25.1.23.. □

Here is a consequence which is not at all obvious directly from the definition:

XIII.25.1.29. COROLLARY. A finite intersection of polyhedra is a polyhedron.

PROOF: A finite intersection of polyhedra is compact, and locally conical by XIII.25.1.25.. 👍

XIII.25.1.30. PROPOSITION. Let X be a polyhedron in $\mathbb{R}^n$. Then the convex hull of X is a cell. In particular, a convex polyhedron is a cell.

PROOF: X is a finite union of cells $C_1, \ldots, C_r$. Let S be the set of all extreme points of $C_1, \ldots, C_r$. Then S is a finite set and the convex hull of S is the convex hull of X. 👍

We then obtain one direction of XIII.25.1.11.:

XIII.25.1.31. COROLLARY. Let X be a compact set in $\mathbb{R}^n$ which is a finite intersection of half-spaces. Then X is a cell.

PROOF: By XIII.25.1.25., X is locally conical, hence a polyhedron, and X is also convex. 👍

XIII.25.1.32. Let X be a subset of $\mathbb{R}^n$. If $\boldsymbol{a} \in X$, a *star* of $\boldsymbol{a}$ in X is a closed neighborhood of $\boldsymbol{a}$ in X which is a cone of the form $\boldsymbol{a}L$, where L is a compact subset of X not containing $\boldsymbol{a}$ ($L = \emptyset$ is allowed, in which case $\boldsymbol{a}L = \{\boldsymbol{a}\}$). An ϵ-star of $\boldsymbol{a}$ in X is a star with $L = \dot{N}_\epsilon(\boldsymbol{a}, X)$ provided this set is compact (e.g. if X is compact).

XIII.25.1.33. PROPOSITION. Let $X \subseteq \mathbb{R}^n$. Then every point of X has a star if and only if X is locally compact and locally conical.

PROOF: If X is locally compact and locally conical, and $\boldsymbol{a} \in X$, then $\dot{N}_\epsilon(\boldsymbol{a}, X)$ is compact for sufficiently small ϵ, so $\boldsymbol{a}$ has a star. Conversely, if $\boldsymbol{a}L$ is a star of $\boldsymbol{a}$, it is a compact neighborhood of $\boldsymbol{a}$, and $N_\epsilon(\boldsymbol{a}, X)$ is an ϵ-star for any $\epsilon < \rho_\infty(\boldsymbol{a}, L)$, so if every point of X has a star, then X is locally compact and locally conical. 👍

XIII.25.1.34. In PL topology, a polyhedron is defined to simply be a subset of $\mathbb{R}^n$ in which every point has a star, i.e. a locally compact locally conical subset. While it is useful in PL topology to consider locally conical sets (polyhedra) which are not compact, we will not need to do so, so to avoid having to constantly write "compact polyhedron" we will require polyhedra to be compact.

Enclosing Compact Sets in Polyhedra

XIII.25.1.35. THEOREM. Let X be a compact subset of $\mathbb{R}^n$, and U an open set in $\mathbb{R}^n$ containing X. Then there is a polyhedron $P \subseteq U$ with $X \subseteq P^\circ$.

PROOF: For each $x \in X$ there is a closed coordinate rectangle R_x centered at x contained in U. The interiors of the R_x cover X, so there is a finite subcover $\{R_{x_1}^\circ, \ldots, R_{x_m}^\circ\}$. Then $P = \cup_{k=1}^m R_{x_k}$ is the desired polyhedron. 👍

The picture for general n is complicated, but in the case $n = 2$ it is fairly simple, since the boundary of P is then a finite union of simple closed polygonal curves with edges parallel to the coordinate axes (which may intersect at finitely many vertices). Thus we have, using the Jordan Curve Theorem (XIII.19.1.20.):

XIII.25.1.36. COROLLARY. Let X be a compact subset of $\mathbb{R}^2$ and U an open set in $\mathbb{R}^2$ containing X. Then there are finitely many simple closed polygonal curves $\{\gamma_1, \ldots, \gamma_r\}$ such that each γ_k and its inside V_k is contained in U and $X \subseteq \cup_{k=1}^r V_k$.

XIII.25.1.37. With a little more work, it can be shown that under the hypotheses of XIII.25.1.35. there are finitely many disjoint smooth copies $\{\Sigma_1, \ldots, \Sigma_m\}$ of S^{n-1} whose insides (XIII.19.1.23.) V_k are disjoint, with all Σ_k and V_k contained in U, and with X contained in the union of the V_k. In the case of XIII.25.1.36. this amounts to replacing the γ_k by pairwise disjoint smooth curves (e.g. by "rounding off corners").

XIII.25.2. Complexes

XIII.25.2.1. DEFINITION. A *cell complex* in $\mathbb{R}^n$ is a finite collection $\mathcal{K}$ of cells in $\mathbb{R}^n$ with the following properties:

(i) If $C \in \mathcal{K}$ and F is a face in C, then $F \in \mathcal{K}$.

(ii) If $C_1, C_2 \in \mathcal{K}$ then $C_1 \cap C_2$ is a face of both C_1 and C_2 (we make the convention that $\emptyset$ is a face of every cell, so $C_1 \cap C_2 = \emptyset$ is allowed).

The *dimension* of $\mathcal{K}$ is maximum of the dimensions of the cells of $\mathcal{K}$.

The *vertices* of $\mathcal{K}$ are the 0-cells of $\mathcal{K}$ and the *edges* of $\mathcal{K}$ are the 1-cells.

If $\mathcal{K}$ is a cell complex in $\mathbb{R}^n$, the union of the cells in $\mathcal{K}$ is a polyhedron in $\mathbb{R}^n$ denoted $|\mathcal{K}|$.

A cell complex $\mathcal{K}$ is a collection of cells that fit together nicely. The cell complex $\mathcal{K}$ can be thought of as the polyhedron $|\mathcal{K}|$ with a specified nice subdivision of $|\mathcal{K}|$ into cells. The vertices of $\mathcal{K}$ are the extreme points of the cells in $\mathcal{K}$.

Infinite cell complexes are often used in topology, but for simplicity we will make the convention that cell complexes are finite.

XIII.25.2.2. DEFINITION. A *simplicial complex* in $\mathbb{R}^n$ is a cell complex in which every cell is a simplex. A *triangulation* of a polyhedron X is a simplicial complex $\mathcal{K}$ with $|\mathcal{K}| = X$.

A simplicial complex in $\mathbb{R}^n$ is often called a *geometric simplicial complex* to distinguish it from an abstract simplicial complex (XIII.25.2.12.), which is a combinatorial object.

We will work almost exclusively with simplicial complexes.

XIII.25.2.3. EXAMPLES. (i) Any cell C can be regarded as a cell complex $\mathcal{C}$ consisting of all faces of C. Then $C = |\mathcal{C}|$. In particular, any simplex S can be regarded as a simplicial complex $\mathcal{S}$ consisting of the faces of S. $\mathcal{S}$ is a triangulation of S.

(ii) Let X be a finite union of line segments in $\mathbb{R}^n$, such that any two of the line segments are either disjoint or have only an endpoint in common. Then X is a polyhedron which is the underlying space of a simplicial complex $\mathcal{K}$ consisting of the line segments and their endpoints (plus $\emptyset$); $\mathcal{K}$ is a triangulation of X. In particular, any (simple) polygon in $\mathbb{R}^2$, not including interior, is the underlying space of a simplicial complex. (A simple closed polygon including interior is also the underlying space of a simplicial complex, although this is somewhat harder to show ().)

Subcomplexes

XIII.25.2.4. DEFINITION. Let $\mathcal{K}$ be a cell complex. A *subcomplex* of $\mathcal{K}$ is a subset of $\mathcal{K}$ which is itself a cell complex.

A subset $\mathcal{K}'$ of a complex $\mathcal{K}$ is a subcomplex if and only if, whenever $C \in \mathcal{K}'$, then all faces of C are also in $\mathcal{K}'$. A subcomplex of a simplicial complex is a simplicial complex.

There are important special subcomplexes of any complex:

XIII.25.2.5. DEFINITION. Let $\mathcal{K}$ be a cell complex, and $d \in \mathbb{N} \cup \{0\}$. The collection $\mathcal{K}_d$ of all cells in $\mathcal{K}$ of dimension $\leq d$ is a subcomplex of $\mathcal{K}$ called the *d-skeleton* of $\mathcal{K}$.

Thus the 0-skeleton consists of the vertices, the 1-skeleton the vertices and edges, etc.

Subdivisions

XIII.25.2.6. DEFINITION. Let $\mathcal{K}$ and $\mathcal{K}'$ be cell complexes. $\mathcal{K}'$ is a *subdivision* of $\mathcal{K}$ if $|\mathcal{K}'| = |\mathcal{K}|$ and every cell in $\mathcal{K}'$ is contained in a cell in $\mathcal{K}$.

It is easily seen that $\mathcal{K}'$ is a subdivision of $\mathcal{K}$ if and only if each cell in $\mathcal{K}$ is a union of cells in $\mathcal{K}'$.

Simplicial Maps

XIII.25.2.7. DEFINITION. (i) Let $\mathcal{K}$ be a cell complex in $\mathbb{R}^n$. A function $f : |\mathcal{K}| \to \mathbb{R}^m$ is *simplicial* (with respect to $\mathcal{K}$), or a *simplicial map*, if the restriction of f to each cell of $\mathcal{K}$ is affine.

(ii) Let $\mathcal{K}$ and $\mathcal{K}'$ be cell complexes. A function $f : |\mathcal{K}| \to |\mathcal{K}'|$ is *simplicial* (with respect to $\mathcal{K}$ and $\mathcal{K}'$) if the image of each cell in $\mathcal{K}$ is contained in a cell of $\mathcal{K}'$ and the restriction of f to each cell of $\mathcal{K}$ is affine.

A *simplicial isomorphism* between cell complexes $\mathcal{K}$ and $\mathcal{K}'$ is a bijection f between $|\mathcal{K}|$ and $|\mathcal{K}'|$ such that f and f^{-1} are simplicial.

XIII.25.2.8. A simplicial map is continuous by (), since each cell is closed in $|\mathcal{K}|$ and the restriction to each cell is continuous. A composition of simplicial maps is simplicial.

XIII.25.2.9. Examples. (i) If $\mathcal{K}'$ is a subcomplex of $\mathcal{K}$, the inclusion map from $|\mathcal{K}'|$ to $|\mathcal{K}|$ is simplicial for $\mathcal{K}'$ and $\mathcal{K}$.

(ii) If $\mathcal{K}'$ is a subdivision of $\mathcal{K}$, the identity map on $|\mathcal{K}'| = |\mathcal{K}|$ is simplicial for $\mathcal{K}'$ and $\mathcal{K}$. But it is not simplicial for $\mathcal{K}$ and $\mathcal{K}'$ unless $\mathcal{K}' = \mathcal{K}$.

(iii) Let P be a (simple closed) polygon in $\mathbb{R}^2$, not including interior, with n sides. Then P can be regarded as a simplicial complex $\mathcal{P}$ with n 0-simplexes (the vertices) and n 1-simplexes (the sides). If Q is another polygon with n sides, regarded as a simplicial complex $\mathcal{Q}$, then $\mathcal{P}$ and $\mathcal{Q}$ are simplicially isomorphic.

But if P and Q are convex polygons with n sides and the interiors are included, regarded as cell complexes $\mathcal{P}$, $\mathcal{Q}$ with one 2-cell and n 1-cells and 0-cells as above, then $\mathcal{P}$ and $\mathcal{Q}$ are not generally simplicially isomorphic, and the conditions for simplicial isomorphism are restrictive: for example, if P is a square, then $\mathcal{P}$ and $\mathcal{Q}$ are simplicially isomorphic if and only if the quadrilateral Q is a parallelogram.

For simplicial complexes, conditions for simplicial isomorphism are much less stringent (XIII.25.2.10.).

XIII.25.2.10. Proposition. Let $\mathcal{K}$ and $\mathcal{K}'$ be simplicial complexes, and let ϕ be a one-one correspondence between the simplexes in $\mathcal{K}$ and the simplexes in $\mathcal{K}'$ with the property that if $S \in \mathcal{K}$ and F is a face of S, then $\phi(F)$ is a face of $\phi(S)$. Then there is a unique simplicial isomorphism $f : |\mathcal{K}| \to |\mathcal{K}'|$ such that $f(S) = \phi(S)$ for every $S \in \mathcal{K}$.

Proof: By counting numbers of faces, it follows that ϕ must give a bijection between the d-simplexes in $\mathcal{K}$ and the d-simplexes of $\mathcal{K}'$ for each d. Since the 0-simplexes are just the vertices, ϕ gives a one-one correspondence between the vertices of $\mathcal{K}$ and the vertices of $\mathcal{K}'$. If $\boldsymbol{v}_0, \ldots, \boldsymbol{v}_n$ are the vertices of $\mathcal{K}$, set $\boldsymbol{w}_k = \phi(\boldsymbol{v}_k)$ for each k. Then if S is a simplex in $\mathcal{K}$ with vertices $\boldsymbol{v}_{i_1}, \ldots, \boldsymbol{v}_{i_r}$, then $\phi(S)$ must be a simplex in $\mathcal{K}'$ with vertices $\boldsymbol{w}_{i_i}, \ldots, \boldsymbol{w}_{i_r}$, and we may define $f : S \to \phi(S)$ by

$$f\left(\sum_{k=1}^{r} \lambda_k \boldsymbol{v}_{i_k}\right) = \sum_{k=1}^{r} \lambda_k \boldsymbol{w}_{i_k} \ .$$

It is easily checked that if $\boldsymbol{x} \in |\mathcal{K}|$, this definition of $f(\boldsymbol{x})$ is independent of which of the simplexes of $\mathcal{K}$ containing $\boldsymbol{x}$ is used, and thus we obtain a well-defined function $f : |\mathcal{K}| \to |\mathcal{K}'|$ which obviously has the right properties. 👍

Barycentric Coordinates

XIII.25.2.11. The construction in the proof of XIII.25.2.10. can be thought of in another way. If $\mathcal{K}$ is a simplicial complex and $\boldsymbol{v}_0, \ldots, \boldsymbol{v}_n$ are the vertices of $\mathcal{K}$, and $\boldsymbol{x} \in |\mathcal{K}|$, then for any simplex S of $\mathcal{K}$ containing $\boldsymbol{x}$ with vertices $\boldsymbol{v}_{i_1}, \ldots, \boldsymbol{v}_{i_r}$, $\boldsymbol{x}$ has barycentric coordinates () λ_{i_k} with respect to $\boldsymbol{v}_{i_k}$. These barycentric coordinates are defined for any vertex of any simplex of $\mathcal{K}$ containing $\boldsymbol{x}$, and do not depend on which simplex containing $\boldsymbol{x}$ and that vertex is used. If $\boldsymbol{v}_j$ is a vertex of $\mathcal{K}$ and $\boldsymbol{x}$ is not contained in any simplex of $\mathcal{K}$ with $\boldsymbol{v}_j$ a vertex, set the barycentric coordinate $\lambda_j(\boldsymbol{x})$ equal to 0. Thus the barycentric coordinates

$\lambda_0(\boldsymbol{x}), \ldots, \lambda_n(\boldsymbol{x})$ of $\boldsymbol{x}$ are well defined for every vertex, and satisfy $\lambda_k(\boldsymbol{x}) \geq 0$ for all k and $\sum_{k=0}^{n} \lambda_k(\boldsymbol{x}) = 1$. We may symbolically write

$$\boldsymbol{x} = \sum_{k=0}^{n} \lambda_k(\boldsymbol{x}) \boldsymbol{v}_k$$

interpreted as follows: if the set of vertices $\boldsymbol{v}_k$ for which $\lambda_k(\boldsymbol{x}) > 0$ is $\{\boldsymbol{v}_{i_1}, \ldots, \boldsymbol{v}_{i_r}\}$, then the simplex S with vertices $\boldsymbol{v}_{i_1}, \ldots, \boldsymbol{v}_{i_r}$ is in $\mathcal{K}$ and $\boldsymbol{x}$ is the point of S with barycentric coordinates $\lambda_{i_1}(\boldsymbol{x}), \ldots, \lambda_{i_r}(\boldsymbol{x})$ with respect to $\boldsymbol{v}_{i_1}, \ldots, \boldsymbol{v}_{i_r}$.

Abstract Simplicial Complexes

The existence of barycentric coordinates (XIII.25.2.11.) in any simplicial complex allows the definition of simplicial complexes as combinatorial objects:

XIII.25.2.12. DEFINITION. An *abstract simplicial complex* is a collection $\mathcal{K}$ of subsets of a finite set $\{v_0, \ldots, v_n\}$ such that $\{v_k\} \in \mathcal{K}$ for all k and if $S \in \mathcal{K}$, then all subsets of S are also in $\mathcal{K}$. The v_k are called the *vertices* of $\mathcal{K}$.

If $\mathcal{K}$ and $\mathcal{K}'$ are abstract simplicial complexes with sets of vertices V and V' respectively, a *simplicial isomorphism* between $\mathcal{K}$ and $\mathcal{K}'$ is a bijection ϕ from V to V' such that $F \subseteq V$ is in $\mathcal{K}$ if and only if $\phi(F) \in \mathcal{K}'$.

A *geometric realization* of an abstract simplicial complex $\mathcal{K}$ is a (geometric) simplicial complex $\mathcal{K}'$ and a bijection ϕ from the set $\{v_0, \ldots, v_n\}$ of vertices of $\mathcal{K}$ to the vertices of $\mathcal{K}'$, say $\boldsymbol{w}_k = \phi(v_k)$, such that the simplex with vertices $\{\boldsymbol{w}_{i_1}, \ldots, \boldsymbol{w}_{i_r}\}$ is in $\mathcal{K}'$ if and only if $\{v_{i_1}, \ldots, v_{i_r}\} \in \mathcal{K}$.

The next result is obvious from XIII.25.2.10.:

XIII.25.2.13. PROPOSITION. Let $\mathcal{K}$ be an abstract simplicial complex. Then there is a unique simplicial isomorphism between any two geometric realizations of $\mathcal{K}$ which extends the identification of the vertices by the realizations. More generally, if $\mathcal{K}$ and $\mathcal{K}'$ are abstract simplicial complexes and ϕ is a simplicial isomorphism from $\mathcal{K}$ to $\mathcal{K}'$, then there is a unique simplicial isomorphism from any geometric realization of $\mathcal{K}$ to any geometric realization of $\mathcal{K}'$ extending the identification of the vertices via ϕ.

XIII.25.2.14. Every abstract simplicial complex has a geometric realization. In fact, if an ordering $v_0, v_1, \ldots, v_n$ on the vertices of an abstract simplicial complex $\mathcal{K}$ is fixed, there is a corresponding *standard realization* of $\mathcal{K}$ as a subcomplex $\mathcal{K}'$ of the standard n-simplex Σ_n: just let $\mathcal{K}'$ be the collection of all faces of Σ_n with vertices $\{\mathbf{e}_{i_1}, \ldots, \mathbf{e}_{i_r}\}$ for sets $\{v_{i_1}, \ldots, v_{i_r}\}$ in $\mathcal{K}$.

Thus there is a natural one-one correspondence between simplicial isomorphism classes of abstract simplicial complexes and simplicial isomorphism classes of geometric simplicial complexes.

XIII.25.3. Triangulations

Recall (XIII.25.2.2.) that a *triangulation* of a polyhedron P is a simplicial complex $\mathcal{K}$ with $|\mathcal{K}| = P$.

XIII.25.3.1. THEOREM. Every polyhedron has a triangulation.

Triangulations of Topological Spaces

XIII.25.3.2. DEFINITION. Let X be a topological space (usually a compact Hausdorff space). A *weak triangulation* of X is a simplicial complex $\mathcal{K}$ and a continuous function $f : X \to |\mathcal{K}|$ such that every vertex of $\mathcal{K}$ is in the range of f. A weak triangulation f of X is a *triangulation* of X if f is a homeomorphism from X onto $|\mathcal{K}|$.

This terminology is consistent: if P is a polyhedron, then a triangulation of P in the simplicial sense (XIII.25.2.2.) is a triangulation in the topological sense (XIII.25.3.2.) when P is regarded as a topological space. The other direction is not well defined, since a polyhedron is more than a topological space: it also has a "local affine structure" (XIII.25.4.1.) which is not part of the topological structure. See () for further comments.

Note that a topological space with a triangulation must be homeomorphic to a polyhedron, hence a compact metrizable space. But spaces which are not compact and/or metrizable can have weak triangulations: for example, any constant function from a topological space X to $\mathbb{R}^n$ is a weak triangulation.

Triangulations and Partitions of Unity

Weak triangulations of a topological space X are effectively the same thing as finite partitions of unity on X.

XIII.25.3.3. Let X be a topological space and $\{f_0, \ldots, f_n\}$ a finite partition of unity on X. Define a continuous function f from X to the standard n-simplex Σ_n by

$$f(x) = \sum_{k=0}^{n} f_k(x)\mathbf{e}_k \ .$$

If Σ_n is regarded as a simplicial complex, then f is a weak triangulation of X. (The requirement that each f_k take the value 1 is precisely the same as the requirement that the range of f contain all vertices of Σ_n.) Note that the range of f may well be contained in a proper subcomplex of Σ_n containing all the vertices.

XIII.25.3.4. Conversely, let f be a weak triangulation from X to a simplicial complex $\mathcal{K}$, and let $\{\boldsymbol{v}_0, \ldots, \boldsymbol{v}_n\}$ be the vertices of $\mathcal{K}$. If $\boldsymbol{a} \in |\mathcal{K}|$, let $\lambda_k(\boldsymbol{a})$ be the barycentric coordinate of $\boldsymbol{a}$ with respect to $\boldsymbol{v}_k$ in $\mathcal{K}$ (). For each k set $f_k = \lambda_k \circ f$, i.e. for $x \in X$ set $f_k(x) = \lambda_k(f(x))$. Then the f_k give a finite partition of unity on X.

XIII.25.3.5. Suppose $f : X \to |\mathcal{K}|$ is a weak triangulation, and let $\boldsymbol{v}_0, \ldots, \boldsymbol{v}_n$ be the vertices of $\mathcal{K}$ and $f_0, \ldots, f_n$ the corresponding partition of unity. For each k let V_k be the set of $\boldsymbol{a} \in |\mathcal{K}|$ with $\lambda_k(\boldsymbol{a}) > 0$; V_k is the set of points $\boldsymbol{a}$ of $|\mathcal{K}|$ such that every simplex in $\mathcal{K}$ containing $\boldsymbol{a}$ has $\boldsymbol{v}_k$ as a vertex. Then V_k is open in $|\mathcal{K}|$, and if $U_k = f^{-1}(V_k) = \{x \in X : f_k(x) > 0\}$, then $\mathcal{U} = \{U_0, \ldots, U_n\}$ is an open cover of X, and $\{f_0, \ldots, f_n\}$ is a partition of unity subordinate to $\mathcal{U}$.

XIII.25.3.6. So if X is a compact Hausdorff space, the theory of partitions of unity assures the existence of "fine" weak triangulations. In fact, we have:

XIII.25.3.7. THEOREM. Let X be a compact Hausdorff space and $\mathcal{W}$ an open cover of X. Then there is a surjective weak triangulation $f : X \to |\mathcal{K}|$ such that the cover $\mathcal{U}$ of XIII.25.3.5. is a refinement of $\mathcal{W}$.

PROOF: By passing to a subcover, we may assume $\mathcal{W}$ is finite. Let $\mathcal{V}$ be an open star-refinement of $\mathcal{W}$, which we may also assume finite, and $\{f_0, \ldots, f_n\}$ a partition of unity subordinate to $\mathcal{V}$. The corresponding weak triangulation $f : X \to \mathcal{K}' = \Sigma_n$ works except that f may not be surjective.

We modify f in stages and reduce $\mathcal{K}'$ to a subcomplex, beginning with the largest simplex. To do the modification on a simplex S which is not a face of another simplex in $\mathcal{K}'$, suppose the interior of S is not entirely contained in the range of f (if it is, no modification for this S is necessary). If $\boldsymbol{a}$ is an interior point of S not contained in the range, there is a retraction r (e.g. radial projection from $\boldsymbol{a}$) from $S \setminus \{\boldsymbol{a}\}$ onto its boundary. Replace $\mathcal{K}'$ by $\mathcal{K}' \setminus \{S\}$ and f by $r \circ f$. Then the inverse image of the star of any vertex in the reduced complex under $r \circ f$ is contained in the inverse image of the star of that vertex in $\mathcal{K}'$ under f, so is contained in one of the sets of $\mathcal{W}$. The modified $r \circ f$ agrees with f on any $x \in X$ for which $f(x)$ is not in the interior of S. Repeat the reduction through all simplexes in $\mathcal{K}'$ which are not faces of remaining simplexes after the previous reduction. Since all vertices of $\mathcal{K}'$ are in the range of f at every stage, after a finite number of steps a subcomplex $\mathcal{K}$ and modified f will be surjective. 👍

XIII.25.3.8. COROLLARY. Let X be a compact metrizable space, ρ a fixed metric on X, and $\epsilon > 0$. Then there is a surjective weak triangulation $f : X \to |\mathcal{K}|$ of X, such that for every vertex $\boldsymbol{v}_k$ of $|\mathcal{K}|$, the ρ-diameter of $f^{-1}(V_k)$ is less than ϵ.

PROOF: Let $\mathcal{W}$ be the open cover of X by balls of ρ-diameter $< \epsilon$. 👍

The Nerve of an Open Cover

XIII.25.4. Piecewise-Linear Maps

XIII.25.4.1. If X is a polyhedron and $\boldsymbol{a} \in X$, then for any $\boldsymbol{b} \in X$ sufficiently close to $\boldsymbol{a}$ (within a star of $\boldsymbol{a}$ in X) there is an unambiguous notion of the line segment from $\boldsymbol{a}$ to $\boldsymbol{b}$ in X, and of $\lambda\boldsymbol{a} + (1-\lambda)\boldsymbol{b}$ for $0 \le \lambda \le 1$, i.e. X has a "local affine structure." (Existence of such a structure does not characterize polyhedra, however; for example, any convex set also has such a local affine structure.)

The local affine structure is "continuous":

XIII.25.4.2. PROPOSITION. Let X be a subset of $\mathbb{R}^n$, $\boldsymbol{a} \in X$, and $\boldsymbol{a}L$ a star of $\boldsymbol{a}$ in X (with L compact). If $(\lambda_n\boldsymbol{a} + (1-\lambda_n)\boldsymbol{b}_n)$ is a sequence in $\boldsymbol{a}L$ (with $0 \le \lambda_n \le 1$ and $\boldsymbol{b}_n \in L$ for all n), then $\lambda_n\boldsymbol{a} + (1-\lambda_n)\boldsymbol{b}_n \to \lambda\boldsymbol{a} + (1-\lambda)\boldsymbol{b} \in \mathbb{R}^n$ with $\boldsymbol{b} \in L$ if and only if $\lambda_n \to \lambda$ and, if $\lambda \ne 1$, $\boldsymbol{b}_n \to \boldsymbol{b}$.

PROOF: If $\lambda_n \to \lambda$ and $\boldsymbol{b}_n \to \boldsymbol{b}$, then $\lambda_n\boldsymbol{a} + (1-\lambda_n)\boldsymbol{b}_n \to \lambda\boldsymbol{a} + (1-\lambda)\boldsymbol{b}$, and $\boldsymbol{b} \in L$ since L is closed in $\mathbb{R}^n$. Conversely, suppose $\lambda_n\boldsymbol{a} + (1-\lambda_n)\boldsymbol{b}_n \to \lambda\boldsymbol{a} + (1-\lambda)\boldsymbol{b}$ with $\boldsymbol{b} \in L$. Since $[0,1]$ and L are compact, any subsequence of $(\lambda_n\boldsymbol{a}+(1-\lambda_n)\boldsymbol{b}_n)$ has a subsubsequence $(\lambda_{k_n}\boldsymbol{a}+(1-\lambda_{k_n})\boldsymbol{b}_{k_n})$ such that (λ_{k_n}) and $(\boldsymbol{b}_{k_n})$ both converge, say to μ and $\boldsymbol{c}$ respectively, with $0 \le \mu \le 1$ and $\boldsymbol{c} \in L$. Then $(\lambda_{k_n}\boldsymbol{a}+(1-\lambda_{k_n})\boldsymbol{b}_{k_n}) \to \mu\boldsymbol{a}+(1-\mu)\boldsymbol{c}$. By uniqueness of limits in $\mathbb{R}^n$, $\mu\boldsymbol{a} + (1-\mu)\boldsymbol{c} = \lambda\boldsymbol{a} + (1-\lambda)\boldsymbol{b}$, and by uniqueness of representation of points of $\boldsymbol{a}L$, we must have $\mu = \lambda$ and, if $\lambda \ne 1$, $\boldsymbol{c} = \boldsymbol{b}$. Thus every subsequence of (λ_n) has a subsubsequence

converging to λ, and if $\lambda \neq 1$ every subsequence of $(\boldsymbol{b}_n)$ has a subsubsequence converging to $\boldsymbol{b}$, so $\lambda_n \to \lambda$ and, if $\lambda \neq 1$, $\boldsymbol{b}_n \to \boldsymbol{b}$ by ().

We can use the local affine structure to define piecewise-linear maps between polyhedra:

XIII.25.4.3. DEFINITION. Let X and Y be polyhedra in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively. A function $f : X \to Y$ is *piecewise-linear (PL)* if for every $\boldsymbol{a} \in X$ there are $\delta > 0$, $\epsilon > 0$ such that

(i) $\boldsymbol{a}$ has a δ-star in X and $f(\boldsymbol{a})$ has an ϵ-star in Y

(ii) $f(N_\delta(\boldsymbol{a}, X)) \subseteq N_\epsilon(f(\boldsymbol{a}), Y)$

(iii) $f(\lambda\boldsymbol{a} + (1-\lambda)\boldsymbol{b}) = \lambda f(\boldsymbol{a}) + (1-\lambda)f(\boldsymbol{b})$ for all $\boldsymbol{b} \in N_\delta(\boldsymbol{a}, X)$, $0 \leq \lambda \leq 1$.

Such a function might be more properly called something like *locally affine*, but the name "piecewise-linear" is standard, and is appropriate since X can indeed be broken up into pieces on which f is linear (affine) (XIII.25.4.6.).

The next fact may seem obvious, but requires proof:

XIII.25.4.4. PROPOSITION. Let X and Y be polyhedra in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, and $f : X \to Y$ a PL function. Then f is continuous.

PROOF: Let $(\boldsymbol{c}_n)$ be a sequence in X with $\boldsymbol{c}_n \to \boldsymbol{a}$. Let $\delta > 0$ and $\epsilon > 0$ be as in XIII.25.4.3. for $\boldsymbol{a}$. Passing to a tail, we may assume $\boldsymbol{c}_n \in N_\delta(\boldsymbol{a}, X)$ for all n. Write $\boldsymbol{c}_n = \lambda_n\boldsymbol{a} + (1-\lambda_n)\boldsymbol{b}_n$ for $0 \leq \lambda_n \leq 1$ and $\boldsymbol{b}_n \in N_\delta(\boldsymbol{a}, X)$. Since $\boldsymbol{c}_n \to \boldsymbol{a}$, we have $\lambda_n \to 1$ by XIII.25.4.2.. We have

$$f(\boldsymbol{c}_n) = \lambda_n f(\boldsymbol{a}) + (1-\lambda_n)f(\boldsymbol{b}_n) \to f(\boldsymbol{a}) + \boldsymbol{0} = f(\boldsymbol{a})$$

since $\lambda_n \to 1$ and $(f(\boldsymbol{b}_n))$ is a bounded sequence.

XIII.25.4.5. PROPOSITION. Let X and Y be polyhedra in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, and $f : X \to Y$ a function. Then f is PL if and only if the graph $\Gamma(f)$ is a polyhedron in $\mathbb{R}^{n+m}$.

PROOF: It is easy to verify that $\Gamma(f)$ is compact and locally conical if and only if f is PL.

XIII.25.4.6. COROLLARY. Let X and Y be polyhedra in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, and $f : X \to Y$ a PL function. Then there is a triangulation of X such that f is simplicial for the triangulation. Conversely, such a map is PL.

PROOF: If f is PL, triangulate the polyhedron $\Gamma(f)$. The projection map from $\Gamma(f)$ to X is affine, and is a homeomorphism, so the projections of the simplexes in the triangulation of $\Gamma(f)$ are simplexes in X and give a triangulation of X as desired. The converse is obvious.

This result justifies the name "piecewise-linear."

XIII.25.5. Exercises

XIII.25.5.1. (a) Show that every affine subspace of $\mathbb{R}^n$ is a finite intersection of (closed) half-spaces.

(b) Let C be a cell in $\mathbb{R}^n$ with vertices $\boldsymbol{v}_1, \ldots, \boldsymbol{v}_m$. Suppose C generates $\mathbb{R}^n$ as an affine subspace. For $1 \leq k \leq m$, let C_k be the cone (in the vector space sense) generated by C with vertex $\boldsymbol{v}_k$, i.e. the union of all rays from $\boldsymbol{v}_k$ passing through other points of C. Show that $C = C_1 \cap \cdots \cap C_m$. [Use an argument like the one in the proof of XIII.25.1.28..]

(c) Show that each C_k is a finite intersection of half-spaces.

(d) Conclude that every cell is a finite intersection of half-spaces. Use this to give a direct proof of (i) $\Rightarrow$ (iii) of XIII.25.1.23..

XIII.25.5.2. Let T be an open triangle in $\mathbb{R}^2$ with one vertex added. Show that T is locally conical, but not a polyhedron in the PL sense (XIII.25.1.34.) since it is not locally compact.

XIII.26. Absolute Retracts and Absolute Neighborhood Retracts

There is an important class of nicely behaved spaces called *absolute retracts* and, more generally, *absolute neighborhood retracts*. We can work within various classes of spaces; we work first with compact Hausdorff spaces (compacta), and in Section () with more general classes.

The two standard references for this subject are [Bor67] and [**?**]. [vM89] is also a good reference. These references contain much more than we present here.

XIII.26.1. Retractions

XIII.26.1.1. Definition. Let X be a topological space and $Y \subseteq X$. A *retraction* of X to Y is a map (continuous function) $r : X \to Y$ with $r(y) = y$ for all $y \in Y$. Y is a *retract* of X if there is a retraction from X to Y.

XIII.26.1.2. Examples. (i) If X is any topological space, the identity map ι_X is a retraction from X to X.

(ii) Let X be a topological space, and $p \in X$. Then the constant function $f(x) = p$ for all $x \in X$ is a retraction of X to $\{p\}$. Thus every singleton subset of X is a retract of X.

(iii) Let X and Y be topological spaces, and $x_0 \in X$, $y_0 \in Y$. Then the projection functions $f((x, y)) = (x, y_0)$ and $g((x, y)) = (x_0, y)$ are retractions of $X \times Y$ (with the product topology) to $X \times \{y_0\}$ and $\{x_0\} \times Y$ respectively. Thus the horizontal and vertical slices of $X \times Y$ are retracts of $X \times Y$.

(iv) Let X be the closed unit ball in $\mathbb{R}^n$ ($n \geq 1$), and Y the unit sphere. The Brouwer Fixed-point Theorem implies that there is no retraction from X to Y, i.e. Y is not a retract of X.

XIII.26.1.3. A retraction from X to a subspace is just an idempotent map, a map $f : X \to X$ with $f \circ f = f$: such a map is a retraction onto its range.

XIII.26.1.4. Proposition. If X is Hausdorff, any retract of X is a closed subset.

Proof: Let Y be a retract of X, and $r : X \to Y$ a retraction. Let $x_0 \in X \setminus Y$, and set $y_0 = r(x_0)$. Then $y_0 \neq x_0$ since $y_0 \in Y$. Let U and V be disjoint open neighborhoods of x_0 and y_0 respectively. Then by continuity of r there is an open neighborhood W of x_0, contained in U, such that $r(W) \subseteq V$. If $x \in W$, then $r(x) \in V$, which is disjoint from W, so $r(x) \neq x$ and $x \notin Y$. Thus $X \setminus Y$ is open. 👍

This result can fail if X is not Hausdorff (e.g. XIII.26.1.2.(ii) if X is not T_1; see also Exercise XIII.26.6.1.).

XIII.26.1.5. One can more generally define an *r-map* between topological spaces X and Y to be a map $f : X \to Y$ which has a (continuous) right inverse (cross-section), a map $g : Y \to X$ such that $f \circ g = \iota_Y$. A retraction is an r-map. If f is an r-map from X to Y, f must be surjective, g must be a homeomorphism from Y to $g(Y)$, and $g \circ f$ a retraction from X to $g(Y)$. Thus an r-map is precisely a retraction composed with a homeomorphism.

A composition of r-maps is an r-map. A homeomorphism is an r-map. Thus the class of topological spaces, or any subclass, with r-maps as morphisms, forms a category.

Deformation Retractions

Retractions must be carefully distinguished from deformation retractions:

XIII.26.1.6. Definition. Let X be a topological space, and $Y \subseteq X$. A *deformation retraction* from X to Y is a map $h : X \times [0,1] \to Y$ such that $h(x,0) = x$ and $h(x,1) \in Y$ for all $x \in X$ and $h(y,1) = y$ for all $y \in Y$. The map h is a *strong deformation retraction* if $h(y,t) = y$ for all $y \in Y$ and all $t \in [0,1]$. Y is a [strong] deformation retract of X if there is a [strong] deformation retraction form X to Y.

XIII.26.1.7. A deformation retraction from X to Y "continuously moves" all points of X into Y, with points of Y ending up unmoved. A strong deformation retraction is one where the points of Y are never moved at all. If we set $f_t : X \to Y$ by $f_t(x) = h(x,t)$, then $f_0 = \iota_X$ and f_1 is a retraction of X to Y. Thus a deformation retraction from X to Y can be thought of as a retraction from X to Y which is homotopic to the identity on X, and a strong deformation retraction is a retraction which is homotopic to the identity on X relative to the points of Y ().

XIII.26.1.8. A deformation retract of X is a retract of X. But being a deformation retract is much more restrictive than being a retract. For example, if X is a space which is not contractible (e.g. a space which is not connected, or S^1), and $p \in X$, then $\{p\}$ is a retract of X (XIII.26.1.2.(ii)) but not a deformation retract. In fact, a singleton $\{p\}$ in a topological space X is a [strong] deformation retract of X if and only if X is [strongly] contractible to p.

XIII.26.2. Absolute Retracts

In this section, we will deal only with compacta (compact Hausdorff spaces). The primary interest will be the metrizable case, but this restriction is not necessary for the basic theory.

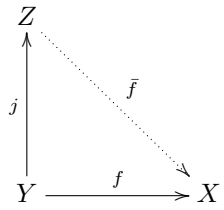
XIII.26.2.1. Definition. A compactum X is an *absolute retract (AR)* if, whenever X is embedded as a (necessarily closed) subset of a compactum Z, X is a retract of Z (i.e. there is a retraction of Z onto X).

XIII.26.2.2. Examples. (i) By XIII.26.1.2.(ii), a singleton space is an AR.

(ii) If $[0,1]$ is embedded in a compactum Z, the identity map on $[0,1]$ extends to a map from Z to $[0,1]$ by the Tietze Extension Theorem (), giving a retraction of Z to $[0,1]$. Thus $[0,1]$ is an AR.

(iii) A two-point space with the discrete topology is not an AR: embed $\{0,1\}$ into $[0,1]$.

(iv) A circle is not an AR: it is not a retract of a disk.



We will obtain many more examples later.

Absolute Extensors

Here is a closely related (*extremely* closely related – see XIII.26.2.6.) but seemingly more restrictive notion:

XIII.26.2.3. DEFINITION. A compactum X is an *absolute extensor (AE)* if, whenever Z is a compactum and Y a closed subspace of Z, every map $f : Y \to X$ extends to a map $\bar{f} : Z \to X$.

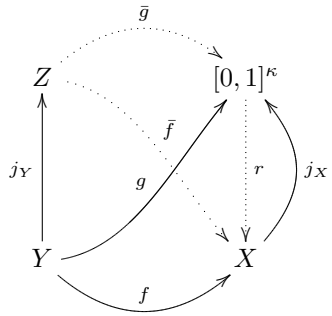
In other words, the following commutative diagram can always be completed in the category of compacta, where j is the inclusion map:

i.e. X is an injective object in this category.

XIII.26.2.4. An AE is an AR: if X is an AE, embedded in Z, extend ι_X to a map from Z to X.

XIII.26.2.5. EXAMPLES. (i) A singleton is trivially an AE.

(ii) The Tietze Extension Theorem implies that $[0, 1]$ is an AE.



(iii) An arbitrary product of AEs is an AE (just extend every coordinate function; Tikhonov's Theorem () is needed to conclude that the product is a compactum). In particular, any cube (product of $[0, 1]$'s) is an AE.

The main theorem is:

XIII.26.2.6. THEOREM. A compactum is an AE if and only if it is an AR.

PROOF: We have already observed that an AE is an AR. Conversely, let X be an AR. Then X embeds in a cube $[0, 1]^\kappa$ (), and there is a retraction $r : [0, 1]^\kappa \to X$. Let Z be a compactum and Y a closed subspace of Z, and $f : Y \to X$ a map. Regard f as a function g from Y to $[0, 1]^\kappa$. Since $[0, 1]^\kappa$ is an AE, g extends to a $\bar{g}$ from Z to $[0, 1]^\kappa$. Then $\bar{f} = r \circ \bar{g} : Z \to X$ is an extension of f to Z.

The following commutative diagram summarizes the construction, where j_X and j_Y are the embeddings:

The next result has a simple direct proof, but follows immediately from XIII.26.2.6. and XIII.26.2.5.(iii):

XIII.26.2.7. Corollary. An arbitrary product of ARs is an AR.

A proof very similar to the proof of XIII.26.2.6. shows:

XIII.26.2.8. Proposition. A retract of an AR is an AR.

XIII.26.2.9. Corollary. Let X be a compactum. Then X is an AR if and only if it is (homeomorphic to) a retract of a cube.

Proof: Since any cube is an AR, a retract of a cube is an AR. Conversely, any compactum X embeds in a cube, and if X is an AR there is a retraction onto the image. 👍

Strong Contractibility

An important property of ARs is that they are strongly contractible:

XIII.26.2.10. Theorem. Let X be an AR and $p \in X$. Then X is strongly contractible to p.

Proof: Let Z be the cone over X: $Z = X \times [0,1]$ with $X \times \{1\}$ collapsed to a point. Let

$$Y = (X \times \{0\}) \cup (\{p\} \times [0,1]) \subseteq Z \ .$$

Y consists of the base of the cone plus a vertical spike from p to the vertex (Fig. ()). There is an obvious map $f : Y \to X$ given by $f((x,0)) = x$ for all $x \in X$ and $f((p,t)) = p$ for $t \in [0,1]$. An extension of f to Z is a strong contraction of X to p. 👍

A similar proof shows more generally [take $X_0 = \{p\}$ and Z_0 the vertical spike]:

XIII.26.2.11. Proposition. Let X be an AR, and X_0 a closed subspace. Let Z be a compactum containing X, and Z_0 a closed set in Z with $Z_0 \cap X = X_0$. Then any retraction from Z_0 to X_0 extends to a retraction from Z to X. In particular, if X_0 is also an AR, there is a retraction r from Z to X with $r(Z_0) = X_0$.

Proof: Let r_0 be a retraction from Z_0 to X_0. Let $Y = X \cup Z_0$; then Y is a closed subset of Z. Define $f : Y \to X$ by

$$f(y) = \begin{cases} y & \text{if} \quad y \in X \\ r_0(y) & \text{if} \quad y \in Z_0 \end{cases} \ .$$

It is easily checked that f is continuous, and an extension of f to Z is the desired retraction. 👍

The next property follows from XIII.26.2.10. and XV.1.1.21.:

XIII.26.2.12. PROPOSITION. An AR X is locally strongly contractible to any point of X.

Since a [locally] contractible space is [locally] path-connected, we have:

XIII.26.2.13. COROLLARY. An AR is path-connected and locally path-connected.

Homotopies

Any two maps from any compactum into an AR are homotopic. In fact, any two maps from any space into a contractible space are homotopic. But ARs have a much stronger property as a target space:

XIII.26.2.14. PROPOSITION. Let X be an AR, Z a compactum, Y a closed subspace of Z, and f_0, f_1 maps from Z to X. Suppose $\theta : Y \times [0,1]$ is a homotopy from $f_0|_Y$ to $f_1|_Y$. Then there is a homotopy $h : Z \times [0,1] \to X$ from f_0 to f_1 extending θ.

PROOF: Let $W = (Z \times \{0\}) \cup (Z \times \{1\}) \cup (Y \times [0,1])$. W is a closed subset of $Z \times [0,1]$, and there is an obvious map $\phi : W \to X$ which is f_0 on $Z \times \{0\}$, f_1 on $Z \times \{1\}$, and θ on $Y \times [0,1]$. Extend ϕ to $h : Z \times [0,1] \to X$. 👍

The following special case is especially important:

XIII.26.2.15. COROLLARY. Let X be an AR, Z a compactum, Y a closed subspace of Z, and f_0, f_1 maps from Z to X. Suppose f_0 and f_1 agree on Y. Then there is a homotopy $h : Z \times [0,1] \to X$ from f_0 to f_1 with $h(y,t) = f_0(y) = f_1(y)$ for all $y \in Y$, $t \in [0,1]$.

Continuous Strong Contractions

XIII.26.2.16. XIII.26.2.15. can be used to extend XIII.26.2.10.: not only can an AR X be strongly contracted to any $p \in X$, but the strong contractions can be made to "vary continuously" as p varies, as follows.

Let X be an AR. Apply XIII.26.2.15. with $Z = X \times X$ and Y the diagonal. Define f_0, f_1 by $f_0(x,y) = x$ and $f_1(x,y) = y$ (coordinate projections from $X \times X$ to X). Then f_0 and f_1 agree on Y. Let h be a homotopy from f_0 to f_1 leaving Y pointwise fixed, i.e. $h(x,y,0) = x$ and $h(x,y,1) = y$ for all $x, y \in X$, and $h(y,y,t) = y$ for all $y \in X$ and $t \in [0,1]$. A space with such an h is called *equiconnected* ([Fox43], [Bor69]).

If y is fixed and h is regarded as a function of x and t, i.e. $h_y(x,t) = h(x,y,t)$, then h_y is a strong contraction of X to y; and the h_y vary continuously in the strongest reasonable sense.

The Fixed-Point Property

Every AR has the fixed-point property (XIII.21.6.1.). This follows from:

XIII.26.2.17. PROPOSITION. Let Z be a topological space, and X a retract of Z. If Z has the fixed-point property, then so does X.

PROOF: Let j be the inclusion map from X to Z, and r a retraction from Z to X. Let $\phi : X \to X$ be a map. Define $\psi = j \circ \phi \circ r : Z \to Z$. Then ψ has a fixed point x. Since the range of ψ is contained in X, $x \in X$; and $\psi(x) = \phi(x)$ since $r(x) = x$. 👍

XIII.26.2.18. COROLLARY. Every AR has the fixed-point property.

PROOF: Every AR is a retract of a cube, which has the fixed-point property by XIII.21.6.3.. 👍

The Metrizable Case

Not all ARs by definition XIII.26.2.1. are metrizable: for example, any cube, no matter how large, is an AR. But metrizable ARs are particularly nice; in fact, many references require ARs to be metrizable. So for the rest of this section, "AR" will mean "metrizable AR".

The first observation is that we can work exclusively with metrizable compacta:

XIII.26.2.19. PROPOSITION. Let X be a metrizable compactum. The following are equivalent:
(i) X is an AR (by definition XIII.26.2.1.).
(ii) X is (homeomorphic to) a retract of the Hilbert cube.
(iii) Whenever X is embedded in a metrizable compactum Z, there is a retraction from Z to X.

PROOF: (i) ⇒ (iii) is trivial. (iii) ⇒ (ii) since X embeds in the Hilbert cube (), which is a metrizable compactum. And (ii) ⇒ (i) by XIII.26.2.8. since the Hilbert cube is an AR. 👍

As a sample of what can be proved in the metrizable case, we have the following assembly result:

XIII.26.2.20. THEOREM. Let X be a metrizable compactum, X_1 and X_2 closed subspaces with $X_0 = X_1 \cap X_2$.
(i) If X_0, X_1, X_2 are ARs, then X is an AR.
(ii) If X and X_0 are ARs, then X_1 and X_2 are ARs.

PROOF: (i): Embed X in a metrizable compactum Z. Since Z is completely normal (XIII.10.1.1.), there are closed subspaces Z_1, Z_2 of Z such that $Z_j \cap X = X_j$ for $j = 1, 2$ (XIII.10.6.12.). Then $Z_0 = Z_1 \cap Z_2$ satisfies $Z_0 \cap X = X_0$. There is a retraction r_0 from Z_0 to X_0. This retraction extends to retractions r_1 from Z_1 to X_1 and r_2 from Z_2 to X_2 by XIII.26.2.11.. These retractions combine to give a retraction from Z to X.
(ii): There are retractions r_1 from X_1 to X_0 and r_2 from X_2 to X_0. Set

$$r(x) = \begin{cases} x & \text{if} \quad x \in X_1 \\ r_2(x) & \text{if} \quad x \in X_2 \end{cases} .$$

Then r is a retraction from X to X_1. Since X is an AR, X_1 is an AR by XIII.26.2.8.. Similarly X_2 is an AR. 👍

XIII.26.2.21. The proof of (ii) does not use metrizability and works equally well in the nonmetrizable case. But the proof of (i) uses complete normality, which does not hold in general in nonmetrizable compacta (XIII.10.6.11.(d)). In fact, (i) can fail in the nonmetrizable case (Exercise XIII.26.6.7.).

XIII.26.2.22. This result can be rephrased to say that if two (metrizable) ARs are joined by identifying sub-ARs of each, the join is also an AR. See XIII.26.2.23. for a generalization. An important special case is that if two ARs are joined by a single point, the join is an AR. Applying this repeatedly, we obtain that any finite tree is an AR. Actually, one-dimensional (metrizable) ARs can be characterized: they are precisely the *dendrites*, metrizable compacta which are connected and locally connected (hence path-connected and locally path-connected by the Hahn-Mazurkiewicz Theorem) and contain no simple closed curves, or alternatively are unicoherent (). See XIII.19.5.1., XIII.19.6.10., and XIII.19.6.11. for some interesting examples; another example is a *countable star*, the one-point compactification of a sequence of copies of $(0, 1]$. Higher-dimensional ARs are much more complicated, and no complete description is known. Some pathological ones can be found in [Bor67]; cf. XIII.19.5.3..

A harder and stranger generalization of XIII.26.2.20.(i), due to J. H. C. Whitehead [], concerns identification spaces. See e.g. [Bor67, V.9.1] for the proof.

XIII.26.2.23. Theorem. Let X_1 and X_2 be metrizable ARs, and X_0 a subset of X_1 which is also an AR. Let $f : X_0 \to X_2$ be a continuous function. Then $X_1 \cup_f X_2$ () is an AR.

XIII.26.2.24. Note that ϕ need not be injective or surjective (the injective case is XIII.26.2.20.(i)), and $f(X_0)$ need not be an AR; in fact, it can be a very complicated set (cf. XIII.26.2.25.(ii)). Even if $f(X_0)$ is an AR, the identification space can be bizarre (cf. XIII.26.2.25.(i), XIII.26.2.25.(iii)).

XIII.26.2.25. Examples. (i) Let X_1 and X_2 be copies of $[0, 1]^2$. Let X_0 be an arc, say one edge, in X_1. Let f be a space-filling curve, a surjective map of X_0 onto X_2. Then $X = X_1 \cup_f X_2$ is an AR. X is a square in which X_0 has been "expanded" into a second square. Actually X_2 can be any metrizable AR, since any metrizable AR is a continuous image of $[0, 1]$ by XIII.26.2.13. and the Hahn-Mazurkiewicz Theorem ().

(ii) In (i), $f(X_0)$ is an AR. Instead, let Y be a copy of the Sierpiński carpet () inside X_2. There is a surjective function f from X_0 onto Y by the Hahn-Mazurkiewicz Theorem. The identification space is again an AR, although X_0 has become a copy of the Sierpiński carpet, which is far from an AR.

(iii) An interesting special case is when X_2 is a single point and f is a constant function. The identification space then amounts to taking the quotient of X_1 by collapsing X_0 to a point. So a quotient of an AR by collapsing a sub-AR to a point is again an AR. An interesting example is to consider a wild arc (XIII.19.5.39.) embedded in a 3-ball. Collapsing the arc to a point p gives a 3-dimensional AR X with complicated local topology around p: for example, no deleted neighborhood of p is simply connected; thus X is not locally Euclidean at p.

Example (iii) can be generalized, due to the following consequence of a theorem of S. Smale (see [Bor67, V.12.1] for a proof):

XIII.26.2.26. THEOREM. Let Z be a (metrizable) AR, X a (necessarily metrizable) finite-dimensional compactum, and $f : Z \to X$ a surjective map. If $f^{-1}(\{x\})$ is an AR for every $x \in X$, then X is also an AR.

Using (), this can be rephrased:

XIII.26.2.27. COROLLARY. Let Z be a (metrizable) AR, and $\sim$ a usc decomposition of Z into sub-ARs. Then the quotient space $X = Z/\sim$, if finite-dimensional, is also an AR.

Using this, an enormous supply of pathological ARs can be constructed; see e.g. Exercises ().

XIII.26.3. Absolute Neighborhood Retracts

Absolute retracts are nice, but the class is too restrictive to include many spaces of interest even though there are many pathological examples (e.g. ARs must be contractible). There is a much larger class of absolute neighborhood retracts (ANRs), spaces which behave locally like ARs, which include most compacta commonly considered in topology, including all finite CW-complexes (in particular all polyhedra) and all compact topological manifolds with or without boundary, and more generally all finite-dimensional locally contractible metrizable compacta.

Much of the theory of ANRs is parallel to the theory of ARs, with similar but often somewhat more complicated proofs.

XIII.26.3.1. DEFINITION. Let X be a compactum. X is an *absolute neighborhood retract (ANR)* if, whenever X is embedded in a compactum Z, there is a retraction from an open neighborhood U of X in Z to X.

XIII.26.3.2. EXAMPLES. (i) Any AR is an ANR.

(ii) A finite separated union of ANRs is an ANR. In particular, a finite separated union of ARs (e.g. a finite discrete space) is an ANR.

XIII.26.3.3. Since any compactum embeds in a cube, any ANR is a retract of an open set in a cube. The converse also holds ().

Since every open neighborhood of a closed set in a compactum contains a compact neighborhood, the definition can be rephrased:

XIII.26.3.4. PROPOSITION. A compactum X is an ANR if and only if, whenever X is embedded in a compactum Z, there is a retraction from a compact neighborhood U of X in Z to X.

Absolute Neighborhood Extensors

As with ARs, we can extend the definition:

XIII.26.3.5. DEFINITION. A compactum X is an *absolute neighborhood extensor (ANE)* if, whenever Z is a compactum and Y a closed subspace, and $f : Y \to X$ is a map, then f can be extended to an open neighborhood of Y in Z.

XIII.26.3.6. THEOREM. A compactum is an ANR if and only if it is an ANE.

PROOF: If X is an ANE, embedded in a compactum Z, extend the identity map of X to a map $\bar{f}$ from some open neighborhood U of X in Z to X. Then g is a retraction from U to X. So X is an ANR.

Conversely, suppose X is an ANR. Embed X in a cube K. There is a retraction r of an open set V in K containing X onto X. If Z is a compactum and Y a closed subspace of Z, and $f : Y \to X$ is a map, regard f as a map from Y to K. Since K is an AR, f extends to $g : Z \to K$. Set $U = g^{-1}(V)$; then U is an open set in Z containing Y. Set $\bar{f} = r \circ g|_U$; then $\bar{f}$ maps U into X and extends f to U. 👍

A similar argument shows:

XIII.26.3.7. PROPOSITION. A compactum which is a retract of an open set in an ANR is an ANR.

PROOF: Let X be an ANR, V an open set in X, and r a retraction from V to a closed subset X_0 of X. Let Z be a compactum, Y a closed subset of Z, and $f : Y \to X_0$ a map. Regard f as a map from Y to X. Then f extends to a map g from an open set W in Z containing Y to X. Set $U = g^{-1}(V)$; then U is open in W, hence in Z, and g maps U into V. Then $\bar{f} = r \circ g|_U$ maps U into X_0 and extends f. 👍

XIII.26.3.8. EXAMPLE. The n-sphere S^n is a radial retract of $B^{n+1} \setminus \{0\}$, and B^{n+1} is an AR; thus S^n is an ANR.

This will be greatly extended ().

Local Strong Contractibility

An ANR need not be contractible, or even connected. However:

XIII.26.3.9. THEOREM. An ANR is locally strongly contractible.

PROOF: We argue similarly to the proofs of XIII.26.2.10. and XV.1.1.21.. Let X be an ANR, and $p \in X$. Let Y be the subspace $(X \times \{0\}) \cup (\{p\} \times [0,1])$ of CX. The obvious map $f : Y \to X$ extends to a map g from an open neighborhood A of Y to X. By compactness of $[0,1]$, there is an open neighborhood W of p in X with $CW \subseteq A$. Let h be the restriction of g to CW; then h gives a strong contraction of W to p within X.

Let U be an open neighborhood of p in X; we may assume $U \subseteq W$ without loss of generality. Then $B = h^{-1}(U)$ is an open neighborhood of $(U \times \{0\}) \cup (\{p\} \times [0,1])$ in CW, so there is an open neighborhood V of p in X with $CV \subseteq B$. Then $h|_{CV}$ gives a strong contraction of V to p within U. 👍

XIII.26.3.10. Corollary. The path components of an ANR are clopen sets. In particular, an ANR has only finitely many connected components.

Thus, for example, an infinite totally disconnected compactum (e.g. the Cantor set, or even the one-point compactification of $\mathbb{N}$) is not an ANR. This can easily be seen directly.

The Homotopy Extension Theorem

One of the most important facts about ANRs is that homotopies can be extended:

XIII.26.3.11. Theorem. [Homotopy Extension Theorem] Let X be an ANR, Z a compactum, Y a closed subspace of Z. Let f_0, f_1 be maps from Y to X, and $h : Y \times [0,1] \to X$ a homotopy from f_0 to f_1. If f_0 extends to a map $\bar{f}_0$ from Z to X, then the entire homotopy h extends to a homotopy $\bar{h} : Z \times [0,1] \to X$. In particular, f_1 extends to a function $\bar{f}_1 : Z \to X$ which is homotopic to $\bar{f}_0$.

For the proof, we need a lemma:

XIII.26.3.12. Lemma. Let Z be a normal space, and Y a closed subspace of Z. For every open neighborhood V of $A = (Z \times \{0\}) \cup (Y \times [0,1])$ in $Z \times [0,1]$ there is a map $\phi : Z \times [0,1] \to V$ which is the identity on A.

Proof: By compactness of $[0,1]$ there is an open neighborhood U of Y in Z such that $U \times [0,1] \subseteq V$. By Urysohn's Lemma there is a map $g : Z \to [0,1]$ which is 1 on Y and 0 on $Z \setminus U$. Set

$$\phi(z,t) = (z, g(z)t)$$

for $z \in Z$, $t \in [0,1]$. Then ϕ is the identity on A and the range of ϕ is contained in $(Z \times \{0\}) \cup (U \times [0,1]) \subseteq V$. 👍

We now give the proof of Theorem XIII.26.3.11..

Proof: Let $A = (Z \times \{0\}) \cup (Y \times [0,1])$, and define $g : A \to X$ by

$$g((z,t)) = \begin{cases} \bar{f}_0(z) & \text{if} \quad t = 0 \\ h(z,t) & \text{if} \quad z \in Y \end{cases} .$$

Then g extends to an open neighborhood V of A in $Z \times [0,1]$. Since Z is normal, there is a map $\phi : Z \times [0,1] \to V$ which is the identity on A. Set

$$\bar{h}(z,t) = g(\phi(z,t)$$

for $z \in Z$, $t \in [0,1]$ is the desired extension. 👍

If X is an AR, the proof simplifies greatly and Lemma XIII.26.3.12. is not needed, since we can take V to be all of $Z \times [0,1]$.

The Homotopy Extension Theorem has many applications, such as:

XIII.26.3.13. COROLLARY. An ANR is an AR if and only if it is contractible.

PROOF: An AR is a contractible ANR. Conversely, suppose X is a contractible ANR, embedded in a compactum Z. If h is a contraction of X, written as a homotopy from a constant function $f_0 : X \to \{p\} \subseteq X$ to $f_1 = \iota_x$, then f_0 extends to a (constant) function from Z to X, and hence ι_X extends to a map from Z to X, which is a retraction. Thus X is an AR. 👍

XIII.26.3.14. In fact, a nearly identical proof shows that the homotopy extension property characterizes ARs among all contractible compacta. However, it does not characterize ANRs: a zero-dimensional compactum like the Cantor set trivially has the homotopy extension property. It is much more difficult to say whether it characterizes ANRs among locally path-connected or locally contractible compacta.

Homotopy of Close Maps

Another property related to the Homotopy Extension Theorem is that "sufficiently close" maps from a space into an ANR are homotopic, even homotopic by maps that remain "close."

XIII.26.3.15. DEFINITION. Let X be a topological space and $\mathcal{U}$ an open cover of X. Two functions f and g from a set Z into X are *$\mathcal{U}$-close* if for every $z \in Z$, there is a $U \in \mathcal{U}$ with $f(z)$ and $g(z)$ both in $\mathcal{U}$. If Z is a topological space, a homotopy (f_t) from f_0 to f_1 is a *$\mathcal{U}$-homotopy* if for every $z \in Z$ there is a $U \in \mathcal{U}$ with $f_t(z) \in \mathcal{U}$ for all $t \in [0,1]$. If (X, ρ) is a metric space, two functions f and g are *ϵ-close* ($\epsilon > 0$) if $\rho(f(z), g(z)) < \epsilon$ for all $z \in Z$. An ϵ-homotopy from f_0 to f_1 is a homotopy for which $\rho(f_t(z), f_s(z)) < \epsilon$ for all $z \in Z$, $s, t \in [0,1]$.

If (X, ρ) is a metric space and $\epsilon > 0$, ϵ-close functions are $\mathcal{U}$-close and ϵ-homotopies are $\mathcal{U}$-homotopies, where $\mathcal{U}$ is the covering of X by open balls of radius $\frac{\epsilon}{2}$.

XIII.26.3.16. THEOREM. Let X be an ANR. Then for every open cover $\mathcal{U}$ of X there is a refinement $\mathcal{V}$ such that, whenever Z is a topological space and f and g are $\mathcal{V}$-close maps from Z to X, then f and g are $\mathcal{U}$-homotopic. If X is metrizable by a metric ρ, then for any $\epsilon > 0$ there is a $\delta > 0$ such that if Z is a topological space and f and g are δ-close maps from Z to X, then f and g are ϵ-homotopic.

Note that $\mathcal{V}$ depends on $\mathcal{U}$ but not on Z, f, g, and in the metrizable case δ depends on ρ and ϵ but not on Z, f, g.

PROOF: Embed X in a cube K. There is a retraction r from an open neighborhood W of X to X. Let $\tilde{\mathcal{U}} = \{r^{-1}(U) : U \in \mathcal{U}\}$; then $\tilde{\mathcal{U}}$ is an open cover of W. Since K has a convex structure and a base for its topology consisting of convex open sets, there is a refinement $\tilde{\mathcal{V}}$ of $\tilde{\mathcal{U}}$ consisting of convex open sets. Set $\mathcal{V} = \{\tilde{V} \cap X : \tilde{V} \in \tilde{\mathcal{V}}\}$; then $\mathcal{V}$ is an open cover of X refining $\mathcal{U}$.

Let Z be a topological space and f, g $\mathcal{V}$-close maps from Z to X. If f and g are regarded as maps into W, they are $\tilde{\mathcal{V}}$-close. Since the sets in $\tilde{\mathcal{V}}$ are convex, we may define, for $z \in Z$ and $t \in [0,1]$,

$$\tilde{f}_t(z) = \tilde{h}(z,t) = tg(z) + (1-t)f(z) \ .$$

Then $\tilde{h}$ is a $\mathcal{V}$-homotopy from $\tilde{f}_0 = f$ to $\tilde{f}_1 = g$ as maps from Z to W. Set $h = r \circ \tilde{h}$, i.e. $f_t = r \circ \tilde{f}_t$; then h is a $\mathcal{U}$-homotopy from f to g as functions from Z to X.

For the metrizable case, see Exercise XIII.26.6.8.. 👍

This argument is a nice application of convexity in topology.

Products of ANRs

XIII.26.3.17. An arbitrary product of ARs is an AR. It is easily seen that a finite product of ANRs is an ANR, but an arbitrary product of ANRs is not an ANR in general: for example, neither the Cantor set (an infinite product of two-point spaces) nor an infinite product of circles is an ANR (for one thing, they are not locally contractible). In fact, we have

XIII.26.3.18. PROPOSITION. If $\{X_i : i \in I\}$ is a set of compacta, then $\prod_i X_i$ is an ANR if and only if each X_i is an ANR and all but finitely many are ARs.

Metrizable ANRs

We have, in analogy with ():

XIII.26.3.19. PROPOSITION. Let X be a metrizable compactum. The following are equivalent:
(i) X is an ANR.
(ii) X is (homeomorphic to a) retract of an open set in the Hilbert cube.
(iii) Whenever X is embedded in a metrizable compactum Z, there is a retraction from an open neighborhood U of X in Z to X.

One unsatisfying thing about the definition of an ANR (even the variation in XIII.26.3.4.) is that, although it deals with compacta, it involves open sets (neighborhoods) in compacta and thus is not phrased entirely in terms of compacta. There is an alternate form of the definition in the metrizable case, which not only remedies this but also has a straightforward translation to a useful condition (semiprojectivity) for noncommutative C*-algebras [**?**]:

XIII.26.3.20. PROPOSITION. Let X be a metrizable compactum. The following are equivalent:
(i) X is an ANR.
(ii) Whenever X is embedded in a metrizable compactum Z, and (Y_n) is a decreasing sequence of closed sets in Z with $\cap_n Y_n = X$, there is a retraction from Y_n to X for some n (hence for all sufficiently large n).
(iii) Whenever Z is a metrizable compactum and (Y_n) is a decreasing sequence of closed sets in Z with $Y = \cap_n Y_n$, and f is a map from Y to X, there is an extension of f to a map from Y_n to X for some n (hence for all sufficiently large n).

PROOF: (i) $\Rightarrow$ (iii): Extend f to an open set U containing Y in Z. The open sets $(Z \setminus Y_n)$ increase and cover the compact set $Z \setminus U$, so $Z \setminus U \subseteq X \setminus Y_n$ and thus $Y_n \subseteq U$ for some (all sufficiently large) n.
(ii) $\Rightarrow$ (i): Fix a metric ρ on Z. If $X \subseteq Z$, for each n let $U_n = \left\{z \in Z : \rho(z, X) < \frac{1}{n}\right\}$ and $Y_n = \bar{U}_n$. Then $\cap_n Y_n = X$. Extend ι_X to Y_n for some n; the extension gives a retraction of U_n to X.
(iii) $\Rightarrow$ (ii) is trivial. 👍

Assembly

There is an analog of XIII.26.2.20.. The proof is similar but slightly more complicated; see e.g. [Bor67,].

XIII.26.3.21. THEOREM. Let X be a metrizable compactum, X_1 and X_2 closed subspaces with $X_0 = X_1 \cap X_2$.
(i) If X_0, X_1, X_2 are ANRs, then X is an ANR.
(ii) If X and X_0 are ANRs, then X_1 and X_2 are ANRs.

Similarly, XIII.26.2.23. has a direct analog:

XIII.26.3.22. THEOREM. Let X_1 and X_2 be metrizable ANRs, and X_0 a subset of X_1 which is also an ANR. Let $f : X_0 \to X_2$ be a continuous function. Then $X_1 \cup_f X_2$ () is an ANR.

This has an important consequence:

XIII.26.3.23. COROLLARY. Every finite CW-complex (in particular, any polyhedron) is an ANR.

XIII.26.3.24. There are many important results about approximation of ANRs by polytopes which can be found in the standard references.

A Characterization of Metrizable ANRs

ANRs are locally strongly contractible. Conversely:

XIII.26.3.25. THEOREM. Let X be a finite-dimensional metrizable compactum. Then X is an ANR if and only if it is locally contractible.

See e.g. [Bor67,] for a proof.

XIII.26.3.26. Finite-dimensionality cannot be eliminated here: there is an example, due to Borsuk, of an infinite-dimensional metrizable compactum which is locally contractible but not an ANR (see e.g. [Bor67,]). However, the following seems to be a reasonable conjecture:

XIII.26.3.27. **Conjecture:** A metrizable compactum is an ANR if and only if it is locally strongly contractible.

XIII.26.3.28. It is surprising that this conjecture does not seem to have appeared in the literature. No counterexamples appear to be known. In fact, topologists do not seem to have appreciated the notion of local strong contractibility, which is not generally mentioned in the literature; when XIII.26.3.25. is discussed, only Borsuk's counterexample in the infinite-dimensional case is mentioned. Indeed, the reason Borsuk's example is not an ANR is essentially precisely because it is *not* locally strongly contractible. Actually, one interesting consequence of XIII.26.3.25. is that local contractibility and local strong contractibility coincide for finite-dimensional metrizable compacta. See XIII.26.6.5., [Bor69], and [vM89, 5.1.2] for closely related conjectures.

A simple consequence is:

XIII.26.3.29. Corollary. Any compact topological manifold, with or without boundary, is an ANR.

Proof: If X is a compact topological manifold and $p \in X$, then there is a local base for the topology at p consisting of open sets strongly contractible to p. 👍

The Countable Chain Condition

Although an ANR, even an AR, need not be metrizable or even separable (a large enough cube is not), we have:

XIII.26.3.30. Proposition. Every ANR is measurably separable (XIII.24.1.7.), and hence has the Countable Chain Condition (XIII.24.1.9.).

Proof: Every cube is MS (XIII.24.1.12.); hence any open set in a cube is MS (XIII.24.1.11.), and any continuous image of an open set in a cube is MS (XIII.24.1.10.). 👍

This result requires some version of the AC.

XIII.26.4. The Noncompact Case

The theory of ARs and ANRs can be extended to more general classes of spaces, with some restrictions and technical complications. This increased generality not only has some direct applications, but is even relevant to the structure of compact ARs and ANRs. We will only survey this extended theory, with some relevant proofs.

Actually, from a purely logical standpoint we have probably done things backwards: the standard references do the general or metrizable case first and then go on to the compact or compact metrizable case. But some things, notably the equivalence of retracts and extensors, are much easier in the compact case, and the compact case is the primary one of interest anyway, so we chose to do it first.

XIII.26.4.1. We will work only with Hausdorff spaces, so "space" will mean "Hausdorff space." We consider various classes $\mathcal{C}$ of spaces which are *weakly hereditary*: if a space X is in $\mathcal{C}$, so is every closed subspace (in particular, every singleton is in $\mathcal{C}$). Some important examples are:

$\mathcal{N}$, the class of all normal spaces.

$\mathcal{M}$, the class of all metrizable spaces.

$\mathcal{K}$, the class of all compacta.

$\mathcal{KM}$, the class of all metrizable compacta.

There are many other weakly hereditary classes such as the class of perfectly normal spaces or locally compact metrizable spaces. It turns out that only classes of normal spaces give anything interesting in this theory (XIII.26.4.4.).

XIII.26.4.2. Definition. Let $\mathcal{C}$ be a weakly hereditary class of spaces.

(i) A space X is an *AR($\mathcal{C}$)* if, whenever X is embedded as a closed subspace of a $Z \in \mathcal{C}$, there is a retraction from Z to X.

(ii) A space X is an *AE($\mathcal{C}$)* if, whenever $Z \in \mathcal{C}$ and Y is a closed subspace of Z, any map from Y to X extends to a map from Z to X.

(iii) A space X is an *ANR($\mathcal{C}$)* if, whenever X is embedded as a closed subspace of a $Z \in \mathcal{C}$, there is a retraction from an open neighborhood of X in Z to X.

(iv) A space X is an *ANE($\mathcal{C}$)* if, whenever $Z \in \mathcal{C}$ and Y is a closed subspace of Z, any map from Y to X extends to a map from an open neighborhood of Y in Z to X.

XIII.26.4.3. An AR($\mathcal{C}$) is an ANR($\mathcal{C}$), and an AE($\mathcal{C}$) is an ANE($\mathcal{C}$). A space which is an ANR($\mathcal{C}$) must be in $\mathcal{C}$ since $\mathcal{C}$ is weakly hereditary; but by this definition an AE($\mathcal{C}$) or ANE($\mathcal{C}$) is not required to be in $\mathcal{C}$. An AE($\mathcal{C}$) [ANE($\mathcal{C}$)] which is in $\mathcal{C}$ is an AR($\mathcal{C}$) [ANR($\mathcal{C}$)] by the standard argument. The converse is trickier than in the compact case. An AE($\mathcal{C}$) [ANE($\mathcal{C}$)] is also an AE($\mathcal{D}$) [ANE($\mathcal{D}$)] for any subclass $\mathcal{D}$ of $\mathcal{C}$; the same is true for an AR($\mathcal{C}$) [ANR($\mathcal{C}$)] if the space is in $\mathcal{D}$.

An AR in the sense of () is precisely an AR($\mathcal{K}$), and an ANR in the sense of () is precisely an ANR($\mathcal{K}$). A metrizable AR [ANR] is precisely an AR($\mathcal{KM}$) [ANR($\mathcal{KM}$)]. The terms AR and ANR with no class qualification will continue to have their previous meanings.

If $\mathcal{C}$ is too large, there are no nontrivial ANE($\mathcal{C}$)s:

XIII.26.4.4. Proposition. [**?**, II.2.3] If $\mathcal{C}$ is a weakly hereditary class containing a nonnormal space, then no space with more than one point is an ANE($\mathcal{C}$).

Proof: Let X be a (Hausdorff) space and p and q distinct points of X. Let V and W be disjoint open neighborhoods of p and q. Let Z be a nonnormal space in $\mathcal{C}$, and A and B disjoint closed sets in Z which do not have disjoint open neighborhoods. Let $Y = A \cup B$, and define $f : Y \to X$ by $f(y) = p$ if $y \in A$ and $f(y) = q$ if $y \in B$. Suppose f extends to a map $\bar{f} : U \to X$ for some open neighborhood U of Y. Then $\bar{f}^{-1}(V)$ and $\bar{f}^{-1}(W)$ are disjoint open neighborhoods of A and B, a contradiction. 👍

Thus from now on we will consider only normal spaces.

Embedding in Convex Sets

In the compact case, the proof that an AR [ANR] is an AE [ANE] is a simple consequence of the Tietze Extension Theorem and the fact that a compactum embeds as a closed subset of a cube. A different argument is needed in the noncompact case: the Tietze Extension Theorem is replaced by the Dugundji Extension Theorem (), and the embedding in a cube must be replaced by an embedding as a closed subset of a convex set in a locally convex topological vector space.

XIII.26.4.5. THEOREM. [DUGUNDJI EXTENSION THEOREM] Let V be a locally convex topological vector space, Z a metrizable space, Y a closed subspace of Z. If f is a map from Y to V, then f extends to a map $\bar{f}$ from Z to V with $\bar{f}(Z)$ contained in the convex hull of $f(X)$.

The proof is complicated and beyond the scope of this book, and apparently only works for metrizable Z. See the standard references.

XIII.26.4.6. COROLLARY. Any convex set in a locally convex topological vector space is an AE($\mathcal{M}$).

Note that such a convex set need not itself be metrizable, hence need not be an AR($\mathcal{M}$); but it is an AR($\mathcal{M}$) if it is metrizable.

The metrizable version of the Tietze Extension is the special case of XIII.26.4.6. for a convex set (interval) in $\mathbb{R}$. But the Tietze Extension Theorem also applies in the (normal) metrizable case, i.e. an interval in $\mathbb{R}$ is an AE($\mathcal{N}$).

The proof of the next result is simple but uses some heavy functional analysis machinery.

XIII.26.4.7. PROPOSITION. Let X be a completely regular space. Then there is a precompact convex set Z in a locally convex topological vector space whose set of extreme points is closed in Z and homeomorphic to X. If X is second countable, Z can be chosen metrizable. (Conversely, the completely regular condition is necessary since any subset of a Hausdorff topological group is completely regular.)

PROOF: X embeds in a cube K. The Bauer simplex Δ_K () is a weak-* compact convex subset of $C(K)^*$, where $C(K)$ is the Banach space of real-valued continuous functions on K, and the set of extreme points of Δ_K is closed and homeomorphic to K. Let Z be the convex hull of X in Δ_K. We have $K \cap Z = X$ since every point of K is an extreme point of Δ_K; thus X is closed in Z, and the points of X are extreme points (all the extreme points) of Z. If X is second countable, K can be chosen to be the Hilbert cube. 👍

XIII.26.4.8. This result is a variation of a theorem of KURATOWSKI and WOJDYSŁAWSKI, which gives a different embedding of a metrizable space as a closed subset of a convex set in a Banach space. In our construction the convex set Z is a "noncompact Bauer simplex": every point of Z is uniquely a convex combination of points of X. (The closure of Z in Δ_K is isomorphic to $\Delta_{\bar{X}}$.)

With these two results, the proof of the following result is essentially identical to the proofs of () and ():

XIII.26.4.9. THEOREM. An AR($\mathcal{M}$) [ANR($\mathcal{M}$)] is an AE($\mathcal{M}$) [ANE($\mathcal{M}$).

This result can be extended somewhat to nonmetrizable spaces; cf. [**?**, II.16.1].

Retracts of ANRs

Proposition () has a considerable extension in the noncompact case, with an identical proof:

XIII.26.4.10. PROPOSITION. Let $\mathcal{C}$ be a weakly hereditary class. Then any retract of an open set (in particular, any open set) in an ANE($\mathcal{C}$) is an ANE($\mathcal{C}$).

XIII.26.4.11. COROLLARY. Any retract of an open set (in particular, any open set) in an ANR($\mathcal{M}$) is an ANR($\mathcal{M}$).

The Homotopy Extension Theorem

The Homotopy Extension Theorem (XIII.26.3.11.) works identically with the same proof in the general case of ANEs, since the proof only uses that Z is normal:

XIII.26.4.12. THEOREM. [GENERAL HOMOTOPY EXTENSION THEOREM] Let $\mathcal{C}$ be a weakly hereditary class of normal spaces, X be an ANE($\mathcal{C}$), $Z \in \mathcal{C}$, Y a closed subspace of Z. Let f_0, f_1 be maps from Y to X, and $h : Y \times [0,1] \to X$ a homotopy from f_0 to f_1. If f_0 extends to a map $\bar{f}_0$ from Z to X, then the entire homotopy h extends to a homotopy $\bar{h} : Z \times [0,1] \to X$. In particular, f_1 extends to a function $\bar{f}_1 : Z \to X$ which is homotopic to $\bar{f}_0$. Taking $\mathcal{C} = \mathcal{M}$, ANE($\mathcal{C}$) can be replaced by ANR($\mathcal{M}$).

XIII.26.4.13. COROLLARY. Let $\mathcal{C}$ be a weakly hereditary class of normal spaces. An ANE($\mathcal{C}$) is an AE($\mathcal{C}$) if and only if it is contractible. An ANR($\mathcal{M}$) is an AR($\mathcal{M}$) if and only if it is contractible.

The Close Homotopy Theorem XIII.26.3.16. has a version for ANR($\mathcal{M}$)s. The proof is identical except that XIII.26.4.7. is used in place of embedding in a cube.

XIII.26.4.14. THEOREM. Let X be an ANR($\mathcal{M}$). Then for every open cover $\mathcal{U}$ of X there is a refinement $\mathcal{V}$ such that, whenever Z is a topological space and f and g are $\mathcal{V}$-close maps from Z to X, then f and g are $\mathcal{U}$-homotopic.

XIII.26.4.15. There appears to be a possibility of extending this result to nonmetrizable $\mathcal{C}$, since only XIII.26.4.7., which holds for arbitrary $\mathcal{C}$, and not the Dugundji Extension Theorem, is used in the proof. However, there is a subtlety: for the proof to work, X must be embeddable as a closed subset of a convex set *which is in* $\mathcal{C}$. It is unclear what classes besides $\mathcal{K}$, $\mathcal{M}$, and $\mathcal{KM}$ have this property. And even in the metrizable case, the $\epsilon - \delta$ version does not follow and is likely false in general, since an open cover of a noncompact metric space does not generally have a Lebesgue number.

Applications to the Compact Case

XIII.26.4.16. Proposition. Every AR [ANR] is an AE($\mathcal{N}$) [ANE($\mathcal{N}$)], and hence an AR($\mathcal{N}$) [ANR($\mathcal{N}$), A metrizable AR [ANR] is an AR($\mathcal{M}$) [ANR($\mathcal{M}$)].

This is a simple consequence of XIII.26.4.10. and the fact that any cube is an AE($\mathcal{N}$) by the Tietze Extension Theorem.

There is a local characterization of ANR($\mathcal{M}$)s:

XIII.26.4.17. Theorem. Let X be a metrizable space. Then X is an ANR($\mathcal{M}$) if (and only if) every point of X has an open neighborhood which is an ANR($\mathcal{M}$).

XIII.26.4.18. Corollary. Let X be a metrizable compactum. If every point of X has a compact neighborhood which is an ANR, then X is an ANR.

XIII.26.4.19. It is a consequence of XIII.26.4.11. that any ANR($\mathcal{M}$) (e.g. metrizable ANR) can be covered by open ANR($\mathcal{M}$)s of arbitrarily small diameter, i.e. there is a base for the topology consisting of ANR($\mathcal{M}$)s.

It might be asked whether a metrizable ANR can be covered by open sets of arbitrarily small diameter whose closures are ANRs, or even ARs. However, this is false in general: An example is given in [Bor67, VI.4] of a two-dimensional metrizable AR X such that every proper sub-AR of X is nowhere dense; thus X cannot be written as a countable union of proper sub-ARs, and hence there are points of x with no local base of ARs.

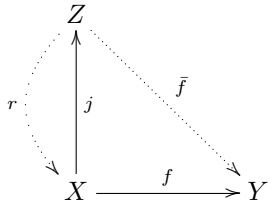
XIII.26.5. Affine Structure in ARs and ANRs

Whenever an AR X is embedded in a compact convex set K, the affine structure on K can be transferred to X via a retraction. This can also be done locally for an ANR. There is a particularly nice way to do this which is "almost canonical."

XIII.26.5.1. If X is a compactum, we can form the Bauer simplex Δ_X (), which is a compact convex set in the dual of the Banach space $C(X)$ of real-valued continuous functions on X. The elements of Δ_X can (at least if X is metrizable) be identified with the Borel probability measures on X, and the extreme points are the point masses at points of X, so the set of extreme points is closed and can be identified topologically with X.

A retraction from Δ_X to X transfers the affine structure of Δ_X to X. One gets not only a notion of convex combinations of points of X, but even a well-defined barycenter for any Borel probability measure on X. The affine structure on Δ_X does not depend on how X is identified with the extreme points of Δ_X, since a homeomorphism of X induces an affine homeomorphism of Δ_X. The induced affine structure on X does depend on what retraction is chosen, however, and is not invariant under homeomorphisms of X in general.

XIII.26.5.2. If X is an ANR, there is only a retraction of an open neighborhood U of X in Δ_X to X. If $p \in X$, there is a compact neighborhood A_p of p such that the closed convex hull of A_p is contained in U (); this closed convex hull is isomorphic to Δ_{A_p} (). Thus the affine structure of Δ_{A_p} can be transferred to X, so in a sense X has a "local affine structure." These are in a way even nicer than local coordinate systems on a manifold: when two of them overlap they agree on the overlap.



However, the local affine structure obtained from A_p is not an affine structure on A_p in general (e.g. a point of an ANR need not have a contractible neighborhood, cf. ()): a convex combination of points of A_p may lie outside p, although will lie in a "small" neighborhood of A_p in X (e.g. if V is an open neighborhood of p in X, A_p can be chosen so that convex combinations of points in A_p, or barycenters of measures, are always in V).

XIII.26.5.3. It is unclear whether these affine structures are well-behaved enough to be useful, but they are intriguing.

XIII.26.6. Exercises

XIII.26.6.1. Let X be an infinite set. Define $r : X \times \{0,1\} \to X \times \{0,1\}$ by $r((x,n)) = (x,0)$ for $x \in X$, $n \in \{0,1\}$. Show that if $X \times \{0,1\}$ has the finite complement topology (), then r is a retraction whose range is not closed.

XIII.26.6.2. Here is a variation on XIII.26.2.6.. Let X be an AR, embedded in a compactum Z. If Y is any topological space and $f : X \to Y$ a map, then f extends to a map $\bar{f} : Z \to Y$. [Let r be a retraction from Z to X, and set $\bar{f} = f \circ r$.]

XIII.26.6.3. Prove the following generalization of XIII.26.2.10.:

THEOREM. Let X be an AR. If X is embedded as a subspace of another AR Z, there is a strong deformation retraction of Z onto X.

(a) Let r be a retraction from Z to X, and let W be the mapping cylinder (XIII.9.5.10.) of r. Let Y be the subspace $(Z \times \{0\}) \cup (X \times [0,1])$ of W. There is an obvious function $f : Y \to Z$.

(b) An extension of f to W gives a strong deformation retraction of Z to X.

(c) Use the theorem to show that a compactum is an AR if and only if it is a strong deformation retract of a cube.

(d) Obtain XIII.26.2.10. as a special case of this theorem.

(e) Similarly show:

THEOREM. Let Z be an AR, and X a (necessarily closed) subset of Z. Any retraction from Z to X is strongly homotopic to the identity map ι_Z (i.e. homotopic with the points of X pointwise fixed).

XIII.26.6.4. Let Z be a finite-dimensional metrizable AR, and (Z_n) a sequence of pairwise disjoint sub-ARs of Z.

(a) Consider the decomposition $\sim$ of Z into the Z_n and singletons. Show that if the diameters of the Z_n (in some, hence any, metric on Z) go to zero, then the decomposition is usc.

(b) Let $X = Z/\sim$ be the quotient space. Show (cf. XIII.9.5.11.) that $dim(X) \leq dim(Z)$. Conclude from XIII.26.2.27. that X is an AR. X is "Z with all the Y_n collapsed to points."

(c) More generally, let f_n be a map of Z_n onto an AR Y_n for each n. Decompose Z into the preimages of points of the Y_n and singletons (show that this is usc), and let X be the quotient space. Show that X is an AR. [This does not follow from XIII.26.2.27., but an argument based on XIII.26.2.23. can be used.] By () we have $dim(X) \leq \max(dim(Z), \sup_n dim(Y_n))$.

The construction can also be done if the f_n are not surjective, but is more delicate since then the X is not a quotient of Z; it is tricky to even give the proper definition of X.

XIII.26.6.5. (a) Show that XIII.26.2.16. is equivalent to:

PROPOSITION. Let X be an AR. Then there is a horizontal strong deformation retraction of $X \times X$ onto the diagonal ["horizontal" means horizontal slices remain globally invariant].

(b) Similarly show that if κ is any cardinal, then there is a horizontal strong deformation retraction of X^κ to the diagonal.

(c) Does the property in (a) or (b) characterize ARs among all compacta? All metrizable compacta? (See [Bor69] for related results.)

(d) Discuss similar results and problems for ANRs.

XIII.26.6.6. Here is a nice application of XIII.26.6.4.(c) (see [Bor67,] for a nearly identical example). If $k \geq 3$, say a *k-star* consists of k copies of $[0,1]$ joined at 0. Fix $d \geq 2$, and let Z be the closed d-ball B^d or the d-cube $[0,1]^d$. Let S be an infinite subset of $\mathbb{N}$, and $\boldsymbol{k} = (k_1, k_2, \dots)$ a sequence listing the elements of S, with each $k \in S$ occurring infinitely often. Let (Z_n) be a sequence of pairwise disjoint subsets of the interior of Z whose diameters go to 0, where Z_n is a k_n-star, with $\cup_n Z_n$ dense in Z.

(a) Show that a k-star is an AR for any k.

(b) Let f_n be the obvious map of Z_n onto $[0,1]$ identifying together all the spikes. Use XIII.26.6.4.(c) to show that the quotient space $X_{\boldsymbol{k}}$ is an AR. (The notation is a little ambiguous, since $X_{\boldsymbol{k}}$ depends not only on $\boldsymbol{k}$ but also on how the Y_n are chosen.) $X_{\boldsymbol{k}}$ consists of Z with each star "puckered together."

(c) If S and S' are infinite subsets of $\mathbb{N}$ with $S \triangle S'$ infinite, and $\boldsymbol{k}$ and $\boldsymbol{k}'$ corresponding sequences, show that no open set in $X_{\boldsymbol{k}}$ can be homeomorphic to an open subset of $X_{\boldsymbol{k}'}$.

(d) Show that $dim(X_{\boldsymbol{k}}) = d$ for any $\boldsymbol{k}$.

(e) Conclude that there are $2^{\aleph_0}$ pairwise incomparable metrizable ARs of dimension d.

(f) Fix $\boldsymbol{k}$. Let C be the boundary sphere of Z. Then C embeds naturally in $X_{\boldsymbol{k}}$ since all the Y_n are disjoint from C. A space like $X_{\boldsymbol{k}}$ is described in [Bor67] as "a $(d-1)$-sphere with a membrane attached." Since $X_{\boldsymbol{k}}$ is contractible, C can be contracted to a point in $X_{\boldsymbol{k}}$. Show that C cannot be contracted to a point in any proper subcontinuum of $X_{\boldsymbol{k}}$ containing it.

(g) If $\boldsymbol{k}$ has no repeated terms, the identical construction gives a two-dimensional AR $X_{\boldsymbol{k}}$ which is totally inhomogeneous. There are $2^{\aleph_0}$ pairwise nonhomeomorphic such $X_{\boldsymbol{k}}$ (although they are not all pairwise incomparable). Compare with XIII.19.6.11..

XIII.26.6.7. [**?**,] Let $T = [0,1]^\kappa$, where κ is uncountable. Denote by $\mathbf{0}$ the point of T with all coordinates 0. Let $Z = [0,1] \times T$; then $Z \cong T$ is an AR. Set $X_1 = [0,1] \times \{\mathbf{0}\}$ and $X_2 = \{0\} \times T$. Then $X_1 \cong [0,1]$ and $X_2 \cong T$ are ARs, and $X_1 \cap X_2 = \{(0,\mathbf{0})\}$ is also an AR. If $X = X_1 \cup X_2$, show that there is no retraction of Z onto X, so X is not an AR; in fact there is no retraction of any neighborhood of X in Z to X, so X is not an ANR. [$X_1 \setminus \{(0,\mathbf{0})\}$ and $X_2 \setminus \{(0,\mathbf{0})\}$ do not have disjoint neighborhoods in $Z \setminus \{(0,\mathbf{0})\}$.] Contrast with XIII.26.2.20.(i).

XIII.26.6.8. Let X be a metrizable ANR. Prove the metric statement in XIII.26.3.16., as follows:

(a) Show that if the statement is true for one metric, it is true (with possibly different δ) for any other metric. [By compactness, any two metrics are uniformly equivalent.]

(b) Let $\epsilon > 0$. Let $\mathcal{U}$ be the covering of X by balls of radius $\frac{\epsilon}{2}$. Define $\tilde{\mathcal{U}}$, $\tilde{\mathcal{V}}$, $\mathcal{V}$ as in the proof.

(c) Let $\delta > 0$ be a Lebesgue number for the cover $\mathcal{V}$. Show that this δ works.

XIII.26.6.9. Let X be a compact subset of $\mathbb{R}^n$. If there is a retraction of X onto ∂X, show that $X = \partial X$, i.e. the interior X° of X is empty. [Embed X in a closed ball B, and let S be the boundary sphere of B. Show there is a retraction of B onto $B \setminus X^\circ$. If $X^\circ \neq \emptyset$, compose this retraction with a retraction of $B \setminus X^\circ$ to S, contradicting the Brouwer Fixed-Point Theorem.] In particular, if U is a bounded open set in $\mathbb{R}^n$, there is no retraction of $\bar{U}$ onto ∂U.

XIII.26.6.10. Let X be a subset of $\mathbb{R}^n$ which is an ANR. Show that $\mathbb{R}^n \setminus X$ has only finitely many components, as follows.

(a) Let U be a bounded open neighborhood of X in $\mathbb{R}^n$ with a retraction r from U to X. Show that every component C of $\mathbb{R}^n \setminus X$ meets $\mathbb{R}^n \setminus U$. [If C is a component of $\mathbb{R}^n \setminus X$ contained in U, then $\partial C \subseteq X$ and r defines a retraction of $\bar{C}$ to ∂C, contradicting XIII.26.6.9..]

(b) Let B be a closed ball containing U, and $\mathcal{C} = \{C_i : i \in I\}$ the set of all components of $\mathbb{R}^n \setminus X$. Show that $\mathcal{C}$ is an open cover of $B \setminus U$. So $\mathcal{C}$ has a finite subcover. Since the sets in $\mathcal{C}$ are pairwise disjoint, conclude that I is finite.

(c) If X is an AR and $n > 1$, show that $\mathbb{R}^n \setminus X$ is connected.

XIII.26.6.11. Prove or disprove: if X is an AR, and (X_n) a decreasing sequence of sub-ARs of X, then $\cap_n X_n$ is also an AR. [Consider the pseudo-arc.]

The corresponding statement for ANRs is false: the Cantor set is a counterexample.

XIII.26.6.12. Is every compact convex set in a locally convex topological vector space homeomorphic to a cube? Is such a set at least an AR? This is true in the metrizable case by [Kle55].

Chapter XIV

Differential Geometry and Topology

In this chapter, we describe the basics of the theory of smooth manifolds and smooth maps between them, although it is beyond the scope of this book to give anything close to a complete treatment of this entire large branch of mathematics.

XIV.1. Smooth Manifolds

Smooth manifolds are a generalization of smooth curves and surfaces. They are topological manifolds in the sense of XIII.20.1.7. with extra structure allowing notions of calculus and geometry to be sensibly used. They are the basic objects of study in differential geometry and topology.

There are at least two reasonable approaches to the concept of smooth manifolds. We can define them to be

(1) Nicely behaved subsets of $\mathbb{R}^n$ (*concrete (smooth) manifolds*)

or

(2) Abstract spaces with a collection of local charts covering the space smoothly compatible on the intersections (*abstract (smooth) manifolds*)

The second approach is apparently more general, although it motivates the definition of "nicely behaved" in the first approach. But the Whitney Embedding Theorem says the two approaches are equivalent: every abstract (smooth) n-manifold is diffeomorphic to a concrete (smooth) manifold, in fact a (smooth) submanifold of $\mathbb{R}^{2n+1}$.

Each approach has its advantages and disadvantages. Concrete manifolds have a conceptual advantage since they are, well, *concrete*: they can generally be pictured as geometric objects. There are also considerable technical advantages in working with concrete manifolds. On the other hand, there are some disadvantages:

(i) Any concrete manifold sits in a specific way in a Euclidean space. Two concrete manifolds can be diffeomorphic () but sit differently in Euclidean space, even in spaces of different dimensions. It can be difficult to separate intrinsic (up to diffeomorphism) properties of a manifold from properties depending on how it is embedded in Euclidean space.

(ii) Some important manifolds (e.g. Lie groups) do not have a natural embedding in Euclidean space, and the various ways they can be embedded can be complicated. For example, it is a large and important industry to describe how Lie groups can be represented as (closed) subgroups of $GL_n(\mathbb{R})$ for various n ().

(iii) Abstract manifolds arising in applications frequently have additional structure, e.g. a Riemannian metric, which play a crucial role. As a simple example, a Lie group has a volume form from Haar measure (). These additional structures do not necessarily come from Euclidean space via an embedding.

For ease of exposition, we will mostly take the first approach, but will describe the second also. Thus for us, "manifold" will generally mean "concrete manifold" unless otherwise specified.

There are various flavors of smooth manifolds. We will mostly consider only $\mathcal{C}^\infty$-manifolds, which are generally the most important; there are also $\mathcal{C}^r$-manifolds for any $r \in \mathbb{N}$, and (real and complex) analytic manifolds. (The study of $\mathcal{C}^r$-manifolds is important in some contexts, but can be largely reduced to the $\mathcal{C}^\infty$ case since every $\mathcal{C}^r$-manifold has an essentially unique compatible structure as a $\mathcal{C}^\infty$-manifold. Analytic manifolds are another story, cf. ().) To avoid unnecessary verbosity, in this chapter "smooth" will always mean $\mathcal{C}^\infty$, and "manifold" will mean "smooth manifold" (i.e. $\mathcal{C}^\infty$-manifold) unless specifically qualified otherwise.

We will change some of our notational conventions from vector calculus. In particular, we will not use boldface to denote points in Euclidean space or functions between Euclidean spaces. Some indexing conventions will also be different.

XIV.1.1. Concrete Manifolds

XIV.1.1.1. Definition. Let $m.p \in \mathbb{N}$, $m \leq p$, $r \in \mathbb{N} \cup \{0\} \cup \{\infty\}$. A *concrete $\mathcal{C}^r$ m-submanifold of $\mathbb{R}^p$* is a nonempty subset M of $\mathbb{R}^p$ with the property that for every $x \in M$, there is an open neighborhood U of x (in $\mathbb{R}^p$) and a $\mathcal{C}^r$-diffeomorphism f from U onto an open ball B around 0 in $\mathbb{R}^p$ such that $f(U \cap M) = B \cap \mathbb{R}^m$, where $\mathbb{R}^m$ is regarded as the subspace of $\mathbb{R}^p$ whose last $p - m$ coordinates are 0. The preimages of the first m coordinate axes under f are a *set of local coordinates* for M around x. Such an f is a *local straightening function* around x, and $f^{-1}|_{\mathbb{R}^m}$ a *local coordinate function* or *local parametrization* around x.
A *(concrete $\mathcal{C}^r$) m-manifold* is a concrete $\mathcal{C}^r$ m-submanifold of $\mathbb{R}^p$ for some $p \geq m$.
(Recall that a $\mathcal{C}^r$ diffeomorphism is a bijection such that both f and f^{-1} are $\mathcal{C}^r$.)

XIV.1.1.2. We will almost exclusively consider the case $r = \infty$, and in this section "manifold" without additional qualification will mean "$\mathcal{C}^\infty$-manifold." Most of what we do generalizes to the $\mathcal{C}^r$ case for $r \geq 1$ ($\mathcal{C}^0$-manifolds are essentially just topological manifolds).

XIV.1.1.3. A $\mathcal{C}^r$ m-manifold M in $\mathbb{R}^p$ has a natural topology, the relative topology from $\mathbb{R}^p$ (we will always use this topology), which is locally Euclidean, and which is obviously metrizable, hence M is a topological m-manifold in the sense of XIII.20.1.7.. Thus all results from that section apply.

XIV.1.1.4. By this definition, the local dimension m of an m-manifold is constant. We could more generally let the local dimension vary, but this is of little benefit and it is cleaner to work with manifolds of constant dimension. (The local dimension would always be at least locally constant, hence constant on connected components; we primarily consider connected manifolds anyway.) It is convenient notation to denote the dimension of M by m.

XIV.1.1.5. The ambient space $\mathbb{R}^p$ is generally unimportant, at least for this section; it is sort of a geometric version of a set-theoretic universe which just facilitates picturing and working with manifolds. However, a concrete submanifold M of $\mathbb{R}^p$ inherits additional structure from the ambient space not part of its manifold structure: for example, m-dimensional Hausdorff measure on $\mathbb{R}^p$ (XVII.6.4.3.) defines a σ-finite measure (m-volume) on M which depends greatly on how M is embedded.

XIV.1.1.6. An m-submanifold M is not generally closed in $\mathbb{R}^p$, although every point of M has a neighborhood (in the relative topology) which is compact and thus closed in $\mathbb{R}^p$. For example, if $m = p$, any m-submanifold of $\mathbb{R}^m$ is an open set by Invariance of Domain () (or by the Inverse Function Theorem); conversely, any nonempty open set in $\mathbb{R}^m$ is an m-submanifold: the local coordinate function f could be just taken to be a translation.

XIV.1.1.7. We can extend the definition to the case $m = 0$: a 0-submanifold (automatically smooth) in $\mathbb{R}^p$ is just a set of points which is discrete in the relative topology. (We could also let $p = 0$, taking $\mathbb{R}^0 = \{0\}$, not a very interesting case.)

XIV.1.1.8. Being an m-submanifold of $\mathbb{R}^p$ is strictly a local property: if $M \subseteq \mathbb{R}^p$ has the property that for each $x \in M$, there is an open neighborhood V of x in $\mathbb{R}^p$ such that $M \cap V$ is an m-submanifold, then M is also an m-submanifold. (Specifying m is necessary here since we are requiring constant local dimension.) The converse is also trivially true; in fact if M is an m-submanifold, then so is $M \cap V$ for every open set V in $\mathbb{R}^p$ for which $M \cap V \neq \emptyset$. (We do not consider $\emptyset$ to be a manifold: what would its dimension be?)

Local Coordinate Functions

XIV.1.1.9. There is, of course, nothing unique about a local straightening function or local coordinates around a point x of a manifold. We could require that $f(x) = 0$, but it is sometimes convenient not to do this. We could also relax or modify the definition of a local straightening function to allow the target set B to be any open set in $\mathbb{R}^p$, since such a function could be restricted to have an open ball as image. We could also require that B be a different kind of open set such as a rectangle centered at 0

$$\{(x_1, \ldots, x_p) : -a_j < x_j < a_j\}$$

for $a_j > 0$, $1 \leq j \leq p$, or an open cube

$$\{(x_1, \ldots, x_p) : -a < x_j < a\}$$

for $a > 0$, since such a set contains an open ball around 0, and conversely. By scaling, we could require the target set to be the open unit ball or open cube with $a = 1$. We could even require the target to be the entire space $\mathbb{R}^p$, although this is rarely useful.

Examples

XIV.1.1.10. As noted above, $\mathbb{R}^m$ itself, or any nonempty open set in $\mathbb{R}^m$, is an m-submanifold of $\mathbb{R}^m$.

XIV.1.1.11. Any m-dimensional affine subspace of $\mathbb{R}^p$ is an m-submanifold. Local straightening functions can be taken to be affine functions.

XIV.1.1.12. Let U be an open set in $\mathbb{R}^m$, and g a smooth function from U to $\mathbb{R}^n$. Then the graph $\Gamma = \{(x, g(x)) : x \in U\}$ of g is an m-submanifold of $\mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$: a local (even global) straightening function f can be defined by $f(x, y) = (x, y - g(x))$. Thus, for example, S^m is an m-submanifold of $\mathbb{R}^{m+1}$ for any m since it is locally the graph of a smooth function (cf. XIV.1.1.8.). More generally, many subsets of Euclidean space arising as in VIII.5.1.18. are submanifolds by the Implicit Function Theorem.

XIV.1.1.13. If M is an m-submanifold of $\mathbb{R}^p$ and N an n-submanifold of $\mathbb{R}^q$, then $M \times N$ is a $(m+n)$-submanifold of $\mathbb{R}^p \times \mathbb{R}^q = \mathbb{R}^{p+q}$. The product of two local straightening functions is a local straightening function (cf. XIV.1.1.9.).

XIV.1.2. Smooth Maps and Diffeomorphisms

If U is an open set in $\mathbb{R}^q$, there is a well-defined notion of a smooth ($\mathcal{C}^\infty$) map from U to $\mathbb{R}^p$ for any p (). Note that this is strictly a local condition. We extend this to arbitrary subsets of $\mathbb{R}^q$:

XIV.1.2.1. Definition. Let $X \subseteq \mathbb{R}^q$, $Y \subseteq \mathbb{R}^p$, and $f : X \to Y$ be a function. Then f is a *smooth function* if for each $x \in X$, there is an open neighborhood U of x in $\mathbb{R}^q$ and a smooth function $h : U \to \mathbb{R}^p$ such that $h|_{U \cap X} = f|_{U \cap X}$, i.e. f locally extends to a smooth function on a neighborhood of each point. The function f is a *diffeomorphism* if f is a smooth bijection and f^{-1} is also smooth, and is a *local diffeomorphism* if for each $x \in X$ there is a relatively open set V containing x such that $f(V)$ is relatively open in Y and $f|_V$ is a diffeomorphism of V to $f(V)$.

It is obvious (from the corresponding result on open sets, i.e. the Chain Rule) that a composition of smooth maps is smooth.

XIV.1.2.2. Note that a diffeomorphism from X to Y does not necessarily extend even locally to a diffeomorphism of point neighborhoods. In fact, X and Y could be subsets of Euclidean spaces of different dimensions. Even if the dimensions of the ambient spaces are the same, it is not obvious that a diffeomorphism extends locally to diffeomorphisms of neighborhoods (it does for submanifolds, cf.()).

The next result gives an important alternate characterization of manifolds:

XIV.1.2.3. Theorem. Let M be a nonempty subset of $\mathbb{R}^p$. Then M is an m-submanifold of $\mathbb{R}^p$ if and only if M is locally diffeomorphic to $\mathbb{R}^m$, i.e. for every $x \in M$, there is a relatively open neighborhood V of x which is diffeomorphic to $\mathbb{R}^m$ (or to an open ball or open cube in $\mathbb{R}^m$). The preimage of the coordinate axes under such a local diffeomorphism is a set of local coordinates for M around x.

Proof: If M is an m-submanifold of $\mathbb{R}^p$ and $x \in M$, a local straightening function from an open neighborhood U of x in $\mathbb{R}^p$ to an open ball B in $\mathbb{R}^q$ gives a local diffeomorphism of $V = U \cap M$ onto the open ball $B \cap \mathbb{R}^m$. Conversely, suppose for each $x \in M$ there is a neighborhood V of x in M and a diffeomorphism h from V to $\mathbb{R}^m$. Fix x, V, and h. Since h is smooth, there is an open neighborhood U of x in $\mathbb{R}^p$ with $U \cap M \subseteq V$ and a smooth map $g : U \to \mathbb{R}^m$ extending h. The map g must have rank m at all points of a (possibly smaller) neighborhood of X. Thus, by the Domain Straightening Theorem (), there is a neighborhood W of x in $\mathbb{R}^p$ contained in U and a change of coordinates in W such that $g|_W$ consists of projection onto the first m coordinates followed by a diffeomorphism, giving a local straightening function around x. Thus M is an m-submanifold of $\mathbb{R}^p$.

We will often use this alternate characterization.

XIV.1.2.4. Corollary. Let $M \subseteq \mathbb{R}^p$ and $N \subseteq \mathbb{R}^q$. If M and N are diffeomorphic, and M is an m-submanifold of $\mathbb{R}^p$, then N is an m-submanifold of $\mathbb{R}^q$.

XIV.1.2.5. We often regard diffeomorphic manifolds as being the "same," and the main goal of differential topology is to understand manifolds up to diffeomorphism.

Submanifolds

XIV.1.2.6. Definition. Let M be a submanifold of $\mathbb{R}^p$. A *submanifold* of M is a subset of M which is also a submanifold of $\mathbb{R}^p$.

XIV.1.2.7. This definition is consistent with the previous use of "submanifold": a submanifold of $\mathbb{R}^p$ is a submanifold of the submanifold $\mathbb{R}^p$ of $\mathbb{R}^p$. Any open subset of an m-submanifold M of $\mathbb{R}^p$ is a submanifold. See XIV.1.2.8.(ii) for a converse, a version of Invariance of Domain.

XIV.1.2.8. Theorem. Let M be an m-submanifold of $\mathbb{R}^p$, and N a submanifold of M which is an n-submanifold of $\mathbb{R}^p$. Then

(i) $n \leq m$.

(ii) If $n = m$, then N is an open subset of M.

(iii) For any $x \in N$, there is a straightening function f for M around x which is also a straightening function for N around x. Equivalently, there is a set of local coordinates for M around x such that the first n of the coordinates are a set of local coordinates for N around x.

Proof: Let $x_0 \in N$, and let g be a straightening function for M around x_0, i.e. $g : U \to B$ a diffeomorphism with $g(U \cap M) = B \cap \mathbb{R}^m$ and U an open neighborhood of x_0 in $\mathbb{R}^p$. Then $g(U \cap N)$ is a subset of $\mathbb{R}^m$ diffeomorphic to $U \cap N$, which is a manifold; hence $N' = g(U \cap N)$ is a submanifold of $\mathbb{R}^m$ (thus $n \leq m$, proving (i)). Let $y_0 = g(x_0)$, and let h be a straightening function for $N' \subseteq \mathbb{R}^m$ around y_0, i.e. $h : V \to A$ a diffeomorphism with $h(V \cap N') = A \cap \mathbb{R}^n$, A an open ball in $\mathbb{R}^m$, and V an open neighborhood of y_0 in $\mathbb{R}^m$.

If $n = m$, N' fills an entire neighborhood of y_0 in $\mathbb{R}^m$, and hence N fills an entire neighborhood of x_0 in M. Since x_0 is an arbitrary point of N, N is open in M, proving (ii).

Suppose $n < m$. There is an open neighborhood W of y_0 in $\mathbb{R}^m$ contained in V such that $W \times C \subseteq B$, where C is an open ball around 0 in $\mathbb{R}^{m-n}$. The diffeomorphism h extends to a diffeomorphism ϕ on $W \times C$ defined by $\phi(y, z) = (h(y), z)$. The diffeomorphism $f = \phi \circ g$ defined on a smaller neighborhood of x_0 is a simultaneous straightening function for M and N around x_0. 👍

XIV.1.2.9. This can be iterated: any (finite) chain of submanifolds can be simultaneously straightened.

XIV.1.3. Tangent Space and Tangent Bundle

A curve in $\mathbb{R}^2$ has a tangent line at each point, and a surface in $\mathbb{R}^3$ has a tangent plane at each point (). If the curve or surface is the graph of a function, the tangent line or plane can be described simply. Every submanifold of $\mathbb{R}^p$ has a tangent space at each point generalizing these.

XIV.1.3.1. Let M be an m-submanifold of $\mathbb{R}^p$, and $x \in M$. To define the tangent space to M at x, let f be a straightening function for M around x, a diffeomorphism from an open set in $\mathbb{R}^p$ containing x onto an open ball B in $\mathbb{R}^p$ around 0, with $f(U \cap M) = B \cap \mathbb{R}^m$ and $f(x) = 0$. The inverse map f^{-1} has invertible total differential $d(f^{-1})(0)$, an invertible linear transformation from $\mathbb{R}^p$ to $\mathbb{R}^p$. This linear transformation sends $\mathbb{R}^m$ onto an m-dimensional vector subspace of $\mathbb{R}^p$.

XIV.1.3.2. Definition. The image of $\mathbb{R}^m$ under $d(f^{-1})(0)$ is the *tangent space* to M at x, denoted T_xM.

XIV.1.3.3. To see that this subspace is independent of the straightening function, let g be another straightening function around x. By cutting down neighborhoods, $f \circ g^{-1}$ is a diffeomorphism of a neighborhood of 0 to another neighborhood of 0 leaving the intersection with $\mathbb{R}^m$ invariant, so $d(f \circ g^{-1})(0)$ is an invertible linear map on $\mathbb{R}^p$ sending $\mathbb{R}^m$ onto $\mathbb{R}^m$. Thus $d(g^{-1})(0)$, which equals $d(f^{-1})(0) \circ d(f \circ g^{-1})(0)$ by the Chain Rule, sends the subspace $\mathbb{R}^m$ to the same subspace as $d(f^{-1})(0)$.

XIV.1.3.4. Here is a better way to think of the tangent space at x. Let ϕ be a local diffeomorphism from M to $\mathbb{R}^m$ around x with $\phi(x) = 0$. Then ϕ^{-1} is a smooth function from $\mathbb{R}^m$ to $\mathbb{R}^p$ with $\phi^{-1}(0) = x$, so $d(\phi^{-1})(0)$ is a linear transformation from $\mathbb{R}^m$ to $\mathbb{R}^p$. The tangent space T_xM is the range of $d(\phi^{-1})(0)$, as is easily seen from the proof of (). The trouble with defining the tangent space this way is that it is (slightly) harder to see directly that it is an m-dimensional subspace, i.e. that $d(\phi^{-1})(0)$ has rank m.

XIV.1.3.5. The tangent space T_xM to M at x is a vector subspace of $\mathbb{R}^p$, and hence goes through the origin and (usually) not x. But it can be translated by x to give the affine space tangent to M at x, thinking of a vector $v \in T_xM$ as a vector "beginning at x" to $x + v$, as is easily seen in the curve and surface cases where it can be pictured.

The Tangent Bundle

The tangent spaces to M can all be tied together into one space:

XIV.1.3.6. Definition. Let M be an m-submanifold of $\mathbb{R}^p$. The *tangent bundle* of M, denoted TM, is

$$TM = \{(x, v) : x \in M, v \in T_xM\} \subseteq \mathbb{R}^p \times \mathbb{R}^p \cong \mathbb{R}^{2p} .$$

XIV.1.3.7. Proposition. If M is an m-manifold in $\mathbb{R}^p$, then TM is a $2m$-manifold in $\mathbb{R}^{2p}$.

XIV.1.3.8. TM is also a vector bundle over M in the sense of (). The local triviality can be seen by straightening, since a straightening around a point x is also a straightening around y for any y sufficiently close to x.

XIV.1.3.9. EXAMPLE. Even if M is the graph of a function from $\mathbb{R}$ to $\mathbb{R}$, the simplest kind of 1-manifold in $\mathbb{R}^2$, the tangent bundle is a 2-manifold in $\mathbb{R}^2 \times \mathbb{R}^2 \cong \mathbb{R}^4$ and thus is difficult to visualize. Suppose g is a smooth function from $\mathbb{R}$ to $\mathbb{R}$ and Γ is its graph. If $x_0 \in \mathbb{R}$, a smoothing for Γ around $(x_0, g(x_0))$ is given by $f(x, y) = (x - x_0, y - g(x))$, so $f^{-1}(x, y) = x + x_0, y + g(x + x_0))$ and we have

$$D(f^{-1})(0,0) = \begin{bmatrix} 1 & 0 \\ g'(x_0) & 1 \end{bmatrix}$$

so $T_{(x_0,g(x_0))}\Gamma$ is the subspace of $\mathbb{R}^2$ spanned by the image of (1,0):

$$T_{(x_0,g(x_0))}\Gamma = \{(t, g'(x_0)t) : t \in \mathbb{R}\}$$

which is the line through the origin with slope $g'(x_0)$, as it should be.

This can be seen alternately by taking the local homeomorphism $\phi : \Gamma \to \mathbb{R}^1$ given by $\phi(x, g(x)) = x - x_0$. Then $\phi^{-1}(x) = (x + x_0, g(x + x_0))$, so

$$D(\phi^{-1})(0) = \begin{bmatrix} 1 \\ g'(x_0) \end{bmatrix}$$

and $T_{(x_0,g(x_0))}\Gamma$ is the range of the linear transformation with this matrix.

The tangent bundle is thus

$$T\Gamma = \{(x, y, z, w) : y = g(x), w = g'(x)z)\} = \{(x, g(x), z, g'(x)z) : x, z \in \mathbb{R}\} \subseteq \mathbb{R}^4 \ .$$

This can be pictured by ignoring the second coordinate (projecting into (x, z, w)-space), i.e. "straightening" the graph. We obtain the surface

$$S = \{(x, z, g'(x)z) : x, z \in \mathbb{R}\}$$

which is the graph of the function $h(x, z) = g'(x)z$. The section of this surface by the plane parallel to the zw-plane with x-coordinate x_0 is the straight line through the origin with slope $g'(x_0)$.

Chapter XV

Algebraic Topology

Algebraic topology is one of the most important parts of the vast subject of topology. In a nutshell, it is the process of assigning algebraic invariants to topological spaces and using algebraic techniques to obtain results about the topology of spaces. One of the most important uses is to distinguish topological spaces by showing that an algebraic invariant differs.

Algebraic topology is an outgrowth of "combinatorial topology" (Emmy Noether was one of the most influential people in the transition in the 1920s and 1930s), and much of algebraic topology has a distinct combinatorial flavor. Indeed, homological algebra (which can be thought of as "algebraic topology with the topology abstracted out") is heavily combinatorial.

Topology is often thought of as dividing into two rather separate parts: "point-set topology" and "algebraic topology" ("point-set topology" is the subject matter of Chapter ()). Almost all topology texts are strictly limited to one or the other, although algebraic topology texts must include a certain amount, generally small, of point-set topology. Algebraic topology has developed into a huge discipline in its own right. But an arguably better point of view is that algebraic topology is a fundamental tool within the overall subject of topology, where "point-set topology" is the foundational material. A good, but imperfect, analogy is to compare algebraic topology within topology to functional analysis as a part of analysis; in this analogy point-set topology might be analogous to calculus. There are other subdisciplines in topology such as "low-dimensional topology," just as there are other subdisciplines in analysis such as differential equations; low-dimensional topology heavily uses algebraic topology as a tool, just as the subject of differential equations uses functional analysis.

The Limitations of Algebraic Topology

Although algebraic topology is extremely powerful within its domain of application, it has at least two important limitations:

(i) Most algebraic topology techniques only apply or are useful within a tiny corner of the world of topological spaces, although this corner consists of the most nicely-behaved and arguably most interesting and important topological spaces (manifolds, cell complexes, etc.)

(ii) Even within this well-behaved corner, algebraic topology invariants are homotopy invariants, and hence cannot distinguish between homotopy-equivalent spaces. Pure algebraic topology cannot even distinguish the real line from a single point! Some elementary point-set topology is needed. A little more point-set topology is needed to distinguish $\mathbb{R}^1$ from $\mathbb{R}^2$, or $\mathbb{R}^n$ and $\mathbb{R}^m$ for $n \neq m$ (the one-point compactification operation

plus some algebraic topology is the easiest way). Algebraic topology cannot even always distinguish between spaces which are not homotopy equivalent, such as the real line and the long line (), where some elementary point-set topology does the trick.

The moral is that algebraic and point-set techniques are intertwined and need to be used together.

Our treatment of algebraic topology will be rudimentary, partly because much of it is somewhat off the subject of analysis. A far better and more complete online treatment is [Hat02]. There are also many books on the subject. Actually algebraic topology is such a large discipline that no book can treat the entire subject, so interested readers should explore widely.

XV.1. Homotopy and the Fundamental Group

XV.1.1. Homotopy

Homotopy is the careful mathematical formulation of the notion of "continuous deformation," one of the most important ideas in topology and the basis for the entire subject of algebraic topology. There are several slight variations which we will discuss. If f and g are continuous functions between topological spaces X and Y, we want to describe how f can be "continuously deformed" to g; the intuitive idea is that there should be a "continuous path" (f_t) (say, for $0 \le t \le 1$) of continuous functions with $f_0 = f$, $f_1 = g$. Experience shows that the following definition is the appropriate one:

XV.1.1.1. DEFINITION. Let X and Y be topological spaces, and $f_0, f_1 : X \to Y$ continuous functions. A *homotopy* from f_0 to f_1 is a continuous function $H : X \times [0,1] \to Y$ with $H(x,0) = f_0(x)$ and $H(x,1) = f_1(x)$ for all $x \in X$. Two continuous functions f and g from X to Y are *homotopic*, written $f \simeq g$, if there exists a homotopy from f to g.

XV.1.1.2. We can then define, for fixed $t \in [0,1]$, a continuous function $f_t : X \to Y$ by $f_t(x) = H(x,t)$ for $x \in X$. The functions f_t "vary continuously" from f_0 to f_1 as t varies from 0 to 1. The f_t are "jointly continuous" in x and t. We often think of the homotopy H as being the family (f_t) of deformations of f_0 to f_1.

XV.1.1.3. The choice of $[0,1]$ for the parametrizing interval is arbitrary, as is the specification that H goes from $X \times [0,1]$ to Y instead of from $[0,1] \times X$ to Y (the opposite convention is also common in references). To add to the potential notational confusion, in many applications the space X will also be $[0,1]$.

XV.1.1.4. In considering homotopies, the target space Y must be carefully specified or understood. If Y is a subspace of a larger space Z, and $f, g : X \to Y$, then f and g can well be homotopic as maps from X to Z but not as maps from X to Y, i.e. a homotopy might necessarily pass through points of Z outside Y. Thus we should really write $f \simeq g$ in Y (although we usually don't).

XV.1.1.5. If $f \simeq g$ via a homotopy H, then for any $x \in X$ the function $\gamma_x : [0,1] \to Y$ defined by $\gamma_x(t) = H(x,t)$ is a continuous path in Y from $f(x)$ to $g(x)$. In particular, if $f \simeq g$, then for every $x \in X$, $f(x)$ and $g(x)$ must be in the same path component of Y.

XV.1.1.6. EXAMPLES. (i) Two constant functions from X to Y with values y_0 and y_1 are homotopic if and only if y_0 and y_1 are in the same path component of Y. Necessity comes from XV.1.1.5.. Conversely, if $\gamma : [0,1] \to Y$ is a path from y_0 to y_1, set $H(x,t) = \gamma(t)$; then H is a homotopy (via constant functions). In particular, if Y is path-connected, any two constant functions from any X to Y are homotopic.

(ii) A very special but important case is when the space Y is a convex subset of $\mathbb{R}^n$ or, more generally, of a topological vector space. If X is any topological space, then any two continuous functions f and g from X to Y are homotopic by a homotopy of the form

$$H(x,t) = tg(x) + (1-t)f(x) \ .$$

Such a homotopy is called a *linear homotopy*, and is defined only when Y has additional structure from a topological vector space.

The first fundamental property of homotopy is:

XV.1.1.7. PROPOSITION. Let X and Y be topological spaces. Then homotopy is an equivalence relation on the set of maps (continuous functions) from X to Y.

PROOF: Reflexivity and symmetry are very simple, but transitivity, although it is relatively simple also, involves an important notion of concatenation for homotopies.
If $f : X \to Y$, define $H(x,t) = f(x)$ for all x, t. Then H is a homotopy from f to f, so homotopy is reflexive.
If H is a homotopy from f_0 to f_1, define $\tilde{H} : X \times [0,1] \to Y$ by $\tilde{H}(x,t) = H(x, 1-t)$. Then $\tilde{H}$ is a homotopy from f_1 to f_0. Thus homotopy is symmetric.
Let H_1 be a homotopy from f_0 to f_1, and H_2 a homotopy from f_1 to f_2. Define $H : X \times [0,1] \to Y$ by

$$H(x,t) = \begin{cases} H_1(x,2t) & \text{if} \quad 0 \le t \le \frac{1}{2} \\ H_2(x,2t-1) & \text{if} \quad \frac{1}{2} < t \le 1 \end{cases} .$$

Then H is continuous since $H_1(x,1) = H_2(x,0) = f_1(x)$ for all x, and is a homotopy from f_0 to f_2. 👍

Homotopy respects compositions:

XV.1.1.8. PROPOSITION. Let X, Y, Z be topological spaces, and let $f, f_0, f_1 : X \to Y$ and $g, g_0, g_1 : Y \to Z$ with $f_0 \simeq f_1$ and $g_0 \simeq g_1$. Then $g_0 \circ f_0 \simeq g_1 \circ f_1$. In particular, $g \circ f_0 \simeq g \circ f_1$ and $g_0 \circ f \simeq g_1 \circ f$.

PROOF: We need only prove the last statement, since then $g_0 \circ f_0 \simeq g_0 \circ f_1$ and $g_0 \circ f_1 \simeq g_1 \circ f_1$, so $g_0 \circ f_0 \simeq g_1 \circ f_1$ by XV.1.1.7..
If H is a homotopy from f_0 to f_1, define $\tilde{H}(x,t) = g(H(x,t))$; then $\tilde{H}$ is a homotopy from $g \circ f_0$ to $g \circ f_1$.
If H is a homotopy from g_0 to g_1, define $\tilde{H}(x,t) = H(f(x),t)$; then $\tilde{H}$ is a homotopy from $g_0 \circ f$ to $g_1 \circ f$.
👍

Contractible Spaces

XV.1.1.9. DEFINITION. If X and Y are topological spaces, and $f : X \to Y$ is a map, then f is *nullhomotopic* if it is homotopic to a constant function.
A topological space X is *contractible* if the identity map on X is nullhomotopic, i.e. homotopic to a constant function from X to X.

XV.1.1.10. If X is contractible and H is a homotopy from the identity map ι_X to a constant function with value p, then the functions f_t "contract" the space down to the point p, and we say X is *contractible to p*. But a contractible space is path-connected since every point of X can be connected to p by a path, so if X is contractible to p it is also contractible to q for any other point q.

XV.1.1.11. EXAMPLES. (i) If X is a convex subset of $\mathbb{R}^n$, or more generally of a topological vector space, then X is contractible to any point vis a linear homotopy (XV.1.1.6.(ii)). In particular, $[0,1]$ is contractible, as is any ball in $\mathbb{R}^n$.

(ii) Let X be the infinite comb (). Then X is contractible by first moving all points down to the x-axis and then moving them to $\mathbf{0}$.

(iii) It is a fundamental theorem of topology, equivalent to the Brouwer fixed-point theorem, that S^n is not contractible for any n (). Note that S^n is path-connected for $n > 0$.

The next result is a special case of XV.1.1.8..

XV.1.1.12. PROPOSITION. Let X and Y be topological spaces. If either X or Y is contractible, then every map from X to Y is nullhomotopic. If Y is path-connected, any two maps from X to Y are homotopic.

Homotopy Relative to a Subspace

An important variation is homotopy relative to a subspace:

XV.1.1.13. DEFINITION. Let X and Y be topological spaces, and $A \subseteq X$, $B \subseteq Y$. Let f_0, f_1 be maps from X to Y for which $f_0(A), f_1(A) \subseteq B$. Then a *homotopy from f_0 to f_1 relative to* (A, B) is a continuous function $H : X \times [0,1] \to Y$ such that $H(x,0) = f_0(x)$ and $H(x,1) = f_1(x)$ for all $x \in X$ and $H(x,t) \in B$ for all $x \in A$ and all t. If there is such a homotopy, write $f_0 \simeq f_1$ rel (A, B).

XV.1.1.14. A homotopy relative to a subspace is a homotopy. But the notion is much more restrictive, since the image of the set A must remain within B under the entire homotopy. In many applications, A and B are sets with only one or two points, and the restriction that f take A into B amounts to specifying the value of f at the point(s) of A.

XV.1.1.15. An important example of relative homotopy is when $X = [0,1]$ and $A = \{0,1\}$. A map γ from $[0,1]$ to Y is a path in Y. If γ_0 and γ_1 are paths in Y with the same initial point p and final point q, then γ_0 and γ_1 are always homotopic since they are both homotopic to the constant map with value p; but if $B = \{p, q\}$ a homotopy rel (A, B) is one in which all intermediate paths also go from p to q (as long as p and q have disjoint neighborhoods in Y), so γ_0 and γ_1 may not be homotopic rel (A, B). For example, if Y is the unit circle in $\mathbb{R}^2$ and γ_0 and γ_1 are paths in Y from $p = (-1, 0)$ to $q = (1, 0)$ via the upper and lower semicircles respectively, then γ_0 and γ_1 are not homotopic rel $(\{0,1\}, \{p, q\})$ (this seems intuitively obvious, but requires a nontrivial proof, and is equivalent to the Brouwer fixed-point theorem in the plane). In this case we often notationally suppress the B (if γ_0 and γ_1 have the same endpoints) and simply write $\gamma_0 \simeq \gamma_1$ rel $\{0,1\}$. Even the A is often understood in this context, but a reader must carefully understand whether it is assumed (as it most commonly is) that homotopies of paths fix endpoints.

XV.1.1.16. An especially important special case of XV.1.1.15. comes when $p = q$, i.e. B is a singleton p. We thus consider *loops with basepoint p*, maps $\gamma : [0,1] \to Y$ with $\gamma(0) = \gamma(1) = p$. Two such loops are *homotopic rel p* if they are homotopic rel $(\{0,1\}, \{p\})$, i.e. homotopic via loops γ_t with basepoint p for all t. These will be discussed in detail in ().

XV.1.1.17. Here is another interesting special case. If X is a topological space and $p \in X$, then X is *contractible to p relative to p* (rel p) if the identity map is homotopic to the constant map with value p relative to $(\{p\}, \{p\})$, i.e. if the space can be contracted to p in a way leaving p fixed. A convex set X in a topological vector space is contractible to p rel p for any $p \in X$, but if X is the infinite comb and p is a point on the y-axis other than $\mathbf{0}$, then X is not contractible to p rel p since all points must move through $\mathbf{0}$ in any contraction to p (XV.1.5.4.).

A slight variation of the proofs of XV.1.1.7. and XV.1.1.8. (left to the reader) show:

XV.1.1.18. PROPOSITION. Let X, Y, Z be topological spaces, and $A \subseteq X$, $B \subseteq Y$, $C \subseteq Z$. Then

(i) Homotopy rel (A, B) is an equivalence relation on the set of maps from X to Y.

(ii) If $f_0, f_1 : X \to Y$, $f_0 \simeq f_1$ rel (A, B), and $g_0, g_1 : Y \to Z$, $g_0 \simeq g_1$ rel (B, C), then $g_1 \circ f_1 \simeq g_0 \circ f_0$ rel (A, C).

Strong and Local Contractibility

XV.1.1.19. DEFINITION. Let X be a topological space, and $p \in X$. Then X is *strongly contractible to p* if it is contractible to p rel $\{p\}$. X is *locally [strongly] contractible to p* if for every open neighborhood U of p, there is an open neighborhood V of p, contained in U, such that V is [strongly] contractible to p within U.

XV.1.1.20. These notions are all distinct. A circle is locally strongly contractible to any point, but not contractible. The infinite comb () is contractible to any point but not strongly contractible or locally contractible to points on the y-axis (this also shows that a contractible space can be strongly contractible to some points but not others). The example of () is locally contractible to any point but not locally strongly contractible or strongly contractible to some points.

XV.1.1.21. PROPOSITION. Let X be a topological space and $p \in X$. If X is strongly contractible to p, then X is locally strongly contractible to p.

PROOF: Let $h : X \times [0,1] \to X$ be a strong contraction to p, i.e. $h(x, 0) = x$ and $h(x, 1) = p$ for all $x \in X$, and $h(p, t) = p$ for all t. Let U be an open neighborhood of p. Let $W = h^{-1}(U)$; then W is an open neighborhood of $\{p\} \times [0,1]$ in $X \times [0,1]$. Since $[0,1]$ is compact, there is an open neighborhood V of p such that $V \times [0,1] \subseteq W$ (). Then h strongly contracts V to p within U. 👍

XV.1.1.22. This result is false in general if "strongly" is removed, as the infinite comb shows.

Homotopy Equivalence

XV.1.1.23. DEFINITION. Let X and Y be topological spaces. Then X and Y are *homotopy equivalent* if there are maps $f : X \to Y$ and $g : Y \to X$ with $g \circ f \simeq \iota_X$ and $f \circ g \simeq \iota_Y$.
X *homotopically dominates* Y if there are maps $f : X \to Y$ and $g : Y \to X$ with $f \circ g \simeq \iota_Y$.

XV.1.1.24. It is an easy consequence of XV.1.1.8. that homotopy dominance is transitive and homotopy equivalence is an equivalence relation. Homotopy dominance is a sort of "homotopy retraction" ().

XV.1.1.25. Examples. (i) Every topological space homotopically dominates any contractible space. A topological space is homotopy equivalent to a contractible space if and only if it is contractible. Any two contractible spaces are homotopy equivalent.

(ii) A circle in $\mathbb{R}^2$ is not homotopy equivalent to $\mathbb{R}^2$ since $\mathbb{R}^2$ is contractible. But a circle is homotopy equivalent to $\mathbb{R}^2$ with a point removed.

(iii) The Greek letter θ and a figure 8 are homotopy equivalent.

(iv) A cylinder and a Möbius strip are homotopy equivalent since each is homotopy equivalent to a circle.

(v) If X and Y are homotopy equivalent, they each homotopy dominate the other. But the converse is false in general:

XV.1.1.26. Homotopy equivalence is *much* weaker than homeomorphism in general: for example, every contractible space is homotopy equivalent to a one-point space. (Homeomorphism can be concluded from homotopy equivalence in some special cases.) Most methods and results of algebraic topology do not distinguish between homotopy equivalent spaces, i.e. algebraic topology describes and studies topological spaces up to homotopy equivalence.

XV.1.1.27. We can also define relative homotopy equivalence. If $A \subseteq X$ and $B \subseteq Y$, a homotopy equivalence between X and Y rel (A, B) is a pair of maps $f : X \to Y$ and $g : Y \to X$ with $f(A) \subseteq B$, $g(B) \subseteq A$, and $g \circ f \simeq \iota_X$ rel (A, A) and $f \circ g \simeq \iota_Y$ rel (B, B). Relative homotopy dominance can be defined similarly.

Smooth Homotopy

XV.1.1.28. In situations where there is a notion of differentiability, one also wants to consider smooth homotopies. For example, if X and Y are $\mathcal{C}^r$-manifolds and f, g are $\mathcal{C}^r$ maps from X to Y, we say f and g are $\mathcal{C}^r$-homotopic if there is a homotopy H which is a $\mathcal{C}^r$ function from $X \times [0, 1]$ to Y. The relation between ordinary homotopies and smooth homotopies in this context is somewhat subtle, but in good cases an ordinary homotopy can be "smoothed" to a smooth one ().

Isotopy

In some applications in topology, such as knot theory, it is important not to allow the image to "pass through itself" during the deformation. This is accomplished by the notion of isotopy.

XV.1.1.29. Definition. Let X and Y be topological spaces, and f_0, f_1 topological embeddings of X into Y (homeomorphisms onto their images). An *isotopy* from f_0 to f_1 is a homotopy $H = (f_t)$ from f_0 to f_1 in which each f_t $(0 \leq t \leq 1)$ is a topological embedding.

Isotopic maps are obviously homotopic, but the converse is false:

XV.1.1.30. EXAMPLES. (i) Let $X = [0,1]$, $Y = [0,1]$ (or $Y = \mathbb{R}$). Let $f_0(t) = t$, and $f_1(t) = 1-t$. Then $f_0 \simeq f_1$ (any two maps from X to Y are homotopic). But f_0 and f_1 are not isotopic: if (f_t) is a homotopy from f_0 to f_1, there is a t such that $f_t(0) = f_t(1)$, so f_t is not injective [set $\phi(t) = f_t(1) - f_t(0)$ and apply the Intermediate Value theorem].

(ii) Any two knots () are homotopic as maps from S^1 to $\mathbb{R}^3$. But a nontrivial knot like the trefoil () is not isotopic to an unknot. In fact, two knots are isotopic if and only if they are equivalent as knots.

(iii) The Fox-Artin wild arc () is isotopic to an ordinary arc as maps from $[0,1]$ to $\mathbb{R}^3$ [pull in the ends a little]. But the more complicated embedding of $[0,1]$ into $\mathbb{R}^3$ outlined at the end of () which is wild at every point is not isotopic to an ordinary arc.

Ambient Isotopy

XV.1.2. The Fundamental Group

XV.1.3. Covering Spaces

XV.1.4. Other Homotopy Groups

n-Homotopy

XV.1.4.1. If $n \in \mathbb{N}$, and $f_0, \ldots, f_n$ are $n+1$ maps from X to Y, an *n-homotopy* of $f_0, \ldots, f_n$ is a map h from $X \times \Delta_n$ to Y, where Δ_n is the n-simplex (), with $h(x, e_k) = f_k(x)$ for $0 \leq k \leq n$, where e_k is the k'th vertex of Δ_n. A 1-homotopy is just a homotopy. Possible variations include n-homotopies relative to a subspace of X or relative to specified 1-homotopies between the f_k.

An n-homotopy of $f_0, \ldots, f_n$ gives an m-homotopy of any $m+1$ of the functions, for $1 \leq m \leq n$, but is more than that: it gives a coherent family of such homotopies.

This notion is only interesting when smaller m-homotopies are specified:

XV.1.4.2. PROPOSITION. Let $f_0, \ldots, f_n$ be maps from X to Y. If the f_k are pairwise homotopic, then there is an n-homotopy of $f_0, \ldots, f_n$.

PROOF: We write the proof for $n = 2$; the general case is similar but notationally more complicated. Let $h_1 : X \times [0,1] \to Y$ be a homotopy from f_0 to f_1 and h_2 a homotopy from f_0 to f_2. Let L be the line segment in Δ_2 from e_0 to the midpoint of the edge between e_1 and e_2. Define $h : X \times \Delta_2 \to Y$ as follows. If $p \in L$, for $x \in X$ set $h(x,p) = f_0(x)$. If $p = te_1 + (1-t)q$ for $q \in L$, for $x \in X$ set $h(x,p) = h_1(x,t)$, and if $p = te_2 + (1-t)q$ for $q \in L$ set $h(x,p) = h_2(x,t)$. Then h is a 2-homotopy of f_0, f_1, f_2. 👍

XV.1.4.3. EXAMPLE. If 1-homotopies between the f_k are specified, a compatible 2-homotopy need not exist. Let $X = \{p\}$ be a singleton and Y a circle, and y_0, y_1, y_2 vertices of an equilateral triangle in Y. Let f_0, f_1, f_2 be the functions sending p to y_0, y_1, y_2 respectively. Specify the homotopies to move the points cyclically along the minor arcs between points. Then there is no 2-homotopy, which would effectively be a retraction of a disk onto a circle.

This example shows that existence of n-homotopies with specified boundary behavior is closely related to higher-order connectedness.

XV.1.5. Exercises

XV.1.5.4. Let X be the infinite comb (), and p a point of X on the y-axis with positive y-coordinate. Then X is contractible to p. Show that X is not contractible to p rel p:

(a) If q is a point of X with positive x-coordinate, then any path in X from q to p must pass through $\mathbf{0}$.

(b) Let (p_n) be a sequence in X of points with positive x-coordinate with $p_n \to p$. If H is a contraction of X to p, then for each n there must be a t_n with $H(p_n, t_n) = \mathbf{0}$.

(c) If t_0 is a limit point of the sequence (t_n), then $H(p, t_0) = \mathbf{0}$. Thus we cannot have that H is a contraction of X to p rel p.

XV.2.2. Simplicial Homology

XV.3. Homological Algebra

XV.3.1. Preliminaries

Diagram Chasing

A common proof technique in homological algebra is diagram chasing. We illustrate the technique with a basic result called the *Five Lemma*. The film *It's My Turn* has a scene where Jill Clayburgh presents a diagram chase proof of the Snake Lemma (XV.3.1.10.).

XV.3.1.1. Theorem. [Basic Five Lemma] Let R be a ring, and let

$$\begin{array}{ccccccccc} A_{11} & \xrightarrow{\alpha_1} & A_{12} & \xrightarrow{\alpha_2} & A_{13} & \xrightarrow{\alpha_3} & A_{14} \\ \downarrow{\scriptstyle \phi_1} & & \downarrow{\scriptstyle \phi_2} & & \downarrow{\scriptstyle \phi_3} & & \downarrow{\scriptstyle \phi_4} \\ A_{21} & \xrightarrow{\beta_1} & A_{22} & \xrightarrow{\beta_2} & A_{23} & \xrightarrow{\beta_3} & A_{24} \end{array}$$

be a commutative diagram of R-modules, with exact rows. If ϕ_2 and ϕ_4 are injective and ϕ_1 is surjective, then ϕ_3 is injective.

The result applies for either left or right modules. Since abelian groups are the same thing as $\mathbb{Z}$-modules, it also applies to abelian groups. In fact, it is valid in any abelian category ().

The result can be rephrased:

XV.3.1.2. Theorem. [Basic Five Lemma] Let R be a ring, and let

$$\begin{array}{ccccccccc} & & & & 0 & & & & \\ & & & & \downarrow & & & & \\ & & 0 & & B & & 0 & & \\ & & \downarrow & & \downarrow & & \downarrow & & \\ A_{11} & \xrightarrow{\alpha_1} & A_{12} & \xrightarrow{\alpha_2} & A_{13} & \xrightarrow{\alpha_3} & A_{14} \\ \downarrow{\scriptstyle \phi_1} & & \downarrow{\scriptstyle \phi_2} & & \downarrow{\scriptstyle \phi_3} & & \downarrow{\scriptstyle \phi_4} \\ A_{21} & \xrightarrow{\beta_1} & A_{22} & \xrightarrow{\beta_2} & A_{23} & \xrightarrow{\beta_3} & A_{24} \\ \downarrow & & & & & & \\ 0 & & & & & & \end{array}$$

be a commutative diagram of R-modules, with exact rows and columns. Then $B = 0$.

Proof: We will use the following notation. If $1 \leq j, k \leq 4$, write x_{jk} for a generic element of A_{jk}. If x_{jk} has been specified, and $j \leq m \leq 4$, $k \leq n \leq 4$, write x_{mn} for the image of x_{jk} in A_{mn} (this image is unambiguous since the diagram commutes). Also since the map from B into A_{13} is injective, we may regard B as a subset

of A_{13}. So let $x_{13} \in B \subseteq A_{13}$; we want to show $x_{13} = 0$. The image x_{23} of x_{13} in A_{23} is 0 by exactness; thus $x_{24} = 0$. Since ϕ_4 is injective, $x_{14} = 0$. Thus x_{13} has a preimage $x_{12} \in A_{12}$ by exactness. The image $x_{22} \in A_{22}$ goes to $x_{23} = 0$, and thus by exactness x_{22} has a preimage $x_{21} \in A_{21}$. Since ϕ_1 is surjective, x_{21} has a preimage $x_{11} \in A_{11}$. If y is the image of x_{11} in A_{12}, y and x_{12} have the same image x_{22} in A_{22}, and thus $y = x_{12}$ since ϕ_2 is injective. Thus x_{12} is in the image of A_{11}, and so the image x_{13} in A_{13} is 0 by exactness. 👍

We have named the elements in each module to make the argument clearer and more complete; but in serious diagram chasing it is considered unsporting to give the elements names – one just starts with an element somewhere and moves ("chases") it around the diagram.

There is a dual version:

XV.3.1.3. THEOREM. [BASIC FIVE LEMMA, DUAL VERSION] Let R be a ring, and let

$$\begin{array}{ccccccc} A_{11} & \xrightarrow{\alpha_1} & A_{12} & \xrightarrow{\alpha_2} & A_{13} & \xrightarrow{\alpha_3} & A_{14} \\ \downarrow{\scriptstyle \phi_1} & & \downarrow{\scriptstyle \phi_2} & & \downarrow{\scriptstyle \phi_3} & & \downarrow{\scriptstyle \phi_4} \\ A_{21} & \xrightarrow{\beta_1} & A_{22} & \xrightarrow{\beta_2} & A_{23} & \xrightarrow{\beta_3} & A_{24} \end{array}$$

be a commutative diagram of R-modules, with exact rows. If ϕ_1 and ϕ_3 are surjective and ϕ_4 is injective, then ϕ_2 is surjective.

The result again applies for either left or right modules, and even in any abelian category ().

The result can be rephrased:

XV.3.1.4. THEOREM. [BASIC FIVE LEMMA, DUAL VERSION] Let R be a ring, and let

$$\begin{array}{ccccccc} & & & & & & 0 \\ & & & & & & \downarrow \\ A_{11} & \xrightarrow{\alpha_1} & A_{12} & \xrightarrow{\alpha_2} & A_{13} & \xrightarrow{\alpha_3} & A_{14} \\ \downarrow{\scriptstyle \phi_1} & & \downarrow{\scriptstyle \phi_2} & & \downarrow{\scriptstyle \phi_3} & & \downarrow{\scriptstyle \phi_4} \\ A_{21} & \xrightarrow{\beta_1} & A_{22} & \xrightarrow{\beta_2} & A_{23} & \xrightarrow{\beta_3} & A_{24} \\ \downarrow & & \downarrow & & \downarrow & & \\ 0 & & B & & 0 & & \\ & & \downarrow & & & & \\ & & 0 & & & & \end{array}$$

be a commutative diagram of R-modules, with exact rows and columns. Then $B = 0$.

This can be proved either by dualizing, or by a direct diagram chase. The direct proof is left as an exercise for the reader (), and is good practice in diagram chasing. It is slightly more complex than the proof of XV.3.1.2., but similar.

Putting the two versions together, we obtain the commonly stated version, which is the origin of the name *Five Lemma*:

XV.3.1.5. Corollary. [Five Lemma, Common Version] Let R be a ring, and let

$$\begin{array}{ccccccccc} A_{11} & \xrightarrow{\alpha_1} & A_{12} & \xrightarrow{\alpha_2} & A_{13} & \xrightarrow{\alpha_3} & A_{14} & \xrightarrow{\alpha_4} & A_{15} \\ \downarrow{\scriptstyle \phi_1} & & \downarrow{\scriptstyle \phi_2} & & \downarrow{\scriptstyle \phi_3} & & \downarrow{\scriptstyle \phi_4} & & \downarrow{\scriptstyle \phi_5} \\ A_{21} & \xrightarrow{\beta_1} & A_{22} & \xrightarrow{\beta_2} & A_{23} & \xrightarrow{\beta_3} & A_{24} & \xrightarrow{\beta_4} & A_{25} \end{array}$$

be a commutative diagram of R-modules, with exact rows. If ϕ_1, ϕ_2, ϕ_4, and ϕ_5 are isomorphisms, then ϕ_3 is also an isomorphism.

The special case of short exact sequences is worth stating:

XV.3.1.6. Corollary. [Five Lemma, Short Version] Let R be a ring, and let

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A_{12} & \xrightarrow{\alpha_2} & A_{13} & \xrightarrow{\alpha_3} & A_{14} & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \phi_2} & & \downarrow{\scriptstyle \phi_3} & & \downarrow{\scriptstyle \phi_4} & & \\ 0 & \longrightarrow & A_{22} & \xrightarrow{\beta_2} & A_{23} & \xrightarrow{\beta_3} & A_{24} & \longrightarrow & 0 \end{array}$$

be a commutative diagram of R-modules, with short exact rows. If ϕ_2 and ϕ_4 are injective [resp. surjective, isomorphisms], then ϕ_3 is also injective [resp. surjective, an isomorphism].

Connecting Homomorphisms and the Snake Lemma

XV.3.1.7. Consider left R-modules over a fixed ring R (this is not important; we could work in any abelian category). If $\phi : A \to B$ is a module homomorphism, as usual define $ker(\phi) = \{x \in A : \phi(x) = 0\}$. This is a submodule of A. Also define $coker(\phi) = B/\phi(A)$, a quotient module. There is then an exact sequence

$$0 \longrightarrow ker(\phi) \xrightarrow{\iota} A \xrightarrow{\phi} B \xrightarrow{\pi} coker(\phi) \longrightarrow 0$$

where ι is the inclusion map and π the quotient map. Conversely, if

$$0 \longrightarrow K \longrightarrow A \xrightarrow{\phi} B \longrightarrow C \longrightarrow 0$$

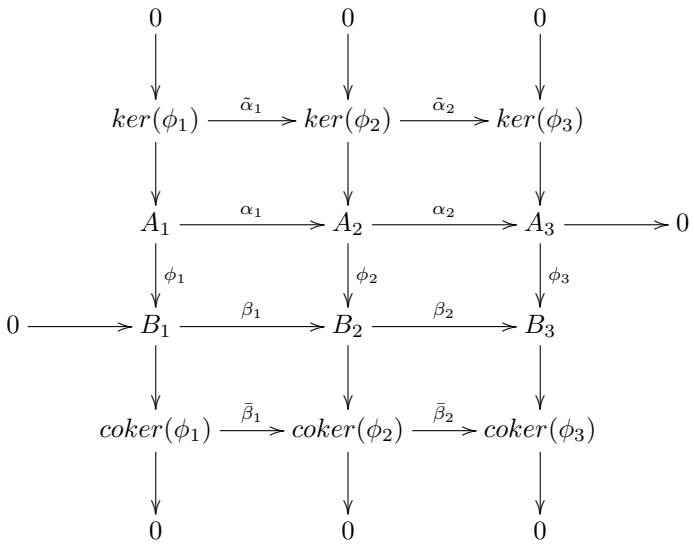
is an exact sequence including ϕ, then K and C are naturally isomorphic to $ker(\phi)$ and $coker(\phi)$ respectively, so the exact sequence is essentially unique.

XV.3.1.8. If

$$\begin{array}{ccccc} A_1 & \xrightarrow{\alpha_1} & A_2 & \xrightarrow{\alpha_2} & A_3 \\ \downarrow{\scriptstyle \phi_1} & & \downarrow{\scriptstyle \phi_2} & & \downarrow{\scriptstyle \phi_3} \\ B_1 & \xrightarrow{\beta_1} & B_2 & \xrightarrow{\beta_2} & B_3 \end{array}$$

is a commutative diagram, then α_1 maps $ker(\phi_1)$ into $\ker(\phi_2)$ and α_2 maps $ker(\phi_2)$ into $\ker(\phi_3)$ by commutativity. Similarly, β_1 maps $\phi_1(A_1)$ into $\phi_2(A_2)$ and β_2 maps $\phi_2(A_2)$ into $\phi_3(A_3)$ by commutativity; thus β_1 drops to a homomorphism $\bar{\beta}_1$ from $coker(\phi_1)$ to $coker(\phi_2)$, and β_2 to a homomorphism $\bar{\beta}_2 : coker(\phi_2) \to coker(\phi_3)$, and we get a commutative diagram

$$\begin{array}{ccccc} 0 & & 0 & & 0 \\ \downarrow & & \downarrow & & \downarrow \\ ker(\phi_1) & \xrightarrow{\tilde{\alpha}_1} & ker(\phi_2) & \xrightarrow{\tilde{\alpha}_2} & ker(\phi_3) \\ \downarrow & & \downarrow & & \downarrow \\ A_1 & \xrightarrow{\alpha_1} & A_2 & \xrightarrow{\alpha_2} & A_3 \\ \downarrow{\scriptstyle \phi_1} & & \downarrow{\scriptstyle \phi_2} & & \downarrow{\scriptstyle \phi_3} \\ B_1 & \xrightarrow{\beta_1} & B_2 & \xrightarrow{\beta_2} & B_3 \\ \downarrow & & \downarrow & & \downarrow \\ coker(\phi_1) & \xrightarrow{\bar{\beta}_1} & coker(\phi_2) & \xrightarrow{\bar{\beta}_2} & coker(\phi_3) \\ \downarrow & & \downarrow & & \downarrow \\ 0 & & 0 & & 0 \end{array}$$



with exact columns, where $\tilde{\alpha}_k$ is the restriction of α_k.

If the original diagram is a little bigger with exact rows, the expanded diagram has exact rows too:

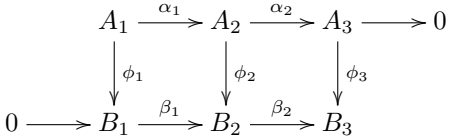
XV.3.1.9. Proposition. Let

$$\begin{array}{ccccccc} & A_1 & \xrightarrow{\alpha_1} & A_2 & \xrightarrow{\alpha_2} & A_3 & \longrightarrow 0 \\ & \downarrow{\scriptstyle \phi_1} & & \downarrow{\scriptstyle \phi_2} & & \downarrow{\scriptstyle \phi_3} & \\ 0 \longrightarrow & B_1 & \xrightarrow{\beta_1} & B_2 & \xrightarrow{\beta_2} & B_3 & \end{array}$$

be a commutative diagram of left R-modules with exact rows. Then the expanded commutative diagram

has exact rows (and columns).

PROOF: Consider the first row. The map $\tilde{\alpha}_2 \circ \tilde{\alpha}_1$ is 0 since $\alpha_2 \circ \alpha_1 = 0$. Conversely, let $x \in ker(\phi_2)$ with $\tilde{\alpha}_2(x) = 0$. Then $\alpha_2(x) = 0$, so there is a $y \in A_1$ with $\alpha_1(y) = x$. Since $x \in ker(\phi_2)$, we have $\beta_1 \circ \phi_1(y) = 0$, and hence $\phi_1(y) = 0$ since β_1 is injective. Thus $y \in ker(\phi_1)$.

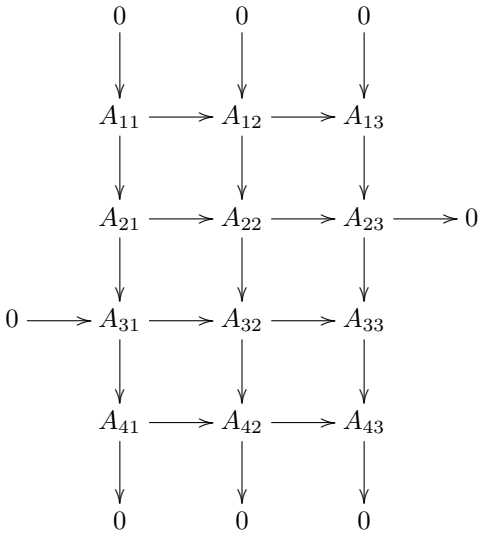


Now consider the last row. We have $\bar{\beta}_2 \circ \bar{\beta}_1 = 0$ since $\beta_2 \circ \beta_1 = 0$. Conversely, let $x \in B_2$ with $[x] \in coker(\phi_2)$ satisfying $\bar{\beta}_2([x]) = 0$. This exactly means $\beta_2(x) \in \phi_3(A_3)$, i.e. there is $y \in A_3$ with $\phi_3(y) = \beta_2(x)$. Since α_2 is surjective, there is $z \in A_2$ with $\alpha_2(z) = y$. We have $\beta_2(x - \phi_2(z)) = 0$, so by exactness there is $w \in B_1$ with $\beta_1(w) = x - \phi_2(z)$. Since $\phi_2(z) \in \phi_2(A_2)$, we have $[x - \phi_2(z)] = [x]$ in $coker(\phi_2)$, and

$$\bar{\beta}_1([w]) = [x - \phi_2(z)] = [x] \ .$$

The following result is called the *Snake Lemma* or the *Connecting Homomorphism Theorem*. The existence of connecting homomorphisms of this type is one of the most important features of homological algebra, particularly for applications in topology.

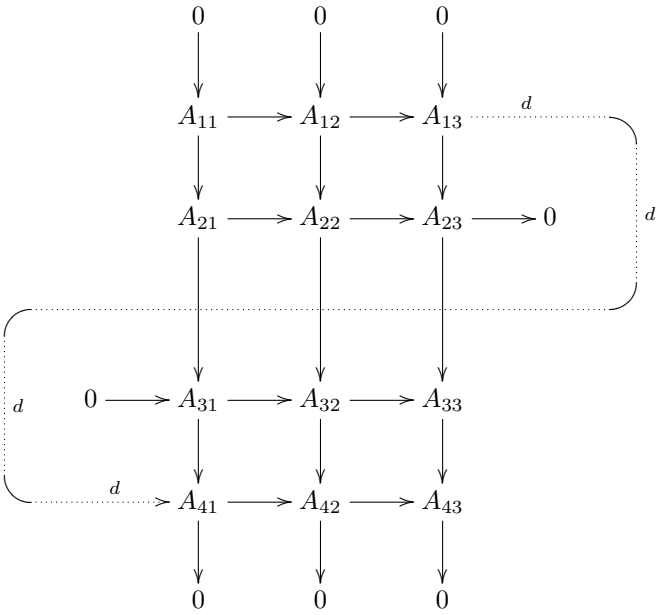
XV.3.1.10. THEOREM. [SNAKE LEMMA] Let



be a commutative diagram of R-modules (or in any abelian category), with exact rows. Then there is a natural connecting homomorphism $d : ker(\phi_3) \to coker(\phi_1)$ making the following sequence exact:

$$ker(\phi_1) \xrightarrow{\tilde{\alpha}_1} ker(\phi_2) \xrightarrow{\tilde{\alpha}_2} ker(\phi_3) \xrightarrow{d} coker(\phi_1) \xrightarrow{\bar{\beta}_1} coker(\phi_2) \xrightarrow{\bar{\beta}_2} coker(\phi_3)$$

To construct the connecting homomorphism and prove the theorem, in light of Proposition XV.3.1.9. it suffices to prove the following, where we change notation to make a diagram chase proof more efficient, and suppress the names of the maps:



XV.3.1.11. THEOREM. [SNAKE LEMMA] Let

be a commutative diagram of R-modules (or in any abelian category), with exact rows and columns. Then there is a natural connecting homomorphism $d : A_{13} \to A_{41}$ making the following sequence exact:

$$A_{11} \longrightarrow A_{12} \longrightarrow A_{13} \xrightarrow{d} A_{41} \longrightarrow A_{42} \longrightarrow A_{43}$$

To see why this is called the Snake Lemma, the diagram can be drawn like this:

PROOF: The proof will consist of several steps:

(i) Definition of d.

(ii) Showing that d is well defined.

(iii) Showing that d is a homomorphism.

(iv) Showing the sequence is exact at A_{13}.

(v) Showing the sequence is exact at A_{41}.

(Note that by hypothesis the sequence is exact at A_{12} and A_{42}; cf. XV.3.1.9..) We use the notational conventions of the proof of XV.3.1.2., and regard $A_{1k} \subseteq A_{2k}$ for $1 \leq k \leq 3$.

(i): We first define d. Let $x_{13} \in A_{13}$. Then $x_{23} = x_{13} \in A_{23}$, so by exactness of the second row there is an $x_{22} \in A_{22}$ whose image is x_{23}. We have $x_{33} = 0$ by exactness of the third column, so by exactness of the third row x_{32} has a unique preimage $x_{31} \in A_{31}$ (i.e. $x_{31} = x_{32}$ if we regard $A_{31} \subseteq A_{32}$). Let x_{41} be the image of x_{31} in A_{41}, and set $d(x_{13}) = x_{41}$.

(ii) To show that d is well defined, we must show it does not depend on the choice of x_{22}. If y_{22} is another preimage of x_{23} in A_{22}, then $y_{22} - x_{22}$ has a preimage z_{21} in A_{21} by exactness. The elements x_{31} and y_{31} differ in A_{31} by the image z_{31} of z_{21}, i.e. by an element in the image of A_{21}; hence their images in A_{41} agree. Thus d is well defined.

(iii) Once d is known to be well defined, it is routine to check that it is a homomorphism, and the argument is left to the reader (it is just a matter of choosing the x_{22} properly).

(iv): To show that the sequence is exact at A_{13}, first let $x_{12} \in A_{12}$. Then $x_{32} = x_{31} = 0$ by exactness of the second column, so $x_{41} = 0$. Conversely, if $x_{13} \in A_{13}$ with $d(x_{13}) = 0$, there is a preimage y_{21} of $x_{31} = x_{32}$ in

A_{21}. Since $y_{32} = x_{32}$, $z_{12} = x_{22} - y_{22} \in A_{12}$ by exactness of the second column. We have $z_{23} = x_{23}$ since $y_{23} = 0$ by exactness of the third row, so $z_{13} = z_{23} = x_{23} = x_{13}$ and x_{13} is in the image of A_{12}.

(v): To show the sequence is exact at A_{41}, let $x_{13} \in A_{13}$. Then x_{32} is the image of x_{22}, hence in the image of A_{22} in A_{32} and $x_{42} = 0$. Conversely, suppose x_{41} satisfies $x_{42} = 0$. If x_{31} is a preimage of x_{41}, this means precisely that x_{32} has a preimage $x_{22} \in A_{22}$. We have $x_{33} = 0$ by exactness of the third row, so x_{23} has a preimage $x_{13} \in A_{13}$ by exactness of the third column, and $d(x_{13}) = x_{41}$. 👍

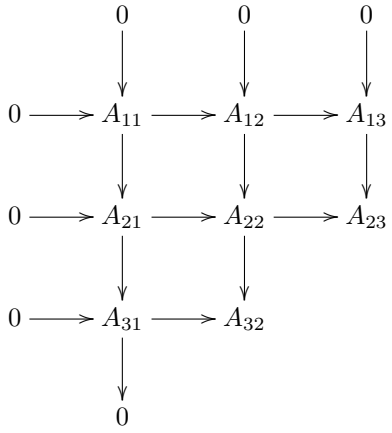
XV.3.1.12. There is one part of the theorem not yet proved: naturality. This means: suppose we also have another diagram

$$\begin{array}{ccccccccc}
 & & 0 & & 0 & & 0 & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & B_{11} & \longrightarrow & B_{12} & \longrightarrow & B_{13} & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & B_{21} & \longrightarrow & B_{22} & \longrightarrow & B_{23} & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & B_{31} & \longrightarrow & B_{32} & \longrightarrow & B_{33} & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & B_{41} & \longrightarrow & B_{42} & \longrightarrow & B_{43} & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & 0 & & 0 & & 0 & &
\end{array}$$

and $\gamma_{jk} : A_{jk} \to B_{jk}$ for $1 \leq j, k \leq 4$ making a three-dimensional commutative diagram, and d and d' are the connecting maps from the two diagrams. Then

$$\begin{array}{ccccccccccc}
A_{11} & \longrightarrow & A_{12} & \longrightarrow & A_{13} & \overset{d}{\longrightarrow} & A_{41} & \longrightarrow & A_{42} & \longrightarrow & A_{43} \\
\downarrow{\scriptstyle \gamma_{11}} & & \downarrow{\scriptstyle \gamma_{12}} & & \downarrow{\scriptstyle \gamma_{13}} & & \downarrow{\scriptstyle \gamma_{41}} & & \downarrow{\scriptstyle \gamma_{42}} & & \downarrow{\scriptstyle \gamma_{43}} \\
B_{11} & \longrightarrow & B_{12} & \longrightarrow & B_{13} & \overset{d'}{\longrightarrow} & B_{41} & \longrightarrow & B_{42} & \longrightarrow & B_{43}
\end{array}$$

commutes (i.e. the center square commutes). The proof is easy and similar to the proof of (iii) above, and is left to the reader.

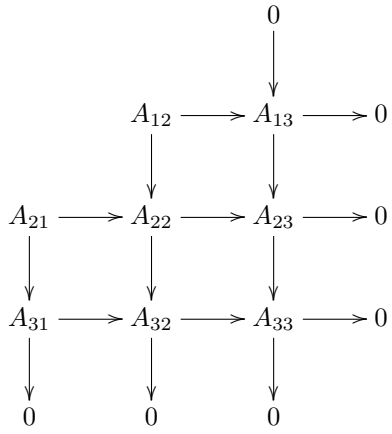


XV.3.2. Chain Complexes

XV.3.3. Exercises

XV.3.3.1. Use a diagram chase to prove the dual Basic Five Lemma XV.3.1.3..

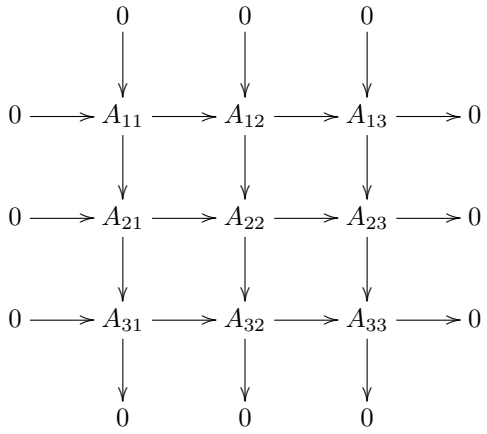
XV.3.3.2. (a) Use a diagram chase to prove the following:



THEOREM. [BASIC NINE LEMMA] Let R be a ring, and let

be a commutative diagram of R-modules, with exact columns and exact middle row. Then the first row is exact if and only if the third row is exact.

(b) Prove the dual version either by duality or by a similar but somewhat trickier diagram chase:



THEOREM. [BASIC NINE LEMMA, DUAL VERSION] Let R be a ring, and let

be a commutative diagram of R-modules, with exact columns and exact middle row. Then the first row is exact if and only if the third row is exact.

(c) Put the two together to obtain the common version of the Nine Lemma ([Fre64] suggests that the *Three-by-three Lemma* would be a more appropriate name):

Corollary. [Common Nine Lemma] Let R be a ring, and let

be a commutative diagram of R-modules, with exact columns and exact middle row. Then the first row is exact if and only if the third row is exact.

XV.3.3.3. Show that all the versions of the Five Lemma, the Nine Lemma, and the Snake Lemma are valid in an arbitrary abelian category (), with "injective" and "surjective" replaced by "monomorphism" and "epimorphism" respectively.

XV.3.3.4. The following exercise appears in [Lan02]:

Exercise. Take any book on homological algebra, and prove all the theorems without looking at the proofs given in that book.

Chapter XVI

Measurable Spaces and Subset Structures

In this chapter, we will set up the structures on which measures can be naturally defined. While these structures are of interest in their own right, the reader should not lose sight of the primary goal of this work: developing a good notion of measure and integration. In this context, this chapter should be regarded as a set of elaborate and technical preliminary work necessary to obtain a good theory of measure. Strictly speaking, not all of the material of this chapter will be necessary for basic measure theory, but it makes sense to give a reasonably complete study of these topics all at once.

The set structures discussed in this chapter should be compared to topologies, another very important kind of set structure discussed in Chapter (). Although the various kinds of set structures have properties making them useful in different contexts, all are of the same general nature and have many features in common.

XVI.1. Algebras and σ-Algebras of Sets

XVI.1.1. Set Operations

In this subsection, we review standard operations on subsets of a set X. Throughout the section, X will be a fixed set which we will regard as our "universe."

XVI.1.1.1. We first recall basic set operations on subsets of X. If $A, B \subseteq X$, then

The *union* $A \cup B$ is $\{x \in X : x \in A \text{ or } x \in B\}$.

The *intersection* $A \cap B$ is $\{x \in X : x \in A \text{ and } x \in B\}$.

The *complement* of A is $A^c = \{x \in X : x \notin A\}$.

The *difference* $A \setminus B$ is $A \cap B^c = \{x \in A : x \notin B\}$.

The *symmetric difference* $A \triangle B$ is $\{x \in X : x \in A \text{ or } x \in B \text{ but not both}\} = (A \setminus B) \cup (B \setminus A)$.

More generally, if $\{A_i : i \in I\}$ is an indexed collection of subsets of X, then

$$\cup_{i \in I} A_i = \{x \in X : x \in A_i \text{ for some } i \in I\}$$

$$\cap_{i \in I} A_i = \{x \in X : x \in A_i \text{ for all } i \in I\}$$

Limits of Sequences of Sets

XVI.1.1.2. Let $(A_1, A_2, \dots)$ be a sequence of subsets of X. Define

$$\limsup_{n \to \infty} A_n = \bigcap_n \bigcup_{k \geq n} A_k$$

$$\liminf_{n \to \infty} A_n = \bigcup_n \bigcap_{k \geq n} A_k$$

(the $n \to \infty$ is often notationally omitted).

Note that a set-theoretic lim sup or lim inf has, at least on the surface, nothing to do with the notion of the lim sup or lim inf of a sequence of numbers (); the terminology is just an analogy. (It is actually somewhat more than an analogy, though – see XVI.1.1.9.(iv).)

XVI.1.1.3. Proposition. Let $(A_1, A_2, \dots)$ be a sequence of subsets of X.

(i) $\limsup A_n$ is the set of all $x \in X$ which are in infinitely many A_n (we say such an x is *frequently in* A_n).

(ii) $\liminf A_n$ is the set of all $x \in X$ which are in all but (at most) finitely many A_n, i.e. which are in A_n for all sufficiently large n (we say such an x is *eventually in* A_n).

In particular, $\liminf A_n \subseteq \limsup A_n$.

The proof is a good exercise left to the reader.

XVI.1.1.4. De Morgan's Laws (or direct inspections) show:

$$(\limsup A_n)^c = \liminf(A_n^c)$$

$$(\liminf A_n)^c = \limsup(A_n^c)$$

XVI.1.1.5. Simple examples show that for a general sequence (A_n) of subsets of a set X, $\liminf A_n$ is "usually" a proper subset of $\limsup A_n$. For example, if $A, B \subseteq X$, and $A_n = A$ for n odd and $A_n = B$ for n even, then

$$\limsup A_n = A \cup B, \quad \liminf(A_n) = A \cap B \ .$$

But it can happen that the sets are equal; if so, we say the sequence (A_n) of subsets *converges*, and we write

$$\lim_{n\to\infty} A_n = \limsup_{n\to\infty} A_n = \liminf_{n\to\infty} A_n \ .$$

The sequence (A_n) converges if and only if every $x \in X$ is either eventually in A_n or eventually in A_n^c.

There are situations where sequences automatically converge:

XVI.1.1.6. PROPOSITION. Let (A_n) be a sequence of subsets of X.
(i) If (A_n) is increasing, i.e. $A_n \subseteq A_{n+1}$ for all n, then (A_n) converges, and

$$\lim_{n\to\infty} A_n = \bigcup_{n=1}^{\infty} A_n \ .$$

(ii) If (A_n) is decreasing, i.e. $A_n \supseteq A_{n+1}$ for all n, then (A_n) converges, and

$$\lim_{n\to\infty} A_n = \bigcap_{n=1}^{\infty} A_n \ .$$

(iii) If the A_n are pairwise disjoint, then (A_n) converges, and $\lim A_n = \emptyset$.
(iv) If (A_n) converges, then (A_n^c) converges, and $\lim(A_n^c) = (\lim A_n)^c$.

Indicator Functions

XVI.1.1.7. DEFINITION. Let A be a subset of X. The *indicator function* of A is the function $\chi_A : X \to [0,1]$ defined by

$$\chi_A(x) = \begin{cases} 1 & \text{if} \quad x \in A \\ 0 & \text{if} \quad x \notin A \end{cases} \ .$$

The term *indicator function* is standard in probability theory; the name *characteristic function* is more standard in set theory and analysis. But the term "characteristic function" is also used to mean something else (), so we will standardize on "indicator function."

XVI.1.1.8. Conversely, any function f from X to $\{0,1\}$ is an indicator function: $f = \chi_A$, where $A = \{x \in X : f(x) = 1\}$. Thus $\mathcal{P}(X)$ can be identified with the set of functions from X to $\{0,1\}$, often called 2^X, cf. (). (More generally, a function $f : X \to [0,1]$ can be regarded as a "fuzzy subset" of X: if $x \in X$, $f(x)$ is the probability that x belongs to the corresponding subset.)

Set operations correspond to algebraic operations on the indicator functions:

XVI.1.1.9. Proposition. (i) Let A and B be subsets of X. Then

$$\chi_{A\cup B} = \chi_A \vee \chi_B = \max(\chi_A, \chi_B) \ .$$

$$\chi_{A\cap B} = \chi_A\chi_B = \min(\chi_A, \chi_B) \ .$$

(ii) Let $\{A_i : i \in I\}$ be a collection of subsets of X. Then

$$\chi_{\cup_i A_i} = \max_i \chi_{A_i} \ .$$

$$\chi_{\cap_i A_i} = \min_i \chi_{A_i} \ .$$

(iii) If $A \subseteq B \subseteq X$, then $\chi_{B\setminus A} = \chi_B - \chi_A$. In particular, $\chi_{A^c} = 1 - \chi_A$.
(iv) If (A_n) is a sequence of subsets of X, then

$$\chi_{\limsup A_n} = \limsup \chi_{A_n} \ .$$

$$\chi_{\liminf A_n} = \liminf \chi_{A_n} \ .$$

In particular, if (A_n) converges, then (χ_{A_n}) converges pointwise to $\chi_{\lim A_n}$. Conversely, if (χ_{A_n}) converges pointwise, then (A_n) converges.

XVI.1.2. Rings, Semirings, and Semialgebras

In this subsection, we will discuss various types of collections of subsets of a set X which are important to a greater or lesser extent in measure theory. Throughout the section, X will be a fixed set which we will regard as our "universe."

XVI.1.2.1. Definition. A nonempty collection $\mathcal{S}$ of subsets of X is a *semiring* if

(i) $\mathcal{S}$ is closed under finite intersections.

(ii) If $A, B \in \mathcal{S}$, then $A \setminus B$ is a finite disjoint union of sets in $\mathcal{S}$.

A semiring $\mathcal{S}$ for which $X \in \mathcal{S}$ is a *semialgebra*. A semiring $\mathcal{S}$ with the property that X is a countable union of sets in $\mathcal{S}$ is *of countable type*. A semialgebra is a semiring of countable type.

Taking $B = A$ in (ii), it follows that $\emptyset$ is in any semiring.

The definition of a semiring may look strange at first, but many important collections of subsets which naturally arise in analysis turn out to be semirings, and on the other hand semirings have enough structure that important constructions can be done with them.

XVI.1.2.2. EXAMPLES. (i) Here is perhaps the most important example. Let $\mathcal{I}$ be the set of intervals in $\mathbb{R}$, either open, closed, or half-open; include in $\mathcal{I}$ the "degenerate" intervals $\emptyset$ and singleton sets $\{x\}$ (intervals of length 0). $\mathcal{I}$ is closed under finite intersections (in fact under arbitrary intersections), and the complement of one interval in another is either an interval or the disjoint union of two intervals, so $\mathcal{I}$ is a semiring. In fact, $\mathcal{I}$ is a semialgebra.
(ii) As a variation of (i), let $\mathcal{I}_f$ be the set of bounded intervals in $\mathbb{R}$, including degenerate intervals. By the same argument, $\mathcal{I}_f$ is a semiring. It is not a semialgebra, but it is a semiring of countable type.
(iii) Similarly, if $\delta > 0$, let $\mathcal{I}_\delta$ be the set of intervals in $\mathbb{R}$ of length $\leq \delta$, again including degenerate intervals. By the same argument, using the Archimedean property of $\mathbb{R}$, $\mathcal{I}_\delta$ is a semiring of countable type.
(iv) If $\mathcal{C}$ is any semiring (e.g. an algebra or σ-algebra) on X, and $\{A_i : i \in I\}$ is a nonempty collection of sets in $\mathcal{C}$, then $\mathcal{S} = \{S \in \mathcal{C} : S \subseteq A_i \text{ for some } i \in I\}$ is a semiring. More generally, if P is a property of sets inherited by all subsets, then the set of $C \in \mathcal{C}$ with property P form a semiring.

XVI.1.2.3. The intersection of two semirings is not necessarily a semiring, and hence if $\mathcal{C}$ is a collection of subsets of X, there is not necessarily a smallest semiring containing $\mathcal{C}$. But there is a standard construction of a semiring containing $\mathcal{C}$, which is particularly important in probability:

XVI.1.2.4. PROPOSITION. Let $\mathcal{C}$ be any nonempty collection of subsets of X, and let

$$\mathcal{D} = \{A \setminus B : A, B \in \mathcal{C}\} .$$

Let $\mathcal{S}$ be the set of finite intersections of sets in $\mathcal{C} \cup \mathcal{D}$. Then $\mathcal{S}$ is a semiring containing $\mathcal{C}$.

Note that $\emptyset \in \mathcal{D}$ since it is $A \setminus A$ for any $A \in \mathcal{C}$; if $\emptyset \in \mathcal{C}$, then $\mathcal{C} \subseteq \mathcal{D}$ since $A = A \setminus \emptyset$ for any A.
PROOF: *(Outline)* This is completely routine, but tedious to write out carefully; see XVI.1.7.1.. The proof consists of repeated applications of the following facts for subsets A, B, C of X:

$(A \cap B) \setminus C = (A \setminus C) \cap (B \setminus C)$.

$(A \setminus B) \setminus C = (A \setminus B) \cap (A \setminus C)$.

$A \setminus (B \setminus C)$ is the disjoint union of $A \setminus B$ and $A \cap B \cap C$.

$A \setminus (B \cap C)$ is the disjoint union of $A \setminus B$ and $(A \cap B) \setminus C$.

The details of the proof are left to the reader, who should at least verify the above facts. 👍

A similar proof shows the following:

XVI.1.2.5. PROPOSITION. Let $\mathcal{C}$ be a nonempty collection of subsets of X with the property that $A \in \mathcal{C}$ implies $A^c \in \mathcal{C}$. Let $\mathcal{S}$ be the collection of finite intersections of sets in $\mathcal{C}$. Then $\mathcal{S}$ is a semialgebra.

Collections with more structure behave more nicely and are of central importance in measure theory:

XVI.1.2.6. DEFINITION. A *ring* of subsets of a set X is a nonempty collection of subsets of X which is closed under finite unions and relative complements.

XVI.1.2.7. PROPOSITION. A ring is closed under symmetric difference and finite intersections; in particular, a ring is a semiring.

PROOF: If $A, B \subseteq X$, then $A \triangle B = (A \setminus B) \cup (B \setminus A)$ and $A \cap B = (A \cup B) \setminus (A \triangle B)$. 👍

XVI.1.2.8. The converse also holds: a nonempty collection of subsets of X closed under finite intersections and symmetric differences is a ring, because of the relations

$$A \cup B = (A \triangle B) \triangle (A \cap B), \quad A \setminus B = A \triangle (A \cap B)$$

for subsets of X. This explains the use of the term "ring": the operations $A + B = A \triangle B$ and $AB = A \cap B$ make $\mathcal{P}(X)$ into a ring in the algebraic sense of III.3.6.3. (in fact, a special kind of ring called a *Boolean algebra*); a ring of subsets is precisely a subring of $\mathcal{P}(X)$ with these operations. This use of *ring* (of subsets) is apparently due to HALMOS [Hal50].

In many references, especially older ones, $A \cap B$ is written AB, and in many of these $A \cup B$ is written $A + B$ and called the *sum* of A and B. But $\mathcal{P}(X)$ is not a ring under these algebraic operations. Also, for sets of numbers or subsets of a topological group, these notations are commonly used to denote something quite different (). Thus we will not use the notation AB or $A + B$ for set-theoretic operations. ✋

XVI.1.2.9. Any intersection of rings is a ring (the intersection is nonempty since $\emptyset$ is in every ring). Thus if $\mathcal{C}$ is any collection of subsets of X, there is a smallest ring of subsets containing $\mathcal{C}$, called the *ring generated by* $\mathcal{C}$ (there is at least one ring containing $\mathcal{C}$, namely $\mathcal{P}(X)$). The ring generated by $\emptyset$ is $\{\emptyset\}$.

XVI.1.2.10. PROPOSITION. Let $\mathcal{S}$ be a semiring. The ring generated by $\mathcal{S}$ is precisely the set of finite disjoint unions of sets in $\mathcal{S}$.

PROOF: Let $\mathcal{A}$ be the set of finite disjoint unions of sets in $\mathcal{S}$. We show that $\mathcal{A}$ is closed under finite intersections, then finite unions and relative complements.

For finite intersections, let A be the disjoint union of $A_1, \ldots, A_n \in \mathcal{S}$ and B the disjoint union of $B_1, \ldots, B_m \in \mathcal{S}$. Then $A \cap B$ is the disjoint union of

$$\{A_j \cap B_k : 1 \leq j \leq n, 1 \leq k \leq m\} .$$

For finite unions, it suffices to show that if $A_1, \ldots, A_n, B \in \mathcal{S}$ with $A_1, \ldots, A_n$ pairwise disjoint, then $A_1 \cup \cdots \cup A_n \cup B$ can be written as a finite disjoint union of sets in $\mathcal{S}$. For each j, $B \setminus A_j$ can be written as a finite disjoint union of sets in $\mathcal{S}$. Thus by the previous argument

$$B \setminus (A_1 \cup \cdots A_n) = (B \setminus A_1) \cap \cdots \cap (B \setminus A_n)$$

can be written as a finite disjoint union of sets in $\mathcal{S}$; the union of these sets and the A_j is $A_1 \cup \cdots \cup A_n \cup B$.

Now let $A, B \in \mathcal{A}$, with A the disjoint union of $A_1, \ldots, A_n \in \mathcal{S}$ and B the disjoint union of $B_1, \ldots, B_m \in \mathcal{S}$. We have

$$A \setminus B = \bigcup_{j=1}^{n} \bigcap_{k=1}^{m} (A_j \setminus B_k)$$

and each $A_j \setminus B_k$ is a finite disjoint union of sets in $\mathcal{S}$, hence in $\mathcal{A}$. So $A \setminus B$ is in $\mathcal{A}$ by the previous arguments. 👍

XVI.1.2.11. COROLLARY. A semiring which is closed under finite disjoint unions is a ring.

XVI.1.2.12. COROLLARY. Let $\mathcal{S}$ be a semiring, A, A_1, ..., A_n sets in $\mathcal{S}$ with $A_j \subseteq A$ for all j and the A_j pairwise disjoint. Then there are finitely many sets $B_1, \ldots, B_m \in \mathcal{S}$ such that $\{A_1, \ldots, A_n, B_1, \ldots, B_m\}$ are pairwise disjoint and

$$A = \left(\bigcup_{j=1}^{n} A_j \right) \cup \left(\bigcup_{k=1}^{m} B_k \right) .$$

PROOF: Let $\mathcal{A}$ be the ring generated by $\mathcal{S}$. If $D = \cup_{j=1}^{n} A_j$, then $D \in \mathcal{A}$, so $(A \setminus D) \in \mathcal{A}$, i.e. $A \setminus D$ can be written as a finite disjoint union of sets in $\mathcal{S}$. 👍

XVI.1.2.13. PROPOSITION. Let $\mathcal{S}$ be a semiring of subsets of a set X, and let A, A_1, A_2, ... be sets in $\mathcal{S}$. Suppose $A \subseteq \cup_{n=1}^{\infty} A_n$. Then there is a sequence (B_k) of pairwise disjoint sets in $\mathcal{S}$ with each B_k contained in a unique A_n, only finitely many B_k in each A_n, such that $A = \cup_k B_k$.

PROOF: Set $B_1 = A \cap A_1 \in \mathcal{S}$. Write $A \setminus A_1 = C_{11} \cup \cdots \cup C_{1m_1}$ with the C_{1j} pairwise disjoint sets in $\mathcal{S}$. Set $B_2 = A_2 \cap C_{11}$, ..., $B_{m_1+1} = A_2 \cap C_{1m_1}$. Then the B_k $(1 \leq k \leq m_1 + 1)$ are in $\mathcal{S}$ and are pairwise disjoint, $B_1 \subseteq A_1$, $B_k \subseteq A_2 \setminus A_1$ for $2 \leq k \leq m_1 + 1$, and

$$\bigcup_{k=1}^{m_1+1} B_k = A \cap (A_1 \cup A_2) .$$

Write $A \setminus A_2 = C_{21} \cup \cdots \cup C_{2m_2}$ with the C_{2j} pairwise disjoint sets in $\mathcal{S}$. The next set of B_k's (for $m_1 + 2 \leq k \leq m_1 + m_1 m_2 + 1$) are of the form $A_3 \cap C_{1i} \cap C_{2j}$ for $1 \leq i \leq m_1$ and $1 \leq j \leq m_2$. The new B_k are pairwise disjoint and contained in $A_3 \setminus (A_1 \cup A_2)$, and

$$\bigcup_{k=1}^{m_1+m_1m_2+1} B_k = A \cap (A_1 \cup A_2 \cup A_3) .$$

The process can be continued inductively, although the notation becomes increasingly complicated. At the end we have

$$\bigcup_{k=1}^{\infty} B_k = A \cap \left(\bigcup_{n=1}^{\infty} A_n \right) = A .$$

👍

XVI.1.3. Algebras and σ-Algebras

For measure theory purposes, the most important set structures are algebras and especially σ-algebras.

XVI.1.3.1. DEFINITION. Let X be a set. An *algebra* of subsets of X is a set $\mathcal{A}$ of subsets of X satisfying:

(i) $\emptyset, X \in \mathcal{A}$.

(ii) If $A \in \mathcal{A}$, then $A^c \in \mathcal{A}$.

(iii) $\mathcal{A}$ is closed under finite unions.

$\mathcal{A}$ is a *σ-algebra* of subsets of X if it is an algebra and closed under countable unions. Algebras and σ-algebras are also sometimes called *fields* and *σ-fields* respectively, especially in probability.

Note that the set X and the phrase "of subsets of X" is crucial to specify (e.g. if $Y \subseteq X$, then $\mathcal{P}(Y)$ is a σ-algebra of subsets of Y but not of X); thus a statement like "Let $\mathcal{A}$ be a σ-algebra" is technically incorrect or at least incomplete unless the X is understood (as it often is).

XVI.1.3.2. Since $\emptyset$ is in any algebra or σ-algebra, the requirement that a σ-algebra be closed under finite unions as well as countable unions is redundant, i.e. a collection $\mathcal{A} \subseteq \mathcal{P}(X)$ is a σ-algebra if and only if

(i) $\emptyset, X \in \mathcal{A}$.

(ii) If $A \in \mathcal{A}$, then $A^c \in \mathcal{A}$.

(iii) $\mathcal{A}$ is closed under countable unions.

By de Morgan's laws, a collection $\mathcal{A} \subseteq \mathcal{P}(X)$ is an algebra [resp. σ-algebra] if and only if

(i) $\emptyset, X \in \mathcal{A}$.

(ii) If $A \in \mathcal{A}$, then $A^c \in \mathcal{A}$.

(iii) $\mathcal{A}$ is closed under finite [resp. countable] intersections.

In particular, an algebra is closed under finite intersections, and a σ-algebra under countable intersections (including finite intersections).

Requirement (i) can be relaxed (in the presence of (ii) and (iii)) to only require that $\mathcal{A}$ be nonempty, since if $A \in \mathcal{A}$, then $A \cup A^c = X \in \mathcal{A}$ and $A \cap A^c = \emptyset \in \mathcal{A}$.

XVI.1.3.3. An algebra of subsets of X is a ring of subsets of X; a ring $\mathcal{R}$ of subsets of X is an algebra if and only if $X \in \mathcal{R}$ (see XVI.1.4.7. for a precise version).

XVI.1.3.4. EXAMPLES. (i) $\mathcal{P}(X)$ and $\{\emptyset, X\}$ are σ-algebras of subsets of X, and are the largest and smallest σ-algebras on X.

(ii) Let X be an infinite set. The collection of all finite subsets of X and their complements (*cofinite sets*) is an algebra of subsets of X which is not a σ-algebra.

(iii) Let X be an uncountable set. The collection of all countable subsets of X and their complements (*cocountable sets*) is a σ-algebra of subsets of X.

There are many much more interesting examples which will take some effort to define.

Generated Algebras and σ-Algebras

XVI.1.3.5. The intersection of any family of algebras [resp. σ-algebras] of subsets of a set X is an algebra [resp. σ-algebra] of subsets of X. So if $\mathcal{S}$ is any collection of subsets of a set X, there is a smallest algebra [resp. σ-algebra] containing $\mathcal{S}$, the intersection of all algebras [resp. σ-algebras] containing $\mathcal{S}$ (there is at least one, $\mathcal{P}(X)$), called the *algebra [resp. σ-algebra] generated by* $\mathcal{S}$.

If $\mathcal{R}$ is a ring of subsets of X, there is a simple description of the algebra generated by $\mathcal{R}$:

XVI.1.3.6. Proposition. Let $\mathcal{R}$ be a ring of subsets of a set X, and $\mathcal{A}$ the algebra of subsets of X generated by $\mathcal{R}$. Then $\mathcal{A}$ consists precisely of the sets in $\mathcal{R}$ and all sets of the form $A \cup B^c$ for $A, B \in \mathcal{R}$.

Proof: Let $\mathcal{B}$ be this collection of subsets of X. Then $\mathcal{R} \subseteq \mathcal{B} \subseteq \mathcal{A}$, so we need only show that $\mathcal{B}$ is an algebra. Since $\emptyset \in \mathcal{R}$, $\emptyset \cup \emptyset^c = X \in \mathcal{B}$. If $A \in \mathcal{R}$, then $\emptyset \cup A^c = A^c \in \mathcal{B}$, and if $A, B \in \mathcal{R}$, then

$$(A \cup B^c)^c = A^c \cap B = B \setminus A \in \mathcal{R} \subseteq \mathcal{B}$$

so $\mathcal{B}$ is closed under complements. Since $\mathcal{R}$ is closed under finite unions and intersections, if $A, B, C \in \mathcal{R}$, then $A \cup (B \cup C^c) = (A \cup B) \cup C^c \in \mathcal{B}$, and if $A, B, C, D \in \mathcal{R}$, then

$$(A \cup B^c) \cup (C \cup D^c) = (A \cup C) \cup (B^c \cup D^c) = (A \cup C) \cup (B \cap D)^c \in \mathcal{B}$$

do $\mathcal{B}$ is closed under finite unions. 👍

See XVI.1.4.7. for a consequence, and XVI.1.3.11. for a generalization.

XVI.1.3.7. The σ-algebra generated by a collection of subsets, even a ring, is much more complicated to describe. To do this, if $\mathcal{S} \subseteq \mathcal{P}(X)$, use the following notation: $\tilde{S} = \{A^c : A \in \mathcal{S}\}$; $\mathcal{S}_\sigma$ denotes the set of countable unions of sets in $\mathcal{S}$; and $\mathcal{S}_\delta$ the set of countable intersections of sets in $\mathcal{S}$. (Note that $\mathcal{S} \subseteq \mathcal{S}_\sigma$ and $\mathcal{S} \subseteq \mathcal{S}_\delta$ by unions or intersections of constant sequences.) ✋

Fix $\mathcal{S} \subseteq \mathcal{P}(X)$. For countable ordinals α, define $\mathcal{S}^\sigma_\alpha$ recursively as follows. Set $\mathcal{S}^\sigma_0 = \mathcal{S} \cup \{\emptyset\}$ (it is only necessary for the construction to include $\emptyset$ if $\mathcal{S}$ is empty). Suppose $\mathcal{S}^\sigma_\alpha$ has been defined. Set

$$\mathcal{S}^\sigma_{\alpha+1} = (S^\sigma_\alpha \cup \widetilde{\mathcal{S}^\sigma_\alpha})_\sigma \ .$$

If α is a limit ordinal, set $\mathcal{S}^\sigma_\alpha = \cup_{\beta<\alpha}\mathcal{S}^\sigma_\beta$. Similarly, set $\mathcal{S}^\delta_0 = \mathcal{S} \cup \{\emptyset\}$. Suppose $\mathcal{S}^\delta_\alpha$ has been defined. Set

$$\mathcal{S}^\delta_{\alpha+1} = (S^\delta_\alpha \cup \widetilde{\mathcal{S}^\delta_\alpha})_\delta \ .$$

If α is a limit ordinal, set $\mathcal{S}^\delta_\alpha = \cup_{\beta<\alpha}\mathcal{S}^\delta_\beta$. We clearly have $\mathcal{S}^\sigma_\beta \subseteq \mathcal{S}^\sigma_\alpha$ and $\mathcal{S}^\delta_\beta \subseteq \mathcal{S}^\delta_\alpha$ if $\beta < \alpha$, so these sets are nested.

XVI.1.3.8. Theorem. Let $\mathcal{S}$ be a collection of subsets of a set X, and $\mathcal{A}$ the σ-algebra of subsets of X generated by $\mathcal{S}$. Then

$$\mathcal{A} = \bigcup_{\alpha<\omega_1} \mathcal{S}^\sigma_\alpha = \bigcup_{\alpha<\omega_1} \mathcal{S}^\delta_\alpha$$

(where ω_1 is the first uncountable ordinal, i.e. the union is over all countable ordinals).

PROOF: Let $\mathcal{B} = \bigcup_{\alpha<\omega_1} \mathcal{S}^\sigma_\alpha$. Then $\mathcal{S} \subseteq \mathcal{S}^\sigma_0 \subseteq \mathcal{B}$, and it is easily seen recursively that any σ-algebra containing $\mathcal{S}$ must contain $\mathcal{S}^\sigma_\alpha$ for any α; thus $\mathcal{B} \subseteq \mathcal{A}$. Thus it suffices to show that $\mathcal{B}$ is a σ-algebra. If $A \in \mathcal{S}^\sigma_\alpha$, then $A^c \in \mathcal{S}^\sigma_{\alpha+1}$, so $\mathcal{B}$ is closed under complements, and since $\emptyset \in \mathcal{S}^\sigma_0 \subseteq \mathcal{B}$, $X \in \mathcal{S}^\sigma_1 \subseteq \mathcal{B}$. If (A_n) is a sequence of sets in $\mathcal{B}$, say $A_n \in \mathcal{S}^\sigma_{\alpha_n}$, there is a countable α such that $\alpha_n \leq \alpha$ for all n; thus $A_n \in \mathcal{S}^\sigma_\alpha$ for all n, and so $\cup_n A_n \in \mathcal{S}^\sigma_{\alpha+1} \subseteq \mathcal{B}$. Thus $\mathcal{B}$ is closed under countable unions.

A similar proof shows that $\mathcal{A} = \bigcup_{\alpha<\omega_1} \mathcal{S}^\delta_\alpha$, or just note that by de Morgan, $\mathcal{S}^\delta_\alpha \subseteq \mathcal{S}^\sigma_{\alpha+1}$ and $\mathcal{S}^\sigma_\alpha \subseteq \mathcal{S}^\delta_{\alpha+1}$ for all α. 👍

XVI.1.3.9. In some situations, the transfinite sequences $\mathcal{S}^\sigma_\alpha$ and $\mathcal{S}^\delta_\alpha$ stabilize at some $\alpha < \omega_1$, even occasionally for some finite α, but in general, and even in the most important cases (cf. ()), they do not stabilize and the construction must be carried out uncountably.

XVI.1.3.10. There is a similar but finite process to explicitly construct the algebra generated by a collection $\mathcal{S}$ of subsets of a set X, involving both unions and intersections. Set $\mathcal{S}_0 = \mathcal{S} \cup \tilde{\mathcal{S}} \cup \{\emptyset, X\}$, let $\mathcal{S}_1$ be the set of finite intersections of sets in $\mathcal{S}_0$, and $\mathcal{S}_2$ the set of finite unions of sets in $\mathcal{S}_1$.

XVI.1.3.11. PROPOSITION. $\mathcal{S}_2$ is the algebra $\mathcal{A}$ of subsets of X generated by $\mathcal{S}$.

PROOF: We have $\mathcal{S} \subseteq \mathcal{S}_0 \subseteq \mathcal{S}_1 \subseteq \mathcal{S}_2 \subseteq \mathcal{A}$ and $\emptyset, X \in \mathcal{S}_0 \subseteq \mathcal{S}_2$. $\mathcal{S}_1$ is closed under finite intersections and $\mathcal{S}_2$ closed under finite unions. $\mathcal{S}_2$ is closed under finite intersections too: if $A, B \in \mathcal{S}_2$, $A = \cup_{j=1}^n A_j$, $B = \cup_{k=1}^m B_k$ with $A_j, B_k \in \mathcal{S}_1$, then

$$A \cap B = \bigcup_{j=1}^{n} \bigcup_{k=1}^{m} (A_j \cap B_k) \in \mathcal{S}_2 \ .$$

We now show $\mathcal{S}_2$ is closed under complements. Let $A \in \mathcal{S}_2$. Then $A = \cup_{j=1}^n A_j$, where $A_j \in \mathcal{S}_1$; $A_j = \cap_{k=1}^{m_j} A_{jk}$ for $A_{jk} \in \mathcal{S}_0$. We have

$$A^c = \bigcap_{j=1}^{n} \bigcup_{k=1}^{m_j} A^c_{jk} \ .$$

Since $\mathcal{S}_0$ is closed under complements, $A^c_{jk} \in \mathcal{S}_0 \subseteq \mathcal{S}_2$ for all j, k; since $\mathcal{S}_2$ is closed under finite unions and intersections, $A^c \in \mathcal{S}_2$. Thus $\mathcal{S}_2$ is an algebra, so $\mathcal{A} \subseteq \mathcal{S}_2$. 👍

XVI.1.4. σ-Rings and δ-Rings

It is useful for some purposes to have two other types of structures intermediate between rings and σ-algebras.

XVI.1.4.1. DEFINITION. Let X be a set. A ring $\mathcal{D}$ of subsets of X is a *σ-ring* if it is closed under countable unions. $\mathcal{D}$ is a *δ-ring* if it is closed under countable intersections.

Note that a σ-algebra is a σ-ring, and a σ-ring is a σ-algebra if and only if it contains X. In fact, a σ-ring $\mathcal{D}$ of subsets of X can only fail to be a σ-algebra because there are subsets of X which are "too large" to be in $\mathcal{D}$. In fact, if $\mathcal{D}$ is a σ-ring or δ-ring of subsets of a set X, and $Y \in \mathcal{D}$, then $\mathcal{D}_Y = \{A \in \mathcal{D} : A \subseteq Y\}$ is a σ-algebra of subsets of Y.

XVI.1.4.2. PROPOSITION. Let X be a set. A ring $\mathcal{D}$ of subsets of X is a δ-ring if and only if whenever $\{A_n : n \in \mathbb{N}\}$ is a sequence in $\mathcal{D}$, and there is a $B \in \mathcal{D}$ with $A_n \subseteq B$ for all n, then $\cup_{n=1}^{\infty} A_n \in \mathcal{D}$.

PROOF: Suppose $\mathcal{D}$ is a δ-ring, and the A_n and B are as in the statement. For each n, set $B_n = B \setminus A_n$. Then $B_n \in \mathcal{D}$, so $\cap_{n=1}^{\infty} B_n \in \mathcal{D}$. Then

$$\bigcup_{n=1}^{\infty} A_n = B \setminus \left(\bigcap_{n=1}^{\infty} B_n \right) \in \mathcal{D} \ .$$

Conversely, if $\mathcal{D}$ has the property in the statement, and (B_n) is a sequence in $\mathcal{D}$, set $A_n = B_1 \setminus B_n$ for each n. We have $A_n \in \mathcal{D}$ and $A_n \subseteq B_1$ for each n, so $\cup_{n=1}^{\infty} A_n \in \mathcal{D}$. Then

$$\bigcap_{n=1}^{\infty} B_n = B_1 \setminus \left(\bigcup_{n=1}^{\infty} A_n \right) \in \mathcal{D} \ .$$

XVI.1.4.3. COROLLARY. A σ-ring is a δ-ring.

XVI.1.4.4. EXAMPLES. (i) Let X be an uncountable set. The collection $\mathcal{D}$ of countable subsets of X is a σ-ring.

(ii) Let X be a set, and $Y \subseteq X$. Any σ-ring (e.g. any σ-algebra) of subsets of Y is a σ-ring of subsets of X.

(iii) The collection of all bounded subsets of $\mathbb{R}$ is a δ-ring of subsets of $\mathbb{R}$ which is not a σ-ring. This, or slight modifications, is the prototype example.

(iv) Another (not too interesting) example of a δ-ring which is not a σ-ring: let X be an infinite set, and $\mathcal{D}$ the collection of finite subsets of X.

(v) If X is a locally compact Hausdorff space which is not σ-compact, the collection of subsets of X whose closure is σ-compact is a σ-ring.

(vi) If X is any set, then $\{\emptyset\}$ is a (not very interesting) σ-ring.

XVI.1.4.5. Any intersection of σ-rings [resp. δ-rings] of subsets of a set X is a σ-ring [resp. δ-ring] of subsets of X. So if $\mathcal{S}$ is any collection of subsets of X, there is a smallest σ-ring [resp. δ-ring] containing $\mathcal{S}$, called the *σ-ring [resp. δ-ring] generated by $\mathcal{S}$*; it is the intersection of all σ-rings [resp. δ-ring] containing $\mathcal{S}$ (there is at least one, $\mathcal{P}(X)$).

Hereditary Subcollections and a Characterization

XVI.1.4.6. Let X be a set, and $\mathcal{S}$ a collection of subsets of X (in applications $\mathcal{S}$ will usually be at least a ring, but this is not necessary for the definitions). A nonempty subcollection $\mathcal{H}$ of $\mathcal{S}$ is called *hereditary* if $A \in \mathcal{H}$, $B \in \mathcal{S}$, $B \subseteq A$ implies $B \in \mathcal{H}$. If $\mathcal{R}$ is another nonempty collection of subsets of X (in applications $\mathcal{R}$ will usually be a ring contained in $\mathcal{S}$, but this is not necessary for the definition), write

$$\mathcal{H}_{\mathcal{R}}(\mathcal{S}) = \{B \in \mathcal{S} : B \subseteq A \text{ for some } A \in \mathcal{R}\} .$$

Then it is easily checked that $\mathcal{H}_{\mathcal{R}}(\mathcal{S})$, if nonempty (automatic if $\mathcal{R} \subseteq \mathcal{S}$), is a hereditary subset of $\mathcal{S}$, and $\mathcal{R} \subseteq \mathcal{H}$ if $\mathcal{R} \subseteq \mathcal{S}$. (Every hereditary subcollection $\mathcal{H}$ of $\mathcal{S}$ is of this form: we have $\mathcal{H} = \mathcal{H}_{\mathcal{H}}(\mathcal{S})$.)

If $\mathcal{S}$ is a ring, and $\mathcal{R}$ is closed under finite unions (e.g. if $\mathcal{R}$ is also a ring), then $\mathcal{H}_{\mathcal{R}}(\mathcal{S})$ is also a ring: since $\emptyset \in \mathcal{S}$ and $\mathcal{R} \neq \emptyset$, $\emptyset \in \mathcal{H}_{\mathcal{R}}(\mathcal{S})$, so $\mathcal{H}_{\mathcal{R}}(\mathcal{S}) \neq \emptyset$; if $A, B \in \mathcal{H}_{\mathcal{R}}(\mathcal{S})$, then $A \subseteq D$ for some $D \in \mathcal{R}$, so $A \setminus B \subseteq A \subseteq D$ and $A \setminus B \in \mathcal{S}$, so $A \setminus B \in \mathcal{H}_{\mathcal{R}}(\mathcal{S})$; and if $A, B \in \mathcal{H}_{\mathcal{R}}(\mathcal{S})$, then $A \subseteq C$ and $B \subseteq D$ for some $C, D \in \mathcal{R}$, and therefore $A \cup B \in \mathcal{S}$ and $A \cup B \subseteq C \cup D \in \mathcal{R}$, so $A \cup B \in \mathcal{H}_{\mathcal{R}}(\mathcal{S})$, and thus $\mathcal{H}_{\mathcal{R}}(\mathcal{S})$ is closed under finite unions. If $\mathcal{S}$ is a δ-ring, so is $\mathcal{H}_{\mathcal{R}}(\mathcal{S})$. Similarly, if $\mathcal{R}$ is closed under countable unions and $\mathcal{S}$ is a σ-ring, then $\mathcal{H}_{\mathcal{R}}(\mathcal{S})$ is also a σ-ring.

If $\mathcal{R}$ is a ring, there is a nice connection with the algebra it generates:

XVI.1.4.7. Proposition. Let X be a set, $\mathcal{R}$ a ring of subsets of X, and $\mathcal{A}$ the algebra of subsets of X generated by $\mathcal{R}$. Then $\mathcal{R} = \mathcal{H}_{\mathcal{R}}(\mathcal{A})$.

Proof: We have $\mathcal{R} \subseteq \mathcal{H}_{\mathcal{R}}(\mathcal{A})$ since $\mathcal{R} \subseteq \mathcal{A}$. Conversely, we use the characterization in XVI.1.3.6.. Suppose $A \in \mathcal{H}_{\mathcal{R}}(\mathcal{A})$. Then either $A \in \mathcal{R}$, in which case there is nothing to prove, or $A = B \cup C^c$ for $B, C \in \mathcal{R}$, and there is a $D \in \mathcal{R}$ with $A \subseteq D$. Then $D \setminus C \in \mathcal{R}$, and $C^c \subseteq D$, so $C^c = D \setminus C \in \mathcal{R}$, and thus $A = B \cup (D \setminus C) \in \mathcal{R}$. Thus $\mathcal{H}_{\mathcal{R}}(\mathcal{A}) \subseteq \mathcal{R}$. 👍

There is a similar characterization of δ-rings (and, in particular, σ-rings):

XVI.1.4.8. Theorem. et X be a set, $\mathcal{D}$ a δ-ring of subsets of X, and $\mathcal{A}$ the σ-algebra of subsets of X generated by $\mathcal{D}$. Then $\mathcal{D} = \mathcal{H}_{\mathcal{D}}(\mathcal{A})$.

Proof: We have $\mathcal{D} \subseteq \mathcal{H}_{\mathcal{D}}(\mathcal{A})$ since $\mathcal{D} \subseteq \mathcal{A}$. Conversely, we use the construction in XVI.1.3.8.. It suffices to show by transfinite induction that (using the notation of XVI.1.3.8.) $\mathcal{H}_{\mathcal{D}}(\mathcal{D}^{\delta}_{\alpha}) \subseteq \mathcal{D}$ for every $\alpha < \omega_1$. We have $\mathcal{H}_{\mathcal{D}}(\mathcal{D}^{\delta}_{0}) \subseteq \mathcal{D}^{\delta}_{0} = \mathcal{D}$. If α is a limit ordinal and $\mathcal{H}_{\mathcal{D}}(\mathcal{D}^{\delta}_{\beta}) \subseteq \mathcal{D}$ for all $\beta < \alpha$, then clearly $\mathcal{H}_{\mathcal{D}}(\mathcal{D}^{\delta}_{\alpha}) \subseteq \mathcal{D}$. Now suppose $\mathcal{H}_{\mathcal{D}}(\mathcal{D}^{\delta}_{\alpha}) \subseteq \mathcal{D}$. Suppose $A \in \mathcal{H}_{\mathcal{D}}(\mathcal{D}^{\delta}_{\alpha} \cup \widetilde{\mathcal{D}^{\delta}_{\alpha}})$. Then there is a $B \in \mathcal{D}$ with $A \subseteq B$, and $A \in \mathcal{D}^{\delta}_{\alpha} \cup \widetilde{\mathcal{D}^{\delta}_{\alpha}}$. If $A \in \mathcal{D}^{\delta}_{\alpha}$, then $A \in \mathcal{H}_{\mathcal{D}}(\mathcal{D}^{\delta}_{\alpha}) \subseteq \mathcal{D}$. If $A \in \widetilde{\mathcal{D}^{\delta}_{\alpha}}$, then $A^c \in \mathcal{D}^{\delta}_{\alpha} \subseteq \mathcal{D}$. So $A = B \setminus A^c \in \mathcal{D}$. Finally, if $A \in \mathcal{H}_{\mathcal{D}}(\mathcal{D}^{\delta}_{\alpha+1}) = \mathcal{H}_{\mathcal{D}}([\mathcal{D}^{\delta}_{\alpha} \cup \widetilde{\mathcal{D}^{\delta}_{\alpha}}]_{\delta})$, then there is a $B \in \mathcal{D}$ with $A \subseteq B$, and a sequence (A_n) in $\mathcal{D}^{\delta}_{\alpha} \cup \widetilde{\mathcal{D}^{\delta}_{\alpha}}$ with $A = \cap_n A_n$. Fix n. If $A_n \in \mathcal{D}^{\delta}_{\alpha}$, then $B \cap A_n \in \mathcal{D}^{\delta}_{\alpha}$ since $\mathcal{D} \subseteq \mathcal{D}^{\delta}_{\alpha}$ and $\mathcal{D}^{\delta}_{\alpha}$ is closed under finite (even countable) intersections. Thus $B \cap A_n \in \mathcal{H}_{\mathcal{D}}(\mathcal{D}^{\delta}_{\alpha}) \subseteq \mathcal{D}$. And if $A_n \in \widetilde{\mathcal{D}^{\delta}_{\alpha}}$, then $A_n^c \in \mathcal{D}^{\delta}_{\alpha}$, so $B \cap A_n^c \in \mathcal{D}$ by the same argument, and thus $B \cap A_n = B \setminus (B \cap A_n^c) \in \mathcal{D}$. Therefore $B \cap A_n \in \mathcal{D}$ for all n, so $A = \cap_n (B \cap A_n) \in \mathcal{D}$. This completes the inductive argument. 👍

XVI.1.4.9. **Caution:** Putting together XVI.1.4.8. and XVI.1.4.7., if $\mathcal{D}$ is a δ-ring, $\mathcal{A}$ the σ-algebra generated by $\mathcal{D}$, and $\mathcal{B}$ the algebra generated by $\mathcal{D}$, we have $\mathcal{H}_{\mathcal{D}}(\mathcal{A}) = \mathcal{H}_{\mathcal{D}}(\mathcal{B}) = \mathcal{D}$. However, this does *not* mean that $\mathcal{A} = \mathcal{B}$! ($\mathcal{B}$ will not be closed under countable unions in general.) But if $\mathcal{D}$ is a σ-ring, it is true that $\mathcal{A} = \mathcal{B}$: an argument nearly identical to the one in XVI.1.3.6. shows that $\mathcal{B}$ is closed under countable unions and is thus a σ-algebra (this argument gives a simpler proof of XVI.1.4.8. if $\mathcal{D}$ is a σ-ring).

Locally Measurable Sets

In measure theory, the sets in a specified collection of subsets of a fixed set, typically at least a δ-ring and normally a σ-algebra, are called "measurable" sets since a numerical size or measure is assigned to them. For general collections of subsets, there is a more general notion of "measurability" which is useful:

XVI.1.4.10. Definition. Let $\mathcal{S}$ be a collection of subsets of a set X. A subset E of X is *locally $\mathcal{S}$-measurable* if $E \cap A \in \mathcal{S}$ for every $A \in \mathcal{S}$.

XVI.1.4.11. If $\mathcal{S}$ is understood, we just say "locally measurable" instead of "locally $\mathcal{S}$-measurable." If $\mathcal{S}$ is closed under finite intersections, then every set in $\mathcal{S}$ is locally measurable; the converse holds if $X \in \mathcal{S}$. Thus if $\mathcal{S}$ is an algebra, then the locally $\mathcal{S}$-measurable sets are precisely the sets in $\mathcal{S}$. Local measurability is most important if $\mathcal{S}$ is a δ-ring which is not a σ-algebra.

XVI.1.4.12. If $\mathcal{S}$ is closed under finite intersections, so is the collection $\mathcal{M}$ of locally $\mathcal{S}$-measurable sets since $(E \cap F) \cap A = (E \cap A) \cap (F \cap A)$, and $\mathcal{S}$ is a hereditary subset of $\mathcal{M}$, motivating the term "locally measurable." If $\mathcal{R}$ is a ring, then the collection $\mathcal{M}$ of locally $\mathcal{R}$-measurable sets is an algebra, since if $E \in \mathcal{M}$ and $A \in \mathcal{R}$, then $E^c \cap A = A \setminus (A \cap E) \in \mathcal{R}$. If $\mathcal{D}$ is a δ-ring, then $\mathcal{M}$ is a σ-algebra and $\mathcal{D}$ is a hereditary subset of $\mathcal{M}$ (). If $\mathcal{A}$ is the σ-algebra generated by the δ-ring $\mathcal{D}$, then $\mathcal{A} \subseteq \mathcal{M}$ by (). The containment is proper in general unless $\mathcal{D}$ is σ-finite: for example, if X is an uncountable set and $\mathcal{D}$ is the σ-ring of countable subsets of X, then $\mathcal{A}$ is the collection of countable and cocountable sets, but every subset of X is locally measurable.

XVI.1.5. π-Systems, λ-Systems, and Monotone Classes

We will occasionally have use for some collections of sets with other combinations of closure properties, and it will be convenient to have names for them.

XVI.1.5.1. Definition. Let X be a set.

A nonempty collection $\mathcal{Q}$ of subsets of X is a *π-system* if it is closed under finite intersections.

A collection $\mathcal{L}$ of subsets of X is a *λ-system* if it contains X and is closed under complements and countable disjoint unions.

A nonempty collection $\mathcal{N}$ of subsets of X is a *monotone class* if it is closed under countable monotone unions and intersections: if (A_n) is an increasing sequence in $\mathcal{N}$, then $\cup_{n=1}^{\infty} A_n \in \mathcal{N}$, and if (B_n) is a decreasing sequence in $\mathcal{N}$, then $\cap_{n=1}^{\infty} B_n \in \mathcal{N}$.

XVI.1.5.2. EXAMPLES. (i) A semiring is a π-system. A σ-algebra is both a λ-system and a monotone class. A λ-system contains $\emptyset$, and is thus also closed under finite disjoint unions.

(ii) A π-system need not be a semiring. For example, a topology on X is a π-system but usually not a semiring.

(iii) A λ-system need not be closed under even finite unions. For example, let X be a finite set with an even number of elements (> 2), and $\mathcal{L}$ the collection of all subsets with an even number of elements. Then $\mathcal{L}$ is a λ-system, but is not closed under finite unions. $\mathcal{L}$ is also a monotone class.

(iv) A monotone class need not be closed under either finite unions or finite intersections, or even finite disjoint unions. In fact, any finite collection of subsets of a set X is a monotone class.

(v) Any intersection of π-systems (on a fixed set X) is a π-system, and similarly for λ-systems and monotone classes. So if $\mathcal{S}$ is any collection of subsets of a set X, there is a smallest π-system containing $\mathcal{S}$, denoted $\pi(\mathcal{S})$; similarly there is a smallest λ-system $\lambda(\mathcal{S})$ and a smallest monotone class $\upsilon(\mathcal{S})$ containing $\mathcal{S}$. $\pi(\mathcal{S})$ just consists of all finite intersections of sets in $\mathcal{S}$, but $\lambda(\mathcal{S})$ and $\upsilon(\mathcal{S})$ do not have simple descriptions in general.

XVI.1.5.3. PROPOSITION. (i) A λ-system of subsets of a set X is closed under relative monotone complements: if $A, B \in \mathcal{L}$ and $A \subseteq B$, then $B \setminus A \in \mathcal{L}$.

(ii) Let $\mathcal{L}$ be a collection of subsets of a set X containing X and closed under relative monotone complements and finite and countable disjoint unions. Then $\mathcal{L}$ is a λ-system.

PROOF: (i): $B \setminus A = [A \cup B^c]^c$, and $A \cap B^c = \emptyset$.
(ii): If $A \in \mathcal{L}$, then $A^c = X \setminus A \in \mathcal{L}$ since $X \in \mathcal{L}$. 👍

XVI.1.5.4. PROPOSITION. A collection $\mathcal{A}$ of subsets of a set X which is both a π-system and a λ-system is a σ-algebra.

PROOF: $\mathcal{A}$ is closed under complements and finite intersections, hence an algebra. Thus $\mathcal{A}$ is closed under relative complements. If (A_n) is a sequence of sets in A, let $B_1 = A_1$ and $B_n = A_n \setminus A_{n-1}$ for $n > 1$, then (B_n) is a pairwise disjoint sequence of sets in $\mathcal{A}$, so $\cup_{n=1}^{\infty} B_n = \cup_{n=1}^{\infty} A_n \in \mathcal{A}$, so $\mathcal{A}$ is closed under countable unions. 👍

The following variation of this result will be important:

XVI.1.5.5. THEOREM. [DYNKIN'S $(\pi - \lambda)$-THEOREM] Let X be a set, $\mathcal{Q}$ a π-system in X, and $\mathcal{L}$ a λ-system in X. If $\mathcal{Q} \subseteq \mathcal{L}$, then $\sigma(\mathcal{Q}) \subseteq \mathcal{L}$.

PROOF: By XVI.1.5.4., it suffices to show that $\lambda(\mathcal{Q})$ is a π-system, since $\lambda(\mathcal{Q})$ is a λ-system contained in $\mathcal{L}$ by minimality.

If $A \subseteq X$, let

$$\mathcal{L}_A = \{B \subseteq X : A \cap B \in \lambda(\mathcal{Q})\} .$$

If $A \in \lambda(\mathcal{Q})$, then we show that $\mathcal{L}_A$ is a λ-system. X is trivially in $\mathcal{L}_A$. If $B, C \in \mathcal{L}_A$, $C \subseteq B$, then $A \cap B$ and $A \cap C$ are in $\lambda(\mathcal{Q})$, so $A \cap (B \setminus C) = (A \cap C) \setminus (A \cap B) \in \lambda(\mathcal{Q})$ by XVI.1.5.3.(i), since $\lambda(\mathcal{Q})$ is a λ-system. Thus $B \setminus C \in \mathcal{L}_A$ and $\mathcal{L}_A$ is closed under relative monotone complements. If (B_n) is a pairwise disjoint sequence in $\mathcal{L}_A$, then $(A \cap B_n)$ is a pairwise disjoint sequence in $\lambda(\mathcal{Q})$, hence $A \cap [\cup_{n=1}^{\infty} B_n] = \cup_{n=1}^{\infty}(A \cap B_n) \in \lambda(\mathcal{Q})$, i.e. $\cup_{n=1}^{\infty} B_n \in \mathcal{L}_A$, and $\mathcal{L}_A$ is closed under countable disjoint unions. So $\mathcal{L}_A$ is a λ-system if $A \in \lambda(\mathcal{Q})$, and in particular if $A \in \mathcal{Q}$.

Now suppose $A \in \mathcal{Q}$. If $B \in \mathcal{Q}$, then $A \cap B \in \mathcal{Q}$ since $\mathcal{Q}$ is a π-system, and thus $B \in \mathcal{L}_A$. So if $A \in \mathcal{Q}$, then $\mathcal{Q} \subseteq \mathcal{L}_A$, and thus $\lambda(\mathcal{Q}) \subseteq \mathcal{L}_A$ by minimality of $\lambda(\mathcal{Q})$.

Note that if $A, B \subseteq X$, then $B \in \mathcal{L}_A$ if and only if $A \in \mathcal{L}_B$. If $A \in \mathcal{Q}$ and $B \in \lambda(\mathcal{Q})$, then $B \in \mathcal{L}_A$ since $\lambda(\mathcal{Q}) \subseteq \mathcal{L}_A$, and thus $A \in \mathcal{L}_B$. Thus, for $B \in \lambda(\mathcal{Q})$, $\mathcal{Q} \subseteq \mathcal{L}_B$, and hence $\lambda(\mathcal{Q}) \subseteq \mathcal{L}_B$ by minimality of $\lambda(\mathcal{Q})$. If $B, C \in \lambda(\mathcal{Q})$, we have $C \in \mathcal{L}_B$, i.e. $B \cap C \in \lambda(\mathcal{Q})$, so $\lambda(\mathcal{Q})$ is a π-system. 👍

We have similar results for monotone classes, due to Halmos, which will be useful:

XVI.1.5.6. Proposition. An algebra of subsets of a set X which is also a monotone class is a σ-algebra.

Proof: Let $\mathcal{A}$ be an algebra of subsets of X, and suppose $\mathcal{A}$ is also a monotone class. Let (A_n) be a sequence of sets in $\mathcal{A}$. For each n, set $B_n = \cap_{k=1}^{n} A_k$. Then (B_n) is a decreasing sequence of sets in $\mathcal{A}$ since $\mathcal{A}$ is an algebra, and hence $\cap_{n=1}^{\infty} B_n = \cap_{n=1}^{\infty} A_n \in \mathcal{A}$ since $\mathcal{A}$ is a monotone class. 👍

XVI.1.5.7. Theorem. [Monotone Class Theorem] Let X be a set, $\mathcal{A}$ an algebra of subsets of a set X, and $\mathcal{N}$ a monotone class of subsets of X. If $\mathcal{A} \subset \mathcal{N}$, then $\sigma(\mathcal{A}) \subseteq \mathcal{N}$.

XVI.1.6. Measurable Spaces and Measurable Functions

XVI.1.6.1. Definition. A *measurable space* $(X, \mathcal{A})$ is a set X with a specified σ-algebra $\mathcal{A}$ of subsets.

Measurable spaces are the natural setting for measure theory, which will be developed in (). Note the analogy with the definition of a topological space. Measurable spaces are often called *Borel spaces*, especially (but not necessarily) if they come from a topological space as in ().

As usual with mathematical theories, it is important not only to have sets with a structure, but to have a class of functions which preserve the structure to serve as the morphisms of the theory. Experience shows that the appropriate morphisms between measurable spaces are the *measurable functions*:

XVI.1.6.2. Definition. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measurable spaces, and $f : X \to Y$ a function. Then f is $(\mathcal{A}, \mathcal{B})$-*measurable* (or just *measurable* if the $\mathcal{A}$ and $\mathcal{B}$ are understood) if $f^{-1}(B) \in \mathcal{A}$ for every $B \in \mathcal{B}$.

Note the close analogy with the definition of a continuous function between topological spaces () (although there is no useful notion of "measurability at a point.") When measurable spaces are called Borel spaces, measurable functions between them are often called *Borel functions*, although this terminology can sometimes be slightly ambiguous.

XVI.1.6.3. PROPOSITION. Let $(X, \mathcal{A})$, $(Y, \mathcal{B})$, and $(Z, \mathcal{C})$ be measurable spaces, and $f : X \to Y$ and $g : Y \to Z$ functions. If f is $(\mathcal{A}, \mathcal{B})$-measurable and g is $(\mathcal{B}, \mathcal{C})$-measurable, then $g \circ f$ is $(\mathcal{A}, \mathcal{C})$-measurable.

The proof is virtually identical to the proof that a composition of continuous functions is continuous.

XVI.1.6.4. Thus the measurable spaces and measurable functions form a category. An isomorphism in this category, i.e. a bijection f such that both f and f^{-1} are measurable, is often called a *Borel isomorphism*. An isomorphism (Borel isomorphism) between measurable spaces $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ is a bijection $f : X \to Y$ such that, for $A \subseteq X$, $f(A) \in \mathcal{B}$ if and only if $A \in \mathcal{A}$.

XVI.1.6.5. Just as with continuity, the larger $\mathcal{A}$ is, or the smaller $\mathcal{B}$ is, the easier it is for a function to be measurable. Given $\mathcal{A}$, there is a largest $\mathcal{B}$ making f measurable, and similarly, given $\mathcal{B}$, there is a smallest corresponding $\mathcal{A}$. These are given by the following construction:

XVI.1.6.6. DEFINITION. Let X and Y be sets, and $f : X \to Y$ a function. If $\mathcal{A}$ is a σ-algebra on X, set

$$f^{\rightarrow}(\mathcal{A}) = \{B \subset Y : f^{-1}(B) \in \mathcal{A}\}.$$

If $\mathcal{B}$ is a σ-algebra on Y, set

$$f^{\leftarrow}(\mathcal{B}) = \{f^{-1}(B) : B \in \mathcal{B}\}.$$

XVI.1.6.7. PROPOSITION. Let X and Y are measurable spaces and $f : X \to Y$ a function.

(i) If $\mathcal{A}$ is a σ-algebra on X, then $f^{\rightarrow}(\mathcal{A})$ is a σ-algebra on Y.

(ii) If $\mathcal{B}$ is a σ-algebra on Y, then $f^{\leftarrow}(\mathcal{B})$ is a σ-algebra on X.

PROOF: Both parts follow easily from the fact that $f^{-1}(\emptyset) = \emptyset$, $f^{-1}(Y) = X$, $f^{-1}(B^c) = [f^{-1}(B)]^c$, and $f^{-1}(\cup_{n=1}^{\infty} B_n) = \cup_{n=1}^{\infty} f^{-1}(B_n)$ for any $B, B_n \subseteq Y$ (). 👍

XVI.1.6.8. In fact, if $(X, \mathcal{A})$ is a measurable space and Y is a set, and $f : X \to Y$ is a function, then $f^{\rightarrow}(\mathcal{A})$ is the largest σ-algebra on Y making f measurable. Similarly, if $f : X \to (Y, \mathcal{B})$, then $f^{\leftarrow}(\mathcal{B})$ is the smallest σ-algebra on X making f measurable.

Note, however, that $f^{\rightarrow}(\mathcal{A})$ and $f^{\leftarrow}(\mathcal{B})$ can be quite degenerate: for example, if f is a constant function, then $f^{\rightarrow}(\mathcal{A}) = \mathcal{P}(Y)$ and $f^{\leftarrow}(\mathcal{B}) = \{\emptyset, X\}$ no matter what $\mathcal{A}$ and $\mathcal{B}$ are. There are examples where $f^{\rightarrow}(\mathcal{A}) = \{\emptyset, Y\}$ even for nondegenerate f and $\mathcal{A}$ (); $f^{\leftarrow}(\mathcal{B})$ is less degenerate in general.

Although it would appear that $f^{\rightarrow}$ and $f^{\leftarrow}$ are "inverse" to each other, this is not the case in general: we always have that $f^{\leftarrow}(f^{\rightarrow}(\mathcal{A})) \subseteq \mathcal{A}$ and $f^{\rightarrow}(f^{\leftarrow}(\mathcal{B})) \supseteq \mathcal{B}$, but equality does not hold in general ().

The next theorem is one of the most useful facts about mappings of σ-algebras.

XVI.1.6.9. THEOREM. Let X and Y be sets, $f : X \to Y$ a function, and $\mathcal{B}$ a σ-algebra on Y. If $\mathcal{C} \subseteq \mathcal{B}$ is a subset which generates $\mathcal{B}$ as a σ-algebra, then $f^{\leftarrow}(\mathcal{C}) = \{f^{-1}(C) : C \in \mathcal{C}\}$ generates $f^{\leftarrow}(\mathcal{B})$ as a σ-algebra.

PROOF: Let $\mathcal{A}$ be the σ-algebra on X generated by $f^{\leftarrow}(\mathcal{C})$. Then $\mathcal{A} \subseteq f^{\leftarrow}(\mathcal{B})$ since by XVI.1.6.7. $f^{\leftarrow}(\mathcal{B})$ is a σ-algebra containing $f^{\leftarrow}(\mathcal{C})$. Let

$$\mathcal{B}_0 = f^{\rightarrow}(\mathcal{A}) \cap \mathcal{B} = \{B \in \mathcal{B} : f^{-1}(B) \in \mathcal{A}\}.$$

By XVI.1.6.7., $\mathcal{B}_0$ is the intersection of two σ-algebras, hence is a σ-algebra; and $\mathcal{B}_0 \subseteq \mathcal{B}$. Also, $\mathcal{C} \subseteq \mathcal{B}_0$. But $\mathcal{C}$ generates $\mathcal{B}$ as a σ-algebra, so $\mathcal{B}_0 = \mathcal{B}$, and hence $f^{-1}(B) \in \mathcal{A}$ for any $B \in \mathcal{B}$, i.e. $f^{\leftarrow}(\mathcal{B}) \subseteq \mathcal{A}$, so $\mathcal{A} = f^{\leftarrow}(\mathcal{B})$. 👍

XVI.1.6.10. COROLLARY. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measurable spaces, $f : X \to Y$ a function, and $\mathcal{C}$ a subset of $\mathcal{B}$ which generates $\mathcal{B}$ as a σ-algebra. Then f is measurable if and only if $f^{-1}(C) \in \mathcal{A}$ for every $C \in \mathcal{C}$.

PROOF: It is obvious that if f is measurable, then $f^{-1}(C) \in \mathcal{A}$ for every $C \in \mathcal{C}$. The converse follows immediately from XVI.1.6.9., since by assumption the σ-algebra on X generated by $f^{\leftarrow}(\mathcal{C})$, which by the theorem is $f^{\leftarrow}(\mathcal{B})$, is contained in $\mathcal{A}$. 👍

The next simple observation is extraordinarily useful in defining measurable functions piecewise:

XVI.1.6.11. PROPOSITION. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measurable spaces, and let (E_n) be a sequence in $\mathcal{A}$ with $\cup_{n=1}^{\infty} E_n = X$. (Since $\emptyset \in \mathcal{A}$, (E_n) could also be a finite sequence.) Let $f : X \to Y$ be a function, and set $f_n = f|_{E_n} : E_n \to Y$. If each f_n is measurable, then f is measurable.

PROOF: Let $B \in \mathcal{B}$. We need to show that $f^{-1}(B) \in \mathcal{A}$. By assumption, $f_n^{-1}(B) = \{x \in E_n : f_n(x) = f(x) \in B\}$ is in $\mathcal{A}$. But $f^{-1}(B) = \cup_{n=1}^{\infty} f_n^{-1}(B)$. 👍

A slight rephrasing is usually used in piecewise definition of functions:

XVI.1.6.12. COROLLARY. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measurable spaces, and let (E_n) be a sequence in $\mathcal{A}$ which partitions X, i.e. the E_n are pairwise disjoint and $\cup_{n=1}^{\infty} E_n = X$. (Since $\emptyset \in \mathcal{A}$, (E_n) could also be a finite sequence.) For each n, let $f_n : E_n \to Y$ be a function, and define $f : X \to Y$ by $f(x) = f_n(x)$ if $x \in E_n$. If each f_n is measurable, then f is measurable.

XVI.1.6.13. We can also rephrase the last two results in another way. If $(X, \mathcal{A})$ is a measurable space, and $E \in \mathcal{A}$, the *restriction* of $\mathcal{A}$ to E is

$$\mathcal{A}_E = \{A \cap E : A \in \mathcal{A}\} = \{B : B \in \mathcal{A}, B \subseteq E\}$$

which can be easily verified to be a σ-algebra of subsets of E (). The measurable space $(E, \mathcal{A}_E)$ is called a *measurable subspace*, or *Borel subspace*, of $(X, \mathcal{A})$.

XVI.1.6.14. DEFINITION. (i) If $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ are measurable spaces, the *sum* or *disjoint union* is the measurable space $(Z, \mathcal{C})$, where Z is the disjoint union $X \sqcup Y$ () and

$$\mathcal{C} = \{A \sqcup B : A \in \mathcal{A}, B \in \mathcal{B}\}$$

(it is easy to check that $\mathcal{C}$ is a σ-algebra of subsets of $X \sqcup Y$). The sum is denoted $(X, \mathcal{A}) \oplus (Y, \mathcal{B})$.
(ii) Let $(X_n, \mathcal{A}_n)$ be a finite or countable set of measurable spaces. The *sum* or *disjoint union*, denoted $\bigoplus_n (X_n, \mathcal{A}_n)$, is the measurable space $(Z, \mathcal{C})$, where $Z = \sqcup_n X_n$ and

$$\mathcal{C} = \{\sqcup_n A_n : A_n \in \mathcal{A}_n \text{ for all } n\}$$

(it is again easy to check that $\mathcal{C}$ is a σ-algebra of subsets of Z (Exercise ()).)

Then XVI.1.6.11. can be rephrased:

XVI.1.6.15. PROPOSITION. Let $(X, \mathcal{A})$ be a measurable space, and let (E_n) be a sequence in $\mathcal{A}$ which partitions X, i.e. the E_n are pairwise disjoint and $\cup_{n=1}^{\infty} E_n = X$. (Since $\emptyset \in \mathcal{A}$, (E_n) could also be a finite sequence.) Let f_n be the inclusion map of E_n into X, and $f : \sqcup_n E_n \to X$ the induced map. Then f is a Borel isomorphism from $\bigoplus_n (E_n, \mathcal{A}_{E_n})$ onto $(X, \mathcal{A})$. In particular, if $E \in \mathcal{A}$, then $(X, \mathcal{A})$ is Borel isomorphic to $(E, \mathcal{A}_E) \oplus (X \setminus E, \mathcal{A}_{X \setminus E})$.

The Schröder-Bernstein Theorem for Measurable Spaces

XVI.1.6.16. THEOREM. If $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ are measurable spaces, $(X, \mathcal{A})$ is Borel isomorphic to a measurable subspace of $(Y, \mathcal{B})$, and $(Y, \mathcal{B})$ is Borel isomorphic to a measurable subspace of $(X, \mathcal{A})$, then $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ are Borel isomorphic.

The proof is a simple adaptation of the proof of the Schröder-Bernstein Theorem of set theory. See Exercise XVI.1.7.3..

XVI.1.7. Exercises

XVI.1.7.1. This exercise should convince the reader of (1) the truth of the statement of XVI.1.2.4. and (2) the author's wisdom in not attempting to write out a full proof. Adopt the situation and notation of XVI.1.2.4..

(a) Verify the four identities in the proof outline.

(b) Let A_i, B_i, C_i, D_i $(i = 1, 2)$ be sets in $\mathcal{C}$. Show that

$$[(A_1 \setminus B_1) \cap (A_2 \setminus B_2)] \setminus [(C_1 \setminus D_1) \cap (C_2 \setminus D_2)]$$

is a finite disjoint union of finite intersections of sets in $\mathcal{C} \cup \mathcal{D}$, using the four identities. [The first step is to use the fourth identity to rewrite the set as

$$[(A_1 \setminus B_1) \cap (A_2 \setminus B_2)] \setminus (C_1 \setminus D_1) \sqcup \{[(A_1 \setminus B_1) \cap (A_2 \setminus B_2)] \cap (C_1 \setminus D_1)\} \setminus (C_2 \setminus D_2)$$

where $\sqcup$ denotes disjoint union.]

XVI.1.7.2. Let $\mathcal{E}$ be a collection of subsets of a set X. Set $\tilde{\mathcal{E}} = \{X \setminus E : E \in \mathcal{E}\}$.

(a) Show that if $\mathcal{E}$ is closed under finite unions and finite intersections, and $\mathcal{E} \cap \tilde{\mathcal{E}}$ is nonempty, then $\mathcal{E} \cap \tilde{\mathcal{E}}$ is an algebra of subsets of X and is the largest algebra contained in $\mathcal{E}$.

(b) Show that if $\mathcal{E}$ is closed under countable unions and countable intersections, and $\mathcal{E} \cap \tilde{\mathcal{E}}$ is nonempty, then $\mathcal{E} \cap \tilde{\mathcal{E}}$ is a σ-algebra of subsets of X and is the largest σ-algebra contained in $\mathcal{E}$.

(c) Even if $\mathcal{E}$ is infinite and closed under countable unions and countable intersections, $\mathcal{E} \cap \tilde{\mathcal{E}}$ can be empty. [Let $\mathcal{E}$ be the collection of countable subsets of an uncountable set.]

XVI.1.7.3. Prove the Schröder-Bernstein Theorem for measurable spaces. [Mimic the proof of the Schröder-Bernstein Theorem of set theory (II.5.6.11.).]

XVI.1.7.4. Modify the construction in XVI.1.3.11., replacing finite unions and intersections with countable unions and intersections in the construction of $\mathcal{S}_1$ and $\mathcal{S}_2$. Is $\mathcal{S}_2$ then the σ-algebra generated by $\mathcal{S}$? Where does the proof break down?

XVI.1.7.5. Let X be an infinite set, and $\mathcal{A}$ an algebra of subsets of X containing a sequence of distinct subsets (this will hold if $\mathcal{A}$ is infinite if the Countable AC is assumed).

(a) Show by recursion (without any form of Choice) that $\mathcal{A}$ contains a sequence of pairwise disjoint nonempty subsets of X. [If (A_n) is the sequence (we may assume no A_n is X or $\emptyset$), then either $\{A_1 \cap A_n : n > 1\}$ or $\{A_1^c \cap A_n : n > 1\}$ (or both) contains infinitely many distinct sets. If the first holds, set $B_1 = A_1^c$ and if not set $B_1 = A_1$. Repeat replacing X by A_1 in the first case and A_1^c in the second, and A_n by $A_1 \cap A_n$ or $A_1^c \cap A_n$ (reduced to a subsequence of distinct nonempty proper subsets of A_1 or A_1^c respectively).]

(b) Show that if $\mathcal{A}$ is a σ-algebra, then $\mathcal{A}$ has cardinality at least $2^{\aleph_0}$. In fact, $\mathcal{A}$ contains a chain of (distinct) sets order-isomorphic to $\mathbb{R}$, i.e. a collection $\{C_r : r \in \mathbb{R}\}$ with $C_r \subseteq C_s$ if and only if $r \leq s$. [Index the B's by $\mathbb{Q}$ and let $C_r = \cup_{q<r} B_q$; cf. II.9.5.21..]

(c) If $\mathcal{A}$ is a σ-algebra, the sets in (a) can be chosen to have union all of X. This is not possible in general if $\mathcal{A}$ is just an algebra. [Consider the algebra of finite/cofinite subsets of an uncountable set.]

XVI.1.8. Filters and Ultrafilters

Filters are another important type of subspace structure. Filters are useful in a wide variety of mathematical applications, especially in topology.

XVI.1.8.1. DEFINITION. Let X be a set. A *filter* on X is a nonempty collection $\mathcal{F}$ of subsets of X such that

(i) $\mathcal{F}$ is closed under finite intersections.

(ii) $\mathcal{F}$ has the *superset property*: if $A \in \mathcal{F}$ and $A \subseteq B \subseteq X$, then $B \in \mathcal{F}$.

(iii) $\emptyset \notin \mathcal{F}$.

A filter on X which is not properly contained in any other filter on X is called an *ultrafilter* on X.

XVI.1.8.2. It follows from the superset property that a filter $\mathcal{F}$ is closed under arbitrary unions, and, since $\mathcal{F}$ is nonempty, that $X \in \mathcal{F}$. Thus a filter is somewhat similar to a topology. But property (iii) gives a crucial difference between a filter and a topology (a topology also does not have the superset property in general).

In fact, if $\mathcal{F}$ is a filter on X and $A \subseteq X$, we cannot have both A and A^c in $\mathcal{F}$, since then we would have $A \cap A^c = \emptyset \in \mathcal{F}$. It can happen, though, that neither A nor A^c is in $\mathcal{F}$. (This cannot happen in an ultrafilter, and in fact gives a characterization of ultrafilters (XVI.1.8.12.).)

XVI.1.8.3. A useful point of view, which is helpful in determining abstract properties of filters and appropriate for some, but not all, applications, is to regard a filter (especially an ultrafilter) as giving a notion of "size" for subsets of X: sets in the filter are regarded as "large" subsets and those not in the filter as "small" subsets.

XVI.1.8.4. As with many other subset structures, the intersection of any collection $\{\mathcal{F}_i : i \in I\}$ of filters on X is a filter on X (note that the intersection is a nonempty collection of subsets since $X \in \mathcal{F}_i$ for all i). However, the union of two filters is not a filter in general (in fact, see XVI.1.8.8.); but the union of a *chain* (under inclusion) of filters is a filter (Exercise ()).

XVI.1.8.5. If $\mathcal{F}$ is a filter on X, the set $\mathcal{I} = \{A^c : A \in \mathcal{F}\}$ is closed under finite unions and subsets, and does not contain the whole set X. Such a collection is called an *order ideal*. Order ideals and hence filters can be defined in general partially ordered sets ().

XVI.1.8.6. EXAMPLES. (i) Let A be a fixed nonempty subset of X, and let

$$\mathcal{F}_A = \{B \subseteq X : A \subseteq B\} .$$

Then $\mathcal{F}_A$ is a filter on X, which is an ultrafilter if and only if A is a singleton (note that $\mathcal{F}_A \subseteq \mathcal{F}_B$ if and only if $A \supseteq B$). If $x \in X$, write $\mathcal{F}_x$ to mean $\mathcal{F}_{\{x\}}$. Thus $\mathcal{F}_x = \{B \subseteq X : x \in B\}$.

(ii) Let X be an infinite set, and $\mathcal{F}$ the collection of all subsets of X with finite complement. Then $\mathcal{F}$ is a filter on X. This filter is never an ultrafilter (cf. XVI.1.8.12.). More generally, if κ is an infinite cardinal less

than or equal to $card(X)$, the set $\mathcal{F}$ of subsets A of X for which $card(A^c) < \kappa$ is a filter on X; in particular, if X is uncountable, the set of cocountable subsets of X is a filter on X.

(iii) Let $(X, \mathcal{T})$ be a topological space, and $x \in X$. Let $\mathcal{O}_x$ be the collection of all $\mathcal{T}$-neighborhoods () of x. Then $\mathcal{O}_x$ is a filter on X which is contained in $\mathcal{F}_x$; they are not the same in general since $\{x\} \in \mathcal{O}_x$ if and only if x is an isolated point in X (i.e. $\{x\} \in \mathcal{T}$). Thus $\mathcal{O}_x$ is usually not an ultrafilter on X. More generally, x can be replaced by any nonempty subset of X. (The notation $\mathcal{O}_x$ should really include the topology $\mathcal{T}$ since this filter depends on $\mathcal{T}$ as well as x.)

The intersection of all the sets in a filter may be empty (XVI.1.8.6.(ii)) or nonempty (XVI.1.8.6.(i)). We make the following definition:

XVI.1.8.7. Definition. Let $\mathcal{F}$ be a filter on a set X. $\mathcal{F}$ is a *fixed filter* with fixed set A if the intersection of all the sets in $\mathcal{F}$ is the nonempty set A. If the intersection of all sets in $\mathcal{F}$ is empty, $\mathcal{F}$ is a *free filter* on X.

An ultrafilter on a set X is either of the form $\mathcal{F}_x$ (XVI.1.8.6.(i)) for some $x \in X$, or is free. The ultrafilter $\mathcal{F}_x$ is often called the *principal ultrafilter* at the point x.

XVI.1.8.8. If $\mathcal{F}$ and $\mathcal{G}$ are filters on X, then there may not be any filter on X at all containing $\mathcal{F} \cup \mathcal{G}$: this will fail if there is a subset A of X with $A \in \mathcal{F}$ and $A^c \in \mathcal{G}$ (XVI.1.8.2.), e.g. if $\mathcal{F}$ and $\mathcal{G}$ are $\mathcal{F}_x$ and $\mathcal{F}_y$ as in XVI.1.8.6.(i) for distinct x and y. If there is such a set A, $\mathcal{F}$ and $\mathcal{G}$ are said to be *separated* (). Thus an arbitrary collection of nonempty subsets of X need not be contained in a filter on X. We will characterize when a collection of subsets is contained in a filter.

XVI.1.8.9. Definition. A collection $\mathcal{S}$ of subsets of a set X has the *finite intersection property* if the intersection of any finite number of sets in $\mathcal{S}$ is nonempty.

Any subset of a filter on a set X has the finite intersection property. The converse is also true:

XVI.1.8.10. Proposition. Let $\mathcal{S}$ be a collection of subsets of a set X, with the finite intersection property. Then there is a filter on X containing $\mathcal{S}$.

Proof: Let $\mathcal{F}$ be the collection of all subsets of X which contain a finite intersection of sets in $\mathcal{S}$. It is easy to verify that $\mathcal{F}$ is a filter containing $\mathcal{S}$, and is the smallest such filter. 👍

We now aim towards the question of whether every filter is contained in an ultrafilter, and along the way we will obtain an important explicit characterization of ultrafilters. We first obtain a fairly simple, but important, one-step extension theorem.

XVI.1.8.11. Theorem. [Filter Extension Theorem] Let $\mathcal{F}$ be a filter on a set X, and $A \subseteq X$. If $A^c \notin \mathcal{F}$, then there is a filter $\mathcal{G}$ on X containing $\mathcal{F}$ and A, i.e. with $\mathcal{F} \subseteq \mathcal{G}$ and $A \in \mathcal{G}$.

Note that the condition $A^c \notin \mathcal{F}$ is necessary for the existence of $\mathcal{G}$, since otherwise both A and A^c would be in $\mathcal{G}$.

PROOF: Let

$$\mathcal{G} = \{C \subseteq X : C \supseteq (B \cap A) \text{ for some } B \in \mathcal{F}\} .$$

If $B \in \mathcal{F}$, then $B \supseteq (B \cap A)$, so $B \in \mathcal{G}$, and thus $\mathcal{F} \subseteq \mathcal{G}$. We also have $A \in \mathcal{G}$ since $A \supseteq (X \cap A)$.

We show that $\mathcal{G}$ is a filter on X. $\mathcal{G}$ obviously has the superset property, and is nonempty since $\mathcal{F} \subseteq \mathcal{G}$. If $C_1, C_2 \in \mathcal{G}$, with $C_1 \supseteq (B_1 \cap A)$ and $C_2 \supseteq (B_2 \cap A)$ for $B_1, B_2 \in \mathcal{F}$, then

$$C_1 \cap C_2 \supseteq (B_1 \cap A) \cap (B_2 \cap A) = (B_1 \cap B_2) \cap A$$

and $(B_1 \cap B_2) \in \mathcal{F}$, so $(C_1 \cap C_2) \in \mathcal{G}$. Hence $\mathcal{G}$ is closed under finite intersections. Finally, we show $\emptyset \notin \mathcal{G}$. If $\emptyset \in \mathcal{G}$, then $\emptyset \supseteq (B \cap A)$ for some $B \in \mathcal{F}$; for this B, we have $B \cap A = \emptyset$, so $B \subseteq A^c$ and $A^c \in \mathcal{F}$ by the superset property, contrary to hypothesis. Thus $\mathcal{G}$ is the desired filter. 👍

As an immediate consequence, we get a characterization of ultrafilters:

XVI.1.8.12. THEOREM. [ULTRAFILTER CHARACTERIZATION THEOREM] Let $\mathcal{F}$ be a filter on a set X. Then $\mathcal{F}$ is an ultrafilter if and only if, for every subset A of $\mathcal{F}$, exactly one of A and A^c is in $\mathcal{F}$.

PROOF: We cannot have both A and A^c in $\mathcal{F}$ (XVI.1.8.2.). If neither A nor A^c is in $\mathcal{F}$ for some subset A of X, then the filter $\mathcal{G}$ of XVI.1.8.11. properly contains $\mathcal{F}$, so $\mathcal{F}$ is not an ultrafilter. Conversely, if $\mathcal{F}$ is not an ultrafilter, and $\mathcal{G}$ is a filter on X properly containing $\mathcal{F}$, let $A \in \mathcal{G} \setminus \mathcal{F}$. Then $A^c \notin \mathcal{G}$ by XVI.1.8.2., so neither A nor A^c is in $\mathcal{F}$. 👍

Here is another useful observation which is a simple corollary:

XVI.1.8.13. COROLLARY. Let $\mathcal{F}$ be a filter on a set X. Then $\mathcal{F}$ is an ultrafilter if and only if, whenever $A, B \subseteq X$ and $A \cup B \in \mathcal{F}$, we have either $A \in \mathcal{F}$ or $B \in \mathcal{F}$.

PROOF: A filter with this property is an ultrafilter by setting $B = A^c$. Conversely, suppose $\mathcal{F}$ is an ultrafilter and $A \cup B \in \mathcal{F}$. If $A \notin \mathcal{F}$ and $B \notin \mathcal{F}$, we have $A^c \in \mathcal{F}$ and $B^c \in \mathcal{F}$, so

$$A^c \cap B^c = (A \cup B)^c \in \mathcal{F}$$

which contradicts XVI.1.8.2.. 👍

The property in the statement of the corollary is called the *prime property*, and a filter with this property is called a *prime filter*. Thus prime filters and maximal filters (ultrafilters) are the same thing in this context. The notions are not the same in the more general setting of filters on partially ordered sets (), however.

Passing to the set of complements, an order ideal $\mathcal{I}$ is *prime* if $A, B \subseteq X$, $A \cap B \in \mathcal{I}$ implies that $A \in \mathcal{I}$ or $B \in \mathcal{I}$. This looks more like the definition of a prime ideal in a ring (), and is the origin of the term *prime* in this context.

XVI.1.8.14. Every filter which is not an ultrafilter can be extended to a larger filter; by XVI.1.8.11., this can even be done in a very explicit way. The question then becomes whether every filter can be extended to an ultrafilter. As may be expected, the answer depends, like the answer to many similar questions (e.g. (), ...), on the Axiom of Choice:

XVI.1.8.15. THEOREM. (AC) Every filter on a set X is contained in an ultrafilter on X.

The proof of this theorem is a standard Zorn's Lemma argument, and is left to the reader (Exercise ()).

XVI.1.8.16. This theorem cannot be proved without some form of the Axiom of Choice. But the full AC is not needed: the statement of this theorem is equivalent to the Boolean Prime Ideal Theorem (II.6.3.11.), which is strictly weaker than AC.

We cannot even prove without some form of AC that there is a free ultrafilter on $\mathbb{N}$ (this statement actually follows from the Measure Extension Theorem (), which is strictly weaker than the Boolean Prime Ideal Theorem). With AC (or BPI), this is an immediate application of XVI.1.8.15. to the filter of cofinite subsets of $\mathbb{N}$ (XVI.1.8.6.(ii)).

It can be shown even without AC that many sets have a large number of pairwise separated filters. To give the best statement possible without AC, we first discuss two key property of at least some cardinals:

XVI.1.8.17. If κ is a cardinal, and X is a set of cardinality κ, then we denote by κ^2 the cardinality of $X \times X$. We always have $\kappa^2 \geq \kappa$. If $1 < \kappa < \aleph_0$, then $\kappa^2 > \kappa$. If κ is infinite, then it is conceivable that κ^2 always equals κ; this can be proved using AC (and turns out to be equivalent to AC). Without AC the following can be proved:

(i) $\aleph_0^2 = \aleph_0$ ().

(ii) More generally, if $\aleph$ is any aleph (), then $\aleph^2 = \aleph$.

(iii) $(2^{\aleph_0})^2 = 2^{\aleph_0}$ ().

XVI.1.8.18. We now turn to the other cardinal property. Let κ be a cardinal, and X a set of cardinality κ. Let Φ be the set of all finite subsets of X. We have $card(\Phi) \geq card(X)$. If κ is finite, the inequality is strict. For infinite sets, it is conceivable that equality always holds (it holds for $\aleph_0$ by ()); if $card(\Phi) = card(X)$, we say κ has the *finite subset property*.

If $\kappa^2 = \kappa \geq \aleph_0$ and X can be totally ordered, it is not difficult to show that κ has the finite subset property (II.5.6.12.). Thus $\aleph_0$ (in fact, any $\aleph$) and $2^{\aleph_0}$ have the finite subset property. So it follows from AC that every infinite cardinal has the finite subset property. It cannot be proved in ZF that every infinite cardinal has the finite subset property (), i.e. some type of Choice is necessary.

XVI.1.8.19. THEOREM. ([?]; cf. [?], [GJ76, 9.2]) Let κ be a (necessarily infinite) cardinal with $\kappa^2 = \kappa$ and the finite subset property, and X a set of cardinality κ. Then there are 2^{2^κ} pairwise separated filters on X. In particular, there are $2^{2^{\aleph_0}}$ pairwise separated filters on $\mathbb{N}$.

PROOF: Let Φ be the set of all finite subsets of X, and Λ the set of all finite subsets of Φ. Set $\Omega = \Phi \times \Lambda$. Then from $\kappa^2 = \kappa$ and the finite subset property it follows that $card(\Phi) = card(\Lambda) = card(\Omega) = \kappa$.

We will define 2^{2^κ} pairwise separated filters on Ω, which will suffice since $card(\Omega) = card(X)$. First some notation: for $S \subseteq X$, define a subset $\mathcal{B}_S$ of Ω as follows:

$$\mathcal{B}_S = \{(F, \mathcal{L}) \in \Phi \times \Lambda : S \cap F \in \mathcal{L}\} .$$

Write $\mathcal{C}_S$ for the complement of $\mathcal{B}_S$ in Ω. Then, for $\mathcal{S} \subseteq \mathcal{P}(X)$, define

$$\mathfrak{B}_\mathcal{S} = \{\mathcal{B}_S : S \in \mathcal{S}\} \cup \{\mathcal{C}_S : S \notin \mathcal{S}\} \subseteq \mathcal{P}(\Omega) \ .$$

We claim that $\mathfrak{B}_\mathcal{S}$ has the finite intersection property (XVI.1.8.9.). If $\mathfrak{A}$ is a finite subset of $\mathfrak{B}_\mathcal{S}$, the distinct sets in $\mathfrak{A}$ can be numbered as follows:

$$\mathcal{B}_{S_1}, \ldots, \mathcal{B}_{S_k}, \mathcal{C}_{S_{k+1}}, \ldots, \mathcal{C}_{S_n}$$

where $S_1, \ldots, S_n$ are distinct subsets of X. For $i \neq j$ let x_{ij} be an element of X which is in one of S_i and S_j but not the other (note that there are only finitely many choices to be made here, so no form of AC is needed). Let F be the set of all the x_{ij} for $i \neq j$. Then the sets

$$S_1 \cap F, \ldots, S_n \cap F$$

are all distinct since if $i \neq j$, x_{ij} is in one of $S_i \cap F$ and $S_j \cap F$ but not the other. Set

$$\mathcal{L} = \{S_1 \cap F, \ldots, S_k \cap F\} \in \Lambda \ .$$

We have that $S_i \cap F \in \mathcal{L}$ for $1 \leq i \leq k$, and $S_j \cap K \notin \mathcal{L}$ for $k+1 \leq j \leq n$. So $(F, \mathcal{L}) \in \mathcal{B}_{S_i}$ for $1 \leq i \leq k$ and $(F, \mathcal{L}) \in \mathcal{C}_{S_j}$ for $k+1 \leq j \leq n$, and hence the intersection of the sets in $\mathfrak{A}$ is nonempty, proving the claim.

Thus, for each $\mathcal{S} \subseteq \mathcal{P}(X)$, there is a filter $\mathfrak{F}_\mathcal{S}$ on Ω containing $\mathfrak{B}_\mathcal{S}$ by XVI.1.8.10.. If $\mathcal{S}_1$ and $\mathcal{S}_2$ are distinct subsets of $\mathcal{P}(X)$, let S be a subset of X which is in one of them (say $\mathcal{S}_1$) but not the other. Then $\mathcal{B}_S \in \mathfrak{F}_{\mathcal{S}_1}$ and $\mathcal{C}_S \in \mathfrak{F}_{\mathcal{S}_2}$, so $\mathfrak{F}_{\mathcal{S}_1}$ and $\mathfrak{F}_{\mathcal{S}_2}$ are separated. The number of distinct filters constructed is $card(\mathcal{P}(\mathcal{P}(X))) = 2^{2^\kappa}$. 👍

Note that AC is not used in this result. Using AC, the conclusion holds for all infinite cardinals. The full AC is needed here, not just the BPI (since we need $\kappa^2 = \kappa$ for all κ). Combining this result with XVI.1.8.15., we obtain:

XVI.1.8.20. THEOREM. (AC) Let X be an infinite set, of cardinality κ. Then there are exactly 2^{2^κ} free ultrafilters on X.

PROOF: By XVI.1.8.15., each $\mathfrak{F}_\mathcal{S}$ from the proof of XVI.1.8.19. is contained in an ultrafilter. These ultrafilters are all distinct since the $\mathfrak{F}_\mathcal{S}$ are pairwise separated. Thus there are at least 2^{2^κ} ultrafilters on X. On the other hand, there are at most 2^{2^κ} filters on X since there are only 2^{2^κ} sets of subsets of X. Thus there are exactly 2^{2^κ} ultrafilters on X. Only κ of these are fixed, so there are 2^{2^κ} free ones. 👍

In particular, there are $2^{2^{\aleph_0}}$ distinct free ultrafilters on $\mathbb{N}$ (assuming AC, or at least BPI).

XVI.1.9. Exercises

XVI.1.9.1. Verify the assertions in the examples of XVI.1.8.6..

XVI.1.9.2. Verify the assertion in XVI.1.8.7. that every ultrafilter which is not free is of the form $\mathcal{F}_x$ for some x.

XVI.1.9.3. (a) Verify that the set $\mathcal{F}$ defined in the proof of XVI.1.8.10. is a filter.

(b) Show that two filters $\mathcal{F}$ and $\mathcal{G}$ on a set X are separated if and only if $\mathcal{F} \cup \mathcal{G}$ fails to have the finite intersection property. Thus if $\mathcal{F}$ and $\mathcal{G}$ are not separated, they are contained in a common larger filter on X.

XVI.1.9.4. (a) Show that if $\{\mathcal{F}_i : i \in I\}$ is a chain (under inclusion) of filters on a set X, i.e. $\mathcal{F}_i \subseteq \mathcal{F}_j$ or $\mathcal{F}_j \subseteq \mathcal{F}_i$ for all $i, j \in I$, then $\cup_{i \in I} \mathcal{F}_i$ is a filter on X.

(b) Let $\mathcal{F}$ be a filter on a set X, and let $\mathcal{Y} \subseteq \mathcal{P}(\mathcal{P}(X))$ be the set of all filters on X containing $\mathcal{F}$. Partially order $\mathcal{Y}$ by inclusion. Show that every chain in $\mathcal{Y}$ has an upper bound in $\mathcal{Y}$.

(c) Conclude from Zorn's Lemma that $\mathcal{Y}$ contains a maximal element $\mathcal{G}$. Show that $\mathcal{G}$ is an ultrafilter on X.

XVI.1.9.5. Let $(\mathcal{X}, \leq)$ be a partially ordered set. Define an *order ideal* in $(\mathcal{X}, \leq)$ to be a subset $\mathcal{I}$ which is hereditary, i.e. if $y \in \mathcal{I}$, $x \in \mathcal{X}$, and $x \leq y$, then $x \in \mathcal{I}$, and such that any two elements (hence any finite set of elements) of $\mathcal{I}$ have an upper bound in $\mathcal{I}$. Define a *filter* on $(\mathcal{X}, \leq)$ to be the complement of a nonempty proper order ideal.

(a) Let X be a set. Show that order ideals and filters in $(\mathcal{P}(X), \subseteq)$ under this definition are exactly the order ideals and filters under the definitions of this section.

(b) Extend the results of this section as far as possible to filters in general partially ordered sets.

XVI.2. Borel Sets and Borel Measurable Functions

For measure theory purposes, the Borel sets are the most important subsets of $\mathbb{R}$ or $\mathbb{R}^n$. The class of Borel sets is large enough to contain every subset of $\mathbb{R}$ which can be described "naturally", and small enough that measure-theoretic operations behave well on them. Similarly, the Borel measurable functions are the natural ones to consider for integration theory. (Later we will expand the classes of Borel sets and Borel measurable functions to the larger classes of Lebesgue measurable sets and functions, primarily for technical reasons.)

We will give two characterizations of the Borel sets in this section, and a third important one in the next section, along with corresponding descriptions of the Borel measurable functions. Most of the work can be done in a general topological space, but we will emphasize the most important case of $\mathbb{R}$ in examples.

XVI.2.1. Borel Sets

XVI.2.1.1. Definition. Let $(X, \mathcal{T})$ be a topological space. Let $\mathcal{B}_\mathcal{T}$ be the σ-algebra on X generated by $\mathcal{T}$, i.e. the smallest σ-algebra containing the open sets of X. $\mathcal{B}_\mathcal{T}$ is called the class of *Borel sets* of $(X, \mathcal{T})$.

We also often write $\mathcal{B}_X$ for $\mathcal{B}_\mathcal{T}$ when it is the set and not the topology which must be emphasized (although $\mathcal{B}_X$ depends on $\mathcal{T}$ and not just on X!) When additional precision is needed, we write $\mathcal{B}_\mathcal{T}(X)$. When an understood set X such as $\mathbb{R}$ has a natural topology, we will usually just write $\mathcal{B}$ for the class of Borel sets on X, suppressing the subscript $\mathcal{T}$ or X.

XVI.2.1.2. The following sets are Borel sets in $(X, \mathcal{T})$:

(i) All open sets in X.

(i') All closed sets in X.

(ii) Any countable intersection of open sets in X. Such a subset of X is called a G_δ *set*.

(ii') Any countable union of closed sets in X. Such a subset of X is called an F_σ *set*.

(iii) Any countable union of G_δ sets in X. Such a subset of X is called a $G_{\delta\sigma}$ *set*.

(iii') Any countable intersection of F_σ sets in X. Such a subset of X is called a $F_{\sigma\delta}$ *set*.

(iv) $G_{\delta\sigma\delta}$, $F_{\sigma\delta\sigma}$, $G_{\delta\sigma\delta\sigma}$, $\cdots$ sets can be defined analogously.

XVI.2.1.3. In most cases, and in particular if $X = \mathbb{R}$, this process never terminates and must be repeated transfinitely (uncountably many times) to obtain all Borel sets (XVI.3.5.4.). (It is not obvious that these classes are never σ-algebras after finitely or countably many steps for $X = \mathbb{R}$; see () for a proof.) The complement of a G_δ set is an F_σ set, the complement of an $F_{\sigma\delta}$ is a $G_{\delta\sigma}$, etc. For measure theoretic purposes, it is rarely necessary to consider sets more complicated than G_δ's or F_σ's (which are complicated enough already!)

The notation F_σ, G_δ, etc., is due to Hausdorff. There is a more modern notation, described in XVI.3.4., which is used by descriptive set theorists; but Hausdorff's notation is still commonly used by analysts.

It should be obvious that the class of Borel sets in $\mathbb{R}$ includes a great many subsets. For example:

XVI.2.1.4.

(i) Every singleton set $\{x\}$ in $\mathbb{R}$ (or, more generally, in a T_1 space X) is a closed set, hence a Borel set. Every countable subset of $\mathbb{R}$ is thus an F_σ, hence a Borel set, since it is a countable union of singleton sets. In particular, $\mathbb{Q}$ is an F_σ, and hence $\mathbb{J}$ is a G_δ. (It turns out, although it is not obvious, that $\mathbb{Q}$ is not a G_δ, so $\mathbb{J}$ is not an F_σ; see XIII.12.1.5..)

(ii) Every open interval in $\mathbb{R}$ is an F_σ: $(a,b) = \cup_{n=1}^{\infty}[a+\frac{1}{n}, b-\frac{1}{n}]$, and similarly for $(a,+\infty)$ or $(-\infty,b)$. Since every open set in $\mathbb{R}$ is a countable union of open intervals, every open set in $\mathbb{R}$ is an F_σ, and thus every closed set is a G_δ. Of course, every open set is a G_δ, so every closed set is an F_σ.

It is not true that every open set in a general topological space X is an F_σ, but it is true if X is metrizable ().

(iii) A half-open interval in $\mathbb{R}$ is neither open nor closed, but is both an F_σ and a G_δ, and hence a Borel set. The proof is very similar to the proof of (ii), and is left as an exercise.

(iv) An arbitrary (not necessarily countable) union of actual intervals can be written as a countable union of possibly different intervals (), hence is a Borel set (in fact, an F_σ.)

An interesting and useful consequence of the construction of the Borel sets is:

XVI.2.1.5. Proposition. Let $\mathcal{A}$ be a collection of subsets of $\mathbb{R}$ (or any metrizable space) such that

(1) $\mathcal{A}$ contains all closed sets.

(2) $\mathcal{A}$ is closed under countable unions and countable intersections.

Then $\mathcal{A}$ contains all Borel sets.

Proof: $\mathcal{A}$ contains all F_σ's. Since every open set in $\mathbb{R}$ is an F_σ, $\mathcal{A}$ contains all open sets, and hence all G_δ's. Hence $\mathcal{A}$ contains all $F_{\sigma\delta}$'s, all $G_{\delta\sigma}$'s, ..., and by transfinite induction all Borel sets. 👍

XVI.2.1.6. Note that such an $\mathcal{A}$ need not be a σ-algebra, i.e. need not be closed under complements. An example is the collection of analytic sets (). A similar proof shows that a collection of subsets of a metrizable space which contains all open sets and is closed under countable unions and intersections contains all Borel sets.

XVI.2.1.7. Here is an important technicality. If X is a topological space and A is a subset of X, then A has a relative topology (). Write $\mathcal{B}_X$ for the σ-algebra of Borel sets in X. What subsets of A should be called "Borel sets in A"? There are two σ-algebras of subsets of A which are natural candidates: $\mathcal{B}_A$, the σ-algebra generated by the (relatively) open sets in A, the Borel sets for the relative topology, and

$$\mathcal{B}_X^A = \{A \cap B : B \in \mathcal{B}_X\}$$

which could be called the "relatively Borel sets in A." (It is easily checked that $\mathcal{B}_X^A$ is a σ-algebra of subsets of A.) Fortunately, these two σ-algebras coincide:

XVI.2.1.8. PROPOSITION. Let X be a topological space, $A \subseteq X$, and $\mathcal{B}_A$ and $\mathcal{B}_X^A$ as above. Then $\mathcal{B}_A = \mathcal{B}_X^A$.

PROOF: Every relatively open set in A is of the form $A \cap U$ for an open set $U \subseteq X$. Since $U \in \mathcal{B}_X$, every relatively open set in A is in the σ-algebra $\mathcal{B}_X^A$. Since $\mathcal{B}_A$ is the smallest σ-algebra on A containing the relatively open sets, $\mathcal{B}_A \subseteq \mathcal{B}_X^A$. On the other hand, set

$$\mathcal{D} = \{B_1 \cup B_2 : B_1 \in \mathcal{B}_A, B_2 \in \mathcal{B}_{A^c}\} .$$

It is easily checked that $\mathcal{D}$ is a σ-algebra of subsets of X. If U is an open set in X, then $U = (A \cap U) \cup (A^c \cap U)$, and $A \cap U$ is relatively open in A, hence in $\mathcal{B}_A$, and similarly $A^c \cap U \in \mathcal{B}_{A^c}$, so $U \in \mathcal{D}$. It follows that $\mathcal{B}_X \subseteq \mathcal{D}$. Thus

$$\mathcal{B}_X^A = \{A \cap B : B \in \mathcal{B}_X\} \subseteq \{A \cap D : D \in \mathcal{D}\} = \mathcal{B}_A .$$

XVI.2.1.9. Note that in XVI.2.1.8., A could be any subset of X, not necessarily a Borel set. But if A is a Borel set in X, then $\mathcal{B}_X^A = \{B \in \mathcal{B}_X : B \subseteq A\}$. Thus the phrase "Borel subset of A" is totally unambiguous in this case. And if $A \in \mathcal{B}_X$ the σ-algebra $\mathcal{D}$ is exactly $\mathcal{B}_X$; if $A \notin \mathcal{B}_X$, then $\mathcal{D}$ is strictly larger than $\mathcal{B}_X$ since $A \in \mathcal{D}$ (in fact $\mathcal{D}$ is exactly the σ-algebra generated by $\mathcal{B}_X$ and A).

XVI.2.2. Real-Valued Measurable Functions

XVI.2.2.1. Recall () that if $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ are measurable spaces, then $f : X \to Y$ is $(\mathcal{A}, \mathcal{B})$-measurable if $f^{-1}(B) \in \mathcal{A}$ for all $B \in \mathcal{B}$. But how should we define measurability for real-valued (or extended real-valued or complex-valued) functions, i.e. what σ-algebra should we take on the range space? Experience has shown that it is almost always most useful and appropriate to take the Borel sets, and we will always do this unless specifically stated otherwise:

XVI.2.2.2. DEFINITION. Let $(X, \mathcal{A})$ be a measurable space. A real-valued function $f : X \to \mathbb{R}$ is *$\mathcal{A}$-measurable* if it is a measurable as a function from $(X, \mathcal{A})$ to $(\mathbb{R}, \mathcal{B})$ in the sense of (), i.e. if $f^{-1}(B) \in \mathcal{A}$ for every Borel set B in $\mathbb{R}$. Denote by $\mathfrak{B}_{\mathcal{A}}$ the set of $\mathcal{A}$-measurable functions from X to $\mathbb{R}$.

We can similarly define $\mathcal{A}$-measurable functions from a measurable space $(X, \mathcal{A})$ to a topological space $(Y, \mathcal{T})$ to be functions which are $(\mathcal{A}, \mathcal{B}_{\mathcal{T}})$-measurable in the sense of (). Thus we may also define $\mathcal{A}$-measurable functions from X to $\mathbb{R}^n$.

The next proposition is a special case of XVI.1.6.3.:

XVI.2.2.3. PROPOSITION. (a) Let $(X, \mathcal{A})$ and $(Y, \mathcal{C})$ be measurable spaces, $f : X \to Y$ an $(\mathcal{A}, \mathcal{C})$-measurable function, and $g : Y \to \mathbb{R}$ a $\mathcal{C}$-measurable function. Then $g \circ f : X \to \mathbb{R}$ is $\mathcal{A}$-measurable. (Here $\mathbb{R}$ may be replaced by any topological space.)

It is often convenient to use an apparently weaker criterion for measurability of real-valued functions. Here are some of the most useful ones:

XVI.2.2.4. Proposition. Let $(X, \mathcal{A})$ be a measurable space and $f : X \to \mathbb{R}$ a function. Then f is $\mathcal{A}$-measurable if and only if any of the following conditions are satisfied:

(i) $f^{-1}(U) \in \mathcal{A}$ for every open set $U \subseteq \mathbb{R}$.

(ii) $f^{-1}(E) \in \mathcal{A}$ for every closed set $E \subseteq \mathbb{R}$.

(iii) $f^{-1}(U) \in \mathcal{A}$ for every open interval $U \subseteq \mathbb{R}$.

(iv) $f^{-1}((-\infty, a)) \in \mathcal{A}$ for every $a \in \mathbb{R}$.

(v) $f^{-1}((-\infty, a]) \in \mathcal{A}$ for every $a \in \mathbb{R}$.

(vi) $f^{-1}((a, +\infty)) \in \mathcal{A}$ for every $a \in \mathbb{R}$.

(vii) $f^{-1}([a, +\infty)) \in \mathcal{A}$ for every $a \in \mathbb{R}$.

(viii) $f^{-1}((-\infty, a)) \in \mathcal{A}$ for every $a \in \mathbb{Q}$.

(ix) $f^{-1}((-\infty, a]) \in \mathcal{A}$ for every $a \in \mathbb{Q}$.

(x) $f^{-1}((a, +\infty)) \in \mathcal{A}$ for every $a \in \mathbb{Q}$.

(xi) $f^{-1}([a, +\infty)) \in \mathcal{A}$ for every $a \in \mathbb{Q}$.

This proposition is an immediate consequence of XVI.1.6.9., since each of the collections of sets listed generates $\mathcal{B}$ as a σ-algebra.

XVI.2.2.5. Proposition. Let $(X, \mathcal{A})$ be a measurable space, and $A \subseteq X$. Then χ_A is an $\mathcal{A}$-measurable function if and only if $A \in \mathcal{A}$.

Proof: Since χ_A takes only the values 0 and 1, $\chi_A^{-1}((a, +\infty))$ is either $\emptyset$ (if $a \geq 1$), A (if $0 \leq a < 1$), or X (if $a < 0$). Apply XVI.2.4.4.(vi). 👍

More generally, we have:

XVI.2.2.6. Proposition. Let $(X, \mathcal{A})$ be a measurable space, and $\phi = \sum_{i=1}^{n} \alpha_i \chi_{A_i}$ be a simple function from X to $\mathbb{R}$. If each $A_i \in \mathcal{A}$, then ϕ is $\mathcal{A}$-measurable. The converse holds if the α_i are distinct.

The proof is almost identical to the proof of XVI.2.2.5., and is left as an exercise.

Suprema and Pointwise Limits of Measurable Functions

A simple consequence of () is:

XVI.2.2.7. PROPOSITION. Let $(X, \mathcal{A})$ be a measurable space, and (f_n) a sequence of $\mathcal{A}$-measurable functions from X to $\mathbb{R}$. If (f_n) is pointwise bounded (i.e. for every $x \in X$, $\{f_n(x) : n \in \mathbb{N}\}$ is bounded above), then $\sup f_n$ is $\mathcal{A}$-measurable. If (f_n) is pointwise bounded below, then $\inf f_n$ is $\mathcal{A}$-measurable.

PROOF: Let $a \in \mathbb{R}$. Then

$$\{x : \sup f_n(x) \leq a\} = \bigcap_{n\in\mathbb{N}} \{x : f_n(x) \leq a\}$$

$$\{x : \inf f_n(x) \geq a\} = \bigcap_{n\in\mathbb{N}} \{x : f_n(x) \geq a\}$$

and the sets on the right are in $\mathcal{A}$, which is a σ-algebra. 👍

One of the most important facts about the collection of $\mathcal{A}$-measurable real-valued functions on a measurable space $(X, \mathcal{A})$ is that it is closed under pointwise limits:

XVI.2.2.8. PROPOSITION. Let $(X, \mathcal{A})$ be a measurable space and (f_n) a sequence of real-valued functions on X converging pointwise to $f : X \to \mathbb{R}$. If each f_n is $\mathcal{A}$-measurable, so is f.

PROOF: By (), we need only show that $A := \{x \in X : f(x) \leq a\} \in \mathcal{A}$ for every $a \in \mathbb{R}$. Fix a. For $m, n \in \mathbb{N}$, set $A_{m,n} = \{x \in A : f_n(x) \leq a + \frac{1}{m}\}$. Then

$$A = \bigcap_{m\in\mathbb{N}} \bigcup_{k\in\mathbb{N}} \bigcap_{n\geq k} A_{m,n}$$

and by assumption, each $A_{m,n} \in \mathcal{A}$ and $\mathcal{A}$ is a σ-algebra. 👍

See XVI.2.6.12. for an alternate proof, and XVI.2.4.8.–XVI.2.4.11. for additional properties of the set of $\mathcal{A}$-measurable functions.

Approximation by Simple Functions

Every real-valued measurable function is a pointwise limit of simple functions, in a controlled way:

XVI.2.2.9. PROPOSITION. Let $(X, \mathcal{A})$ be a measurable space, and $f : X \to \mathbb{R}$ an $\mathcal{A}$-measurable function. Then

(i) There is a sequence (f_n) of simple $\mathcal{A}$-measurable functions converging pointwise to f.

(ii) If f is bounded, there is a sequence (f_n) of simple $\mathcal{A}$-measurable functions converging uniformly to f.

(iii) If f is nonnegative, there is an increasing sequence (f_n) of simple $\mathcal{A}$-measurable functions converging pointwise to f, uniformly if f is bounded.

PROOF: Fix $n \in \mathbb{N}$. For each $k \in \mathbb{Z}$, let

$$E_{kn}(f) = f^{-1}\left(\left[\frac{k}{n}, \frac{k+1}{n}\right)\right).$$

Then each $E_{kn}(f)$ is in $\mathcal{A}$ since it is the preimage of a Borel set, and for fixed n we have that $\mathbb{R}$ is the disjoint union of the $E_{kn}(f)$'s. Let $f_n(x) = \frac{k}{n}$ if $x \in E_{kn}(f)$. Since $\frac{k}{n} \leq f(x) < \frac{k+1}{n}$ for $x \in E_{kn}(f)$, we have that $f_n(x) \leq f(x)$ and $f(x) - f_n(x) < \frac{1}{n}$ for every x. Thus the sequence (f_n) actually converges uniformly to f. If f is bounded, each f_n is simple, proving (ii). However, f_n is not simple if f is unbounded. To obtain simple functions, let $g_n(x) = f_n(x)$ if $x \in E_{kn}(f)$ for $-n \leq k \leq n$ and $g_n(x) = 0$ otherwise. Then g_n is simple, and $g_n \to f$ pointwise on $\mathbb{R}$ (but not uniformly unless f is bounded.) In case (iii), take a subsequence of the n's, each dividing the next (e.g. powers of 2). 👍

XVI.2.3. Real-Valued Measurable Functions on δ-Rings

XVI.2.3.1. If X and Y are sets, $\mathcal{R}$ is a collection of subsets of X, and $\mathcal{S}$ a collection of subsets of Y, Definition () makes sense (but is relatively uninteresting in this generality) to say that a function $f : X \to Y$ is $(\mathcal{R}, \mathcal{S})$-measurable if $f^{-1}(S) \in \mathcal{R}$ for all $S \in \mathcal{S}$. But if f is a real-valued function on $\mathcal{R}$, the usual definition () of measurability for f with $Y = \mathbb{R}$, $\mathcal{S} = \mathcal{B}$ is no good (never satisfied) unless $X \in \mathcal{R}$, since $f^{-1}(\mathbb{R}) = X$. So even if $\mathcal{R}$ is a σ-ring, this definition must be modified unless $\mathcal{R}$ is a σ-algebra.

XVI.2.3.2. There are several meaningful ways to generalize the definition of measurability. If $\mathcal{D}$ is a collection of subsets of a set X, normally at least a δ-ring, let $\mathcal{A}$ be the σ-algebra generated by $\mathcal{D}$ and $\mathcal{M}$ the σ-algebra of locally $\mathcal{D}$-measurable sets (). Then if $\mathcal{D}$ is a δ-ring, $\mathcal{A} \subseteq \mathcal{M}$ and $\mathcal{D}$ is a hereditary subset of both $\mathcal{A}$ and $\mathcal{M}$ ().

XVI.2.3.3. DEFINITION. Let $\mathcal{D}$ be a δ-ring and $\mathcal{A}$ and $\mathcal{M}$ as above, and let $f : X \to \mathbb{R}$ be a function.
(i) The function f is *locally $\mathcal{D}$-measurable* if it is $\mathcal{M}$-measurable, i.e.

$$A \cap f^{-1}(B) = \{x \in A : f(x) \in B\} \in \mathcal{D}$$

for every $A \in \mathcal{D}$ and Borel set $B \subseteq \mathbb{R}$.
(ii) The function f is *strictly $\mathcal{D}$-measurable* if $N := \{x \in X : f(x) \neq 0\} \in \mathcal{D}$ and

$$N \cap f^{-1}(B) = f^{-1}(B \setminus \{0\}) \in \mathcal{D}$$

for all Borel sets $B \subseteq \mathbb{R}$. (Note that $N = f^{-1}(\mathbb{R} \setminus \{0\})$ so the second condition includes the first.)

XVI.2.3.4. There is a third condition, that f be $\mathcal{A}$-measurable; we could call this *$\mathcal{D}$-measurability*. Since $\mathcal{A} \subseteq \mathcal{M}$, $\mathcal{D}$-measurability implies local $\mathcal{D}$-measurability. If f is strictly $\mathcal{D}$-measurable, then $N^c = \{x \in X : f(x) = 0\} \in \mathcal{A}$, and if B is a Borel set, then $f^{-1}(B)$ is either $N \cap f^{-1}(B)$ (if $0 \notin B$) or $N^c \cup (N \cap f^{-1}(B))$ (if $0 \in B$), and in either case $f^{-1}(B) \in \mathcal{A}$. Thus strictly $\mathcal{D}$-measurable implies $\mathcal{D}$-measurable implies locally $\mathcal{D}$-measurable. If $\mathcal{D}$ is a σ-algebra, then $\mathcal{A} = \mathcal{M} = \mathcal{D}$ and all three kinds of measurability coincide with ordinary measurability. If $\mathcal{D}$ is a δ-ring which is not a σ-algebra, strict $\mathcal{D}$-measurability is the most important of the three: it means that the function is measurable and supported on a set in $\mathcal{D}$, or equivalently that it is supported on a set $N \in \mathcal{D}$ and its restriction to N is measurable in the usual sense with respect to the σ-algebra $\mathcal{D}_N$ of subsets of N. These are functions which can potentially be integrated ().

XVI.2.3.5. For a δ-ring $\mathcal{D}$ which is not a σ-ring, there are two other occasionally useful notions:

A function $f : X \to \mathbb{R}$ is *σ-strictly $\mathcal{D}$-measurable* if it is strictly measurable with respect to the σ-ring generated by $\mathcal{D}$.

A function $f : X \to \mathbb{R}$ is *almost strictly $\mathcal{D}$-measurable* if it is $\mathcal{D}$-measurable and, for every $\epsilon > 0$, $\{x \in X : |f(x)| \geq \epsilon\} \in \mathcal{D}$.

We have (strictly $\mathcal{D}$-measurable) $\Rightarrow$ (almost strictly $\mathcal{D}$-measurable) $\Rightarrow$ (σ-strictly $\mathcal{D}$-measurable) $\Rightarrow$ ($\mathcal{D}$-measurable) $\Rightarrow$ (locally $\mathcal{D}$-measurable). If $\mathcal{D}$ is a σ-ring, the first three coincide, but if $\mathcal{D}$ is not a σ-ring they are distinct. For suppose (A_n) is a sequence of sets in $\mathcal{D}$ for which $A := \cup_n A_n \notin \mathcal{D}$. Then

$\sum_{n=1}^{\infty} 2^{-n} \chi_{A_n}$ is almost strictly $\mathcal{D}$-measurable but not strictly $\mathcal{D}$-measurable.

χ_A is σ-strictly $\mathcal{D}$-measurable but not almost strictly $\mathcal{D}$-measurable.

Almost strictly $\mathcal{D}$-measurable functions can also potentially be integrated ().

XVI.2.3.6. The various types of measurability can be defined analogously for extended real-valued and complex-valued functions. A complex-valued function is measurable in any of the senses if and only if both its real and imaginary parts are measurable in the same sense.

XVI.2.4. Borel Measurable Functions

Along with the Borel sets themselves, the Borel measurable functions are basic objects for study in measure theory.

XVI.2.4.1. Definition. If $(X, \mathcal{T})$ is a topological space, a function $f : X \to \mathbb{R}$ is *Borel measurable* if it is $\mathcal{B}_{\mathcal{T}}$-measurable, i.e. the inverse image of every Borel set in $\mathbb{R}$ is a Borel set in $(X, \mathcal{T})$. Denote by $\mathfrak{B}_{\mathcal{T}}$ the set of Borel measurable functions from X to $\mathbb{R}$. Write $\mathfrak{B}$ for the set of Borel measurable functions from $\mathbb{R}$ to $\mathbb{R}$. We may similarly define Borel measurability for functions from X to $\mathbb{R}^n$, and more generally for functions from X to any topological space $(Y, \mathcal{S})$.

XVI.2.4.2. We most commonly use the term "Borel measurable" for functions from $\mathbb{R}$ to $\mathbb{R}$ (or from $\mathbb{R}^n$ to $\mathbb{R}^m$). We will show that all "reasonable" functions from $\mathbb{R}$ to $\mathbb{R}$ are Borel measurable. In fact, roughly speaking, any function from $\mathbb{R}$ to $\mathbb{R}$ which can be defined or described without using the Axiom of Choice is Borel measurable; in particular, any function which can be defined by a countable number of algebraic, order, or pointwise limit operations is Borel measurable. (Strictly speaking, the first part of this statement is not true; it is possible, but quite complicated, to explicitly describe a subset of $\mathbb{R}$ which is not a Borel set, and hence a function which is not Borel measurable; see ().)

The next proposition is a special case of XVI.2.2.3.:

XVI.2.4.3. Proposition. Let $(X, \mathcal{T})$, $(Y, \mathcal{S})$, and $(Z, \mathcal{R})$ be topological spaces, $f : X \to Y$ and $g : Y \to Z$ Borel measurable functions. Then $g \circ f : X \to Z$ is Borel measurable.

XVI.2.2.4. applies to Borel measurability:

XVI.2.4.4. PROPOSITION. Let $f : \mathbb{R} \to \mathbb{R}$ a function. Then f is Borel measurable if and only if any of the following conditions are satisfied:

(i) $f^{-1}(U) \in \mathcal{B}$ for every open set $U \subseteq \mathbb{R}$.

(ii) $f^{-1}(E) \in \mathcal{B}$ for every closed set $E \subseteq \mathbb{R}$.

(iii) $f^{-1}(U) \in \mathcal{B}$ for every open interval $U \subseteq \mathbb{R}$.

(iv) $f^{-1}((-\infty, a)) \in \mathcal{B}$ for every $a \in \mathbb{R}$.

(v) $f^{-1}((-\infty, a]) \in \mathcal{B}$ for every $a \in \mathbb{R}$.

(vi) $f^{-1}((a, +\infty)) \in \mathcal{B}$ for every $a \in \mathbb{R}$.

(vii) $f^{-1}([a, +\infty)) \in \mathcal{B}$ for every $a \in \mathbb{R}$.

(viii) $f^{-1}((-\infty, a)) \in \mathcal{B}$ for every $a \in \mathbb{Q}$.

(ix) $f^{-1}((-\infty, a]) \in \mathcal{B}$ for every $a \in \mathbb{Q}$.

(x) $f^{-1}((a, +\infty)) \in \mathcal{B}$ for every $a \in \mathbb{Q}$.

(xi) $f^{-1}([a, +\infty)) \in \mathcal{B}$ for every $a \in \mathbb{Q}$.

XVI.2.4.5. COROLLARY. Every continuous function from a topological space $(X, \mathcal{T})$ to $\mathbb{R}$ is Borel measurable. In particular, every continuous function from $\mathbb{R}$ to $\mathbb{R}$ is Borel measurable.

PROOF: Apply (i): if f is continuous and $U \subseteq \mathbb{R}$ is open, then $f^{-1}(U)$ is open in $(X, \mathcal{T})$, and every open set is a Borel set. ☝

The next special case of XVI.1.6.11. (using XVI.2.4.5.) shows that "piecewise-continuous" functions are Borel measurable.

XVI.2.4.6. COROLLARY. Let $(X, \mathcal{T})$ be a topological space, and (E_n) a sequence of Borel subsets of X with $\cup_{n=1}^{\infty} E_n = X$. Let $f : X \to \mathbb{R}$ be a function. If $f|_{E_n}$ is continuous (regarding E_n as a topological space with the relative topology) for each n, then f is Borel measurable.

Many very discontinuous functions are Borel measurable. For example:

XVI.2.4.7. PROPOSITION. If $B \subseteq \mathbb{R}$, then χ_B is a Borel measurable function if and only if B is a Borel set in $\mathbb{R}$.

This is a special case of XVI.2.2.5..

From XVI.2.4.3., in combination with XVI.2.4.5., we obtain an important property of the set $\mathfrak{B}_{\mathcal{A}}$ of $\mathcal{A}$-measurable functions:

XVI.2.4.8. PROPOSITION. Let $(X, \mathcal{A})$ be a measurable space, $f \in \mathfrak{B}_{\mathcal{A}}$, and g a Borel measurable function from $\mathbb{R}$ to $\mathbb{R}$. Then $g \circ f$ is in $\mathfrak{B}_{\mathcal{A}}$. In particular, if $h : \mathbb{R} \to \mathbb{R}$ is continuous, then $h \circ f$ is in $\mathfrak{B}_{\mathcal{A}}$.

XVI.2.4.9. If f is a real-valued function, we define the *positive and negative parts* of f to be f_+ and f_-, where $f_+(x) = \max(f(x), 0)$ and $f_-(x) = \max(-f(x), 0)$. In other words, $f_+ = f$ wherever f is nonnegative, and is zero where f is negative; and $f_- = |f|$ where f is negative and zero where f is nonnegative. Then $f = f_+ - f_-$, $|f| = f_+ + f_-$, and $f_+ f_- = 0$.

XVI.2.4.10. COROLLARY. Let $(X, \mathcal{A})$ be a measurable space, and $f \in \mathfrak{B}_{\mathcal{A}}$. Then f^2, f_+, f_-, and $|f|$ are in $\mathfrak{B}_{\mathcal{A}}$. If $f \geq 0$, then $\sqrt{f} \in \mathfrak{B}_{\mathcal{A}}$.

PROOF: $f^2 = g \circ f$, where $g(t) = t^2$. Similarly, the other functions are the compositions of f with the functions $\max(t, 0)$, $\max(-t, 0)$, $|t|$, and $\sqrt{|t|}$ respectively. 👍

This corollary can also be easily proved directly from XVI.2.4.4..

Our next goal is to show that $\mathfrak{B}_{\mathcal{A}}$ is closed under the usual algebraic operations: sum, product, and scalar multiple. (We say that $\mathfrak{B}_{\mathcal{A}}$ is an *algebra* of functions.) The only step which takes some work is showing closure under addition.

XVI.2.4.11. THEOREM. Let $(X, \mathcal{A})$ be a measurable space, $f, g \in \mathfrak{B}_{\mathcal{A}}$. Then $f + g$ and fg are in $\mathfrak{B}_{\mathcal{A}}$. If $\alpha \in \mathbb{R}$, then $\alpha f \in \mathfrak{B}_{\mathcal{A}}$.

PROOF: Closure under scalar multiplication is obvious from XVI.2.4.4.(vi)-(viii).

We show closure under addition. Let $h = f + g$. To show that $h \in \mathfrak{B}_{\mathcal{A}}$, then by XVI.2.4.4.(vi) it suffices to show that $h^{-1}((a, \infty)) \in \mathcal{A}$ for every $a \in \mathbb{R}$. But if a is fixed, then

$$\begin{aligned} h^{-1}((a, \infty)) &= \{x : f(x) > a - g(x)\} \\ &= \{x : f(x) > r > a - g(x) \text{ for some } r \in \mathbb{Q}\} \\ &= \{x : f(x) > r \text{ and } g(x) > a - r \text{ for some } r \in \mathbb{Q}\} \\ &= \bigcup_{r \in \mathbb{Q}} \left[f^{-1}((r, \infty)) \cap g^{-1}((a - r, \infty)) \right]. \end{aligned}$$

Since f and g are $\mathcal{A}$-measurable, and $\mathbb{Q}$ is countable, the last set is in $\mathcal{A}$.

A trick using XVI.2.4.10. gives closure under multiplication:

$$fg = \frac{1}{2}[(f + g)^2 - f^2 - g^2].$$

👍

Measurable Functions to $\mathbb{R}^n$

As previously noted, we can define $\mathcal{A}$-measurability for functions from a measurable space $(X, \mathcal{A})$ to $\mathbb{R}^n$. We do not get anything essentially new by doing this, however:

XVI.2.4.12. PROPOSITION. Let $(X, \mathcal{A})$ be a measurable space, and $f : X \to \mathbb{R}^n$ a function. Write $f_k : X \to \mathbb{R}$ $(1 \leq k \leq n)$ for the k'th coordinate functions of f, i.e. $f(x) = (f_1(x), \ldots, f_n(x))$ for $x \in X$. Then f is an $\mathcal{A}$-measurable function from X to $\mathbb{R}^n$ if and only if each f_k is an $\mathcal{A}$-measurable function from X to $\mathbb{R}$.

PROOF: We have $f_k = \pi_k \circ f$, where $\pi_k : \mathbb{R}^n \to \mathbb{R}$ is the projection onto the k'th coordinate. Since π_k is continuous, f_k is $\mathcal{A}$-measurable if f is $\mathcal{A}$-measurable by XVI.2.4.8.. Conversely, suppose each f_k is $\mathcal{A}$-measurable. Let $B_1, \ldots, B_n$ be Borel sets in $\mathbb{R}$, and $B = B_1 \times B_2 \times \cdots \times B_n$ the corresponding measurable rectangle in $\mathbb{R}^n$. Then $f^{-1}(B) = f_1^{-1}(B_1) \cap \cdots \cap f_n^{-1}(B_n)$. Since $f_k^{-1}(B_k) \in \mathcal{A}$ for each k, $f^{-1}(B) \in \mathcal{A}$. Measurable rectangles generate the σ-algebra of Borel sets in $\mathbb{R}^n$ (), so f is $\mathcal{A}$-measurable by XVI.1.6.9.. 👍

XVI.2.5. Another Characterization of Borel Sets and Borel Measurable Functions

It turns out that the Borel measurable functions have a simple and useful alternate characterization as the "sequential completion" of the class of continuous functions. The results of this section can be generalized to functions on arbitrary topological spaces, but we will stick to functions from $\mathbb{R}$ to $\mathbb{R}$ for simplicity.

XVI.2.5.1. DEFINITION. Let $\mathfrak{C}$ be the set of continuous functions from $\mathbb{R}$ to $\mathbb{R}$. Let $\bar{\mathfrak{C}}$ be the smallest class of functions from $\mathbb{R}$ to $\mathbb{R}$ containing $\mathfrak{C}$ and which is closed under pointwise sequential limits, i.e. such that if (f_n) is a sequence in $\bar{\mathfrak{C}}$ and $f_n \to f$ pointwise, then $f \in \bar{\mathfrak{C}}$.

A subset A of $\mathbb{R}$ is a *BC set* if $\chi_A \in \bar{\mathfrak{C}}$.

The abbreviation BC stands for "Baire class."

The definition of $\bar{\mathfrak{C}}$ makes sense as the intersection of all classes of functions with the two properties. This collection of classes is nonempty since the class of all functions from $\mathbb{R}$ to $\mathbb{R}$ has the properties.

We will show that the functions in $\bar{\mathfrak{C}}$ are precisely the Borel measurable functions, and the BC sets are precisely the Borel sets. Such sets and functions are very natural to consider in measure and integration, where pointwise limits often arise.

XVI.2.5.2. **Caution:** It is not true that $\bar{\mathfrak{C}}$ is just the set $\mathfrak{BC}_1$ of pointwise limits of sequences of continuous functions. This set $\mathfrak{BC}_1$ is contained in $\bar{\mathfrak{C}}$, but is not closed under pointwise sequential limits (although this is not obvious; see Exercise XVI.2.10.1..) Let $\mathfrak{BC}_2$ be the set of pointwise limits of sequences of functions in $\mathfrak{BC}_1$, and inductively for each ordinal α let $\mathfrak{BC}_{\alpha+1}$ be the set of pointwise limits of sequences of functions in $\mathfrak{BC}_\alpha$, with $\mathfrak{BC}_\alpha = \cup_{\beta<\alpha}\mathfrak{BC}_\beta$ when α is a limit ordinal. Then $\bar{\mathfrak{C}}$ is the union of the $\mathfrak{BC}_\alpha$ over all countable α, and it turns out that $\bar{\mathfrak{C}} \neq \mathfrak{BC}_\alpha$ for any countable α (XVI.2.7.2.). The functions in $\mathfrak{BC}_\alpha$ are said to be of *Baire class* α. ✋

XVI.2.6. Algebraic Properties of $\bar{\mathfrak{C}}$

We first show that, like $\mathfrak{B}_{\mathcal{A}}$ (XVI.2.4.11.), $\bar{\mathfrak{C}}$ is closed under the usual algebraic operations: sum, product, and scalar multiple (i.e. $\bar{\mathfrak{C}}$ is an *algebra* of functions.) It is a standard fact from Calculus that $\mathfrak{C}$ is closed under these operations. It can be easily shown by transfinite induction that each $\mathfrak{BC}_\alpha$ is also closed under the operations, and hence so is $\bar{\mathfrak{C}}$. A cleaner and more elementary proof can be given, however:

XVI.2.6.1. Proposition. Let $f, g \in \bar{\mathfrak{C}}$ and $\alpha \in \mathbb{R}$. Then $f+g$, fg, and αf are all in $\bar{\mathfrak{C}}$.

Proof: First fix $g \in \mathfrak{C}$, and let $\mathfrak{D} = \{f \in \bar{\mathfrak{C}} : f+g \in \bar{\mathfrak{C}}\}$. We claim that $\mathfrak{D} = \bar{\mathfrak{C}}$. Clearly $\mathfrak{D} \subseteq \bar{\mathfrak{C}}$, so we need only show that $\mathfrak{C} \subseteq \mathfrak{D}$ and that $\mathfrak{D}$ is closed under pointwise sequential limits. If $f \in \mathfrak{C}$, then $f+g \in \mathfrak{C} \subseteq \bar{\mathfrak{C}}$, so $f \in \mathfrak{D}$. And if (f_n) is a sequence in $\mathfrak{D}$ (i.e. $f_n \in \bar{\mathfrak{C}}$ and $f_n + g \in \bar{\mathfrak{C}}$), and $f_n \to f$ pointwise, then $f_n \in \bar{\mathfrak{C}}$ for all n, so $f \in \bar{\mathfrak{C}}$; also, $f_n + g \to f+g$ pointwise, and $f_n + g \in \bar{\mathfrak{C}}$, so $f+g \in \bar{\mathfrak{C}}$, i.e. $f \in \mathfrak{D}$. This proves the claim, and therefore the sum of a function in $\mathfrak{C}$ and a function in $\bar{\mathfrak{C}}$ is in $\bar{\mathfrak{C}}$.

Now suppose $g \in \bar{\mathfrak{C}}$, and repeat the argument with $\mathfrak{E} = \{f \in \bar{\mathfrak{C}} : f+g \in \bar{\mathfrak{C}}\}$. As before, we show that $\mathfrak{C} \subset \mathfrak{E}$ (by the first part of the proof) and that $\mathfrak{E}$ is closed under pointwise sequential limits, and thus $\mathfrak{E} = \bar{\mathfrak{C}}$. This shows that $\bar{\mathfrak{C}}$ is closed under addition.

The proof that $\bar{\mathfrak{C}}$ is closed under multiplication is virtually identical, replacing "sum" by "product" everywhere, and is left as an exercise ().

The case of scalar multiplication is a special case of the product, regarding the scalar α as the constant function with value α. 👍

XVI.2.6.2. Corollary. The class of BC sets in $\mathbb{R}$ is a σ-algebra.

Proof: Suppose A is a BC set, i.e. $\chi_A \in \bar{\mathfrak{C}}$. Then $\chi_{A^c} = 1 - \chi_A \in \bar{\mathfrak{C}}$, so A^c is a BC set. If A and B are BC sets, then $\chi_{A\cap B} = \chi_A \chi_B \in \bar{\mathfrak{C}}$, so $A \cap B$ is a BC set. Finally, if (A_n) is a sequence of BC sets and $A = \cap_{n=1}^{\infty} A_n$, set $f_n = \chi_{A_1 \cap \cdots \cap A_n} = \chi_{A_1}\chi_{A_2}\cdots\chi_{A_n}$. Then $f_n \in \bar{\mathfrak{C}}$ and $f_n \to \chi_A$ pointwise, so $\chi_A \in \bar{\mathfrak{C}}$ and so A is a BC set. Thus the class of BC sets is closed under complements and countable intersections. It clearly contains $\mathbb{R}$ since $\chi_{\mathbb{R}}$ is the constant function 1, which is in $\mathfrak{C}$. 👍

XVI.2.6.3. Proposition. Every open interval in $\mathbb{R}$ is a BC set.

Proof: Let (a,b) be an open interval in $\mathbb{R}$. We need to show that $\chi_{(a,b)} \in \bar{\mathfrak{C}}$; we will find a sequence of continuous functions converging pointwise to $\chi_{(a,b)}$. Let f_n be the function with the following graph:

It is easy to check that $f_n \to \chi_{(a,b)}$ pointwise. 👍

XVI.2.6.4. Corollary. Every Borel set is a BC set.

Proof: The class of BC sets is a σ-algebra (XVI.2.6.2.) which contains the open intervals (XVI.2.6.3.). The smallest such σ-algebra is the Borel sets. 👍

Now we show that $\bar{\mathfrak{C}}$ is closed under composition:

XVI.2.6.5. PROPOSITION. Let $f, g \in \bar{\mathfrak{C}}$. Then $f \circ g \in \bar{\mathfrak{C}}$.

PROOF: The proof is very similar to the proof of XVI.2.6.1.. First fix $f \in \mathfrak{C}$, and let $\mathfrak{D} = \{g \in \bar{\mathfrak{C}} : f \circ g \in \bar{\mathfrak{C}}\}$. As in XVI.2.6.1., $\mathfrak{C} \subseteq \mathfrak{D}$ since a composition of continuous functions is continuous. Also, if $g_n \in \mathfrak{D}$ and $g_n \to g$ pointwise, and $x \in \mathbb{R}$, if $y_n = g_n(x)$ and $y = g(x)$ we have that $y_n \to y$, and thus $[f \circ g_n](x) = f(y_n) \to f(y) = [f \circ g](x)$ since f is continuous; thus $f \circ g_n \to f \circ g$ and so $f \circ g \in \bar{\mathfrak{C}}$, $f \in \mathfrak{D}$. Thus $\mathfrak{D} = \bar{\mathfrak{C}}$, i.e. $f \circ g \in \bar{\mathfrak{C}}$ if $f \in \mathfrak{C}$, $g \in \bar{\mathfrak{C}}$.

Now fix $g \in \bar{\mathfrak{C}}$ and let $\mathfrak{E} = \{f \in \bar{\mathfrak{C}} : f \circ g \in \bar{\mathfrak{C}}\}$. By the first part of the proof, $\mathfrak{C} \subseteq \mathfrak{E}$. Also, if (f_n) is a sequence in $\mathfrak{E}$ converging pointwise to f, then $f \in \bar{\mathfrak{C}}$, and $f_n \circ g \to f \circ g$ pointwise (this is true with no restriction on g), and thus $f \circ g \in \bar{\mathfrak{C}}$, $f \in \mathfrak{E}$. Thus $\mathfrak{E} = \bar{\mathfrak{C}}$ and the proposition is proved. 👍

XVI.2.6.6. COROLLARY. If $g \in \bar{\mathfrak{C}}$, then $|g| \in \bar{\mathfrak{C}}$.

PROOF: We have that $|g| = f \circ g$, where $f(x) = |x|$, which is a continuous function. 👍

See problem () for another proof of this result.

A very important consequence of this corollary comes from the following lemma.

XVI.2.6.7. LEMMA. If $x, y \in \mathbb{R}$, then $\max(x, y) = \frac{1}{2}(x + y + |x - y|)$ and $\min(x, y) = \frac{1}{2}(x + y - |x - y|)$. Thus, if f and g are functions from $\mathbb{R}$ to $\mathbb{R}$, then $\max(f, g) = \frac{1}{2}(f+g+|f-g|)$ and $\min(f, g) = \frac{1}{2}(f+g-|f-g|)$.

PROOF: The proof is a straightforward case-by-case verification which is left as an exercise. 👍

XVI.2.6.8. COROLLARY. If f and g are in $\bar{\mathfrak{C}}$, then so are $\max(f, g)$ and $\min(f, g)$.

XVI.2.6.9. A sequence (f_n) of functions from $\mathbb{R}$ to $\mathbb{R}$ is *pointwise bounded* if, for every $x \in \mathbb{R}$, the set $\{f_n(x) : n \in \mathbb{N}\}$ is bounded in $\mathbb{R}$. If (f_n) is pointwise bounded, then $\sup_n f_n$ and $\inf_n f_n$ are defined as functions from $\mathbb{R}$ to $\mathbb{R}$: $[\sup_n f_n](x) = \sup\{f_n(x) : n \in \mathbb{N}\}$, $[\inf_n f_n](x) = \inf\{f_n(x) : n \in \mathbb{N}\}$.

XVI.2.6.10. COROLLARY. Let (f_n) be a pointwise bounded sequence in $\bar{\mathfrak{C}}$. Then $\sup_n f_n$ and $\inf_n f_n$ are in $\bar{\mathfrak{C}}$.

PROOF: Let $g_n = \max(f_1, \ldots, f_n)$ and $h_n = \min(f_1, \ldots, f_n)$. Then $g_n, h_n \in \bar{\mathfrak{C}}$ by XVI.2.6.8., and $g_n \to \sup_n f_n$, $h_n \to \inf_n f_n$ pointwise. 👍

In fact, it turns out that any algebra of functions which is closed under pointwise sequential limits is also closed under countable suprema and infima (Problem ().)

A clever trick yields a converse to this:

XVI.2.6.11. PROPOSITION. Let $\mathfrak{F}$ be a set of real-valued functions on a set X. If $\mathfrak{F}$ is closed under suprema and infima of pointwise bounded sequences, then $\mathfrak{F}$ is closed under pointwise sequential limits.

PROOF: Suppose (f_n) is a sequence in $\mathfrak{F}$, and $f_n \to f$ pointwise. Then, for each $x \in X$, the sequence $(f_n(x))$ is convergent and therefore bounded; thus (f_n) is pointwise bounded. Also, for $x \in X$,

$$f(x) = \lim_n f_n(x) = \limsup_n f_n(x) = \inf_n [\sup_{k \geq n} f_k(x)]$$

and so, if $g_n = \sup_{k \geq n} f_k$, then $g_n \in \mathfrak{F}$ for all n, and therefore $f = \inf_n [\sup_{k \geq n} f_k] = \inf_n g_n \in \mathfrak{F}$. 👍

This applies in particular to the collection of $\mathcal{A}$-measurable real-valued functions on any measurable space $(X, \mathcal{A})$:

XVI.2.6.12. PROPOSITION. Let $(X, \mathcal{A})$ be a measurable space, and $\mathfrak{B}_{\mathcal{A}}$ the set of $\mathcal{A}$-measurable real-valued functions. Then $\mathfrak{B}_{\mathcal{A}}$ is closed under suprema and infima of pointwise bounded sequences, and hence under pointwise sequential limits.

PROOF: Let (f_n) be a locally bounded sequence in $\mathfrak{B}_{\mathcal{A}}$, and let $g = \sup_n f_n$. We will show that $g^{-1}((a, +\infty)) \in \mathcal{A}$ for every $a \in \mathbb{R}$, and use XVI.2.4.4.(vi). If $x \in X$, then $g(x) > a$ if and only if $f_n(x) > a$ for some n, and thus $g^{-1}((a, +\infty)) = \cup_{n=1}^{\infty} f_n^{-1}((a, +\infty))$. By assumption, $f_n^{-1}((a, +\infty)) \in \mathcal{A}$ for all n, so $g^{-1}((a, +\infty))$ is a countable union of sets in $\mathcal{A}$.

The proof for $\inf_n f_n$ is nearly identical, using XVI.2.4.4.(iv). 👍

The set of $\mathcal{A}$-measurable functions on $(X, \mathcal{A})$ is also an algebra (XVI.2.4.11.).

As a consequence, we get a relationship between $\bar{\mathfrak{C}}$ and Borel measurability:

XVI.2.6.13. COROLLARY. Every function in $\bar{\mathfrak{C}}$ is Borel measurable.

PROOF: If $\mathfrak{B}$ is the set of Borel measurable functions, then $\mathfrak{B}$ contains $\mathfrak{C}$ by XVI.2.4.5., and is closed under pointwise sequential limits by XVI.2.6.12.; thus $\mathfrak{B}$ contains $\bar{\mathfrak{C}}$. 👍

XVI.2.6.14. COROLLARY. Every BC set is a Borel set.

PROOF: If A is a BC set, then $\chi_A \in \bar{\mathfrak{C}}$, and hence χ_A is Borel measurable. But this implies that A is a Borel set by XVI.2.2.5.. 👍

Combining XVI.2.6.14. with XVI.2.6.4., we obtain one of the principal facts we needed to prove:

XVI.2.6.15. THEOREM. A subset of $\mathbb{R}$ is a Borel set if and only if it is a BC set.

XVI.2.6.16. Corollary. A simple function is Borel measurable if and only if it is a BC function.

It still remains to prove that every Borel measurable function is in $\bar{\mathfrak{C}}$. Since every simple Borel measurable function is in $\bar{\mathfrak{C}}$ (XVI.2.6.16.), it suffices to show:

XVI.2.6.17. Lemma. Every Borel measurable function is a pointwise limit of simple Borel measurable functions.

This is a special case of XVI.2.2.9..

So we have shown:

XVI.2.6.18. Theorem. $\bar{\mathfrak{C}} = \mathfrak{B}$.

XVI.2.7. The Borel Sets Are Not Countably Constructible

In this section, we will show that none of the Baire classes $\mathfrak{BC}_\alpha$ for countable α are equal to the class of all Borel measurable functions, and hence the set $\mathcal{BC}_\alpha$ of sets of Baire class α (for α countable) is not the entire class of Borel sets. Thus the classes $\mathfrak{BC}_\alpha$ and $\mathcal{BC}_\alpha$ are strictly increasing in α for α countable, i.e. the entire class of Borel sets or Borel measurable functions cannot be constructed in finitely, or even countably, many steps.

This result was proved by Lebesgue in his 1905 paper [**?**], and was the beginning of what today is called *descriptive set theory* (). The following slick refinement of Lebesgue's original argument, due to W. Sierpiński, which uses an "ultimate space-filling curve," is adapted from [vRS82]. For a rather different argument, see [Bil95, p. 30-32].

XVI.2.7.1. Definition. Let $\mathfrak{F}$ be a set of Borel measurable functions from $\mathbb{R}$ to $\mathbb{R}$. A *catalog* for $\mathfrak{F}$ is a Borel measurable function $F : [0,1] \times \mathbb{R} \to \mathbb{R}$ such that, for every $f \in \mathfrak{F}$, there is an $s \in [0,1]$ for which $f(t) = F(s,t)$ for all $t \in \mathbb{R}$.

If $\mathfrak{F}$ has a catalog, then obviously so does any subset of $\mathfrak{F}$.

We will prove:

XVI.2.7.2. Theorem. For each countable α, $\mathfrak{BC}_\alpha$ has a catalog. But $\mathfrak{B}$ does not have a catalog. So $\mathfrak{BC}_\alpha \neq \mathfrak{B}$.

The proof will proceed in a number of steps.

XVI.2.7.3. Proposition. For each n, let $\mathfrak{F}_n$ be a set of Borel measurable functions, and let $\mathfrak{F} = \cup_n \mathfrak{F}_n$. If each $\mathfrak{F}_n$ has a catalog, then $\mathfrak{F}$ has a catalog.

Proof: Let F_n be a catalog for $\mathfrak{F}_n$. Let h_n be a linear (affine) function from $[\frac{1}{2n}, \frac{1}{2n-1}]$ onto $[0,1]$, and define $G_n : [0,1] \times \mathbb{R} \to \mathbb{R}$ by setting $G_n(s,t) = F_n(h_n(s),t)$ if $s \in [\frac{1}{2n}, \frac{1}{2n-1}]$ and $G_n(s,t) = 0$ otherwise. Then G_n is Borel measurable by () and (). The sequence of partial sums of $\sum_n G_n$ converges pointwise on $[0,1] \times \mathbb{R}$ to a function G which is thus Borel measurable; and G is a catalog for $\mathfrak{F}$ since, if $f \in \mathcal{F}_n$ and $f(t) = F_n(s,t)$, then $f(t) = G(h_n^{-1}(s),t)$. 👍

XVI.2.7.4. Corollary. Any countable set of Borel measurable functions has a catalog.

Proof: It is only necessary to observe that if f is a single Borel measurable function, then $\mathfrak{F} = \{f\}$ has a catalog. Set $F(s,t) = f(t)$ for all s. 👍

XVI.2.7.5. If $\mathfrak{F}$ is a set of Borel measurable functions, write $\mathfrak{F}^*$ for the set of functions (also Borel measurable) which are pointwise limits of sequences of functions in $\mathfrak{F}$. For example, $\mathfrak{BC}_\alpha^* = \mathfrak{BC}_{\alpha+1}$. In general, $\mathfrak{F} \subseteq \mathfrak{F}^*$ (use constant sequences).

The most difficult part of the proof of the theorem is to show that if $\mathfrak{F}$ has a catalog, so does $\mathfrak{F}^*$. This will be done using the continuous function ψ of XIII.18.4.4.. We first need a useful variation of the notion of limit of a sequence:

XVI.2.7.6. DEFINITION. Let (a_n) be a sequence of numbers. Define $\mathrm{Lim}_{n\to\infty} a_n = \lim_{n\to\infty} a_n$ if the limit exists, and $\mathrm{Lim}_{n\to\infty} a_n = 0$ if $\lim_{n\to\infty} a_n$ does not exist.

Thus $\mathrm{Lim}_{n\to\infty} a_n$ exists for every sequence (a_n) of numbers. If $(a_n) \subseteq [0,1]$, then $\mathrm{Lim}_{n\to\infty} a_n \in [0,1]$.

XVI.2.7.7. PROPOSITION. Let $(X, \mathcal{A})$ be a measurable space, and (f_n) a sequence of real-valued $\mathcal{A}$-measurable functions on X. Let $C = \{x \in X : (f_n(x)) \text{ converges}\}$. Then $C \in \mathcal{A}$.

PROOF: If $x \in X$, then $x \in C$ if and only if $(f_n(x))$ is a Cauchy sequence. Thus

$$C = \bigcap_{k\in\mathbb{N}} \bigcup_{r\in\mathbb{Q}} \bigcup_{n\in\mathbb{N}} \bigcap_{m\geq n} f_m^{-1}\left(\left[r - \frac{1}{k}, r + \frac{1}{k}\right]\right) .$$

👍

XVI.2.7.8. COROLLARY. Let $(X, \mathcal{A})$ be a measurable space, and (f_n) a sequence of real-valued $\mathcal{A}$-measurable functions on X. For $x \in X$, set $f(x) = \mathrm{Lim}_{n\to\infty} f_n(x)$. Then f is $\mathcal{A}$-measurable.

PROOF: If C is as above, then $C \in \mathcal{A}$, and $f_n \to f$ on C, so $f|_C$ is measurable. f is constant on $X \setminus C$, hence measurable. Thus f is measurable by (). 👍

XVI.2.7.9. THEOREM. If $\mathfrak{F}$ is a set of Borel measurable functions from $\mathbb{R}$ to $\mathbb{R}$, and $\mathfrak{F}$ has a catalog, then $\mathfrak{F}^*$ also has a catalog.

PROOF: Let F be a catalog for $\mathfrak{F}$, and let $\psi : [0,1] \to [0,1]^{\mathbb{N}}$ be an ultimate space-filling curve as in **??**, with coordinate functions ψ_n $(n \in \mathbb{N})$. For each $s \in [0,1]$, $t \in \mathbb{R}$, set $G_n(s,t) = F(\psi_n(s), t)$, and $G(s,t) = \mathrm{Lim}_{n\to\infty} G_n(s,t)$. Since $h_n(s,t) = (\psi_n(s), t)$ is continuous and hence Borel measurable, so is $G_n = F \circ h_n$, and therefore G is Borel measurable by XVI.2.7.8..

We claim G is a catalog for $\mathfrak{F}^*$. Suppose (f_n) is a sequence in $\mathfrak{F}$ with $f_n \to f$ pointwise. For each n there is an $s_n \in [0,1]$ such that $f_n(t) = F(s_n, t)$ for all t. There is an $s \in [0,1]$ such that $s_n = \psi_n(s)$ for all n (). Then $G(s,t) = f(t)$ for all $t \in \mathbb{R}$. 👍

We next show that $\mathfrak{BC}_\alpha$ has a catalog for α countable.

XVI.2.7.10. DEFINITION. If $\mathfrak{F}$ and $\mathfrak{G}$ are sets of Borel measurable functions, we say $\mathfrak{G}$ is *locally uniformly dense in* $\mathfrak{F}$ if, for every $f \in \mathfrak{F}$, $\epsilon > 0$, and $n \in \mathbb{N}$, there is a $g \in \mathfrak{G}$ with $|f(t) - g(t)| < \epsilon$ for all $t \in [-n, n]$.

We usually apply this definition when $\mathfrak{G} \subseteq \mathfrak{F}$.

XVI.2.7.11. EXAMPLE. Here is the most important example for us. Let $\mathfrak{Q}$ be the set of polynomials with rational coefficients. Then by the Weierstrass Approximation Theorem (), $\mathfrak{Q}$ is locally uniformly dense in the set $\mathfrak{C}$ of continuous functions from $\mathbb{R}$ to $\mathbb{R}$.

XVI.2.7.12. PROPOSITION. If $\mathfrak{G}$ is locally uniformly dense in $\mathfrak{F}$, then $\mathfrak{F}^* \subseteq \mathfrak{G}^*$. (If $\mathfrak{G} \subseteq \mathfrak{F}$, it follows that $\mathfrak{G}^* = \mathfrak{F}^*$.)

PROOF: Suppose $f_n \in \mathfrak{F}$ and $f_n \to f$ pointwise. For each n, choose $g_n \in \mathfrak{G}$ with $|f_n(t) - g_n(t)| < \frac{1}{n}$ for all $t \in [-n, n]$. Then it is easily checked that $g_n \to f$ pointwise. 👍

In particular, we have $\mathfrak{Q}^* = \mathfrak{C}^* = \mathfrak{BC}_1$.

XVI.2.7.13. PROPOSITION. $\mathfrak{BC}_\alpha$ has a catalog for every countable α.

PROOF: $\mathfrak{Q}$ is countable, so it has a catalog by **??**. Thus $\mathfrak{Q}^* = \mathfrak{BC}_1$ has a catalog by XVI.2.7.9..

Now proceed by transfinite induction. If $\mathfrak{BC}_\alpha$ has a catalog, then $\mathfrak{BC}_{\alpha+1}$ has a catalog by XVI.2.7.9.. And if α is a countable limit ordinal, then $\mathfrak{BC}_\alpha = \cup_{\beta<\alpha}\mathfrak{BC}_\beta$, a countable union, so $\mathfrak{BC}_\alpha$ has a catalog by **??**. 👍

The next result finishes the proof of XVI.2.7.2.. The proof is strongly reminiscent of Cantor's diagonalization argument.

XVI.2.7.14. PROPOSITION. $\mathfrak{B}$ does not have a catalog.

PROOF: Suppose F is a catalog for $\mathfrak{B}$. Define $f : \mathbb{R} \to \mathbb{R}$ by $f(t) = F(t,t) + 1$ if $t \in [0,1]$, and $f(t) = 0$ otherwise. Then $f|_{[0,1]}$ is a composition of two Borel measurable functions, hence Borel measurable; so f is Borel measurable by (). Since F is a catalog, there is an $s \in [0,1]$ such that $f(t) = F(s,t)$ for all t. But $f(s) = F(s,s) + 1 \neq F(s,s)$, a contradiction. 👍

This completes the proof of XVI.2.7.2.. We have the following consequence:

XVI.2.7.15. COROLLARY. For any countable α, $\mathcal{BC}_\alpha$ is a proper subset of $\mathcal{B}$. Thus the $\mathcal{BC}_\alpha$ are strictly increasing for α countable.

PROOF: Suppose $\mathcal{BC}_\alpha = \mathcal{B}$ for some countable α. Since $\mathfrak{BC}_\alpha$ is an algebra of functions (), it follows that every simple Borel measurable function is in $\mathfrak{BC}_\alpha$. Hence every Borel measurable function is in $\mathfrak{BC}_{\alpha+1}$ by (), a contradiction.

If $\alpha < \beta < \omega_1$ and $\mathcal{BC}_\alpha = \mathcal{BC}_\beta$, any countable intersection of sets in $\mathcal{BC}_\alpha$ is in $\mathcal{BC}_{\alpha+1} \subseteq \mathcal{BC}_\beta = \mathcal{BC}_\alpha$ by (), and so it follows from () that $\mathcal{BC}_\alpha$ is a σ-algebra and hence $\mathcal{BC}_\alpha = \mathcal{B}$, a contradiction. 👍

We then have *a fortiori* that $\mathfrak{BC}_\alpha \neq \mathfrak{BC}_\beta$ for $\alpha < \beta < \omega_1$.

XVI.2.8. The Multiplicity Function

In many settings where a function is being analyzed, it is important to consider the "size" of inverse images of points; this provides, among other things, a description of how far the function is from being one-to-one. The most basic way to do this is via the "multiplicity function" (sometimes called the "counting function"):

XVI.2.8.1. DEFINITION. Let $f : X \to Y$ be a function. The *multiplicity function* of f is the function $N_f : Y \to \{0\} \cup \mathbb{N} \cup \{+\infty\}$ defined by

$$N_f(y) = \begin{cases} card(f^{-1}(\{y\})) & \text{if} \quad f^{-1}(\{y\}) \text{ is finite} \\ +\infty & \text{if} \quad f^{-1}(\{y\}) \text{ is infinite} \end{cases} .$$

The Multiplicity Function is most commonly used when $Y = \mathbb{R}$ (or $\mathbb{R}^n$). Note that in this function, we do not distinguish between cases where $f^{-1}(\{y\})$ is countable and cases where it is uncountable. We can sometimes take this into account by a finer invariant; cf. ().

XVI.2.8.2. EXAMPLES. (i) N_f is the constant function 1 if and only if f is a bijection. If f is one-to-one, then N_f takes only the values 0 and 1.
(ii) If $f : \mathbb{R} \to \mathbb{R}$ is given by $f(x) = x^2$, then

$$N_f(y) = \begin{cases} 0 & \text{if} \quad y < 0 \\ 1 & \text{if} \quad y = 0 \\ 2 & \text{if} \quad y > 0 \end{cases} .$$

(iii) If $f : [0,1] \to [0,1]$ is a coordinate function of a space-filling curve (), then f is continuous and $N_f(y) = +\infty$ for all $y \in [0,1]$ ().

XVI.2.8.3. If $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ are measurable spaces and $f : X \to Y$ is measurable, it is not true in general (cf. XVI.2.8.7.) even if $X = Y = \mathbb{R}$, that N_f is a measurable function (since its range is a countable set, N_f will be measurable if and only if, for each $n \in \{0\} \cup \mathbb{N} \cup \{+\infty\}$ we have that $\{y \in Y : N_f(y) = n\}$ is in $\mathcal{B}$). But in some important special cases this can be shown. The next result is the simplest example, and perhaps the most widely used; the proof can be adapted to broader contexts.

XVI.2.8.4. PROPOSITION. Let f be a real-valued continuous function on an an interval I in $\mathbb{R}$. Then N_f is an extended real-valued Borel measurable function.

PROOF: First suppose I is a bounded interval from a to b (with or without endpoints). For each $n \in \mathbb{N}$, define a function $\phi_n : \mathbb{R} \to \mathbb{N}$ by taking a partition $\{x_0 = a, x_1, \ldots, x_{2^n} = b\}$ of I into 2^n subintervals $J_1, \ldots, J_{2^n}$ of equal length, with $x_k \in J_k$, $x_k \notin J_{k+1}$ for $1 \leq k \leq 2^n - 1$, $a \in J_1$ if $a \in I$, and $b \in J_{2^n}$ if $b \in I$. Then set

$$\phi_n = \sum_{k=1}^{2^n} \chi_{f(J_k)} .$$

We have that $f(J_k)$ is an interval, hence a Borel set; thus ϕ_n is a Borel measurable function from $\mathbb{R}$ to $\mathbb{R}$. For any $y \in \mathbb{R}$, $\phi_n(y)$ is the number of subintervals whose intersection with $f^{-1}(\{y\})$ is nonempty. It is easily seen that $\phi_n \leq \phi_{n+1}$ for each n, and that $N_f = \sup_n \phi_n$. Thus N_f is Borel measurable.

For a general I, write $I = \cup I_m$, where each I_m is a bounded interval and $I_m \subseteq I_{m+1}$. Let $f_m = f|_{I_m}$. Then $N_f = \sup_m N_{f_m}$, and each f_m is Borel measurable, hence so is N_f. ☝

XVI.2.8.5. We can try to adapt this argument to a more general setting of a Borel measurable function f (e.g. a continuous function) between topological spaces X and Y. There are two things which need to be done:

(i) We need a sequence of finite partitions of X, each refining the previous one, into "nice" subsets (e.g. Borel sets), such that distinct elements of X are separated by sufficiently fine partitions in the sequence. This can be done systematically using Borel sets in any Polish space (), hence in any standard Borel space (), e.g. in any Borel subset of $\mathbb{R}^n$; for Borel sets in $\mathbb{R}^n$ there is an obvious approach using grids similar to the approach in the proof of XVI.2.8.4..

(ii) We need to know that if $J_1, \ldots, J_r$ are the sets in the n'th partition, then $f(J_k)$ is a Borel subset of Y. This is false in general (). However, if Y is a Polish space (e.g. $\mathbb{R}^n$), then $f(J_k)$ is an analytic subset of Y if J_k is Borel in X ().

Combining these observations with (), we obtain the most general result which can be easily stated:

XVI.2.8.6. THEOREM. Let $(X, \mathcal{A})$ be a standard Borel space (e.g. a Borel subset of $\mathbb{R}^n$), and $f : X \to \mathbb{R}^m$ a Borel measurable function. Then N_f is a Lebesgue measurable extended real-valued function on $\mathbb{R}^m$.

Lebesgue measurability of N_f can be replaced by μ-measurability, for any measure μ which is the completion of a Borel measure on $\mathbb{R}^m$, e.g. Hausdorff measure $\mathcal{H}^s$ for any s.

XVI.2.8.7. EXAMPLE. This result, which applies to Borel measurable functions from $\mathbb{R}$ to $\mathbb{R}$, cannot be extended to Lebesgue measurable functions from $\mathbb{R}$ to $\mathbb{R}$:

Let K be the usual Cantor set, and $K' \subseteq [0,1]$ a generalized Cantor set of positive measure. Let g be a strictly increasing continuous function from $[0,1]$ onto $[0,1]$ with $g(K) = K'$ (). Let Y be a subset of K' which is not Lebesgue measurable, and set $A = g^{-1}(Y)$. Then A has measure 0 since it is a subset of K. Define $f : \mathbb{R} \to \mathbb{R}$ by

$$f(x) = \begin{cases} g(x) & \text{if} \quad x \in A \\ 2 & \text{if} \quad x \notin A \end{cases} .$$

Then f is Lebesgue measurable (it equals the constant function 2 a.e.), but N_f is not Lebesgue measurable since

$$\{y \in \mathbb{R} : N_f(y) = 1\} = Y .$$

Note that although $f = 2$ a.e., we do not have $N_f = N_2$ a.e. In fact, N_2 (i.e. N_h, where h is the constant function 2) is Borel measurable (it is constant a.e.)

For continuous real-valued functions on a closed bounded interval, there is a close relationship between the Multiplicity Function and the notion of bounded variation (XIX.4.3.1.).

XVI.2.9. Standard Borel Spaces

XVI.2.9.1. DEFINITION. Let $(X, \mathcal{A})$ be a Borel space (measurable space). Then $(X, \mathcal{A})$ is a *standard Borel space* if there is a Polish topology $\mathcal{T}$ on X with $\mathcal{A} = \mathcal{B}_{\mathcal{T}}$.

XVI.2.9.2. EXAMPLES. (i) If X is any countable set, then $(X, \mathcal{P}(X))$ is a standard Borel space.
(ii) $(\mathbb{R}, \mathcal{B})$ is a standard Borel space.

We will see (XVI.2.9.9.) that these are the only ones, i.e. every standard Borel space is isomorphic to one (and only one) of these.

Borel Sets as Clopen Sets

The next remarkable theorem allows us to consider Borel sets in a standard Borel space as clopen sets with respect to a Polish topology.

XVI.2.9.3. THEOREM. Let $(X, \mathcal{T})$ be a Polish space (), and A a Borel set in $(X, \mathcal{T})$. Then there is a Polish topology $\mathcal{S}$ on X stronger than $\mathcal{T}$ such that $\mathcal{B}_{\mathcal{S}}(X) = \mathcal{B}_{\mathcal{T}}(X)$ and such that A is clopen in $(X, \mathcal{S})$.

PROOF: First note that if A is closed in $(X, \mathcal{T})$ and $\mathcal{S}$ is the topology on X generated by $\mathcal{T} \cup \{A\}$, then $(X, \mathcal{S})$ is homeomorphic to the separated union of A and A^c with their relative topologies, each of which is a Polish space, so $(X, \mathcal{S})$ is Polish. To see that $\mathcal{B}_{\mathcal{S}} = \mathcal{B}_{\mathcal{T}}$, first note that $\mathcal{B}_{\mathcal{T}} \subseteq \mathcal{B}_{\mathcal{S}}$. If $\{U_n : n \in \mathbb{N}\}$ is a countable base for $\mathcal{T}$, then $\{U_n \cap A, U_n \cap A^c : n \in \mathbb{N}\}$ is a countable base for $\mathcal{S}$, so every open set in $\mathcal{S}$ is a countable union of these, and is hence in $\mathcal{B}_{\mathcal{T}}$.
Now let $\mathcal{A}$ be the set of all $A \in \mathcal{B}_{\mathcal{T}}$ such that the conclusion holds for A. Then $\mathcal{A}$ contains all closed sets in $(X, \mathcal{T})$, so to show that $\mathcal{A}$ is all of $\mathcal{B}_{\mathcal{T}}$ it suffices to show $\mathcal{A}$ is a σ-algebra. $\mathcal{A}$ is clearly closed under complements, so we need only show $\mathcal{A}$ is closed under countable intersections. Let (A_n) be a sequence in $\mathcal{A}$. For each n let $\mathcal{T}_n$ be a Polish topology on X stronger than $\mathcal{T}$ such that $\mathcal{B}_{\mathcal{T}_n} = \mathcal{B}_{\mathcal{T}}$ and such that A_n is clopen in $(X, \mathcal{T}_n)$. If $\mathcal{T}_\infty$ is the weakest topology on X stronger than all the $\mathcal{T}_n$, then $\mathcal{T}_\infty$ is a Polish topology on X by XIII.10.5.4. and each A_n is closed (clopen) in $(X, \mathcal{T}_\infty)$. If for each n $\{U_k^{(n)} : k \in \mathbb{N}\}$ is a countable base for $(X, \mathcal{T}_n)$, then $\{U_k^{(n)} : k, n \in \mathbb{N}\}$ is a countable subbase for $\mathcal{T}_\infty$, and thus every open set in $(X, \mathcal{T}_\infty)$ is a countable union of finite intersections of these and is hence in $\mathcal{B}_{\mathcal{T}} = \mathcal{B}_{\mathcal{T}_n}$ for each n. So $\mathcal{B}_{\mathcal{T}_\infty} = \mathcal{B}_{\mathcal{T}}$.
Then $A = \cap_n A_n$ is closed in $\mathcal{T}_\infty$, so applying the first part of the proof there is a Polish topology $\mathcal{S}$ on X stronger than $\mathcal{T}_\infty$, with $\mathcal{B}_{\mathcal{S}} = \mathcal{B}_{\mathcal{T}_\infty} = \mathcal{B}_{\mathcal{T}}$ and A clopen in $(X, \mathcal{S})$. Thus $A \in \mathcal{A}$. 👍

With additional applications of XIII.10.5.4., the result can be extended:

XVI.2.9.4. COROLLARY. Let $(X, \mathcal{T})$ be a Polish space (), and (A_n) a sequence of Borel sets in $(X, \mathcal{T})$. Then there is a Polish topology $\mathcal{S}$ on X stronger than $\mathcal{T}$ such that $\mathcal{B}_{\mathcal{S}}(X) = \mathcal{B}_{\mathcal{T}}(X)$ and such that A_n is clopen in $(X, \mathcal{S})$ for each n. The topology $\mathcal{S}$ can be chosen so $(X, \mathcal{S})$ is zero-dimensional ().

PROOF: Apply XVI.2.9.3. to A_n to obtain $\mathcal{T}_n$ for each n, and apply XIII.10.5.4. to get $\mathcal{T}_\infty$. To make a zero-dimensional space, take a countable base for $\mathcal{T}_\infty$, extend the topology to make each basic open set clopen, and iterate, and apply XVI.2.9.3. once more at the end. 👍

XVI.2.9.5. This gets very close to XIII.10.5.5.: in the current language, this result implies that if $(X, \mathcal{T})$ is a perfect Polish space, there is a Polish topology $\mathcal{S}$ on X stronger than $\mathcal{T}$ such that $\mathcal{B}_{\mathcal{S}} = \mathcal{B}_{\mathcal{T}}$ and $(X, \mathcal{S})$ is homeomorphic to $\mathcal{N}$. Actually XVI.2.9.4. is very close to this, since it can be shown that $\mathcal{N}$ is the unique perfect zero-dimensional Polish space in which every compact subset has empty interior ().

There are several important corollaries:

XVI.2.9.6. Corollary. Let $(X, \mathcal{T})$ be a Polish space, and A a Borel set in X. If A is uncountable, then A contains a subset homeomorphic to the Cantor set, and in particular $card(A) = 2^{\aleph_0}$.

Proof: There is a Polish topology $\mathcal{S}$ on X stronger than $\mathcal{T}$ in which A is clopen, hence a Polish space in the relative topology. Then $(A, \mathcal{S}_A)$ contains a subset C homeomorphic to the Cantor set. Since C is compact in the relative $\mathcal{S}$-topology and Hausdorff in the relative $\mathcal{T}$-topology, the topologies coincide on C. 👍

XVI.2.9.7. Corollary. Let $(X, \mathcal{A})$ be a standard Borel space, If $Y \in \mathcal{A}$, then $(Y, \mathcal{A}_Y)$ is also a standard Borel space.

Proof: There is a Polish topology $\mathcal{T}$ on X such that $\mathcal{A} = \mathcal{B}_{\mathcal{T}}$ and Y is clopen. Then $(Y, \mathcal{T}_Y)$ is also Polish. We have $\mathcal{B}_Y = \{Y \cap A : A \in \mathcal{B}_X\} = \mathcal{A}_Y$ by (). 👍

XVI.2.9.8. Corollary. Let $(X, \mathcal{T}_X)$ and $(Y, \mathcal{T}_Y)$ be Polish spaces, and $f : X \to Y$ a measurable (Borel) function. Then there are zero-dimensional Polish topologies $\mathcal{S}_X$ and $\mathcal{S}_Y$ on X and Y, stronger than $\mathcal{T}_X$ and $\mathcal{T}_Y$ respectively with the same Borel sets, such that $f : (X, \mathcal{S}_X) \to (T, \mathcal{S}_Y)$ is continuous.

Proof: Let $\{V_n : n \in \mathbb{N}\}$ be a countable base for the topology of Y. Extend the topologies on Y and X to make each V_n and $f^{-1}(V_n)$ clopen. 👍

Uniqueness of Standard Borel Spaces

XVI.2.9.9. Theorem. Any two uncountable standard Borel spaces are isomorphic. Two standard Borel spaces are isomorphic if and only if they have the same cardinality, and the cardinality can only be countable or $2^{\aleph_0}$.

Proof: We need only prove the first statement. Let $(X, \mathcal{A})$ be an uncountable Borel space. Then there is a Polish topology $\mathcal{T}$ on X such that $\mathcal{A} = \mathcal{B}_{\mathcal{T}}$. By the Cantor-Bendixson Theorem (), X is the disjoint union of a countable discrete open set and a perfect closed subset. By extending $\mathcal{T}$, we may assume these subsets are clopen, i.e. X is the separated union of a countable discrete space and a perfect Polish space. Applying XIII.10.5.5., we may assume the perfect subspace is $\mathcal{N}$, i.e. $(X, \mathcal{T})$ is the separated union of $\mathcal{N}$ and a countable discrete space.

So it suffices to show that if X is such a space, then $(X, \mathcal{B}_X)$ is isomorphic to $(\mathcal{N}, \mathcal{B}_{\mathcal{N}})$. $(\mathcal{N}, \mathcal{B}_{\mathcal{N}})$ is clearly isomorphic to a Borel subspace (the perfect part) of $(X, \mathcal{B}_X)$. Conversely, let D be a countably infinite subset of $\mathcal{N}$, and $Y = D^c$. Then $(Y, \mathcal{B}_Y)$ is an uncountable standard Borel space by XVI.2.9.7., thus has

a topology $\mathcal{S}$ such that $(Y, \mathcal{S})$ is homeomorphic to a separated union of $\mathcal{N}$ and a countable discrete space. Thus $\mathcal{N} = D \cup Y$ has a stronger topology $\mathcal{S}$ with the same Borel sets homeomorphic to the separated union of $\mathcal{N}$ and a countable discrete space. Clearly $(X, \mathcal{B}_X)$ is isomorphic to a Borel subspace of $(\mathcal{N}, \mathcal{S})$. Apply the Schröder-Bernstein Theorem for measurable spaces (XVI.1.6.16.) to conclude $(X, \mathcal{B}_X)$ is isomorphic to $(\mathcal{N}, \mathcal{B}_\mathcal{N})$. 👍

XVI.2.10. Exercises

XVI.2.10.1. Let $\mathfrak{BC}_\alpha$ be the set of functions of Baire class α (). A subset A of $\mathbb{R}$ is a *set of Baire class* α if $\chi_A \in \mathfrak{BC}_\alpha$. Let $\mathcal{BC}_\alpha$ denote the set of subsets of $\mathbb{R}$ of Baire class α.
(a) Show that $\cup_{\alpha<\omega_1}\mathcal{BC}_\alpha$ is precisely the set of Borel sets.
(b) Show by transfinite induction that $\mathfrak{BC}_\alpha$ is an algebra of functions for each α.
(c) Show that each $\mathcal{BC}_\alpha$ is an algebra of sets. [Hint: $\chi_{A\cap B} = \chi_A\chi_B$.]
(d) If $f \in \mathfrak{BC}_1$ and U is an open set in $\mathbb{R}$, then $f^{-1}(U)$ is an F_σ. (The converse is also true: if $f^{-1}(U)$ is an F_σ for every open set U, then $f \in \mathfrak{BC}_1$ [].) [If $f_n \to f$ pointwise and $\alpha \in \mathbb{R}$, then

$$f^{-1}((\alpha,\infty)) = \bigcup_n \bigcup_m \bigcap_{k\geq m} \{t : f_k(t) \geq \alpha + \frac{1}{n}\}.]$$

(e) Show that $A \in \mathcal{BC}_1$ if and only if A is both an F_σ and a G_δ. [If A is both an F_σ and a G_δ, show that there is an increasing sequence (F_n) of closed sets, and a decreasing sequence (U_n) of open sets, such that $A = \cup_n F_n = \cap_n U_n$. If f_n is a continuous function which is 1 on F_n and 0 outside U_n (), then $f_n \to \chi_A$. Deduce the converse from (d).] In particular, any open or closed set is in $\mathcal{BC}_1$ ().
(f) Show that a countable union or countable intersection of sets in $\mathcal{BC}_\alpha$ is in $\mathcal{BC}_{\alpha+1}$. In particular, any F_σ or G_δ is in $\mathcal{BC}_2$.
(g) Since $\mathbb{Q}$ is not a G_δ (), $\mathbb{Q} \notin \mathcal{BC}_1$. But $\mathbb{Q} \in \mathcal{BC}_2$ since it is an F_σ.
(h) Use the argument of (d) to show that if $f \in \mathfrak{BC}_2$ and U is open, then $f^{-1}(U)$ is a $G_{\delta\sigma}$. Conclude that if A is in $\mathcal{BC}_2$, then A is both a $G_{\delta\sigma}$ and an $F_{\sigma\delta}$. Generalize to $\mathfrak{BC}_n$ and $\mathcal{BC}_n$.
In fact, if $\alpha < \beta$ are countable ordinals, then $\mathcal{BC}_\alpha$ is a proper subset of $\mathcal{BC}_\beta$, and hence $\mathcal{BC}_\alpha$ is a proper subset of the class of Borel sets (Appendix B).

XVI.2.10.2. Let f be any function from $\mathbb{R}$ to $\mathbb{R}$. Show that the set of points of continuity of f is a G_δ. [For each n, let U_n be the set of all $a \in \mathbb{R}$ for which there is a $\delta > 0$ such that $|f(x) - f(y)| < \frac{1}{n}$ whenever $|x - a| < \delta$ and $|y - a| < \delta$. Show that U_n is open.]

XVI.2.10.3. (a) If I is an interval, show that there is a Borel measurable $f : \mathbb{R} \to \mathbb{R}$ such that I is exactly the set of discontinuities for f. [If I is closed, consider $\chi_\mathbb{Q}\chi_I$. If I is open, let g be a continuous function which is nonzero precisely on I, and consider $\chi_\mathbb{Q} g$.]
(b) If B is an F_σ containing no interval, show there is a Borel measurable f whose set of discontinuities is precisely B. [Write $B = \cup F_n$, with F_n closed, and consider $\sum 2^{-n}\chi_{F_n}$.]
(c) Show that if A is a G_δ, then there is a Borel measurable $f : \mathbb{R} \to \mathbb{R}$ such that A is exactly the set of points where f is continuous.

XVI.2.10.4. Let $f : \mathbb{R} \to \mathbb{R}$ be continuous.
(a) For $n, k \in \mathbb{N}$, $c \in \mathbb{R}$, let $U_{n,k,c}$ be the set of all a for which there is an x with

$$0 < |x - a| < \frac{1}{n} \quad \text{and} \quad \frac{f(x) - f(a)}{x - a} > c - \frac{1}{k}$$

Show that $U_{n,k,c}$ is open and $\cap_{n,k} U_{n,k,c}$ is the set

$$V_c = \left\{ a \in \mathbb{R} : \limsup_{x \to a} \frac{f(x) - f(a)}{x - a} \geq c \right\}$$

So V_c is a G_δ.
(b) Similarly, if $d \in \mathbb{R}$, show that

$$W_d = \left\{ a \in \mathbb{R} : \liminf_{x \to a} \frac{f(x) - f(a)}{x - a} \leq d \right\}$$

is a G_δ.
(c) Show that the set D of points where f is differentiable is an $F_{\sigma\delta}$. [The complement of D is

$$\left(\bigcup_{\substack{c,d \in \mathbb{Q} \\ d<c}} V_c \cap W_d \right) \cup \left(\bigcap_{c \in \mathbb{Q}} V_c \right) \cup \left(\bigcap_{d \in \mathbb{Q}} W_d \right) .]$$

(d) What if f is not assumed to be continuous? (cf. XVI.2.10.2.)

XVI.2.10.5. Let f be a real-valued function on an interval I which has only countably many discontinuities. Show that f is Baire class 1. [Let (x_n) be a dense sequence in I containing all discontinuities of f, and let f_n be a piecewise-linear continuous function agreeing with f on $\{x_1, \ldots, x_n\}$. Show that $f_n \to f$ pointwise.]

XVI.2.10.6. Let I be an interval in $\mathbb{R}$, and $f : I \to \mathbb{R}$. Extend f to $\tilde{f} : \mathbb{R} \to \mathbb{R}$ by setting $\tilde{f}$ identically 0 outside I. Show that $\tilde{f}$ is Baire class 1 on $\mathbb{R}$ if and only if f is Baire class 1 on I.

XVI.2.10.7. Let I be an interval in $\mathbb{R}$. Let $\mathcal{D}$ be a vector space of real-valued functions on I containing the constant functions, whose uniform closure $\bar{\mathcal{D}}$ has the property that if $f \in \mathcal{D}$, then $|f| \in \bar{\mathcal{D}}$, and let $\tilde{\mathcal{D}}$ be the set of all pointwise limits of sequences in $\mathcal{D}$. Show that $\tilde{\mathcal{D}}$ is closed under uniform limits, as follows.
(a) If f is a pointwise limit of a sequence in $\bar{\mathcal{D}}$, show that f is a pointwise limit of a sequence in $\mathcal{D}$. Thus we may, and will, assume $\mathcal{D}$ is uniformly closed.
(b) If $f \in \mathcal{D}$, then $f_+ = f \vee 0 = \frac{1}{2}(f + |f|) \in \mathcal{D}$. Show that if $a \leq b$, then $(f \vee a) \wedge b \in \mathcal{D}$.
(c) Let (f_n) a sequence in $\mathcal{D}$ which converges uniformly to f on I. Passing to a subsequence, we may assume that $|f_{n+1}(x) - f_n(x)| \leq 2^{-n-1}$ for all n and all $x \in I$. Set $g_1 = f_1$ and $g_{n+1} = f_{n+1} - f_n$ for $n \geq 1$. For each n let (h_{nk}) be a sequence in $\mathcal{D}$ with $h_{nk} \to g_n$ pointwise. Use (b) to show that we may assume $|h_{nk}(x)| \leq 2^{-n}$ for all $n > 1$, all k, and all $x \in I$.
(d) For each k, the infinite series $\sum_{n=1}^{\infty} h_{nk}$ converges uniformly. Let $h_k = \sum_{n=1}^{\infty} h_{nk}$. Then $h_k \in \mathcal{D}$. Show that $h_k \to f$ pointwise.

(e) The hypotheses are satisfied if $\mathcal{D}$ is an algebra of bounded functions on I and contains the constant functions (XX.10.2.9.).

(f) The hypotheses are satisfied if $\mathcal{D} = \mathcal{C}(I)$. Conclude that $\mathfrak{BC}_1(I)$ is uniformly closed.

(g) Show by induction on n that if $g \in \mathfrak{BC}_n(I)$ and f is continuous, then $f \circ g$ is in $\mathfrak{BC}_n(I)$. Conclude that $\mathcal{D} = \mathfrak{BC}_n(I)$ satisfies the hypotheses, and hence that $\mathfrak{BC}_{n+1}(I)$ is closed under uniform limits.

(h) Show that the result of the problem holds if "uniform" is replaced by "u.c." throughout. Thus the class $\mathfrak{BC}_n(I)$ is closed under u.c. limits for each $n \in \mathbb{N}$.

XVI.2.10.8. Let I be an interval in $\mathbb{R}$.

(a) Show that every step function on I is in $\mathfrak{BC}_1(I)$. [Use XVI.2.10.5..]

(b) Show that every regulated function (V.8.6.7.) on I is in $\mathfrak{BC}_1(I)$. [Use XVI.2.10.5. and XVI.2.10.7., or XVI.2.10.5. and V.8.6.7.(a).]

XVI.3. Analytic Sets

There is an important class of subsets of $\mathbb{R}$ (or more general topological spaces) which is slightly larger than the class of Borel sets.

XVI.3.1. Standard Borel Spaces

XVI.3.1.1. Recall that a topological space is a *Polish space* if it is homeomorphic to a separable complete metric space.

The next result says that, although there is an enormous variety of topologically distinct uncountable Polish spaces, they are all "identical" from a measure-theoretic standpoint:

XVI.3.1.2. THEOREM. Let X and Y be uncountable Polish spaces. Then the measurable spaces $(X, \mathcal{B}_X)$ and $(Y, \mathcal{B}_Y)$ are isomorphic (). In particular, $(X, \mathcal{B}_X)$ is isomorphic to $(\mathbb{R}, \mathcal{B})$ and to $([0,1], \mathcal{B}_{[0,1]})$.

This theorem is an easy consequence of the following result of KURATOWSKI [**?**], which is a sharpening of XIII.10.4.7.. The proof is rather involved, although fairly elementary, and we omit it; see, for example, [**?**, 2.4.1].

XVI.3.1.3. THEOREM. Let X be an uncountable Polish space which is dense in itself. Then there is an injective continuous function from $\mathcal{N}$ onto X such that the image of every open set is an F_σ.

Such a function is obviously a Borel isomorphism. To obtain XVI.3.1.2., note that by the Cantor-Bendixson Theorem (XIII.2.5.4.) every Polish space is a disjoint union of a countable open subset and a closed subset which is dense-in-itself.

XVI.3.1.4. So to finish the proof of XVI.3.1.2., note that if Y is $\mathcal{N}$ with a countable number of points removed, then Y is a G_δ in $\mathcal{N}$, hence a Polish space, and Y is dense in itself; so Y is Borel isomorphic to $\mathcal{N}$. Since every countable subset of a T_1-space is a Borel set, it follows that $(\mathcal{N}, \mathcal{B}_\mathcal{N})$ is isomorphic as a Borel space to $(\mathcal{N}, \mathcal{B}_\mathcal{N}) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$ (). Any uncountable Polish space X decomposes into a countable set and a Borel subset Z Borel isomorphic to $\mathcal{N}$ by XVI.3.1.3., so

$$(X, \mathcal{B}_X) \cong (Z, \mathcal{B}_Z) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N})) \cong (\mathcal{N}, \mathcal{B}_\mathcal{N}) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N})) \cong (\mathcal{N}, \mathcal{B}_\mathcal{N}) \ .$$

See problems ()–() for an alternate proof of XVI.3.1.2..

In particular, we have

XVI.3.1.5. COROLLARY. Every uncountable Polish space has cardinality $2^{\aleph_0}$.

XVI.3.1.6. DEFINITION. A measurable space $(X, \mathcal{B})$ is a *standard Borel space* if it is isomorphic to $([0,1], \mathcal{B}_{[0,1]})$, hence to $(Y, \mathcal{B}_Y)$ for any uncountable Polish space Y.

Sometimes measurable spaces of the form $(X, \mathcal{P}(X))$ for a countable set X are also called standard Borel spaces. These are the measurable spaces of the form $(X, \mathcal{B}_X)$ for countable Polish spaces X.

Subspaces of Standard Borel Spaces

XVI.3.1.7. PROPOSITION. Let $(X, \mathcal{A})$ be a measurable space which is countably generated and separates points (i.e. if $x, y \in X$, there is an $A \in \mathcal{A}$ with $x \in A$ and $y \in A^c$). Then there is a subset Y of $\mathcal{C}$ such that $(X, \mathcal{A})$ is Borel isomorphic to $(Y, \mathcal{B}_Y)$.

PROOF: Let $\{A_n : n \in \mathbb{N}\}$ generate $\mathcal{A}$ as a σ-algebra. For $x \in X$, define $f(x) \in \mathcal{C}$ by $f(x)(n) = 1$ if $x \in A_n$, $f(x) = 0$ if $x \notin A_n$. It is easily checked that f is a Borel isomorphism onto $f(X)$. 👍

Such an $(X, \mathcal{A})$ is not necessarily a standard Borel space, even if uncountable (). But if the set Y is an uncountable G_δ in $\mathcal{C}$, then it follows from XIII.10.5.3. that $(X, \mathcal{A})$ is a standard Borel space; We will extend this to show that $(X, \mathcal{A})$ is a standard Borel space if Y is merely an uncountable Borel set in $\mathcal{C}$.

XVI.3.1.8. THEOREM. Let $(X, \mathcal{T})$ be a Polish space and A a Borel set in $(X, \mathcal{T})$. Then there is a Polish topology $\mathcal{S}$ on X which is stronger than $\mathcal{T}$, in which A is a clopen set, and such that every Borel set in $(X, \mathcal{S})$ is a Borel set in $(X, \mathcal{T})$.

PROOF: Let $\mathcal{A}$ be the set of all Borel subsets of X for which such an extension of $\mathcal{T}$ is possible. If F is closed in X, let $\mathcal{S} = \{U, U \cap F : U \in \mathcal{T}\}$. Then $\mathcal{S}$ is a topology on X stronger than $\mathcal{T}$, F is clopen in $\mathcal{S}$, and $\mathcal{S} \subseteq \mathcal{B}_\mathcal{T}$, so $\mathcal{B}_\mathcal{S} = \mathcal{B}_\mathcal{T}$. Also, $(X, \mathcal{S})$ is homeomorphic to $(F, \mathcal{T}_F) \sqcup (F^c, \mathcal{T}_{F^c})$, and $(F, \mathcal{T}_F)$ and $(F^c, \mathcal{T}_{F^c})$ are Polish by (), so $(X, \mathcal{S})$ is Polish. Thus all closed sets in X are in $\mathcal{A}$. $\mathcal{A}$ is clearly closed under complements.

To show that $\mathcal{A}$ is closed under countable unions, suppose (A_n) is a sequence in $\mathcal{A}$. For each n let $\mathcal{S}_n$ be a Polish topology on X stronger than $\mathcal{T}$, with the same Borel sets, in which A_n is clopen. Let $\mathcal{S}_\infty$ be the topology on X generated by $\cup_n \mathcal{S}_n$; then $\mathcal{S}_\infty \subseteq \mathcal{B}_\mathcal{T}$, so $\mathcal{B}_{\mathcal{S}_\infty} = \mathcal{B}_\mathcal{T}$. If σ_n is a $[0,1]$-valued complete metric giving $\mathcal{S}_n$, then $\sigma = \sum_n 2^{-n}\sigma_n$ is a complete metric giving $\mathcal{S}_\infty$. If D_n is a countable dense subset of $(X, \mathcal{S}_n)$, then $D = \cup_n D_n$ is a countable dense subset of $(X, \mathcal{S}_\infty)$. Thus $(X, \mathcal{S}_\infty)$ is Polish. We have that $A = \cup_n A_n$ is open in $(X, \mathcal{S}_\infty)$, so by the first part of the proof there is a Polish topology $\mathcal{S}$ stronger than $\mathcal{S}_\infty$, with the same Borel sets, such that A is clopen in $(X, \mathcal{S})$. Thus $A \in \mathcal{A}$ and $\mathcal{A}$ is a σ-algebra containing $\mathcal{T}$, hence containing $\mathcal{B}_\mathcal{T}$. 👍

XVI.3.1.9. COROLLARY. An uncountable measurable subspace of a standard Borel space is a standard Borel space.

An interesting consequence is the following, which "settles" the Continuum Hypothesis for Borel sets:

XVI.3.1.10. COROLLARY. Let X be a Polish space. Any uncountable Borel subset of X has cardinality $2^{\aleph_0}$.

XVI.3.2. Analytic Sets

XVI.3.2.1. DEFINITION. Let X be a Polish space. A subset Y of X is *analytic* if there is a continuous function from $\mathcal{N}$ onto Y.

XVI.3.2.2. The official definition of an analytic set in a general topological space X is a little different: it is a subset of X of the form $\pi_X(F)$, where F is a closed subset of $X \times \mathcal{N}$. If $Y \subset X$ and there is a continuous function f from $\mathcal{N}$ onto Y, then Y is analytic (let F be the graph of f). Conversely, if X is Polish and $Y = \pi_X(F)$ for a closed subset F of $X \times \mathcal{N}$, then F is Polish, so there is a continuous function g from $\mathcal{N}$ onto F by XIII.10.4.7., and $\pi_X \circ g$ is a continuous function from $\mathcal{N}$ onto Y. Thus the two definitions are equivalent for X Polish.

By XIII.10.4.7., if X is a Polish space, then X itself is analytic in X; and the property of being analytic is independent of the containing space.

It is obvious from the definition that continuous images of analytic sets are analytic:

XVI.3.2.3. Proposition. If X and Z are Polish spaces, $f : X \to Z$ is continuous, and Y is an analytic subset of X, then $f(Y)$ is an analytic subset of Z.

One of the most important results about analytic sets is:

XVI.3.2.4. Theorem. Let X be a Polish space. The collection of analytic subsets of X is closed under countable unions and countable intersections.

Proof: Closure under unions is fairly simple. Let E_n be an analytic set for each n, and $f_n : \mathcal{N} \to E_n$ a surjective continuous function. We can regard f_n as being defined on $\{n\} \times \mathcal{N} \subseteq \mathbb{N} \times \mathcal{N}$. Putting these together, we get a map f from $\mathbb{N} \times \mathcal{N} \cong \mathcal{N}$ onto $\cup E_n$.

Closure under intersections is trickier, and cannot be done simply by taking complements because it is not clear (and in fact turns out to be false) that the complement of an analytic set is analytic. So we proceed as follows. Let ψ be a homeomorphism from $\mathcal{N}$ onto $\mathcal{N}^{\mathbb{N}}$, with coordinate functions ψ_n. (This ψ is an analog of the "ultimate space-filling curve" of ().) Let E_n be an analytic subset of X for each n and f_n a continuous function from $\mathcal{N}$ onto E_n. Let

$$Y = \{s \in \mathcal{N} : f_n(\psi_n(s)) = f_m(\psi_m(s)) \text{ for all } n, m \in \mathbb{N}\} .$$

Y is a closed subset of $\mathcal{N}$. For $s \in Y$, set $f(s) = f_1(\psi_1(s)) = f_n(\psi_n(s))$ for all $n \in \mathbb{N}$. We have that $f(s) \in f_n(\mathcal{N}) = E_n$ for all n, hence the range of f is contained in $\cap E_n$. If $x \in \cap E_n$, then for each n there is an $s_n \in \mathcal{N}$ with $f_n(s_n) = x$. Then there is an $s \in \mathcal{N}$ with $s_n = \psi_n(s)$ for all n; then $s \in Y$ and $f(s) = x$. So the range of f is exactly $\cap E_n$. Since Y is closed in $\mathcal{N}$, it is analytic, and hence $\cap E_n$ is analytic by XVI.3.2.3.. 👍

XVI.3.2.5. Corollary. Let X be a Polish space. Then every Borel subset of X is analytic.

Proof: Every closed subset of X is a Polish space, hence analytic by XIII.10.4.7.. The result then follows from XVI.3.2.4. and (). 👍

This result also follows easily from XVI.3.1.8.: if B is a Borel set in X, there is a Polish topology $\mathcal{S}$ on X stronger than the given topology $\mathcal{T}$ for which B is clopen. B is thus Polish in the relative topology from $\mathcal{S}$; hence by XIII.10.4.7. there is an $\mathcal{S}$-continuous map from $\mathcal{N}$ onto B, which is also $\mathcal{T}$-continuous.

The converse of XVI.3.2.5. is not quite true, since we will see that the complement of an analytic set is not necessarily analytic. But the converse is not "too far" from being true. To see this, we first show that disjoint analytic sets can be separated by Borel sets:

XVI.3.2.6. THEOREM. [LUZIN SEPARATION THEOREM] Let X be a Polish space, and E and F disjoint analytic subsets of X. Then there is a Borel subset B of X such that $E \subseteq B$ and $F \subseteq B^c$.

PROOF: First note that if (Y_n) and (Z_m) are sequences of subsets of X which can be separated by Borel sets, i.e. for each n, m there is a Borel set $B_{n,m}$ with $Y_n \subseteq B_{n,m}$ and $Z_m \subseteq B^c_{n,m}$, then there is a Borel set B separating $\cup_n Y_n$ and $\cup_m Z_m$: $B = \cup_n \cap_m B_{n,m}$ works.

Write $E = \phi(\mathcal{N})$ and $F = \psi(\mathcal{N})$ for continuous functions ϕ, ψ. If $(k_1, \dots, k_n) \in \mathbb{N}^n$, set

$$\mathcal{N}_{k_1,\dots,k_n} = \{(s_1, s_2, \dots) \in \mathcal{N} : s_j = k_j \text{ for } 1 \leq j \leq n\} .$$

and put $E_{k_1,\dots,k_n} = \phi(\mathcal{N}_{k_1,\dots,k_n})$, $F_{k_1,\dots,k_n} = \psi(\mathcal{N}_{k_1,\dots,k_n})$.

Suppose E and F are not separated by a Borel set. Since $E = \cup_k E_k$ and $F = \cup_k F_k$, by the first part of the proof there must be s_1, t_1 such that E_{s_1} and F_{t_1} are not separated by a Borel set. Similarly, since $E_{s_1} = \cup_k E_{s_1,k}$ and $F_{t_1} = \cup_k F_{t_1,k}$, there must be s_2, t_2 such that E_{s_1,s_2} and F_{t_1,t_2} are not separated by Borel sets. Continuing inductively, sequences s and t in $\mathcal{N}$ are constructed such that $E_{s_1,\dots,s_n}$ and $F_{t_1,\dots,t_n}$ cannot be separated by a Borel set. Let $x = \phi(s)$ and $y = \phi(t)$. Then $x \in E$ and $y \in F$, so $x \neq y$. Let U and V be disjoint neighborhoods of x and y in X. By continuity, we must have $E_{s_1,\dots,s_n} = \phi(\mathcal{N}_{s_1,\dots,s_n}) \subseteq U$ and $F_{t_1,\dots,t_n} = \psi(\mathcal{N}_{t_1,\dots,t_n}) \subseteq V$, so U separates $E_{s_1,\dots,s_n}$ and $F_{t_1,\dots,t_n}$, a contradiction. 👍

Note that no form of Choice is needed in this proof: each s_j and t_j can just be chosen to be the smallest one for which the conditions hold (specifically, choose s_j to be the smallest possible for which there is a t_j, and then t_j the smallest possible for this s_j).

XVI.3.2.7. COROLLARY. Let E be an analytic subset of a Polish space X. Then E is a Borel set if and only if E^c is also analytic.

XVI.3.2.8. EXAMPLE. It is not so easy to construct an analytic set which is not a Borel set. Here is a construction of an analytic subset A of $\mathcal{N}$ whose complement in $\mathcal{N}$ is not analytic, hence A is not Borel. Since $\mathcal{N}$ is homeomorphic to the set of irrational numbers $\mathbb{J}$, A may be regarded as an analytic subset of $\mathbb{R}$ whose complement in $\mathbb{R}$ is not analytic (since if it were, $(\mathbb{R} \setminus A) \cap \mathbb{J}$ would be analytic by XVI.3.2.4.). The construction uses a version of Cantor's diagonalization argument.

We first construct a "universal" open set W in $\mathcal{N}^3$ which is a catalog for open sets in $\mathcal{N}^2$, i.e. for every open set V in $\mathcal{N}^2$ there is a $t \in \mathcal{N}$ such that $(r, s) \in V \iff (r, s, t) \in W$. The basic open sets in $\mathcal{N}^2$ (products of sets of the form $\mathcal{N}^{k_1,\dots,k_m}_{n_1,\dots,n_m}$ ()) can be arranged in a sequence (U_n) (this can be done explicitly without any form of AC; cf. Exercise **??**). For each $n \in \mathbb{N}$, define

$$W_n = \{(r, s, t) \in \mathcal{N}^3 | (r, s) \in U_{t_n}\}$$

where as usual we write $t = (t_1, t_2, \dots)$. Then W_n is open: if $(r, s, t) \in W_n$, then

$$\{(r', s', t') \in \mathcal{N}^3 | (r', s') \in U_{t_n}, t'_n = t_n\}$$

is a neighborhood of (r,s,t) contained in W_n. Set $W = \cup_n W_n$. Then W is open in $\mathcal{N}^3$. If V is an open set in $\mathcal{N}^2$, let $t = (t_1, t_2, \dots)$ be the set of n's (in increasing order) such that $U_n \subseteq V$. Then $V = \cup_n U_{t_n}$, so

$$(r,s) \in V \iff (r,s) \in U_{t_n} \text{ for some } n \iff (r,s,t) \in W_n \text{ for some } n \iff (r,s,t) \in W$$

so W is a catalog for open sets in $\mathcal{N}^2$.

Let $G = \mathcal{N}^3 \setminus W$. Then G is a catalog for closed sets if $\mathcal{N}^2$: if $F \subset \mathcal{N}^2$ is closed, let $V = \mathcal{N}^2 \setminus F$. Then there is a $t \in \mathcal{N}$ such that

$$(r,s) \in F \iff (r,s) \notin V \iff (r,s,t) \notin W \iff (r,s,t) \in G \ .$$

Now let $C = \pi_{13}(G) \subseteq \mathcal{N}^2$ be the projection of G onto the first and third coordinates. Then C is an analytic subset of $\mathcal{N}^2$ since G is closed in $\mathcal{N}^2 \times \mathcal{N}$. We claim that C is a catalog for analytic subsets of $\mathcal{N}$. If B is an analytic subset of $\mathcal{N}$, there is a closed set $F \subseteq \mathcal{N}^2$ with $B = \pi_1(F)$. There is then a $t \in \mathcal{N}$ such that $(r,s) \in F \iff (r,s,t) \in G$. We then have, for $r \in \mathcal{N}$,

$$r \in B \iff (r,s) \in F \text{ for some } s \iff (r,s,t) \in G \text{ for some } s \iff (r,t) \in C \ .$$

Finally, let $D = \{(t,t) | (t,t) \in C\} \subseteq \mathcal{N}^2$ and let $A = \pi_1(D)$. D is the intersection of C with the diagonal in $\mathcal{N}^2$, which is a closed, hence analytic, subset of $\mathcal{N}^2$; hence D is analytic in $\mathcal{N}^2$ by XVI.3.2.4., and so A is analytic in $\mathcal{N}$. But $A^c = \mathcal{N} \setminus A$ cannot be analytic, since if it were there would be a $t \in \mathcal{N}$ such that $r \in A^c \iff (r,t) \in C$. But then, for this t,

$$t \in A^c \iff (t,t) \in C \iff (t,t) \in D \iff t \in A$$

which is a contradiction.

XVI.3.3. Suslin Sets and the Suslin Operation

XVI.3.3.1. There is a curious operation on sets called the *Suslin operation*, which is reminiscent of the construction in the proof of XIII.10.4.7.. For each finite sequence $(s_1, \dots, s_n)$ of natural numbers, let $A_{s_1,\dots,s_n}$ be a subset of a set X. The collection of finite sequences in $\mathbb{N}$ is countable, so there are countably many such sets in all. Define

$$S(\{A_{s_1,\dots,s_n}\}) = \bigcup_{s \in \mathcal{N}} \bigcap_{n=1}^{\infty} A_{s_1,\dots,s_n} \ .$$

Although the operation begins with a countable collection of sets, the union is over all sequences (uncountably many) in $\mathcal{N}$.

XVI.3.3.2. Definition. Let X be a Polish space. A *Suslin set* is a subset of X obtained by applying the Suslin operation to a collection of closed subsets of X.

XVI.3.3.3. THEOREM. A subset of a Polish space is a Suslin set if and only if it is analytic.

PROOF: Suppose A is a Suslin set in a Polish space X. Let $A = \cup_{s\in\mathcal{N}} \cap_n F_{s|n}$, where the $F_{s|n}$ are closed sets. Set

$$F = \{(x, s) \in X \times \mathcal{N} : x \in F_{s|n} \text{ for all } n\} \subseteq X \times \mathcal{N} .$$

Then F is a closed subset of $X \times \mathcal{N}$, and $A = \pi_X(F)$, so A is analytic.

Conversely, suppose A is analytic. Fix a complete metric ρ on X. Let $\phi : \mathcal{N} \to A$ be continuous. For each $(s_1, \ldots, s_n)$ set $F_{s_1,\ldots,s_n} = \overline{\phi(\mathcal{N}_{s_1,\ldots,s_n})}$. Then $F_{s_1,\ldots,s_n}$ is closed and for each $s \in \mathcal{N}$, $F_{s|(n+1)} \subseteq F_{s|n}$ for all n, and $diam(F_{s|n}) \to 0$ as $n \to \infty$ since ϕ is continuous. Thus for every $s \in \mathcal{N}$ there is a unique $x_s \in \cap_n F_{s|n}$ since X is complete. Fix s and set $x = x_s$. Then for each n there is an $x_n \in \phi(\mathcal{N}_{s_1,\ldots,s_n})$ with $\rho(x_n, x) < 2^{-n}$, and there is an $s^{(n)} \in \mathcal{N}_{s_1,\ldots,s_n}$ with $\phi(s^{(n)}) = x_n$. We have $s^{(n)} \to s$ since $s^{(n)}|n = s|n$ for all n; thus $\phi(s^{(n)}) \to \phi(s)$. But $\phi(s^{(n)}) = x_n \to x$, so $x = \phi(s)$, i.e. $x \in A$. So $S(\{F_{s_1,\ldots,s_n}\}) \subseteq A$. The reverse containment is obvious, so $A = S(\{F_{s_1,\ldots,s_n}\}) \in \mathcal{S}(\mathcal{F})$. 👍

XVI.3.3.4. THEOREM. Let $(X, \mathcal{A}, \mu)$ be a complete measure space. Then $\mathcal{A}$ is closed under the Suslin operation.

XVI.3.3.5. COROLLARY. Let X be a Polish space, and μ a complete measure defined on a σ-algebra $\mathcal{A}$ of subsets of X containing the Borel sets. Then $\mathcal{A}$ contains all analytic subsets of X.

XVI.3.3.6. The history of Suslin sets and the Suslin operation is unfortunate and somewhat murky, and is an important facet of the story of analysis in the Soviet Union. SUSLIN died of typhus in 1919 at age 24, having published only one paper during his lifetime. LUZIN, his mentor, then refined, expanded on, and published some of SUSLIN'S work (with credit to SUSLIN). Later, ALEKSANDROV claimed that he was responsible for the Suslin operation and the notion of analytic set, and that in the original names "A-operation" and "A-set", used by both SUSLIN and LUZIN, the "A" stood for "Aleksandrov", not "analytic", the term eventually used by LUZIN (LUZIN said this name had been proposed by LEBESGUE). There is some (inconclusive) evidence to support ALEKSANDROV'S claim, but also persuasive evidence to the contrary, and most contemporary scholarship attributes the concept of analytic set to SUSLIN and LUZIN (HAUSDORFF also played a significant and rather independent role); cf. [Lor01]. The relations between ALEKSANDROV and LUZIN began well but soured early, and contained a lot of personal friction and political intrigue during the Stalin era. ALEKSANDROV was an active participant in the attempted political persecution of LUZIN known as the "Luzin affair." Accounts of these and related events vary widely in point of view, and it is quite difficult to get an unbiased picture of what really happened. The story is certainly a complicated one, involving (according to references) politics, mysticism, and homosexuality. See [GK09], [ZD07], and [Sin03] for pieces of the story.

There are many fascinating anecdotes about these personalities in these references (many of which involve their fanatical and occasionally tragic swimming adventures). For example, the usually reserved KOLMOGOROV, a close friend of ALEKSANDROV, once slapped LUZIN in the face during a meeting of the Academy of Sciences (according to [GK09], in response to an insult by LUZIN); the incident came to the personal attention of STALIN, who shrugged it off, saying, "Well, such things occur with us as well." (Fist-fights in the Politburo?) It should be noted that both before and after this incident, KOLMOGOROV had kind things to say about LUZIN, as did ALEKSANDROV earlier in his career.

XVI.3.3.7. Universally measurable sets

XVI.3.4. Addison's Notation and the Projective Hierarchy

In 1958 J. Addison [Add59] introduced coherent new notation not only for the sets in the hierarchy of the construction of the Borel sets, but also for analytic sets and a continuing hierarchy of subsets of $\mathbb{R}$ (or a general topological space). Indexing by ordinals had been part of the subject since the work of Baire, Lebesgue, Hausdorff, and the Russian school.

XVI.3.4.1. Fix a topological space X, usually $\mathbb{R}$ or $\mathcal{N}$. Define the classes $\mathbf{\Sigma}^0_\alpha$ and $\mathbf{\Pi}^0_\alpha$ of subsets of X inductively for $0 < \alpha < \omega_1$ as follows:

$\mathbf{\Sigma}^0_1$ is the class of open sets.

$\mathbf{\Pi}^0_1$ is the class of closed sets.

$\mathbf{\Sigma}^0_\alpha$ is the class of countable unions of sets in $\cup_{\beta<\alpha}\mathbf{\Pi}^0_\beta$.

$\mathbf{\Pi}^0_\alpha$ is the class of countable intersections of sets in $\cup_{\beta<\alpha}\mathbf{\Sigma}^0_\beta$.

Thus $\mathbf{\Sigma}^0_2$ is the class of F_σ's, $\mathbf{\Pi}^0_2$ the class of G_δ's, $\mathbf{\Sigma}^0_3$ the class of $G_{\delta\sigma}$'s, $\mathbf{\Pi}^0_3$ the class of $F_{\sigma\delta}$'s, etc.

A set A is called a $\mathbf{\Sigma}^0_\alpha$-set ($\mathbf{\Pi}^0_\alpha$-set) if $A \in \mathbf{\Sigma}^0_\alpha$ ($A \in \mathbf{\Pi}^0_\alpha$).

XVI.3.4.2. If X is Polish, we have that $\mathbf{\Sigma}^0_\beta \subseteq \mathbf{\Pi}^0_\alpha$ and $\mathbf{\Pi}^0_\beta \subseteq \mathbf{\Sigma}^0_\alpha$ if $\beta < \alpha$. The complement of a $\mathbf{\Sigma}^0_\alpha$-set is a $\mathbf{\Pi}^0_\alpha$-set, and vice versa. Since $\mathbf{\Sigma}^0_1 \subseteq \mathbf{\Sigma}^0_2$ (), by induction we have $\mathbf{\Sigma}^0_\beta \subseteq \mathbf{\Sigma}^0_\alpha$ and $\mathbf{\Pi}^0_\beta \subseteq \mathbf{\Pi}^0_\alpha$ for $\beta < \alpha$. The unions $\cup_{\alpha<\omega_1}\mathbf{\Sigma}^0_\alpha$ and $\cup_{\alpha<\omega_1}\mathbf{\Pi}^0_\alpha$ are both equal to the class of Borel sets (the Countable AC is needed to show that these unions form a σ-algebra and hence contain all Borel sets (XVI.3.5.4.)).

XVI.3.4.3. It follows easily from the results of () that for $X = \mathbb{R}$, these classes strictly increase in α. This was first shown by Lebesgue [**?**], who proved that $\mathbf{\Sigma}^0_\alpha \not\subseteq \mathbf{\Pi}^0_\alpha$ for any $\alpha < \omega_1$ (see ()).

We also define $\mathbf{\Delta}^0_\alpha = \mathbf{\Sigma}^0_\alpha \cap \mathbf{\Pi}^0_\alpha$.

XVI.3.4.4. Now for $n \in \mathbb{N} \cup \{0\}$ define $\mathbf{\Sigma}^1_n$ and $\mathbf{\Pi}^1_n$ inductively as follows.

$\mathbf{\Sigma}^1_0 = \mathbf{\Sigma}^0_1$ is the class of open sets.

$\mathbf{\Pi}^1_n$ is the class of complements of $\mathbf{\Sigma}^1_n$-sets.

$\mathbf{\Sigma}^1_{n+1}$ is the class of π_X images of $\mathbf{\Pi}^1_n$-sets in $X \times \mathcal{N}$.

$\mathbf{\Delta}^1_n = \mathbf{\Sigma}^1_n \cap \mathbf{\Pi}^1_n$.

Thus $\mathbf{\Pi}^1_0$ is the class of closed sets, and $\mathbf{\Sigma}^1_1$ is the class of analytic sets (). $\mathbf{\Delta}^1_1$ is the class of Borel sets (). It follows that $\mathbf{\Sigma}^1_0 \cup \mathbf{\Pi}^1_0 \subseteq \mathbf{\Delta}^1_1$ (there is also a simple direct proof of this) and hence by induction $\mathbf{\Sigma}^1_n \cup \mathbf{\Pi}^1_n \subseteq \mathbf{\Delta}^1_{n+1}$ for all n.

A set in $\cup_n\mathbf{\Sigma}^1_n = \cup_n\mathbf{\Pi}^1_n = \cup_n\mathbf{\Delta}^1_n$ is called a *projective set*.

XVI.3.4.5. To see why the projection operation is natural, and that this hierarchy is analogous to the Borel sets, note that an F_σ ($\mathbf{\Sigma}^0_2$-set) in X is a π_X projection of a closed set ($\mathbf{\Pi}^0_1$-set) in $X \times \mathbb{N}$, and more generally a $\mathbf{\Sigma}^0_{\alpha+1}$-set in X is the π_X projection of a $\mathbf{\Pi}^0_\alpha$-set in $X \times \mathbb{N}$.

XVI.3.4.6. This hierarchy can be extended transfinitely to define $\mathbf{\Sigma}^1_\alpha$ and $\mathbf{\Pi}^1_\alpha$ for $\alpha < \omega_1$. What about $\mathbf{\Sigma}^n_\alpha$, $\mathbf{\Sigma}^\beta_\alpha$, etc.?

XVI.3.4.7. Addison's notation is strongly reminiscent of similar notation used in mathematical logic and model theory, and was in fact inspired by analogies and connections with the logic notation.

XVI.3.5. Exercises

XVI.3.5.1. Let $\mathcal{C} = \{0,1\}^{\mathbb{N}}$ ($\mathcal{C}$ is homeomorphic to the Cantor set ()). Define a map $f : \mathcal{N} \to \mathcal{C}$ by

$$f(n_1, n_2, \dots) = (\underbrace{0, \dots, 0}_{n_1 - 1}, 1, \underbrace{0, \dots, 0}_{n_2 - 1}, 1, \dots) \ .$$

(a) Show that f is a homeomorphism of $\mathcal{N}$ with a subset of $\mathcal{C}$ with countable complement.

(b) Show that $(\mathcal{C}, \mathcal{B}_\mathcal{C})$ is Borel isomorphic to $(\mathcal{N}, \mathcal{B}_\mathcal{N}) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$.

(c) Since $\mathcal{N}$ is also homeomorphic to the irrational numbers in $[0,1]$, $([0,1], \mathcal{B}_{[0,1]})$ is Borel isomorphic to $(\mathcal{N}, \mathcal{B}_\mathcal{N}) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$. Thus $([0,1], \mathcal{B}_{[0,1]})$ is Borel isomorphic to $(\mathcal{C}, \mathcal{B}_\mathcal{C})$.

(d) Show that $(\mathcal{C}, \mathcal{B}_\mathcal{C})$ is also Borel isomorphic to $([0,1]^{\mathbb{N}}, \mathcal{B}_{[0,1]^{\mathbb{N}}})$. [$\mathcal{C}$ is homeomorphic to $\mathcal{C}^{\mathbb{N}}$.]

(e) Since $(\mathbb{N}, \mathcal{P}(\mathbb{N})) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$ is Borel isomorphic to $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$, $(\mathcal{C}, \mathcal{B}_\mathcal{C}) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$ is Borel isomorphic to $(\mathcal{C}, \mathcal{B}_\mathcal{C})$. [Use (b).]

XVI.3.5.2. If (X, ρ) is a perfect complete metric space, show that there is a homeomorphism from $\mathcal{C}$ onto a (compact) subspace of X. Thus $(\mathcal{C}, \mathcal{B}_\mathcal{C})$ is Borel isomorphic to a measurable subspace of $(X, \mathcal{B}_X)$.

XVI.3.5.3. (a) Let X be a Polish space. Then X is homeomorphic to a G_δ in the Hilbert cube (() and ().) Thus $(X, \mathcal{B}_X)$ is Borel isomorphic to a measurable subspace of $(\mathcal{C}, \mathcal{B}_\mathcal{C})$ by ()(d).

(b) If X is an uncountable Polish space, then by () and () $(X, \mathcal{B}_X)$ is Borel isomorphic to $(Y, \mathcal{B}_Y) \oplus (\mathbb{N}, \mathcal{P}(\mathbb{N}))$ for some perfect (uncountable) Polish space Y. Thus $(X, \mathcal{B}_X)$ is Borel isomorphic to a measurable subspace of $(\mathcal{C}, \mathcal{B}_\mathcal{C})$.

(c) If X is an uncountable Polish space, then X has a (compact) subspace homeomorphic to $\mathcal{C}$ (() and ()), and thus $(\mathcal{C}, \mathcal{B}_\mathcal{C})$ is Borel isomorphic to a measurable subspace of $(X, \mathcal{B}_X)$.

(d) Apply the Schröder-Bernstein Theorem for measurable spaces (XVI.1.7.3.) to conclude that if X is any uncountable Polish space, then $(X, \mathcal{B}_X)$ is Borel isomorphic to $(\mathcal{C}, \mathcal{B}_\mathcal{C})$.

XVI.3.5.4. Explain why the Countable AC is needed to show that the unions $\mathcal{A} = \cup_{\alpha<\omega_1} \mathbf{\Sigma}^0_\alpha = \cup_{\alpha<\omega_1} \mathbf{\Pi}^0_\alpha$ (XVI.3.4.2.) form a σ-algebra. (See II.8.6.10..)

Chapter XVII

Measure Theory

XVII.1. Measures

It should come as no surprise that the fundamental concept of measure theory is the notion of measure. Measures live on measurable spaces (), and assign to each measurable set a nonnegative extended real-number "size" for the set. The crucial property a measure must have is countable additivity.

XVII.1.1. Definitions

XVII.1.1.1. DEFINITION. Let $(X, \mathcal{A})$ be a measurable space. A *measure* on $(X, \mathcal{A})$ is a function $\mu : \mathcal{A} \to [0, \infty]$ satisfying

(i) $\mu(\emptyset) = 0$.

(ii) If $A_1, A_2, \ldots$ is a sequence of pairwise disjoint sets in $\mathcal{A}$, then

$$\mu\left(\bigcup_{k=1}^{\infty} A_k\right) = \sum_{k=1}^{\infty} \mu(A_k) \left[= \sup_n \sum_{k=1}^{n} \mu(A_k) = \lim_{n\to\infty} \sum_{k=1}^{n} \mu(A_k)\right]$$

(μ is *countably additive*).

A *measure space* is a triple $(X, \mathcal{A}, \mu)$, where $(X, \mathcal{A})$ is a measurable space and μ is a measure on $(X, \mathcal{A})$.

XVII.1.1.2. Note that specification of the σ-algebra is part of the definition of a measure and of a measure space. While we frequently downplay this specification, especially in contexts where there is some natural σ-algebra of measurable sets, it cannot be ignored. Thus, for example, if $(X, \mathcal{A}, \mu)$ is a measure space and $\mathcal{B}$ is a proper sub-σ-algebra of $\mathcal{A}$, and $\nu = \mu|_{\mathcal{B}}$, then ν is technically a different measure than μ, and the measure spaces $(X, \mathcal{A}, \mu)$ and $(X, \mathcal{B}, \nu)$ are different measure spaces. See XVII.1.6.12..

XVII.1.1.3. Condition (i) in the definition is almost redundant: the only function satisfying (ii) but not (i) is the function μ with $\mu(A) = \infty$ for all $A \in \mathcal{A}$. (To see this, let $A \in \mathcal{A}$, set $A_1 = A$ and $A_n = \emptyset$ for $n > 1$, and apply (ii).)

By a similar argument, we can see:

XVII.1.1.4. PROPOSITION. Let μ be a measure on $(X, \mathcal{A})$. Then μ is *finitely additive*: if $A_1, \ldots, A_n$ are pairwise disjoint sets in $\mathcal{A}$, then

$$\mu\left(\bigcup_{k=1}^{n} A_k\right) = \sum_{k=1}^{n} \mu(A_k) \ .$$

In particular, if $A, B \in \mathcal{A}$ are disjoint, then $\mu(A \cup B) = \mu(A) + \mu(B)$.

PROOF: Set $A_k = \emptyset$ for $k > n$, and apply countable additivity. 👍

XVII.1.1.5. We can define a *finitely additive measure* on a measurable space (X, μ) to be a finitely additive function $\mu : \mathcal{A} \to [0, \infty]$ with $\mu(\emptyset) = 0$. (Actually we only need for $\mathcal{A}$ to be an algebra of subsets of X for this definition to make sense.) XVII.1.1.4. says that every measure is a finitely additive measure; but there are many finitely additive measures which are not measures (e.g. XVII.1.1.6.(vii)–(viii)). A few authors call a finitely additive measure a "measure" (measures in our sense are then called "countably additive measures"), but this terminology is nonstandard. ✋

The theory of finitely additive measures is important in some contexts, and the theory of measure and integration can be developed surprisingly far in this generality (cf. [DS88, Chapter 3]). However, countable additivity is really what gives the theory of measure and integration its power. Countable additivity should be regarded as a sort of continuity condition (cf. XVII.1.2.7.).

Although we cannot yet give any really interesting examples of measures (the interesting ones take considerable effort to construct), here are some simple examples which range from uninteresting to moderately interesting:

XVII.1.1.6. EXAMPLES. (i) Let $(X, \mathcal{A})$ be any measurable space. Set $\mu(A) = 0$ for all $A \in \mathcal{A}$. Then μ is a measure on $(X, \mathcal{A})$, called the *zero measure*.

(ii) Let X be any set. For $A \subseteq X$, set $\mu(A) = 0$ if $A = \emptyset$ and $\mu(A) = \infty$ if $A \neq \emptyset$. Then μ is a measure on $(X, \mathcal{P}(X))$. (This measure can be restricted to any σ-algebra on X.)

(iii) Let X be an uncountable set. If $A \subseteq X$, set $\mu(A) = 0$ if A is countable and $\mu(A) = \infty$ if A is uncountable. Then μ is a measure on $(X, \mathcal{P}(X))$.

(iv) Let X be an uncountable set, $\mathcal{A}$ the σ-algebra of countable/cocountable subsets of X (). If $A \in \mathcal{A}$, set $\mu(A) = 0$ if A is countable and $\mu(A) = 1$ if A is cocountable. Then μ is a measure on $(X, \mathcal{A})$.

(v) Let X be any set, and p a fixed element of X. For $A \subseteq X$, set $\delta_p(A) = 1$ if $p \in A$ and $\delta_p(A) = 0$ if $p \notin A$. Then δ_p is a measure on $(X, \mathcal{P}(X))$, called the *(unit) point mass* (or *Dirac measure*) at p.

(vi) Let X be any set. If $A \subseteq X$, set $\mu(A) = n$ if A is a finite set with n elements, and $\mu(A) = \infty$ if A is infinite. Then μ is a measure on $(X, \mathcal{P}(X))$, called *counting measure* on X. This measure, while very simple, is important, especially in the case $X = \mathbb{N}$; integration theory for this measure is really exactly the theory of infinite series.

(vii) Let X be an infinite set. If $A \subseteq X$, set $\mu(A) = 0$ if A is finite and $\mu(A) = \infty$ if A is infinite. Then μ is a finitely additive measure on $(X, \mathcal{P}(X))$ which is not a measure.

(viii) Let $\mathcal{F}$ be a free ultrafilter () on $\mathbb{N}$. For $A \subseteq \mathbb{N}$, set $\mu(A) = 1$ if $A \in \mathcal{F}$ and $\mu(A) = 0$ if $A \notin \mathcal{F}$. Then μ is a finitely additive measure on $(X, \mathcal{P}(X))$ which is not a measure. The same construction works if $\mathbb{N}$ is replaced by any infinite set whose cardinality is less than the first measurable cardinal.

XVII.1.2. Elementary Properties

Here we develop some of the most basic properties of measures.

XVII.1.2.1. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space. Then

(i) μ is *monotone*: if $A, B \in \mathcal{A}$, $B \subseteq A$, then $\mu(B) \leq \mu(A)$.

(ii) μ is *countably subadditive*: if (A_k) is a sequence in $\mathcal{A}$, then

$$\mu\left(\bigcup_{k=1}^{\infty} A_k\right) \leq \sum_{k=1}^{\infty} \mu(A_k) \ .$$

PROOF: (i): We have $A = B \cup (A \setminus B)$, a disjoint union, and $(A \setminus B) \in \mathcal{A}$, so

$$\mu(A) = \mu(B) + \mu(A \setminus B)$$

by finite additivity, and $\mu(A \setminus B) \geq 0$.
(ii): Disjointize the sequence (A_n) as in (), i.e. set $B_1 = A_1$ and $B_n = A_n \setminus (\cup_{k=1}^{n-1} A_k)$ for $n > 1$. Then the B_n are in $\mathcal{A}$ and are pairwise disjoint, $B_n \subseteq A_n$, and $\cup_{n=1}^{\infty} B_n = \cup_{n=1}^{\infty} A_n$. So, by countable additivity and (i),

$$\mu\left(\bigcup_{n=1}^{\infty} A_n\right) = \mu\left(\bigcup_{n=1}^{\infty} B_n\right) = \sum_{n=1}^{\infty} \mu(B_n) \leq \sum_{n=1}^{\infty} \mu(A_n) \ .$$

As with XVII.1.1.4., we also have

XVII.1.2.2. COROLLARY. Let $(X, \mathcal{A}, \mu)$ be a measure space. Then μ is *finitely subadditive*: if $A_1, \ldots, A_n \in \mathcal{A}$, then

$$\mu\left(\bigcup_{k=1}^{n} A_k\right) \leq \sum_{k=1}^{n} \mu(A_k) \ .$$

In particular, if $A, B \in \mathcal{A}$, then $\mu(A \cup B) \leq \mu(A) + \mu(B)$.

XVII.1.2.3. Note that by a nearly identical proof, a finitely additive measure is also monotone and finitely subadditive. A finitely additive measure need not be countably subadditive: the measure in XVII.1.1.6.(vii) is a counterexample. In fact, a finitely additive measure which is countably subadditive is countably additive, i.e. a measure (Exercise XVII.1.10.1.).

Decompositions of Measure Spaces

The next observation is an immediate consequence of countable additivity. We will often use this result to break up a measure space into a finite or countable number of pieces.

XVII.1.2.4. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, I a finite or countable index set, and $\{X_i : i \in I\}$ a collection of pairwise disjoint measurable subsets of X with $X = \cup_{i\in I} X_i$. Then for any $A \in \mathcal{A}$ we have

$$\mu(A) = \sum_{i\in I} \mu(A \cap X_i) \ .$$

XVII.1.2.5. Note that countability of the index set I is essential. In many examples such as in XVII.1.1.6.(iii), or $\mathbb{R}$ with Lebesgue measure, the entire space X can be decomposed as a disjoint union of singleton subsets, each of which is measurable and has measure zero.

Measures of Differences

XVII.1.2.6. If $(X, \mathcal{A}, \mu)$ is a measure space, and $A, B \in \mathcal{A}$ with $B \subseteq A$, and $\mu(B) < \infty$ (e.g. if $\mu(A) < \infty$), then we have that

$$\mu(A \setminus B) = \mu(A) - \mu(B)$$

where we interpret $\infty - b = \infty$ for $b \in \mathbb{R}$. However, if $\mu(B) = \infty$ (and hence $\mu(A) = \infty$ also by monotonicity), we cannot draw any conclusion about $\mu(A \setminus B)$ (cf. Exercise XVII.1.10.2.). Thus we must be careful in subtracting measures of sets when the measures are infinite.

Upward Continuity

The next property is the first instance of how countable additivity can be regarded as a continuity property. It is called the Baby Monotone Convergence Theorem because it is actually the special case of the Monotone Convergence Theorem for indicator functions.

XVII.1.2.7. PROPOSITION. [BABY MONOTONE CONVERGENCE THEOREM] Let $(X, \mathcal{A}, \mu)$ be a measure space, and (A_n) an increasing sequence in $\mathcal{A}$, i.e. $A_n \subseteq A_{n+1}$ for all n. Then

$$\mu\left(\bigcup_{n=1}^{\infty} A_n\right) = \sup_n \mu(A_n) = \lim_{n\to\infty} \mu(A_n)$$

(μ is *upward continuous*).

PROOF: Disjointize the sequence (A_n) by setting $B_1 = A_1$ and $B_n = A_n \setminus A_{n-1}$ for $n > 1$. Then the B_n are in $\mathcal{A}$ and are pairwise disjoint, $A_n = \cup_{k=1}^{n} B_k$ for all n, and $\cup_{n=1}^{\infty} A_n = \cup_{k=1}^{\infty} B_k$. Then

$$\mu\left(\bigcup_{n=1}^{\infty} A_n\right) = \mu\left(\bigcup_{k=1}^{\infty} B_k\right) = \sum_{k=1}^{\infty} \mu(B_k) = \lim_{n\to\infty} \sum_{k=1}^{n} \mu(B_k) = \lim_{n\to\infty} \mu(A_n) \ .$$

XVII.1.2.8. A finitely additive measure μ is not upward continuous in general, although if (A_n) is an increasing sequence of measurable sets we always have

$$\mu\left(\bigcup_{n=1}^{\infty} A_n\right) \geq \sup_n \mu(A_n) = \lim_{n\to\infty} \mu(A_n)$$

by monotonicity. Example XVII.1.1.6.(vii) is a counterexample to equality. In fact, it is easily seen that upward continuity is equivalent to countable additivity for a finitely additive measure (Exercise XVII.1.10.1.).

Downward Continuity

What about downward continuity? The following example shows that it does not hold in general.

XVII.1.2.9. Example. Let μ be counting measure on $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$. Let $A_n = \{k \in \mathbb{N} : k \geq n\}$. Then $A_n \supseteq A_{n+1}$ for all n. We have $\mu(A_n) = \infty$ for all n. But $\cap_{n=1}^{\infty} A_n = \emptyset$, so

$$0 = \mu\left(\bigcap_{n=1}^{\infty} A_n\right) < \inf_n \mu(A_n) = \lim_{n\to\infty} \mu(A_n) = \infty \ .$$

The difficulty stems from the failure of subtraction for measures of sets (cf. XVII.1.2.6.). In fact, we have:

XVII.1.2.10. Proposition. Let $(X, \mathcal{A}, \mu)$ be a measure space, and (A_n) a decreasing sequence in $\mathcal{A}$, i.e. $A_n \supseteq A_{n+1}$ for all n. If $\mu(A_1) < \infty$, then

$$\mu\left(\bigcap_{n=1}^{\infty} A_n\right) = \inf_n \mu(A_n) = \lim_{n\to\infty} \mu(A_n)$$

(μ is *downward continuous* on sets of finite measure).

Proof: Set $B_n = A_1 \setminus A_n$ for each n. Then the B_n are in $\mathcal{A}$ and are increasing. If $A = \cap_{n=1}^{\infty} A_n$ and $B = \cup_{n=1}^{\infty} B_n$, we have $B = A_1 \setminus A$. We thus have, using XVII.1.2.6. and XVII.1.2.7.,

$$\mu(A_1) - \mu(A) = \mu(B) = \lim_{n\to\infty} \mu(B_n) = \lim_{n\to\infty} [\mu(A_1) - \mu(A_n)] = \mu(A_1) - \lim_{n\to\infty} \mu(A_n)$$

and the result follows. 👍

Note that, by passing to a tail of the sequence, it suffices that $\mu(A_n) < \infty$ for some n.

The First Borel-Cantelli Lemma

We can obtain various more sophisticated results about measures. For example, the next result is particularly important in probability, where it is called the *first Borel-Cantelli Lemma* (). Recall () that if (A_n) is a sequence of subsets of a set X, then

$$\limsup_n A_n = \bigcap_{n=1}^{\infty} \left(\bigcup_{k=n}^{\infty} A_k\right)$$

is the set of $x \in X$ which are in infinitely many of the A_n.

XVII.1.2.11. PROPOSITION. [FIRST BOREL-CANTELLI LEMMA] Let $(X, \mathcal{A}, \mu)$ be a measure space, and (A_n) a sequence in $\mathcal{A}$. If

$$\sum_{k=1}^{\infty} \mu(A_k) < \infty \ ,$$

then

$$\mu(\limsup_n A_n) = 0 \ .$$

PROOF: Let $\epsilon > 0$. Then there is an m such that

$$\sum_{k=1}^{\infty} \mu(A_k) - \sum_{k=1}^{m} \mu(A_k) = \sum_{k=m+1}^{\infty} \mu(A_k) < \epsilon$$

(in fact this holds for all sufficiently large m). For such an m, we have

$$\limsup_n A_n \subseteq \bigcup_{k=m+1}^{\infty} A_k$$

so by monotonicity and countable subadditivity we have

$$\mu(\limsup_n A_n) \leq \mu\left(\bigcup_{k=m+1}^{\infty} A_k\right) \leq \sum_{k=m+1}^{\infty} \mu(A_k) < \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, $\mu(\limsup_n A_n) = 0$. 👍

XVII.1.3. Null Sets and Completeness

XVII.1.3.1. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space. A set $A \in \mathcal{A}$ is a *null set* (or *μ-null set*) if $\mu(A) = 0$.

XVII.1.3.2. In general mathematics, the term "null set" is often used as a synonym for "empty set", but in analysis it is more useful to use the definition we have given. Note that the empty set is always a null set by the analysis definition, but many measure spaces also have other null sets which are nonempty. Of course, whether a set is a null set depends on the measure: if μ and ν are measures on a measurable space $(X, \mathcal{A})$, then a μ-null set is not necessarily a ν-null set.

The idea behind the terminology is that null sets are "negligibly small" for measure-theoretic purposes. A general philosophy in measure theory is that sets or functions can be modified on a null set with no effect. In fact, we will eventually feel quite free to ignore what happens on null sets, although at least at first one should be careful about this.

Unions of Null Sets

XVII.1.3.3. PROPOSITION. A countable union of null sets is a null set. (In particular, a finite union of null sets is a null set.)

This is an immediate consequence of countable subadditivity.

Subsets of Null Sets and Completeness

XVII.1.3.4. It may be surprising that a subset of a null set is not necessarily a null set. It is a trivial consequence of monotonicity that any *measurable* subset of a null set is a null set. However, there are many examples of measure spaces containing null sets with nonmeasurable subsets. Here is perhaps the simplest example:

XVII.1.3.5. Example. Let $\mathcal{A}$ be the σ-algebra of countable/cocountable subsets of $\mathbb{R}$. If $A \in \mathcal{A}$, let $\mu(A) = 1$ if $1 \in A$ and $\mu(A) = 0$ if $1 \notin A$. It is easily checked that μ is a measure on $(\mathbb{R}, \mathcal{A})$ (it is the restriction to $\mathcal{A}$ of the Dirac measure δ_1 of XVII.1.1.6.(v)). We have that $\mathbb{R} \setminus \{1\}$ is a null set, but $(1, +\infty)$ and $(-\infty, 1)$ are not null sets since they are not measurable, i.e. not in $\mathcal{A}$ (each is an uncountable set with uncountable complement).

This example may seem artificial since we arbitrarily chose a smaller σ-algebra than the natural one on which μ is defined (namely $\mathcal{P}(\mathbb{R})$). There are more natural examples such as Lebesgue measure on the Borel sets (), although in a certain sense every example is unnatural (XVII.1.3.7.).

XVII.1.3.6. Definition. Let $(X, \mathcal{A}, \mu)$ be a measure space. Then $(X, \mathcal{A}, \mu)$ is a *complete measure space* if every subset of a null set is a null set (i.e. measurable).

XVII.1.3.7. Theorem. Let $(X, \mathcal{A}, \mu)$ be a measure space, and let $\bar{\mathcal{A}}$ be the σ-algebra of subsets of X generated by $\mathcal{A}$ and all subsets of μ-null sets. Then there is a unique extension $\bar{\mu}$ of μ to $(X, \bar{\mathcal{A}})$, and $(X, \bar{\mathcal{A}}, \bar{\mu})$ is complete. In fact, $\bar{\mathcal{A}}$ is the collection of all subsets of X of the form $A \cup D$, where $A \in \mathcal{A}$ and D is a subset of a μ-null set.

Proof: Let $\mathcal{B}$ be the collection of all subsets of X of the form $A \cup D$, where $A \in \mathcal{A}$ and D is a subset of a μ-null set. Note that $\emptyset$ and X are in $\mathcal{B}$, and it is easy (using XVII.1.3.3.) to check that $\mathcal{B}$ is closed under countable unions. Let $B = A \cup D \in \mathcal{B}$, where $A \in \mathcal{A}$ and $D \subseteq C \in \mathcal{A}$ with $\mu(C) = 0$. Then

$$X \setminus B = (X \setminus [A \cup C]) \cup (C \setminus B)$$

and $X \setminus [A \cup C] \in \mathcal{A}$, $C \setminus B \subseteq C$. Thus $\mathcal{B}$ is a σ-algebra and $\mathcal{A} \subseteq \mathcal{B} \subseteq \bar{\mathcal{A}}$; $\mathcal{B}$ contains all subsets of μ-null sets, so $\mathcal{B} = \bar{\mathcal{A}}$.
For $B = A \cup D$ as above, set $\bar{\mu}(B) = \mu(A)$. This is well defined: if $B = A_1 \cup D_1 = A_2 \cup D_2$ with $D_j \subseteq C_j$, $\mu(C_j) = 0$, then

$$A_1 \setminus C_2 \subseteq A_2 \subseteq A_1 \cup C_1$$

so $\mu(A_1) = \mu(A_2)$. It is clear that $\bar{\mu}$ extends μ and easy to check that $\bar{\mu}$ is countably additive. For uniqueness, if ν extends μ and $B = A \cup D$ with $D \subseteq C$, $\mu(C) = 0$, we must have

$$\mu(A) = \nu(A) \leq \nu(B) \leq \nu(A \cup C) = \mu(A \cup C) \leq \mu(A) + \mu(C) = \mu(A)$$

by monotonicity and subadditivity. Since every subset of a $\bar{\mu}$-null set is a subset of a μ-null set and hence in $\bar{\mathcal{A}}$, $(X, \bar{\mathcal{A}}, \bar{\mu})$ is complete. 👍

XVII.1.3.8. DEFINITION. The measure space $(X, \bar{\mathcal{A}}, \bar{\mu})$ is called the *completion* of $(X, \mathcal{A}, \mu)$ and, by slight abuse of terminology, $\bar{\mu}$ is called the *completion* of μ.

Almost Everywhere

XVII.1.3.9. It is convenient to use the phrase *almost everywhere*, abbreviated *a.e.*, to mean "except on a null set." Thus, for example, if we say "the functions f and g agree almost everywhere," we mean "there is a null set A such that $f(x) = g(x)$ for all $x \notin A$." When the measure μ needs to be specified, we say "μ-almost everywhere," written μ-a.e.

However, if we are dealing with an incomplete measure space, there is a subtlety. Saying "the functions f and g agree almost everywhere" does not necessarily mean "the set of all x for which $f(x) = g(x)$ does not hold (i.e. one or both of $f(x)$ and $g(x)$ is undefined, or both are defined but unequal) has measure zero," because this set could be nonmeasurable (it is only a subset of a set of measure 0). In fact, if f and g agree almost everywhere, and f is measurable, then g is not necessarily even measurable (consider the case where f is identically zero and g is the indicator function of a nonmeasurable subset of a null set). This difficulty disappears when working with complete measure spaces, and is one reason for completing measure spaces (although taking completions also introduces different subtleties; cf. () or ()).

XVII.1.3.10. We can also say that two measurable sets A and B in a measure space $(X, \mathcal{A}, \mu)$ are *almost disjoint* (or *μ-almost disjoint*) if $A \cap B$ is a null set.

The next technical result is very useful and is often applied in the later development of measure and integration:

XVII.1.3.11. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, with completion $(X, \bar{\mathcal{A}}, \bar{\mu})$. If f is an extended real-valued $\bar{\mathcal{A}}$-measurable function, then there is an $\mathcal{A}$-measurable function g with $g = f$ μ-almost everywhere.

PROOF: The proof is a good example of the technique of *bootstrapping*, proving something for all measurable functions by first proving it for indicator functions, then simple functions, and finally general functions by taking pointwise limits. In this case, suppose $f = \chi_C$, where $C \in \bar{\mathcal{A}}$. Then $C = A \cup B$, where $A \in \mathcal{A}$ and $B \subseteq D$ for some μ-null set $D \in \mathcal{A}$. Then $\chi_A = \chi_C$ on $X \setminus B$ and *a fortiori* on $X \setminus D$, and χ_A is $\mathcal{A}$-measurable. Next, if $f_1, \ldots, f_n$ are $\bar{\mathcal{A}}$-measurable functions equal a.e. to $\mathcal{A}$-measurable functions $g_1, \ldots, g_n$ respectively, and if $\alpha_1, \ldots, \alpha_n \in \mathbb{R}$, then $\alpha_1 f_1 + \cdots + \alpha_n f_n$ is equal a.e. to the $\mathcal{A}$-measurable function $\alpha_1 g_1 + \cdots + \alpha_n g_n$ since a finite union of null sets is a null set. In particular, any $\bar{\mathcal{A}}$-measurable simple function is equal a.e. to an $\mathcal{A}$-measurable simple function.

Now let f be a general $\bar{\mathcal{A}}$-measurable function. There is a sequence (f_n) of $\bar{\mathcal{A}}$-measurable simple functions converging pointwise to f. For each n, there is an μ-null set D_n and an $\mathcal{A}$-measurable simple function g_n such that $f_n = g_n$ on $X \setminus D_n$. Let $D = \cup_{n=1}^{\infty} D_n$. Then D is a μ-null set. Let $h_n = g_n = f_n$ on $X \setminus D$ and $h_n = 0$ on D. Then h_n is $\mathcal{A}$-measurable, and (h_n) converges pointwise to a function h which is $\mathcal{A}$-measurable and agrees with f on $X \setminus D$ (in fact, $h_n = g_n \chi_{X \setminus D} = f_n \chi_{X \setminus D}$ and $h = f \chi_{X \setminus D}$).

XVII.1.4. Finite, σ-Finite, and Semifinite Measures

Sets of infinite measure cause difficulties in measure theory. We cannot simply wish them away, however, since many of the most natural and important measure spaces (e.g. $\mathbb{R}$ with Lebesgue measure) have sets of infinite measure. We do want to work with sets of finite measure as much as possible, however. In this subsection we set up some terminology and develop a framework for doing this.

Finite Measure Spaces

The nicest measure spaces are ones with no sets of infinite measure:

XVII.1.4.1. DEFINITION. A measure space $(X, \mathcal{A}, \mu)$ is *finite*, and the measure μ is *finite*, if $\mu(X) < \infty$. The number $\mu(X)$ is the *total mass* of the measure space. The measure space is a *probability measure space*, and μ is a *probability measure*, if $\mu(X) = 1$.

The term "probability measure" comes of course from probability theory (), but the term is used throughout analysis even in contexts unrelated to probability. Any (nonzero) finite measure can be renormalized to a probability measure by taking an appropriate scalar multiple.

XVII.1.4.2. If $(X, \mathcal{A}, \mu)$ is a finite measure space with total mass m, then $\mu(A) \leq m$ for any $A \in \mathcal{A}$ by monotonicity. In particular, if μ is a probability measure, then $0 \leq \mu(A) \leq 1$ for all $A \in \mathcal{A}$.

σ-Finite Measures

It turns out to be almost as good for a set to be a countable union of sets of finite measure, and measure spaces which can be decomposed into countably many finite pieces are well behaved.

XVII.1.4.3. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space. A set $A \in \mathcal{A}$ is of *σ-finite measure* if there is a sequence (A_n) of sets in $\mathcal{A}$ with $A = \cup_{n=1}^{\infty} A_n$ and $\mu(A_n) < \infty$ for all n. The measure space $(X, \mathcal{A}, \mu)$ is *σ-finite*, and μ is a *σ-finite measure*, if X is a set of σ-finite measure, i.e. if there is a sequence (X_n) in $\mathcal{A}$ with $X = \cup_{n=1}^{\infty} X_n$ and $\mu(X_n) < \infty$ for all n.

Note that in this definition, the sets A_n need not have any relation to each other, except they must of course all be measurable subsets of A. In particular, they do not have to be either nested or disjoint. However, if desired it can always be arranged that they are nested or that they are disjoint:

XVII.1.4.4. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $A \in \mathcal{A}$. The following are equivalent:

(i) A has σ-finite measure.

(ii) There is an increasing sequence (B_n) in $\mathcal{A}$ with $A = \cup_{n=1}^{\infty} B_n$ and $\mu(B_n) < \infty$ for all n.

(iii) There is a pairwise disjoint sequence (E_n) in $\mathcal{A}$ with $A = \cup_{n=1}^{\infty} E_n$ and $\mu(E_n) < \infty$ for all n.

PROOF: This is just a consequence of standard nesting or disjointizing operations. (ii) $\Rightarrow$ (i) and (iii) $\Rightarrow$ (i) are trivial. To show (i) $\Rightarrow$ (ii) and (i) $\Rightarrow$ (iii), set $B_n = \cup_{k=1}^{n} A_k$, $E_1 = A_1$, and $E_n = B_n \setminus B_{n-1}$ for $n > 1$. Note that $\mu(E_n) \leq \mu(B_n) \leq \sum_{k=1}^{n} \mu(A_k) < \infty$ by monotonicity and finite subadditivity. 👍

XVII.1.4.5. Corollary. Let $(X, \mathcal{A}, \mu)$ be a σ-finite measure space. Then

(i) There is an increasing sequence (Y_n) of sets in $\mathcal{A}$ with $X = \cup_{n=1}^{\infty} Y_n$ and $\mu(Y_n) < \infty$ for all n.

(ii) There is a pairwise disjoint sequence (Z_n) of sets in $\mathcal{A}$ with $X = \cup_{n=1}^{\infty} Z_n$ and $\mu(Z_n) < \infty$ for all n.

XVII.1.4.6. Proposition. Let $(X, \mathcal{A}, \mu)$ be a measure space. Any measurable subset of a set of σ-finite measure has σ-finite measure. In particular, if the measure space is σ-finite, every measurable set in X has σ-finite measure.

Proof: If $A \in \mathcal{A}$ has σ-finite measure, let (A_n) be a sequence of sets in $\mathcal{A}$ with $A = \cup_{n=1}^{\infty} A_n$ and $\mu(A_n) < \infty$ for all n. If $B \in \mathcal{A}$, $B \subseteq A$, set $B_n = B \cap A_n$ for each n. Then $B = \cup_{n=1}^{\infty} B_n$, and $\mu(B_n) < \infty$ by monotonicity. 👍

Decomposable Measures

The essential feature of σ-finite measure spaces is that the whole space can be chopped up into a countable number of disjoint pieces, each of finite measure. For some purposes it is sufficient that the space can be chopped up in a similar way even if there are uncountably many pieces.

XVII.1.4.7. Definition. A measure space $(X, \mathcal{A}, \mu)$ is *decomposable* (sometimes called *finitely decomposable*) if there is a collection $\{X_i : i \in I\}$ of pairwise disjoint sets in $\mathcal{A}$ with $X = \cup_i X_i$, $\mu(X_i) < \infty$ for all i, and

$$\mu(A) = \sum_{i \in I} \mu(A \cap X_i)$$

for all $A \in \mathcal{A}$ (where the sum is the supremum of the sums over finite subsets of I). By slight abuse of terminology we will also say that μ is decomposable.

XVII.1.4.8. It follows immediately from XVII.1.2.4. that a σ-finite measure space is decomposable; in fact, $(X, \mathcal{A}, \mu)$ is σ-finite if and only if it is decomposable with a countable set I. There are decomposable measures which are not σ-finite, e.g. counting measure on an uncountable set X (where we can take each X_i to be a singleton). There are also measures which are not decomposable, e.g. the ones in XVII.1.1.6.(ii)–(iii).

XVII.1.4.9. **Caution:** For a measure space to be decomposable, it is not enough that it decompose into a disjoint union of measurable sets of finite measure. The example of XVII.1.1.6.(iii) is a simple counterexample: the space is a disjoint union of singletons, each measurable and of finite measure. The problem is not that the subsets have measure 0; see XVII.1.10.7.. ✋

Semifinite Measures

There is a weaker condition than decomposability that is somewhat useful:

XVII.1.4.10. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space. A set $E \in \mathcal{A}$ is *semifinite*, or has *semifinite measure*, if, whenever $A \in \mathcal{A}$, $A \subseteq E$, and $\mu(A) = \infty$, there is a $B \in \mathcal{A}$, $B \subseteq A$, with $0 < \mu(B) < \infty$. $(X, \mathcal{A}, \mu)$ is a *semifinite measure space* if X has semifinite measure. By slight abuse of terminology we will also say that μ is semifinite.

XVII.1.4.11. It is obvious from the definition that every measurable subset of a set of semifinite measure also has semifinite measure. In particular, every measurable set in a semifinite measure space has semifinite measure.

XVII.1.4.12. PROPOSITION. Every decomposable measure space is semifinite. In particular, every σ-finite measure space is semifinite.

PROOF: Let $(X, \mathcal{A}, \mu)$ be decomposable. Let $\{X_i : i \in I\}$ be a pairwise disjoint collection of sets in $\mathcal{A}$ with $X = \cup_i X_i$, $\mu(X_i) < \infty$ for all i, and

$$\mu(A) = \sum_{i \in I} \mu(A \cap X_i)$$

for all $A \in \mathcal{A}$. If $\mu(A) = \infty$, then for any M there is a finite subset F of I such that $\sum_{i \in F} \mu(A \cap X_i) > M$. If $B = \cup_{i \in F}(A \cap X_i)$, then $B \subseteq A$ and by monotonicity

$$M < \mu(B) = \sum_{i \in F} \mu(A \cap X_i) \leq \sum_{i \in F} \mu(X_i) < \infty \ .$$

XVII.1.4.13. There are semifinite measures which are not decomposable (XVII.1.10.3., XVII.1.10.4.). There are also measures which are not semifinite, e.g. the ones in XVII.1.1.6.(ii)–(iii). Measure spaces which do not at least have many subsets of semifinite measure are so pathological that they are rarely useful; for example, integration theory for such measure spaces is completely degenerate.

XVII.1.4.14. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $E \in \mathcal{A}$ of semifinite measure. Then for every $A \in \mathcal{A}$, $A \subseteq E$, we have

$$\mu(A) = \sup\{\mu(B) : B \in \mathcal{A},\ B \subseteq A,\ \mu(B) < \infty\} \ .$$

Conversely, any E with this property has semifinite measure.

PROOF: The formula is trivial (in any measure space) by monotonicity if $\mu(A) < \infty$, so assume $\mu(A) = \infty$. Set

$$M = \sup\{\mu(B) : B \in \mathcal{A},\ B \subseteq A,\ \mu(B) < \infty\} \ .$$

If $M < \infty$, for each n let $B_n \in \mathcal{A}$, $B_n \subseteq A$, and $M - \frac{1}{n} \leq \mu(B_n) < \infty$. Set $D_n = \cup_{k=1}^n B_k$ for each n. Then (D_n) is an increasing sequence, $D := \cup_n D_n \subseteq A$, and

$$\mu(D_n) \leq \sum_{k=1}^n B_k < \infty$$

and therefore $\mu(D_n) \leq M$ for all n. We have $\mu(D) = \sup_n \mu(D_n) \leq M$ by XVII.1.2.7., and since $B_n \subseteq D$ for all n, by monotonicity we have

$$M - \frac{1}{n} \leq \mu(B_n) \leq \mu(D) \leq M$$

for all n. It follows that $\mu(D) = M$.

Since $\mu(A) = \infty$ and $\mu(D) < \infty$, we have $\mu(A \setminus D) = \infty$, and thus by semifiniteness of E there is an $C \in \mathcal{A}$, $C \subseteq A \setminus D$, with $0 < \mu(C) < \infty$. But then $C \cup D \subseteq A$, and

$$M < \mu(C \cup D) = \mu(C) + \mu(D) = \mu(C) + M < \infty$$

contradicting the definition of M. Thus $M = \infty$.

The converse statement is obvious. 👍

XVII.1.5. Discrete and Continuous Measures

XVII.1.5.1. Definition. Let $(X, \mathcal{A}, \mu)$ be a measure space. An *atom* in $(X, \mathcal{A}, \mu)$ is a set $A \in \mathcal{A}$ with the property that $\mu(A) > 0$ and, whenever $B \in \mathcal{A}$, $B \subseteq A$, then either $\mu(B) = 0$ or $\mu(A \setminus B) = 0$.

An atom is a non-null measurable set which is "indivisible" up to null sets. The most obvious examples of atoms are (measurable) singleton subsets of positive measure, when such sets exist, although in general atoms need not be singletons. Measure spaces do not necessarily have any atoms; in fact, most interesting measure spaces do not.

XVII.1.6. Linear Combinations, Restrictions, and Extensions of Measures

We can take sums (finite or infinite) and scalar multiples of measures to obtain new measures, and we can in good circumstances restrict and extend measures. The arguments in this subsection are for the most part virtually trivial, with a few subtleties.

Addition of Measures

XVII.1.6.1. Proposition. Let μ and ν be measures on a measurable space $(X, \mathcal{A})$. Then $\mu + \nu$ is a measure on $(X, \mathcal{A})$. [By $\mu + \nu$ we mean the usual pointwise (setwise) sum, i.e. $(\mu + \nu)(A) = \mu(A) + \nu(A)$ for $A \in \mathcal{A}$, where as usual $x + \infty = \infty$ for $x \in [0, \infty]$.]

Proof: We have $(\mu + \nu)(\emptyset) = 0 + 0 = 0$. If (A_k) is a sequence of pairwise disjoint sets in $\mathcal{A}$, then

$$(\mu+\nu)\left(\bigcup_{k=1}^{\infty} A_k\right) = \mu\left(\bigcup_{k=1}^{\infty} A_k\right) + \nu\left(\bigcup_{k=1}^{\infty} A_k\right) = \sum_{k=1}^{\infty} \mu(A_k) + \sum_{k=1}^{\infty} \nu(A_k) = \sum_{k=1}^{\infty} [\mu(A_k) + \nu(A_k)] = \sum_{k=1}^{\infty} (\mu+\nu)(A_k)$$

where combining the two infinite sums is justified by () since the terms are nonnegative. 👍

Note that we can only add measures defined on the *same* measurable space. We can even add a sequence of measures:

XVII.1.6.2. PROPOSITION. Let (μ_n) be a sequence of measures on a measurable space $(X, \mathcal{A})$. Define $\mu = \sum_{n=1}^{\infty} \mu_n$ on $(X, \mathcal{A})$ by

$$\mu(A) = \left(\sum_{n=1}^{\infty} \mu_n\right)(A) = \sum_{n=1}^{\infty} \mu_n(A)$$

for $A \in \mathcal{A}$. Then μ is a measure on $(X, \mathcal{A})$.

PROOF: We clearly have $\mu(\emptyset) = 0$. If (A_k) is a sequence of pairwise disjoint sets in $\mathcal{A}$, then

$$\mu\left(\bigcup_{k=1}^{\infty} A_k\right) = \sum_{n=1}^{\infty} \mu_n\left(\bigcup_{k=1}^{\infty} A_k\right) = \sum_{n=1}^{\infty}\left(\sum_{k=1}^{\infty} \mu_n(A_k)\right)$$

$$= \sum_{k=1}^{\infty}\left(\sum_{n=1}^{\infty} \mu_n(A_k)\right) = \sum_{k=1}^{\infty} \mu(A_k)$$

where the interchange of order in the double summation is justified by () since the terms are nonnegative. 👍

In fact, an arbitrary set of measures can be added in the same way. See () for this and more general results about combining measures.

Scalar Multiples of Measures

XVII.1.6.3. PROPOSITION. Let μ be a measure on a measurable space $(X, \mathcal{A})$, and $0 \leq \alpha < \infty$. Then $\alpha\mu$ is also a measure on $(X, \mathcal{A})$. [$\alpha\mu$ is defined by $[\alpha\mu](A) = \alpha[\mu(A)]$ for $A \in \mathcal{A}$; here by definition $0 \cdot \infty = 0$.]

PROOF: We obviously have $[\alpha\mu](\emptyset) = 0$. If (A_n) is a sequence of disjoint sets in $\mathcal{A}$, then

$$[\alpha\mu]\left(\bigcup_{k=1}^{\infty} A_k\right) = \alpha\left[\mu\left(\bigcup_{k=1}^{\infty} A_k\right)\right] = \alpha\sum_{k=1}^{\infty} \mu(A_k) = \sum_{k=1}^{\infty} \alpha[\mu(A_k)] = \sum_{k=1}^{\infty} [\alpha\mu](A_k)$$

where the next-to-last step is justified by (). 👍

Linear Combinations of Measures

Combining XVII.1.6.1. and XVII.1.6.3., we obtain:

XVII.1.6.4. PROPOSITION. Any nonnegative linear combination of measures on a measurable space is a measure. Specifically, if $\mu_1, \ldots, \mu_n$ are measures on a measurable space $(X, \mathcal{A})$, and $\alpha_1, \ldots, \alpha_n$ are nonnegative real numbers, then $\sum_{k=1}^{n} \alpha_k\mu_k$ is a measure on $(X, \mathcal{A})$, where $[\sum_{k=1}^{n} \alpha_k\mu_k](A) = \sum_{k=1}^{n} \alpha_k\mu_k(A)$ for $A \in \mathcal{A}$.

We have the same for countable sums, using XVII.1.6.2.:

XVII.1.6.5. PROPOSITION. If $\mu_1, \mu_2, \ldots$ is a sequence of measures on a measurable space $(X, \mathcal{A})$, and $\alpha_1, \alpha_2, \ldots$ is a sequence of nonnegative real numbers, then $\sum_{k=1}^{\infty} \alpha_k \mu_k$ is a measure on $(X, \mathcal{A})$, where $[\sum_{k=1}^{\infty} \alpha_k \mu_k](A) = \sum_{k=1}^{\infty} \alpha_k \mu_k(A)$ for $A \in \mathcal{A}$.

Restrictions and Compressions of Measures

XVII.1.6.6. DEFINITION. Let μ be a measure on a measurable space $(X, \mathcal{A})$, and $E \in \mathcal{A}$.

(i) The *restriction* of μ to E is the measure $\mu|_E$ on $(E, \mathcal{A}_E)$ defined by

$$[\mu|_E](A) = \mu(A)$$

for $A \in \mathcal{A}_E$ (i.e. $A \in \mathcal{A}$ and $A \subseteq E$).

(ii) The *compression* of μ to E is the measure $\mu \llcorner E$ on $(X, \mathcal{A})$ defined by

$$[\mu \llcorner E](A) = \mu(A \cap E)$$

for $A \in \mathcal{A}$.

The measures $\mu|_E$ and $\mu \llcorner E$ are in some sense the "same", but there is a technical difference: $\mu|_E$ is a measure on E, while $\mu \llcorner E$ is a measure on all of X which is supported on E, i.e. $[\mu \llcorner E](X \setminus E) = 0$.

It is a routine exercise (Exercise ()) to verify that $\mu|_E$ and $\mu \llcorner E$ are indeed measures.

XVII.1.6.7. If $(X, \mathcal{A}, \mu)$ is a measure space and $E \subseteq X$, the restriction of μ to E can still be defined even if $E \notin \mathcal{A}$, but it is a little more complicated. The collection $\mathcal{A}_E = \{A \cap E : A \in \mathcal{A}\}$ is a σ-algebra of subsets of E (although it can be quite small; the Countable AC is needed to prove this). If $A \in \mathcal{A}$, define

$$\mu|_E(A \cap E) = \sup\{\mu(B) : B \in \mathcal{A}, B \subseteq A \cap E\} \ .$$

If $A \cap E \in \mathcal{A}$ (and in particular if $E \in \mathcal{A}$), $\mu|_E(A \cap E) = \mu(A \cap E)$.

XVII.1.6.8. PROPOSITION. The function $\mu|_E$ is a measure on $(E, \mathcal{A}_E)$.

PROOF: We have $\mu|_E(\emptyset) = 0$, and $\mu|_E$ is monotone. For countable additivity, let (D_n) be a sequence of pairwise disjoint sets in $\mathcal{A}_E$, and set $D = \cup_n D_n$. If $\mu|_E(D_n) = \infty$ for some n, we have $\mu|_E = \infty$ by monotonicity. So we may assume $\mu|_E(D_n) < \infty$ for all n. Write $D_n = A_n \cap E$ for $A_n \in \mathcal{A}$ (using the Countable AC); then $D = A \cap E$, where $A = \cup_n A_n$. If $B \in \mathcal{A}$, $B \subseteq D$, set $B_n = B \cap A_n \subseteq D_n$. Then

$$\mu(B) = \sum_{n=1}^{\infty} \mu(B_n) \leq \sum_{n=1}^{\infty} \mu|_E(D_n)$$

and taking the supremum over all such B, we obtain

$$\mu|_E(D) \leq \sum_{n=1}^{\infty} \mu|_E(D_n) \ .$$

On the other hand, if $\epsilon > 0$, for each n let $B_n \in \mathcal{A}$ with $B \subseteq D_n$ and $\mu|_E(D_n) \leq \mu(B_n) + 2^{-n}\epsilon$, and set $B = \cup_n B_n$; then $B \in \mathcal{A}$, $B \subseteq D$, and

$$\mu|_E(D) \geq \mu(B) = \sum_{n=1}^{\infty} \mu(B_n) \geq \sum_{n=1}^{\infty} \mu|_E(D_n) - \epsilon$$

and since $\epsilon > 0$ is arbitrary, $\mu(D) \geq \sum_n \mu|_E(D_n)$. 👍

Extensions and Dilations of Measures

XVII.1.6.9. DEFINITION. Let $(X, \mathcal{A})$ be a measurable space, and $E \in \mathcal{A}$. If μ is a measure on $(X, \mathcal{A})$, and ν a measure on $(E, \mathcal{A}_E)$, then μ is an *extension* of ν to X if $\nu = \mu|_E$.

There is nothing unique about extensions of measures in general.

There is always a minimal extension of any measure:

XVII.1.6.10. DEFINITION. Let $(X, \mathcal{A})$ be a measurable space, and $E \in \mathcal{A}$. If ν is a measure on $(E, \mathcal{A}_E)$, the *dilation* of ν to $(X, \mathcal{A})$ is the measure $\nu \uparrow X$ defined by

$$[\nu \uparrow X](A) = \nu(A \cap E)$$

for $A \in \mathcal{A}$.

XVII.1.6.11. It is easily verified that $\nu \uparrow X$ is a measure on $(X, \mathcal{A})$, that $(\nu \uparrow X)$ is an extension of ν to X, that $\nu \uparrow X = (\nu \uparrow X)\llcorner_E$, and that $\nu \uparrow X$ is the unique measure on (X, A) with these properties and the smallest extension of ν to X (in the sense that if μ is any extension, then $\mu \geq (\nu \uparrow X)$.) In fact, if μ is any measure on $(X, \mathcal{A})$, then $\mu = ([\mu|_E] \uparrow X) + ([\mu|_{X\setminus E}] \uparrow X) = (\mu\llcorner_E) + (\mu\llcorner_{X\setminus E})$.

Restriction of Measures to Sub-σ-Algebras

There is another type of restriction of measures:

XVII.1.6.12. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $\mathcal{B}$ a sub-σ-algebra of $\mathcal{A}$. Then the *restriction* of μ to $\mathcal{B}$ is the measure $\mu|_{\mathcal{B}}$ on $(X, \mathcal{B})$ defined by

$$[\mu|_{\mathcal{B}}](B) = \mu(B)$$

for $B \in \mathcal{B}$.

Note that $\mu|_{\mathcal{B}}$ is technically a different measure than μ since the specification of the σ-algebra of measurable subsets is part of the definition of a measure. There are occasions, however, where making an explicit distinction between μ and $\mu|_{\mathcal{B}}$ seems overly pedantic, and we will occasionally overlook the distinction when no confusion can occur. The most important example is restriction of Lebesgue measure to the Borel sets.

XVII.1.6.13. We can also regard the measure μ as an *extension* of $\mu|_{\mathcal{B}}$ to the larger σ-algebra $\mathcal{A}$. Existence of extensions of measures to larger σ-algebras is a very subtle matter and is not possible in general; see II.10.1.1., XVII.1.3.7., () for some instances of extensions and nonexistence of extensions.

Push-Forward of Measures

We can push measures forward by measurable functions:

XVII.1.6.14. DEFINITION. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measure spaces, and $f : X \to Y$ an $(\mathcal{A}, \mathcal{B})$-measurable function (). If μ is a measure on $(X, \mathcal{A})$, then the *push-forward* of μ by f is the measure $f_*(\mu)$ on $(Y, \mathcal{B})$ defined by

$$[f_*(\mu)](B) = \mu(f^{-1}(B))$$

for $B \in \mathcal{B}$.

As usual, it is routine to show that $f_*(\mu)$ is a measure on $(Y, \mathcal{B})$.

XVII.1.6.15. EXAMPLES. (i) If $(X, \mathcal{A})$ is a measurable space and $E \in \mathcal{A}$, and $f : E \to X$ is the inclusion map, and ν is a measure on $(E, \mathcal{A}_E)$, then $f_*(\nu) = \nu \uparrow X$.

(ii) Let $(X, \mathcal{A}, \mu)$ be a measure space, and $\mathcal{B}$ a sub-σ-algebra of $\mathcal{A}$. Let f be the identity map on X, regarded as a measurable function from $(X, \mathcal{A})$ to $(X, \mathcal{B})$. Then $f_*(\mu) = \mu|_{\mathcal{B}}$.

XVII.1.6.16. There is no reasonable way to pull back measures from $(Y, \mathcal{B})$ to $(X, \mathcal{A})$ in general, but this can be done under some special circumstances (e.g. ()).

XVII.1.7. Measures Defined on Rings and σ-Rings

XVII.1.8. Egorov's Theorem

XVII.1.8.1. THEOREM. [EGOROV'S THEOREM] Let $(X, \mathcal{A}, \mu)$ be a finite measure space. Let (f_n) be a sequence of real-valued measurable functions on X converging pointwise a.e. to a real-valued (measurable) function f. Then for every $\epsilon > 0$ there is a set $A \in \mathcal{A}$ with $\mu(X \setminus A) < \epsilon$ and $f_n \to f$ uniformly on A.

PROOF: Fix $\epsilon > 0$. Let $E \in \mathcal{A}$ with $f_n(x) \to f(x)$ for all $x \in E$ and $\mu(X \setminus E) = 0$. For each n and m, set

$$A_{n,m} = \left\{ x \in X : |f_k(x) - f(x)| < \frac{1}{m} \text{ for all } k \geq n \right\} .$$

We have $A_{n,m} \in \mathcal{A}$ for all n, m. For fixed m, we have $A_{n,m} \subseteq A_{n+1,m}$ for all n and $\cup_n A_{n,m} \supseteq E$, i.e. $\cap_n [X \setminus A_{n,m}] \subseteq X \setminus E$. Thus by ()

$$0 \leq \inf_n \mu(X \setminus A_{n,m}) \leq \mu(X \setminus E) = 0$$

and thus there is an n_m such that $\mu(X \setminus A_{n_m,m}) < \frac{\epsilon}{2^m}$.

Let $A = \cap_{m=1}^{\infty} A_{n_m,m}$. Then

$$\mu(X \setminus A) = \mu\left(\bigcup_{m=1}^{\infty} [X \setminus A_{n_m,m}] \right) \leq \sum_{m=1}^{\infty} \mu(X \setminus A_{n_m,m}) < \sum_{m=1}^{\infty} \frac{\epsilon}{2^m} = \epsilon$$

and $f_n \to f$ uniformly of A: if $\delta > 0$, fix m with $\frac{1}{m} \leq \delta$; then, for all $k \geq n_m$ and all $x \in A \subseteq A_{n_m,m}$, we have

$$|f_k(x) - f(x)| < \frac{1}{m} \leq \delta \ .$$

XVII.1.8.2. The first version of this theorem was stated and proved by C. Severini in 1910 and by Egorov independently shortly afterwards. The general version above is due to F. Riesz and W. Sierpiński. Further generalizations were given by Korovkin () and Mokobodski ().

XVII.1.9. Measures on δ-Rings

Measures can be defined on σ-rings, and more generally on δ-rings, with virtually no modification in the theory, and some authors, e.g. [Hal50], take this approach. There is little advantage to this increased generality for ordinary measures, but it is very useful for signed and complex measures ().

XVII.1.10. Exercises

XVII.1.10.1. Let μ be a finitely additive measure on a measurable space $(X, \mathcal{A})$. Show that the following are equivalent:

(i) μ is countably subadditive (XVII.1.2.1.).

(ii) μ is upward continuous (XVII.1.2.7.).

(iii) μ is countably additive, i.e. a measure.

XVII.1.10.2. Let μ be counting measure on $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$. Show that for any $n \in \{0\} \cup \mathbb{N} \cup \{\infty\}$, there are subsets A, B of $\mathbb{N}$ with $B \subseteq A$, $\mu(A) = \mu(B) = \infty$, and $\mu(A \setminus B) = n$.

XVII.1.10.3. Let X be an uncountable set, and x_0 a fixed element of X. Let $\mathcal{A}$ be the collection of all countable subsets of X not containing x_0, and their complements.

(a) Show that $\mathcal{A}$ is a σ-algebra on X.

(b) Let μ be the restriction of counting measure to $\mathcal{A}$. Show that μ is semifinite.

(c) The point x_0 is not contained in any measurable set of finite measure. Conclude that μ cannot be decomposable.

(d) If the cardinality of X is κ, then the cardinality of $\mathcal{A}$ is $\kappa^{\aleph_0}$. In particular, if $card(X) = 2^{\aleph_0}$, then $card(\mathcal{A}) = 2^{\aleph_0}$.

XVII.1.10.4. [Bog07,] Let X be a set of cardinality $\aleph_1$, Y a set of cardinality $\aleph_2$, and $Z = X \times Y$. If $E \subseteq Z$, $x \in X$, and $y \in Y$, write E_x and E^y for the vertical and horizontal cross sections of E at x and y respectively ().

(a) Let $\mathcal{M}$ be the set of all subsets E of Z such that for every $x \in X$, E_x is either countable or cocountable, and for every $y \in Y$, E^y is either countable of cocountable. Show that $\mathcal{M}$ is a σ-algebra.

(b) If $E \in \mathcal{M}$, define

$$\mu(E) = card\{x \in X : E_x \text{ is cocountable}\} + card\{y \in Y : E^y \text{ is cocountable}\}$$

(where $\mu(E) = \infty$ if either set on the right is infinite). Show that μ is a measure on $(Z, \mathcal{M})$. Every countable subset (in particular, every singleton subset) of X is in $\mathcal{M}$ and has measure 0.

(c) Show that μ is semifinite. [If $\mu(E) > 0$, then E contains a set of the form $A \times \{y\}$ for a cocountable subset A of X and some $y \in Y$, or a set of the form $\{x\} \times B$ for cocountable $B \subseteq Y$.]

(d) Suppose μ is decomposable, and let $\{Z_i : i \in I\}$ be a decomposition. For each $y \in Y$, show that the set $(Z_i)^y$ is cocountable for exactly one i.

(e) If $y \in Y$, let $\phi(y)$ be the unique i as in (d). Then ϕ is a function from Y to I. For any $i \in I$, $\phi^{-1}(\{i\})$ is finite. Conclude that $card(I) \geq \aleph_2$.

(f) On the other hand, for each $x \in X$ there is an i such that $(Z_i)_x$ is cocountable. Thus there are only countably many i such that $(Z_i)_x$ is nonempty. Conclude that $card(I) \leq \aleph_1$.

(g) Conclude from (d)–(f) that μ is not decomposable.

XVII.1.10.5. Let I be an uncountable set, and for each $i \in I$ let X_i be a copy of $[0, 1]$. Let X be the disjoint union of the X_i. Let $\mathcal{M}$ be the σ-algebra of Lebesgue measurable sets in $[0, 1]$, and let

$$\mathcal{B} = \{B \subseteq X : B \cap X_i \in \mathcal{M} \text{ for all } i \in I\}$$

and $\mathcal{A}$ the collection of all $A \in \mathcal{B}$ such that $A \cap X_i$ is either $\emptyset$ or X_i for all but countably many i.

(a) Show that $\mathcal{B}$ and $\mathcal{A}$ are σ-algebras.

(b) For $A \in \mathcal{A}$, set $\mu(A) = \sum_{i \in I} \lambda(A \cap X_i)$, where λ is Lebesgue measure on X_i. Show that μ is a complete measure on $(X, \mathcal{A})$.

(c) Show that $\{X_i : i \in I\}$ is a decomposition of $(X, \mathcal{A}, \mu)$, so μ is decomposable and, in particular, semifinite.

(d) If $B \in \mathcal{B}$, set $\nu(B) = \mu(B)$ if $B \in \mathcal{A}$ and $\nu(B) = \infty$ if $B \in \mathcal{B} \setminus \mathcal{A}$. Show that ν is a complete measure on $(X, \mathcal{B})$ extending μ.

(e) If B is a subset of X such that $B \cap X_i$ is a singleton for all i, then $\nu(B) = \infty$, but B contains no subsets of finite positive ν-measure. Thus ν is not semifinite.

Note that this problem, including (e), can be done without using the Axiom of Choice by taking X to be the unit square and the X_i to be (say) horizontal cross sections. The set B of (e) can be taken to be a vertical line segment.

XVII.1.10.6. Let $(X, \mathcal{A}, \mu)$ be a semifinite measure space.

(a) If $\mathcal{A}$ contains only countably many sets of finite measure, show that μ is σ-finite.

(b) [R. Israel] If $\mathcal{A}$ contains only $\aleph_1$ sets of finite measure, and every point of X is contained in a measurable subset of finite measure, then A is decomposable. [Well order the sets of finite measure as $(A_\alpha : \alpha < \omega_1)$, and for each α let $X_\alpha = A_\alpha \setminus (\cup_{\beta<\alpha} A_\beta)$.]

The last condition in (b) is not automatic, at least if the continuum hypothesis is assumed (XVII.1.10.3.).

XVII.1.10.7. Let Y be an uncountable set and ν the measure on $(Y, \mathcal{P}(Y))$ with $\nu(A) = 0$ if A is countable and $\nu(A) = \infty$ if A is uncountable. Let $X = Y \times \{0, 1\}$, and for $A, B \subseteq Y$ set

$$\mu([A \times \{0\}] \cup [B \times \{1\}]) = \nu(A) + |B|$$

where $|B|$ is the number of elements in B (counting measure of B).

(a) Show that μ is a measure on $(X, \mathcal{P}(X))$.

(b) For each $y \in Y$ set $X_y = \{(y, 0), (y, 1)\}$. Then X is the disjoint union of the X_y and $\mu(X_y) = 1$ for all y. In particular, every point of X is contained in a measurable subset of measure 1.

(c) Nonetheless, $(X, \mathcal{P}(X), \mu)$ is not decomposable or even semifinite.

XVII.2. The Metric Space of a Measure Space

If $(X, \mathcal{A}, \mu)$ is a measure space, there is a natural pseudometric on $\mathcal{A}$ for which the metric quotient is complete.

Recall that if A and B are sets, the *symmetric difference* of A and B is

$$A \triangle B = (A \setminus B) \cup (B \setminus A) = (A \cup B) \setminus (A \cap B) \ .$$

$A \triangle B$ consists of elements which are in either A or B, but not both. The size of $A \triangle B$ is a measure of how much the sets A and B differ.
If $\mathcal{A}$ is an algebra of subsets of a set X, and $A, B \in \mathcal{A}$, then $(A \triangle B) \in \mathcal{A}$.

Here are some important simple properties of symmetric difference:
PROPOSITION. Let A, B, C be sets. Then

(i) $(A \triangle B) \triangle C = A \triangle (B \triangle C)$.

(ii) $A \triangle C \subseteq (A \triangle B) \cup (B \triangle C)$.

(iii) $A \triangle B = B \triangle A$.

(iv) $A \triangle A = \emptyset$.

(v) $A \triangle \emptyset = A$.

DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space. If $A, B \in \mathcal{A}$, set

$$\rho_\mu(A, B) = \min(\mu(A \triangle B), 1) \ .$$

PROPOSITION. If $(X, \mathcal{A}, \mu)$ is a measure space, then ρ_μ is a pseudometric on $\mathcal{A}$.

PROOF: It is obvious from XVII.2.(iii) that $\rho_\mu(A, B) = \rho_\mu(B, A) \geq 0$ for any $A, B \in \mathcal{A}$, and the triangle inequality follows from XVII.2.(ii) and monotonicity of μ. 👍

There is inconsistency in the exact way ρ_μ is defined in the literature, but the differences are not important since all standard definitions give uniformly equivalent metrics. The "natural" definition is just $\rho_\mu(A, B) = \mu(A \triangle B)$, but this can take the value ∞, which is not allowed for a pseudometric.

As usual, we can take a quotient of $\mathcal{A}$ on which ρ_μ defines a metric. The equivalence class of a set $A \in \mathcal{A}$ is

$$[A] = \{B \in \mathcal{A} : \mu(A \triangle B) = 0\} \ .$$

The set of equivalence classes is often written $\mathcal{A}/\mathcal{N}$, where $\mathcal{N}$ is the σ-ideal of μ-null sets. We will denote the induced metric on $\mathcal{A}/\mathcal{N}$ also by ρ_μ.
If (A_n) is a sequence of sets, recall the definition of $\limsup_{n\to\infty} A_n$ and $\liminf_{n\to\infty} A_n$ from ().

THEOREM. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $\mathcal{N}$ the set of μ-null sets. Let (A_n) be a Cauchy sequence in $\mathcal{A}$ for ρ_μ. Then

$$\left[\left(\limsup_{n\to\infty} A_n\right) \setminus \left(\liminf_{n\to\infty} A_n\right)\right] \in \mathcal{N}$$

and $[\limsup A_n] = [\liminf A_n] = \lim_{n\to\infty} [A_n]$ in $\mathcal{A}/\mathcal{N}$. Thus $(\mathcal{A}/\mathcal{N}, \rho_\mu)$ is a complete metric space.

Note that this result has nothing to do with completeness of μ. In fact, if $(X, \bar{\mathcal{A}}, \bar{\mu})$ is the completion of $(X, \mathcal{A}, \mu)$, and $\bar{\mathcal{N}}$ is the set of $\bar{\mu}$-null sets, there is a natural bijection between $\bar{\mathcal{A}}/\bar{\mathcal{N}}$ and $\mathcal{A}/\mathcal{N}$, and $\rho_{\bar{\mu}}$ agrees with ρ_μ on this space, so the metric space of $\bar{\mu}$ is the "same" as for μ.

The usual set operations are continuous with respect to the topology on $\mathcal{A}$:

THEOREM. Let $(X, \mathcal{A}, \mu)$ be a measure space and $(\mathcal{A}/\mathcal{N}, \rho_\mu)$ the corresponding metric space. Then

(i) The functions $([A], [B]) \mapsto [A \cup B]$, $([A], [B]) \mapsto [A \cap B]$, $([A], [B]) \mapsto [A \setminus B]$, and $([A], [B]) \mapsto [A \triangle B]$ are well defined and jointly continuous, i.e. continuous functions from $(\mathcal{A}/\mathcal{N}) \times (\mathcal{A}/\mathcal{N})$ to $\mathcal{A}/\mathcal{N}$.

(ii) The function $[A] \mapsto [X \setminus A]$ is a well-defined continuous function from $\mathcal{A}/\mathcal{N}$ to $\mathcal{A}/\mathcal{N}$.

(iii) If $\mathcal{B}$ is an algebra of sets containing $\mathcal{N}$, the closure of $\mathcal{B}/\mathcal{N}$ in $\mathcal{A}/\mathcal{N}$ is $\sigma(B)/\mathcal{N}$, where $\sigma(B)$ is the σ-algebra generated by $\mathcal{B}$.

XVII.3. Probability

"How can we venture to speak of the laws of chance? Is not chance the antithesis of all law?"

J. Bertrand[1]

XVII.3.1. Introduction

XVII.3.1.1. From its first beginnings, probability theory had some of the flavor of primitive measure theory. In 1933, A. KOLMOGOROV [**?**] cemented the connection by giving an axiomatization of probability which serves as the foundation of all modern probability theory. (Of course, KOLMOGOROV did not come up with this axiomatization out of thin air; the ideas were implicit and in fact increasingly explicit in other work in the field.)

XVII.3.1.2. The two basic ingredients of probability are:

(i) A *sample space* Ω, the set of all possible outcomes of a specific process or experiment. A subset of Ω is called an *event*.

(ii) A *probability* $\mathbf{P}$, an assignment to each event E a numerical probability or likelihood $\mathbf{P}(E)$ that E occurs (i.e. that the outcome of the process lies in E). We should have $0 \leq \mathbf{P}(E) \leq 1$ for any E, and $\mathbf{P}(\Omega) = 1$.

XVII.3.1.3. It is virtually a no-brainer that $\mathbf{P}$ should be finitely additive. KOLMOGOROV realized that in order to get a satisfactory theory, one needs $\mathbf{P}$ to actually be countably additive.

XVII.3.1.4. Examples show that it is not possible in general to assign a probability to every subset of Ω in a countably additive way (the process described in I.3.1.17., along with XVII.4.10.5. and II.10.3.6., is an example where it is not reasonably possible). Thus probability can only be assigned to some collection of well-behaved events. This turns out not to be a serious drawback; indeed, experience shows that it is frequently useful to deliberately restrict the set of events to which a probability is assigned.

Nevertheless, it is important to be able to apply sequences of set-theoretic operations to allowable events and stay within the class of allowable events. This leads naturally to the assumption that the set of allowable events forms a σ-algebra of subsets of Ω.

Thus KOLMOGOROV was led to make the following definition:

XVII.3.1.5. DEFINITION. A *probability space* is a triple $(\Omega, \mathcal{E}, \mathbf{P})$, where

Ω is a set, called the *sample space*.

$\mathcal{E}$ is a σ-algebra of subsets of Ω, called the set of *(allowable) events*.

$\mathbf{P}$ is a function from $\mathcal{E}$ to $[0, 1]$ satisfying

(i) $\mathbf{P}(\Omega) = 1$.

[1] [Ber72]; cf. [Poi96, p. 64].

(ii) $\mathbf{P}$ is *countably additive*, i.e. if (E_n) is a sequence of pairwise disjoint sets in $\mathcal{E}$, then

$$\mathbf{P}\left(\bigcup_{n=1}^{\infty} E_n\right) = \sum_{n=1}^{\infty} \mathbf{P}(E_n) \ .$$

Such a $\mathbf{P}$ is called a *probability* on $(\Omega, \mathcal{E})$. If $E \in \mathcal{E}$, $\mathbf{P}(E)$ is called the *probability* of the event E.

XVII.3.1.6. If $(\Omega, \mathcal{E}, \mathbf{P})$ is a probability space, then $(\Omega, \mathcal{E})$ is a measurable space (). We have

$$\mathbf{P}(\emptyset) = \mathbf{P}(\emptyset \cup \emptyset \cup \cdots) = \sum_{n=1}^{\infty} \mathbf{P}(\emptyset) = \infty \cdot \mathbf{P}(\emptyset)$$

and thus $\mathbf{P}(\emptyset) = 0$ (since it is in $[0, 1]$). Therefore $(\Omega, \mathcal{E}, \mathbf{P})$ is a measure space (XVII.1.1.1.), with $\mathbf{P}$ a probability measure. Conversely, any probability measure space is a probability space. Thus probability spaces are precisely the same thing as probability measure spaces, with slightly different notation and terminology.

Therefore, the results of XVII.1.2. apply in probability spaces:

XVII.3.1.7. Proposition. Let $(\Omega, \mathcal{E}, \mathbf{P})$ be a probability space. Then

(i) $\mathbf{P}$ is *finitely additive*: if $E_1, \ldots, E_n \in \mathcal{E}$ are pairwise disjoint, then

$$\mathbf{P}\left(\bigcup_{k=1}^{n} E_k\right) = \sum_{k=1}^{n} \mathbf{P}(E_k) \ .$$

In particular, if $E, F \in \mathcal{E}$ are disjoint, then $\mathbf{P}(E \cup F) = \mathbf{P}(E) + \mathbf{P}(F)$.

(ii) $\mathbf{P}$ is *monotone*: if $E, F \in \mathcal{E}$, $E \subseteq F$, then $\mathbf{P}(E) \leq \mathbf{P}(F)$.

(iii) $\mathbf{P}$ is *countably subadditive*: if (E_n) is a sequence in $\mathcal{E}$, then

$$\mathbf{P}\left(\bigcup_{n=1}^{\infty} E_n\right) \leq \sum_{n=1}^{\infty} \mathbf{P}(E_n) \ .$$

$\mathbf{P}$ is thus also finitely subadditive; in particular, if $E, F \in \mathcal{E}$, then $\mathbf{P}(E \cup F) \leq \mathbf{P}(E) + \mathbf{P}(F)$. (In fact, we have $\mathbf{P}(E \cup F) = \mathbf{P}(E) + \mathbf{P}(F) - \mathbf{P}(E \cap F)$.)

(iv) $\mathbf{P}$ is *upward continuous*: If (E_n) is an increasing sequence in $\mathcal{E}$, then

$$\mathbf{P}\left(\bigcup_{n=1}^{\infty} E_n\right) = \sup_n \mathbf{P}(E_n) = \lim_{n\to\infty} \mathbf{P}(E_n) \ .$$

(v) $\mathbf{P}$ is *downward continuous*: If (E_n) is a decreasing sequence in $\mathcal{E}$, then

$$\mathbf{P}\left(\bigcap_{n=1}^{\infty} E_n\right) = \inf_n \mathbf{P}(E_n) = \lim_{n\to\infty} \mathbf{P}(E_n) \ .$$

XVII.3.2. The Dictionary

The mathematical setup of probability is thus measure theory, using somewhat different language. Here is a dictionary of the correspondence of basic terminology between measure theory and probability. Some other terminology such as "distribution" is common to both.

Measure Theory	Probability
Measurable space	Sample space
Measurable set	Event
Measure	Probability
Real-valued measurable function	Random variable
Integral	Expectation
Almost everywhere (a.e.)	Almost surely (a.s.)
–	Independent

In fact, it is sometimes said that probability is "measure theory plus independence" (although this is clearly somewhat of an oversimplification). It is unfair and not really accurate to say that probability is *part* of measure theory, although modern probability is certainly built on measure theory.

XVII.3.3. Exercises

XVII.3.3.1. A Conditional Probability Paradox?

(a) You have n red balls, n white balls, and n blue balls ($n \geq 3$) in an urn. Your assistant chooses three balls at random from the urn and puts them in a box. What is the probability p that all three balls in the box have the same color?

(b) While the assistant is choosing the balls, your second assistant comes into the room and sees some of what the first assistant is doing. He tells you that he saw one of the balls the first assistant put in the box and it was red. What now is the conditional probability q that all the balls in the box are the same color, given that at least one of the balls is red? Explain why $q < p$, especially since if the second assistant had said that the ball he saw was white, or blue, the conditional probability is also q, and one of these situations must occur, with equal probability since the colors are completely symmetric.

(c) Suppose your second assistant doesn't speak much English, and you know not a word of his native language. He reports to you that the color of the ball he saw was *gloop*, but can't remember the English word for this color. What is the conditional probability that the three balls are the same color, given that at least one of the balls is *gloop*? On the one hand, no matter what *gloop* means, the conditional probability is q; on the other hand, he has given you no information, so the conditional probability should just be the probability p. Explain and resolve the paradox.

(d) The first assistant speaks the second assistant's language fluently, but is temporarily unavailable to translate. Anyway, the first assistant can provide more information than just the meaning of *gloop*; in fact, he knows what the colors of the three balls are. How does this affect the conditional probabilities, if at all?

(e) Do p and/or q depend on n? Explain why or why not.

XVII.3.3.2. ([Bar00], [Sav94]) Suppose we have three fair (cubical) dice whose faces are marked as follows:

$$\#1: \ 18, \ 9, \ 8, \ 7, \ 6, \ 5$$

$$\#2: \ 17, \ 16, \ 15, \ 4, \ 3, \ 2$$

$$\#3: \ 14, \ 13, \ 12, \ 11, \ 10, \ 1$$

We toss the dice, and let A, B, and C be the numbers on dice 1, 2, and 3 respectively. Then A, B, and C are random variables. Note that A, B, and C always have different values.

(a) Show that the probabilities $P(A > B)$, $P(B > C)$, and $P(C > A)$ are all greater than $\frac{1}{2}$.

(b) Show that $P(B > A \text{ and } B > C)$ (i.e. B is the largest of the three) is greater than $P(A > B \text{ and } A > C)$ and $P(C > A \text{ and } C > B)$.

(c) Show that the expected values satisfy $\mathbf{E}(A) < \mathbf{E}(B) < \mathbf{E}(C)$.

XVII.4. Measures Defined by Extensions

The most important construction of measures is by the Carathéodory extension process. One begins with a "premeasure" defined on a collection $\mathcal{C}$ of subsets of a set X, and extends the premeasure to a measure on a σ-algebra containing $\mathcal{C}$. The extension is made via an "outer measure" defined on all subsets of X.

Let us informally outline the process and try to give some motivation for the procedure, which can otherwise seem strange and nonintuitive at first glance. First consider how to define the "area" of a region in the plane. If A is a bounded subset of the plane $\mathbb{R}^2$, a reasonable and commonly-used way to define the area of A is to cover it with a rectangular grid $\mathcal{G}$, and let $\overline{V}(A, \mathcal{G})$ be the sum of the areas of the rectangles in the grid which contain points of A, and $\underline{V}(A, \mathcal{G})$ the sum of the areas of the rectangles in the grid entirely contained in A. $\overline{V}(A, \mathcal{G})$ and $\underline{V}(A, \mathcal{G})$ can be regarded as an "upper" or "outer" estimate, and a "lower" or "inner" estimate, respectively, for the area of A. As $\mathcal{G}$ becomes finer, the outer estimates decrease and the inner estimates increase, and for "nice" A they converge to the same value, which is a reasonable definition of the area of A. See IX.3.2.1. and IX.3.2.10..

It turns out that not enough subsets of the plane are "nice" enough to have an area defined in this way to give a satisfactory theory of measure and integration (i.e. such sets do not form a σ-algebra). But the idea of approximating from the outside and inside is one which, with suitable care, gives a good theory. We begin with a collection $\mathcal{C}$ of sets which have a reasonable "size" already specified, and, to get an "outer estimate" of the "size" of a general set A, consider collections (C_n) of sets in $\mathcal{C}$ which cover A (whose union contains A); the sum of the "sizes" of the C_n is an upper estimate for the "size" of A. There are two differences we allow from the grid covering example, which together give us a notion of "size" with considerably more flexibility:

(1) We allow countable collections (C_n), not just finite collections.

(2) We do not insist that the C_n are disjoint or even "nonoverlapping."

The infimum of all such upper estimates will be called the "outer measure" of the set A, written $\mu^*(A)$.

For the "inner" estimate, it turns out that the allowance of countably infinite covers is incompatible with truly estimating size from the "inside" as in the grid method. But in the grid example, there is a simple change of point of view which does work in the new setting: if R is a large rectangle which is subdivided to make the grid $\mathcal{G}$, it is easily seen that if $V(R)$ is the area of R, then $\underline{V}(A, \mathcal{G}) = V(R) - \overline{V}(R \setminus A, \mathcal{G})$. So, if we are working within subsets of a fixed set Y of finite measure, we can replace inner estimates for the size of our set A by outer estimates for the size of $Y \setminus A$. The criterion that the inner and outer estimates for the size of A should converge to the same limit as the covers get "finer" translates into the requirement that the sum of the outer measure $\mu^*(A)$ and the outer measure $\mu^*(Y \setminus A)$ should be the measure of Y. If the whole set X has finite measure, it turns out that for A to be "measurable" (to have a well-behaved notion of "size") we need only require this condition for $Y = X$; however, in the general setting we must have a technical strengthening: for every $Y \subseteq X$, we require

$$\mu^*(Y \cap A) + \mu^*(Y \cap A^c) = \mu^*(Y) \ .$$

Roughly speaking, the set A is measurable if, for every $Y \subseteq X$, the sets $Y \cap A$ and $Y \cap A^c$ can be finely covered by "almost disjoint" countable families from $\mathcal{C}$.

It turns out then that under reasonable conditions on the size function ("premeasure") on $\mathcal{C}$ we can prove that the collection of "measurable" subsets of X is a σ-algebra containing $\mathcal{C}$, and that μ^* restricts to a measure on this σ-algebra which agrees with the premeasure on $\mathcal{C}$, and in particular the premeasure on $\mathcal{C}$ extends to a measure on a σ-algebra containing $\mathcal{C}$.

We will do most of the construction for "outer measures" defined abstractly, which have the crucial properties of outer measures induced by premeasures. This is essential since there are important outer measures which are not induced (at least not in any useful way) from premeasures.

XVII.4.1. Outer Measures

Outer measures are a crucial technical tool in measure theory. Almost all interesting measures are constructed (at least indirectly) from outer measures.

XVII.4.1.1. DEFINITION. Let X be a set. An *outer measure* on X is a function $\mu^* : \mathcal{P}(X) \to [0, \infty]$ such that

(i) $\mu^*(\emptyset) = 0$

(ii) If $A \subseteq B$, then $\mu^*(A) \leq \mu^*(B)$ (*monotonicity*)

(iii) If $A = \cup_{n=1}^{\infty} A_n$, then $\mu^*(A) \leq \sum_{n=1}^{\infty} \mu^*(A_n)$ (*countable subadditivity*).

There are two important differences between measures and outer measures. First, an outer measure is defined on *all* subsets of X; second, an outer measure is not even finitely additive, let alone countably additive, in general.

XVII.4.1.2. In the case of a measure, monotonicity (condition (ii)) follows from the other properties (), but (ii) does not follow from (i) and (iii) for outer measures in general (take Example XVII.4.5.28. with $\alpha < 1$). In the presence of (i), both (ii) and (iii) can be replaced by the single condition

(iii′) If $A \subseteq \cup_{n=1}^{\infty} A_n$, then $\mu^*(A) \leq \sum_{n=1}^{\infty} \mu^*(A_n)$.

[(iii′) obviously follows from (ii) and (iii), and (iii′) trivially implies (iii); for (iii′) $\Rightarrow$ (ii), if $A \subseteq B$, set $A_1 = B$ and $A_n = \emptyset$ for $n > 1$, and use (i).]

XVII.4.1.3. As with measures, countable subadditivity for outer measures implies *finite subadditivity*: if $A \subseteq \cup_{k=1}^{n} A_k$, then $\mu^*(A) \leq \sum_{k=1}^{n} \mu^*(A_k)$. This follows from countable subadditivity by taking $A_k = \emptyset$ for $k > n$. In particular, if $A, B \subseteq X$, then $\mu^*(A \cup B) \leq \mu^*(A) + \mu^*(B)$.

XVII.4.1.4. **Note:** It must be noted that a substantial number of references, particularly ones concerned with geometric measure theory, call an outer measure a "measure"; in these references, a measure on a set X is defined on all subsets of X, but is only countably additive on a σ-algebra of "measurable" subsets of X. The distinction is largely a semantic one: every measure has a canonical extension to an outer measure, and conversely every outer measure naturally defines a σ-algebra of measurable subsets on which it is countably additive (a measure in our sense). The two processes are almost, but not quite, inverses of each other, however. The terminology we use is more flexible and superior for most purposes: for example, it is often crucial to keep track of the σ-algebra on which a measure is defined, particularly in probability where it is often necessary to consider and distinguish between two or more σ-algebras.

XVII.4.1.5. Most outer measures are constructed beginning with a "measure" defined on a collection of subsets which is too small to be a σ-algebra, usually a semiring. Suppose $\mathcal{C}$ is a collection of subsets of a set X, with the property that $\emptyset \in \mathcal{C}$. Let ι be a function from $\mathcal{C}$ to $[0, \infty]$. We will eventually impose some reasonable measure-like conditions on $\mathcal{C}$ and ι, but to get an outer measure the only requirement on ι is that $\iota(\emptyset) = 0$.

Define a function μ^* from $\mathcal{P}(X)$ to $[0, \infty]$ as follows. If $A \subseteq X$, set

$$\mu^*(A) = \inf \left\{ \sum_{n=1}^{\infty} \iota(C_n) \ : \ C_n \in \mathcal{C}, \ A \subseteq \bigcup_{n=1}^{\infty} C_n \right\} .$$

If A has no countable cover by sets in $\mathcal{C}$, we have a choice: it is standard to set $\mu^*(A) = \infty$, which we will do, but there is another possibility (XVII.4.5.16.).

If $A \subseteq \bigcup_{n=1}^{\infty} C_n$, we say the sequence $\{C_n\}$ *covers* A.

Note that since $\emptyset \in \mathcal{C}$, finite as well as countably infinite covers are allowed in computing $\mu^*(A)$, since a finite cover $\{C_1, \ldots, C_m\}$ of A can be expanded to a countably infinite cover by setting $C_n = \emptyset$ for $n > m$ and using $\iota(\emptyset) = 0$.

XVII.4.1.6. Some authors do not include the requirement that $\emptyset \in \mathcal{C}$ and/or that $\iota(\emptyset) = 0$, obtaining that $\mu^*(\emptyset) = 0$ since $\emptyset$ is covered by the "empty cover" and hence $\mu^*(\emptyset)$ is less than or equal to the "empty sum," which is by definition 0. But there is no advantage in this approach ($\emptyset$ can be added to $\mathcal{C}$ if necessary and $\iota(\emptyset)$ can be defined or redefined to be 0 with no penalty) and it causes technical problems, e.g. when one wants to use finite covers as well as countably infinite ones. The same convention also justifies the definition of $\mu^*(A)$ if A does not have a countable cover from $\mathcal{C}$: $\mu^*(A)$ is an infimum over $\emptyset$, which is by definition $+\infty$.

XVII.4.1.7. PROPOSITION. This function μ^* is an outer measure on X.

PROOF: Since $\emptyset \in \mathcal{C}$, $\{\emptyset\}$ is a cover of $\emptyset$, so $\mu^*(\emptyset) = 0$. If $A \subseteq B$, any countable cover of B is a countable cover of A, so the infimum in calculating $\mu^*(A)$ is over a larger collection of covers, and hence $\mu^*(A) \leq \mu^*(B)$. Finally, suppose $A = \cup_{n=1}^{\infty} A_n$. If $\sum_{n=1}^{\infty} \mu^*(A_n) = \infty$, then clearly $\mu^*(A) \leq \sum_{n=1}^{\infty} \mu^*(A_n)$. In the case that $\sum_{n=1}^{\infty} \mu^*(A_n) < \infty$, so $\mu^*(A_n) < \infty$ for all n, let $\epsilon > 0$, and for each n let $\{C_{nk}\}$ be a cover of A_n with

$$\sum_{k=1}^{\infty} \iota(C_{nk}) \leq \mu^*(A_n) + 2^{-n}\epsilon \ .$$

Then $\{C_{nk} : n, k \in \mathbb{N}\}$ is a cover of A, so

$$\mu^*(A) \leq \sum_{n,k} \iota(C_{nk}) \leq \sum_{n=1}^{\infty} \mu^*(A_n) + \epsilon \ .$$

Since ϵ is arbitrary, $\mu^*(A) \leq \sum_{n=1}^{\infty} \mu^*(A_n)$. 👍

XVII.4.1.8. DEFINITION. The outer measure μ^* is the outer measure *induced* by ι.

This construction of an outer measure from a set function is often called *Method I*. See XVII.6.2.5. for "Method II," and XVII.4.5.16. for another method.

Note that $\mu^*(C) \leq \iota(C)$ for any $C \in \mathcal{C}$, since $\{C\}$ is a cover of C by $\mathcal{C}$; but $\mu^*(C)$ does not equal $\iota(C)$ in general:

XVII.4.1.9. EXAMPLE. Let $X = \mathbb{N}$, $\mathcal{C} = \mathcal{P}(\mathbb{N})$. Set $\iota(A) = 0$ if A is finite and $\iota(A) = 1$ if A is infinite. Then ι is monotone and (finitely) subadditive, but $\mu^*(A) = 0$ for all $A \subseteq \mathbb{N}$.

An outer measure induced by such a set function has an outer regularity property. If $\mathcal{C}$ is a collection of subsets of X containing $\emptyset$, write $\mathcal{C}_\sigma$ for the set of countable unions of sets in $\mathcal{C}$, and $\mathcal{C}_{\sigma\delta}$ for the set of countable intersections of sets in $\mathcal{C}_\sigma$. $\mathcal{C}_\sigma$ and $\mathcal{C}_{\sigma\delta}$ are contained in the σ-algebra generated by $\mathcal{C}$.

XVII.4.1.10. PROPOSITION. Let $\mathcal{C}$ be a set of subsets of X with $\emptyset \in \mathcal{C}$, $\iota : \mathcal{C} \to [0, \infty]$ with $\iota(\emptyset) = 0$, and μ^* the induced outer measure on X. Let $E \subseteq X$ with $\mu^*(E) < \infty$. Then

(i) For every $\epsilon > 0$, there is an $A \in \mathcal{C}_\sigma$ with $E \subseteq A$ and $\mu^*(A) \leq \mu^*(E) + \epsilon$.

(ii) There is a $B \in \mathcal{C}_{\sigma\delta}$ with $E \subseteq B$ and $\mu^*(E) = \mu^*(B)$.

PROOF: (i) Let $\epsilon > 0$. Take a sequence (C_n) in $\mathcal{C}$ with $E \subseteq \cup_{n=1}^\infty C_n$ and $\sum_{n=1}^\infty \iota(C_n) \leq \mu^*(E) + \epsilon$. If $A = \cup_{n=1}^\infty C_n$, then $A \in \mathcal{C}_\sigma$, $E \subseteq A$, and

$$\mu^*(A) \leq \sum_{n=1}^\infty \mu^*(C_n) \leq \sum_{n=1}^\infty \iota(C_n) \leq \mu^*(E) + \epsilon \ .$$

(ii): For each n let $A_n \in \mathcal{C}_\sigma$ with $E \subset A_n$ and $\mu^*(A_n) \leq \mu^*(E) + \frac{1}{n}$. Take $B = \cap_{n=1}^\infty A_n$. Then $B \in \mathcal{C}_{\sigma\delta}$, $E \subseteq B$, and

$$\mu^*(E) \leq \mu^*(B) \leq \mu^*(A_n) \leq \mu^*(E) + \frac{1}{n}$$

for every n, so $\mu^*(B) = \mu^*(E)$. 👍

XVII.4.2. Lebesgue Outer Measure on $\mathbb{R}$

By far the most important example of the process of inducing an outer measure from a function on subsets is Lebesgue outer measure, used to construct Lebesgue measure.

XVII.4.2.1. DEFINITION. Let $\mathcal{C}$ be the set of all open intervals in $\mathbb{R}$ (including $\emptyset$). For an open interval I, let $\ell(I)$ be the length of I. The induced outer measure from ℓ is *Lebesgue outer measure* λ^*. Specifically: for $A \subseteq \mathbb{R}$,

$$\lambda^*(A) = \inf \left\{ \sum_{n=1}^\infty \ell(I_n) \ : \ I_n \in \mathcal{C}, A \subseteq \bigcup_{n=1}^\infty I_n \right\} \ .$$

The use of open intervals is a matter of taste. It is useful to know that the same outer measure is obtained if arbitrary intervals are used:

XVII.4.2.2. PROPOSITION. Let $\mathcal{I}$ be the set of all intervals in $\mathbb{R}$, including $\emptyset$ and singleton subsets. For $I \in \mathcal{I}$, let $\ell(I)$ be the length of I ($\ell(\{a\}) = 0$ for a singleton $\{a\}$). Then the outer measure on $\mathbb{R}$ induced by ℓ on $\mathcal{I}$ is Lebesgue outer measure.

PROOF: Let μ^* be the outer measure on $\mathbb{R}$ induced by ℓ on $\mathcal{I}$. Since $\mathcal{C} \subseteq \mathcal{I}$, any $\mathcal{C}$-cover of a set A is also an $\mathcal{I}$-cover, so the infimum in computing $\mu^*(A)$ is over more covers than for computing $\lambda^*(A)$ and $\mu^*(A) \leq \lambda^*(A)$. To show the opposite inequality, we may assume $\mu^*(A) < \infty$. Let $\epsilon > 0$, and let $\{I_n\}$ be an $\mathcal{I}$-cover of A with $\sum_{n=1}^{\infty} \ell(I_n) \leq \mu^*(A) + \epsilon/2$. Each I_n is an interval (possibly $\emptyset$ or a singleton); for each n, let I'_n be an open interval containing I_n of length $\leq \ell(I_n) + 2^{-n-1}\epsilon$. Then $\{I'_n\}$ is a cover of A by open intervals, so we have

$$\lambda^*(A) \leq \sum_{n=1}^{\infty} \ell(I'_n) \leq \sum_{n=1}^{\infty} \ell(I_n) + \frac{\epsilon}{2} \leq \mu^*(A) + \epsilon \ .$$

Since ϵ is arbitrary, $\lambda^*(A) \leq \mu^*(A)$. 👍

The next corollary can be proved directly in the same way, or by just applying XVII.4.2.2..

XVII.4.2.3. COROLLARY. Let $\mathcal{H}$ be the set of intervals in $\mathbb{R}$ which are open on the left and closed on the right (i.e. of the form $(a, b]$, $(-\infty, b]$, or $(a, +\infty)$), along with the empty set. For $I \in \mathcal{H}$, let $\ell(I)$ be the length of I. Then the outer measure on $\mathbb{R}$ induced by ℓ on $\mathcal{H}$ is Lebesgue outer measure.

PROOF: Let ν^* be the outer measure induced by ℓ on $\mathcal{H}$. Since $\mathcal{H} \subseteq \mathcal{I}$, we have $\mu^*(A) \leq \nu^*(A)$ for any $A \subseteq \mathbb{R}$. If $A \subseteq \mathbb{R}$ and $\{I_n\}$ is a $\mathcal{C}$-cover of A, let I'_n be I_n with right endpoint added (if there is one); then $\{I'_n\}$ is an $\mathcal{H}$-cover of A, and $\sum_{n=1}^{\infty} \ell(I'_n) = \sum_{n=1}^{\infty} \ell(I_n)$; thus $\nu^*(A) \leq \lambda^*(A)$. 👍

It is easily shown that the class $\mathcal{C}_f$ of bounded open intervals also induces Lebesgue outer measure, as do the classes $\mathcal{I}_f$ and $\mathcal{H}_f$; for any $\delta > 0$, the classes $\mathcal{C}_\delta$ of intervals of length $\leq \delta$ and $\mathcal{I}_\delta$, $\mathcal{H}_\delta$ also induce Lebesgue outer measure on $\mathbb{R}$ (Exercise ().)

The next result is crucial, and shows that Lebesgue outer measure has the expected property of extending the interval length function. (In fact, without this theorem it is not even obvious that Lebesgue outer measure is not identically zero.) This result may seem "obvious" but is not, and the proof is somewhat delicate. Some references omit proving this entirely; the proof in [Fol99] (and in some other references) is described as "fussy." We give a slick proof from [GP10], attributed to VON NEUMANN.

XVII.4.2.4. THEOREM. If I is an interval in $\mathbb{R}$, then $\lambda^*(I) = \ell(I)$.

PROOF: We have $\lambda^*(I) \leq \ell(I)$, since $\{I\}$ is a cover of I. To show the reverse inequality, first suppose $I = [a, b]$. Let $\epsilon > 0$, and let (I_k) be a sequence of open intervals which cover $[a, b]$ with $\sum_{k=1}^{\infty} \ell(I_k) \leq \lambda^*(I) + \epsilon$ (so the I_k are necessarily bounded). Since $[a, b]$ is compact, $\{I_1, \ldots, I_n\}$ covers I for some n. Fix such an n.

If J is a bounded interval in $\mathbb{R}$, write $\#(J)$ for the number of integers in J. We have

$$\ell(J) - 1 \leq \#(J) \leq \ell(J) + 1 \ .$$

If $\alpha > 0$, then $\{\alpha I_1, \ldots, \alpha I_n\}$ covers αI, so we have

$$\alpha\ell(I) - 1 = \ell(\alpha I) - 1 \leq \#(\alpha I) \leq \sum_{k=1}^{n} \#(\alpha I_k) \leq \sum_{k=1}^{n} [\ell(\alpha I_k) + 1] = \alpha \left[\sum_{k=1}^{n} \ell(I_k) \right] + n \ .$$

Dividing by α, we obtain

$$\ell(I) - \frac{1}{\alpha} \leq \left[\sum_{k=1}^{n} \ell(I_k) \right] + \frac{n}{\alpha} \ .$$

This is true for all $\alpha > 0$, so letting $\alpha \to +\infty$ we obtain

$$\ell(I) \leq \sum_{k=1}^{n} \ell(I_k) \leq \sum_{k=1}^{\infty} \ell(I_k) < \lambda^*(I) + \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, $\ell(I) \leq \lambda^*(I)$.

Now suppose $I = (a, b)$. By subadditivity,

$$\ell(I) = b - a = \lambda^*([a, b]) \leq \lambda^*(\{a\}) + \lambda^*(I) + \lambda^*(\{b\}) = 0 + \lambda^*(I) + 0 \ .$$

If $I = (a, b]$ or $I = [a, b)$, then $(a, b) \subseteq I \subseteq [a, b]$, so by monotonicity $\lambda^*(I) = \ell(I)$.

If I has infinite length, then either $(a, \infty) \subseteq I$ or $(-\infty, a) \subseteq I$ for some a. If $(a, \infty) \subseteq I$, then $(a, a+n) \subseteq I$ for all n, so by monotonicity

$$n = \lambda^*((a, a + n)) \leq \lambda^*(I)$$

for all n, and $\lambda^*(I) = \infty = \ell(I)$. The argument if $(-\infty, a) \subseteq I$ is similar. 👍

XVII.4.3. The Measure Induced by an Outer Measure

XVII.4.3.1. Definition. Let μ^* be an outer measure on a set X. A subset A of X is *μ^*-measurable* if, for every $Y \subseteq X$,

$$\mu^*(Y) = \mu^*(Y \cap A) + \mu^*(Y \cap A^c) = \mu^*(Y \cap A) + \mu^*(Y \setminus A) \ .$$

Intuitively in the case where μ^* comes from a set function by Method I, A splits any set Y into two pieces $Y \cap A$ and $Y \cap A^c$ which have "almost disjoint" covers.

Note that the inequality $\mu^*(Y) \leq \mu^*(Y \cap A) + \mu^*(Y \cap A^c)$ holds for any Y and A by subadditivity, so only the reverse inequality is needed for measurability of A. This reverse inequality is automatic if $\mu^*(Y) = \infty$, so we obtain:

XVII.4.3.2. Proposition. Let μ^* be an outer measure on a set X, and $A \subseteq X$.

(i) A is μ^*-measurable if and only if

$$\mu^*(Y) \geq \mu^*(Y \cap A) + \mu^*(Y \setminus A)$$

for every $Y \subseteq X$ with $\mu^*(Y) < \infty$.

(ii) A is μ^*-measurable if and only if, for every $Y \subseteq A$ and $Z \subseteq X \setminus A$ with $\mu^*(Y)$, $\mu^*(Z)$ finite,

$$\mu^*(Y \cup Z) \geq \mu^*(Y) + \mu^*(Z) \ .$$

XVII.4.3.3. COROLLARY. Let μ^* be an outer measure on a set X. If $A \subseteq X$ and $\mu^*(A) = 0$, then A is μ^*-measurable.

PROOF: If $Y \subseteq X$, then by monotonicity we have $\mu^*(Y \cap A) = 0$, and

$$\mu^*(Y) \geq \mu^*(Y \cap A^c) = \mu^*(Y \cap A) + \mu^*(Y \cap A^c) \ .$$

The name "measurable" for such sets is explained in the introduction, and justified by the following theorem, which is the main result of this section and one of the fundamental theorems of measure theory:

XVII.4.3.4. THEOREM. [CARATHÉODORY] Let μ^* be an outer measure on a set X, and $\mathcal{M}$ the set of μ^*-measurable subsets of X. Then

(i) $\mathcal{M}$ is a σ-algebra of subsets of X.

(ii) The restriction μ of μ^* to $\mathcal{M}$ is a measure (i.e. countably additive).

(iii) The measure space $(X, \mathcal{M}, \mu)$ is complete.

PROOF: It is obvious from the definition of measurability that $\emptyset, X \in \mathcal{M}$ and that $A \in \mathcal{M}$ implies $A^c \in \mathcal{M}$. Let $A, B \in \mathcal{M}$. If $Y \subseteq X$, then

$$Y \cap (A \cup B) = [Y \cap (A \cap B)] \cup [Y \cap (A \cap B^c)] \cup [Y \cap (A^c \cap B)]$$

and so, by subadditivity,

$$\mu^*(Y \cap (A \cup B)) \leq \mu^*(Y \cap (A \cap B)) + \mu^*(Y \cap (A \cap B^c)) + \mu^*(Y \cap (A^c \cap B)) \ .$$

Thus we have

$$\begin{aligned} \mu^*(Y) &= \mu^*(Y \cap A) + \mu^*(Y \cap A^c) \\ &= \mu^*(Y \cap A \cap B) + \mu^*(Y \cap A \cap B^c) + \mu^*(Y \cap A^c \cap B) + \mu^*(Y \cap A^c \cap B^c) \\ &\geq \mu^*(Y \cap (A \cup B)) + \mu^*(Y \cap A^c \cap B^c) = \mu^*(Y \cap (A \cup B)) + \mu^*(Y \cap (A \cup B)^c) \end{aligned}$$

so $A \cup B$ is μ^*-measurable. Therefore $\mathcal{M}$ is an algebra.

Next suppose $A, B \in \mathcal{M}$ are disjoint. We have

$$\mu^*(A \cup B) = \mu^*((A \cup B) \cap A) + \mu^*((A \cup B) \cap A^c) = \mu^*(A) + \mu^*(B)$$

so μ^* is finitely additive on $\mathcal{M}$.

Now suppose (A_n) is a pairwise disjoint sequence in $\mathcal{M}$, and set $B_n = \cup_{k=1}^n A_k$. Then $B_n \in \mathcal{M}$ for all n. Set $B = \cup_{n=1}^\infty B_n = \cup_{n=1}^\infty A_n$. If $Y \subseteq X$, we have

$$\mu^*(Y) = \mu^*(Y \cap B_n) + \mu^*(Y \cap B_n^c) = \mu^*(Y \cap B_n \cap A_n) + \mu^*(Y \cap B_n \cap A_n^c) + \mu^*(Y \cap B_n^c)$$

$$= \mu^*(Y \cap A_n) + \mu^*(Y \cap B_{n-1}) + \mu^*(Y \cap B_n^c) = \cdots = \sum_{k=1}^n \mu^*(Y \cap A_k) + \mu^*(Y \cap B_n^c) \geq \sum_{k=1}^n \mu^*(Y \cap A_k) + \mu^*(Y \cap B^c)$$

for every n, and hence

$$\mu^*(Y) \geq \sum_{k=1}^{\infty} \mu^*(Y \cap A_k) + \mu^*(Y \cap B^c) \geq \mu^*(Y \cap B) + \mu^*(Y \cap B^c) \geq \mu^*(Y)$$

and thus all the inequalities are equalities. So $B \in \mathcal{M}$ and $\mathcal{M}$ is a σ-algebra (). Applying this last result to $Y = B$, we obtain $\mu^*(B) = \sum_{k=1}^{\infty} \mu^*(A_k)$, so μ^* is countably additive on $\mathcal{M}$.

The fact that $(X, \mathcal{M}, \mu)$ is complete follows immediately from XVII.4.3.3.. 👍

XVII.4.3.5. The set $\mathcal{M}$ of μ^*-measurable subsets is more than just a σ-algebra; for example, unlike a general σ-algebra, it is also closed under the Suslin operation (XVII.4.6.7.).

XVII.4.3.6. The definition of measurable set we have used is due to Carathéodory, and is now standard. Lebesgue's definition of a measurable set (within a bounded interval I of $\mathbb{R}$ with Lebesgue outer measure) was different and apparently less restrictive: $A \subseteq I$ is measurable in Lebesgue's sense if $\lambda^*(A) + \lambda^*(I \setminus A) = \lambda^*(I) = \ell(I)$. The two notions are the same in good cases (XVII.4.5.38.), but not in general. Carathéodory's definition is more generally useful, and even for finite measure spaces gives simpler proofs.

Restrictions and Extensions

XVII.4.3.7. If μ^* is an outer measure on a set X, and $Y \subseteq X$, then the restriction μ^*_Y of μ^* to $\mathcal{P}(Y)$ is an outer measure on Y. How do the μ^*_Y-measurable subsets of Y relate to the subsets of Y which are μ^*-measurable? If Y is not μ^*-measurable, there is clearly a big difference (e.g. Y is μ^*_Y-measurable). But if Y is μ^*-measurable, there is no difference:

XVII.4.3.8. Proposition. Let μ^* be an outer measure on a set X, and Y a μ^*-measurable subset of X. Let μ^*_Y be the restriction of μ^* to $\mathcal{P}(Y)$. Then a subset A of Y is μ^*_Y-measurable if and only if it is μ^*-measurable.

Proof: If $A \subseteq Y$ is μ^*-measurable, then for any $Z \subseteq Y$ we have

$$\mu^*_Y(Z) = \mu^*(Z) = \mu^*(Z \cap A) + \mu^*(Z \cap A^c) = \mu^*(Z \cap A) + \mu^*(Z \cap (Y \setminus A)) = \mu^*_Y(Z \cap A) + \mu^*_Y(Z \cap (Y \setminus A))$$

so A is μ^*_Y-measurable. (This direction does not use that Y is μ^*-measurable.) Conversely, suppose A is μ^*_Y-measurable. Then, for any $Z \subseteq Y$,

$$\mu^*(Z) = \mu^*_Y(Z) = \mu^*_Y(Z \cap A) + \mu^*_Y(Z \cap (Y \setminus A)) = \mu^*(Z \cap A) + \mu^*(Z \cap (Y \cap A^c))$$

So if $W \subset X$, we have

$$\mu^*(W) = \mu^*(W \cap Y) + \mu^*(W \cap Y^c) = \mu^*((W \cap Y) \cap A) + \mu^*((W \cap Y) \cap (Y \cap A^c)) + \mu^*(W \cap Y^c)$$

$$= \mu^*(W \cap A) + \mu^*((W \cap Y) \cap A^c) + \mu^*(W \cap Y^c) \geq \mu^*(W \cap A) + \mu^*(W \cap A^c)$$

by subadditivity, so A is μ^*-measurable. 👍

XVII.4.4. Lebesgue Measure on $\mathbb{R}$

[**Prerequisite:** ()]

XVII.4.4.1. DEFINITION. Let $\mathcal{L}$ be the σ-algebra of λ^*-measurable subsets of $\mathbb{R}$. $\mathcal{L}$ is called the set of *Lebesgue measurable sets* in $\mathbb{R}$. Write λ for the restriction of λ^* to $\mathcal{L}$. Then λ is a measure on $(\mathbb{R}, \mathcal{L})$, called *Lebesgue measure* on $\mathbb{R}$.

XVII.4.4.2. PROPOSITION. $(\mathbb{R}, \mathcal{L}, \lambda)$ is a complete measure space.

This is an immediate consequence of ().

XVII.4.4.3. PROPOSITION. Every Borel set is λ^*-measurable, i.e. $\mathcal{B} \subseteq \mathcal{L}$.

PROOF: This follows immediately from (). However, there is a quicker argument. It suffices to show that (a, ∞) is measurable for any $a \in \mathbb{R}$ (actually just for a in a dense subset of $\mathbb{R}$), since such sets generate $\mathcal{B}$. If $Y \subseteq \mathbb{R}$ with $\lambda^*(Y) < \infty$, we need to show that

$$\lambda^*(Y) \geq \lambda^*(Y \cap (a, \infty)) + \lambda^*(Y \cap (-\infty, a]) \ .$$

Let $\epsilon > 0$, and let (I_n) be a sequence of intervals covering Y with $\sum_{n=1}^{\infty} \ell(I_n) \leq \lambda^*(Y) + \epsilon$. For each n, let $I_n' = I_n \cap (a, \infty)$ and $I_n'' = I_n \cap (-\infty, a]$. Then the I_n' and I_n'' are intervals (some may be empty), $\ell(I_n') + \ell(I_n'') = \ell(I_n)$, (I_n') is a cover of $Y \cap (a, \infty)$, and (I_n'') is a cover of $Y \cap (-\infty, a])$, so

$$\lambda^*(Y \cap (a, \infty)) + \lambda^*(Y \cap (-\infty, a]) \leq \sum_{n=1}^{\infty} \ell(I_n') + \sum_{n=1}^{\infty} \ell(I_n'') = \sum_{n=1}^{\infty} \ell(I_n) \leq \lambda^*(Y) + \epsilon \ .$$

Since ϵ is arbitrary, we conclude the desired inequality. 👍

XVII.4.4.4. COROLLARY. $(\mathbb{R}, \mathcal{L}, \lambda)$ is a σ-finite measure space.

PROOF: For every n, $[-n, n]$ is Lebesgue measurable and $\lambda([-n, n]) = 2n < \infty$, and $\mathbb{R} = \cup_n [-n, n]$. 👍

It is not true that every Lebesgue measurable set is a Borel set. In fact, the cardinality of $\mathcal{B}$ is $2^{\aleph_0}$ (); but every subset of the Cantor set K is Lebesgue measurable (), and $card(K) = 2^{\aleph_0}$, so it follows that $card(\mathcal{L}) = 2^{2^{\aleph_0}}$. For an explicit example of a Lebesgue measurable set which is not a Borel set, see (). However:

XVII.4.4.5. THEOREM. Let $A \in \mathcal{L}$. Then

(i) For any $\epsilon > 0$, there is an open set U containing A with $\lambda(U \setminus A) < \epsilon$.

(ii) For any $\epsilon > 0$, there is a closed set F contained in A with $\lambda(A \setminus F) < \epsilon$. If $\lambda(A) < \infty$, then F may be chosen to be compact.

(iii) There is a G_δ set D containing A with $\lambda(D \setminus A) = 0$.

(iv) There is an F_σ set E contained in A with $\lambda(A \setminus E) = 0$.

In particular, every Lebesgue measurable set differs from a Borel set by a set of measure 0.

PROOF: (i) For each $n \in \mathbb{Z}$, let $A_n = A \cap (n-1, n]$. Then $A_n \in \mathcal{L}$, the A_n are disjoint, $A = \cup_n A_n$, and $\lambda(A_n) \leq 1$. For each n there is a sequence (I_{nm}) of open intervals covering A_n with

$$\sum_{m=1}^{\infty} \ell(I_{nm}) < \lambda(A_n) + 2^{-(|n|+2)}\epsilon \ .$$

If $U_n = \cup_{m=1}^{\infty} I_{nm}$, then U_n is open, $A_n \subseteq U_n$, and

$$\lambda(A_n) \leq \lambda(U_n) \leq \sum_{m=1}^{\infty} \ell(I_{nm}) < \lambda(A_n) + 2^{-(|n|+2)}\epsilon$$

and hence $\lambda(U_n \setminus A_n) < 2^{-(|n|+2)}\epsilon$ since $\lambda(A_n) < \infty$.

Now let $U = \cup_{n\in\mathbb{Z}} U_n$. Then U is open, $A \subseteq U$, and $U \setminus A \subseteq \cup_n (U_n \setminus A_n)$, so

$$\lambda(U \setminus A) \leq \sum_{n\in\mathbb{Z}} \lambda(U_n \setminus A_n) < \sum_{n\in\mathbb{Z}} 2^{-(|n|+2)}\epsilon < \epsilon \ .$$

(ii): Let U be an open set containing A^c such that $\lambda(U \setminus A^c) < \epsilon/2$, and set $E = U^c$. Then E is closed, $E \subseteq A$, and $A \setminus E = U \setminus A^c$, so $\lambda(A \setminus E) < \epsilon/2$. If $\lambda(A) = \infty$, set $F = E$. Suppose $\lambda(A) < \infty$. For $n \in \mathbb{N}$, set $F_n = E \cap [-n, n]$. Then F_n is compact, and $E = \cup_n F_n$, so $A \setminus E = \cap_n A \setminus F_n$. This is a decreasing intersection of sets of finite measure, so $\lambda(A \setminus E) = \inf_n\{\lambda(A \setminus F_n)\} < \epsilon/2$ (). There is thus an n so that $\lambda(A \setminus F_n) < \epsilon$. Set $F = F_n$ for this n.
(iii): For each n let U_n be an open set containing A with $\lambda(U_n \setminus A) < 1/n$, and set $D = \cap_n U_n$.
(iv): For each n let F_n be a closed set contained in A with $\lambda(A \setminus F_n) < 1/n$, and set $E = \cup_n F_n$. 👍

XVII.4.4.6. Thus every Lebesgue measurable set A is "trapped between" a G_δ set D and an F_σ set E (i.e. $E \subseteq A \subseteq D$) with $\lambda(D \setminus E) = 0$, and conversely by completeness any set which is trapped between such D and E is Lebesgue measurable. (Note, however, that for a given A there is nothing unique about D and E.)

XVII.4.5. Extending Premeasures from Semirings

XVII.4.5.1. We will now show that under some reasonable restrictions, a set function $\iota : \mathcal{C} \to [0, \infty]$ extends to a measure μ on a σ-algebra $\mathcal{A}$ containing $\mathcal{C}$. To motivate the restrictions on ι, suppose an extension μ exists. Then a few moment's thought shows that the following must be true:

(i) ι must be monotone on $\mathcal{C}$.

(ii) If $C_1, \ldots, C_n$ are disjoint sets in $\mathcal{C}$, and $C := \cup_{k=1}^n C_k \in \mathcal{C}$, then $\iota(C) = \sum_{k=1}^n \iota(C_k)$.

(ii′) If $C_1, C_2, \ldots$ are disjoint sets in $\mathcal{C}$, and $C := \cup_{k=1}^\infty C_k \in \mathcal{C}$, then $\iota(C) = \sum_{k=1}^\infty \iota(C_k)$.

(iii) If $C, C_1, C_2, \cdots \in \mathcal{C}$ and $C \subseteq \cup_{k=1}^{\infty} C_k$, then $\iota(C) \leq \sum_{k=1}^{\infty} \iota(C_k)$.

(Note that (ii′) does not necessarily imply (ii) unless $\emptyset \in \mathcal{C}$ and $\iota(\emptyset) = 0$.)

It is also reasonable to require that $\mathcal{C}$ be closed under enough set operations to make these restrictions on ι have some teeth. It turns out to be sufficient that $\mathcal{C}$ be a semiring; in fact, (i) will follow automatically from (ii) and (iii) in this case, and in the presence of (i), (ii′) is equivalent to (ii) and (iii) combined.

XVII.4.5.2. DEFINITION. Let $\mathcal{S}$ be a semiring of subsets of a set X. A *premeasure* on $\mathcal{S}$ is a set function $\iota : \mathcal{S} \to [0, \infty]$ with the properties that

(i) $\iota(\emptyset) = 0$.

(ii) If $C_1, \ldots, C_n$ are pairwise disjoint sets in $\mathcal{S}$, and $C := \cup_{k=1}^{n} C_k \in \mathcal{S}$, then $\iota(C) = \sum_{k=1}^{n} \iota(C_k)$ (*finite additivity*).

(iii) If $C, C_1, C_2, \cdots \in \mathcal{S}$ and $C \subseteq \cup_{k=1}^{\infty} C_k$, then $\iota(C) \leq \sum_{k=1}^{\infty} \iota(C_k)$ (*countable subadditivity*).

The premeasure ι is *σ-finite* if there are $C_1, C_2, \cdots \in \mathcal{S}$ with $\iota(C_n) < \infty$ for all n and $\cup_{n=1}^{\infty} C_n = X$. If ι is σ-finite, then $\mathcal{S}$ is necessarily of countable type.

XVII.4.5.3. EXAMPLES. (i) Let $(X, \mathcal{A}, \mu)$ be any measure space, and $\mathcal{S}$ a semiring contained in $\mathcal{A}$. Then $\mu|_{\mathcal{S}}$ is a premeasure on $\mathcal{S}$.
(ii) Let $\mathcal{S}$ be any of the following semirings on $\mathbb{R}$:

All intervals

All bounded intervals

For fixed $\delta > 0$, all intervals of length $\leq \delta$

(in all cases, include the degenerate intervals $\emptyset$ and singletons). Then ℓ is a σ-finite premeasure on $\mathcal{S}$ (cf. XVII.4.2.4., Exercise ()).

XVII.4.5.4. **Note:** There is substantial nonuniformity of use of the term "premeasure," and no consensus on the proper definition of the term. Some authors use it much more broadly than we have, and others more narrowly. I believe our definition of "premeasure" is the most useful one, since it is directly used not only in defining Lebesgue measure and Radon measures (finite Borel measures on $\mathbb{R}$ defined via cumulative distribution functions), but also naturally in defining product measures.

Measure extensions can be defined by more primitive data than a premeasure on a semiring; see [Kön97] for a study.

XVII.4.5.5. PROPOSITION. A premeasure on a semiring is monotone.

PROOF: Let ι be a premeasure on a semiring $\mathcal{S}$, and $C, D \in \mathcal{S}$, $C \subseteq D$. Then $D \setminus C$ is a disjoint union of $C_1, \ldots, C_n \in \mathcal{S}$, and

$$\iota(D) = \iota(C) + \sum_{k=1}^{n} \iota(C_k) \geq \iota(C)$$

since $\iota(C_k) \geq 0$ for all k. 👍

Premeasures can be characterized alternatively by countable additivity, which is sometimes easier to check:

XVII.4.5.6. PROPOSITION. Let $\mathcal{S}$ be a semiring of subsets of a set X, and $\iota : \mathcal{S} \to [0, \infty]$. Then ι is a premeasure if and only if ι satisfies

(i) $\iota(\emptyset) = 0$.

(ii′) If $C_1, C_2, \ldots$ are pairwise disjoint sets in $\mathcal{S}$, and $C := \cup_{k=1}^{\infty} C_k \in \mathcal{S}$, then $\iota(C) = \sum_{k=1}^{\infty} \iota(C_k)$ (*countable additivity*).

Note that (ii′) (countable additivity) does not trivially imply (iii) (countable subadditivity) on semirings, even on algebras, since countable additivity only applies to sequences whose union is in the semiring. The proposition is a consequence of XVI.1.2.12. and XVI.1.2.13., which insure that "sufficiently many" sets in a semiring are finite or countable disjoint unions of sets in the semiring.
PROOF: Suppose ι satisfies (i) and (ii′). Then ι obviously satisfies (ii). Let $C, C_1, C_2, \cdots \in \mathcal{S}$ with $C \subseteq \cup_n C_n$. Then by XVI.1.2.13. there are pairwise disjoint $B_k \in \mathcal{S}$, each contained in a unique C_n, only finitely many in each C_n, such that $C = \cup_k B_k$. For each n, let D_n be the union of the B_k which are in C_n. Then $C_n \setminus D_n$ is a finite disjoint union $A_{n1}, \ldots, A_{nm_n}$ of sets in $\mathcal{S}$ by XVI.1.2.12.; hence we have

$$\iota(C_n) = \sum_{B_k \subseteq C_n} \iota(B_k) + \sum_{j=1}^{m_n} \iota(A_{nj}) \geq \sum_{B_k \subseteq C_n} \iota(B_k)$$

by (ii). Therefore we have by (ii′)

$$\iota(C) = \sum_{k=1}^{\infty} \iota(B_k) = \sum_{n=1}^{\infty} \sum_{B_k \subseteq C_n} \iota(B_k) \leq \sum_{n=1}^{\infty} \iota(C_n)$$

and thus ι satisfies (iii).

Conversely, if ι satisfies (i), (ii), and (iii), let $C_1, C_2, \ldots$ be pairwise disjoint sets in $\mathcal{S}$ with $C = \cup_{n=1}^{\infty} C_n \in \mathcal{S}$. We have $\iota(C) \leq \sum_{n=1}^{\infty} \iota(C_n)$ by (iii). On the other hand, if $D_n = \cup_{k=1}^{n} C_k$, we have that $C \setminus D_n$ is a finite disjoint union of sets $A_{n1}, \ldots, A_{nm_n}$ in $\mathcal{S}$, so

$$\iota(C) = \sum_{k=1}^{n} \iota(C_k) + \sum_{j=1}^{m_n} \iota(A_{nj}) \geq \sum_{k=1}^{n} \iota(C_k)$$

for any n, i.e. $\iota(C) = \sum_{k=1}^{\infty} \iota(C_k)$. 👍

Premeasures are technically simpler to work with if the domain is a ring instead of just a semiring. (In fact, some authors such as [Hal50] define a measure to be what we call a premeasure on a ring.) We do not make this restriction in the definition since many naturally occurring premeasures are only naturally defined on semirings. However, a premeasure on a semiring uniquely extends to a premeasure on the ring it generates, so there is no loss of generality for extension theory in considering just premeasures defined on rings (as some authors do):

XVII.4.5.7. THEOREM. Let ι be a premeasure on a semiring $\mathcal{S}$ of subsets of X, and let $\mathcal{R}$ be the ring of subsets of X generated by $\mathcal{S}$. Then ι extends uniquely to a premeasure on $\mathcal{R}$.

PROOF: Recall () that $\mathcal{R}$ consists of all finite disjoint unions of sets in $\mathcal{S}$. If ι extends to a premeasure κ on $\mathcal{R}$, and $R \in \mathcal{R}$ is a disjoint union of sets $C_1, \ldots, C_n \in \mathcal{S}$, we must have $\kappa(R) = \sum_{k=1}^{n} \iota(C_k)$. We first need to show that this formula gives a well-defined function on $\mathcal{R}$.

Suppose $R \in \mathcal{R}$ has two representations $R = \cup_{k=1}^{n} C_k = \cup_{j=1}^{m} D_j$ as disjoint finite unions of sets in $\mathcal{S}$. For each k and j set $E_{kj} = C_k \cap D_j$. Then each $E_{kj} \in \mathcal{S}$ since $\mathcal{S}$ is closed under finite intersections, and the E_{kj} are pairwise disjoint. Thus

$$\sum_{k=1}^{n} \iota(C_k) = \sum_{k=1}^{n} \sum_{j=1}^{m} \iota(E_{kj}) = \sum_{j=1}^{m} \sum_{k=1}^{n} \iota(E_{kj}) = \sum_{j=1}^{m} \iota(D_j)$$

and so κ is well defined.

To show that κ is a premeasure, we must show (ii) and (iii). For (ii), suppose $R_1, \ldots, R_n \in \mathcal{R}$ are pairwise disjoint and suppose $R := \cup_{k=1}^{n} R_k \in \mathcal{R}$. For each k, write R_k as a disjoint union $\cup_{j=1}^{m_k} C_{kj}$ with $C_{kj} \in \mathcal{S}$. Then

$$\kappa(R) = \sum_{k=1}^{n} \sum_{j=1}^{m_k} \iota(C_{kj}) = \sum_{k=1}^{n} \kappa(R_k) \ .$$

To show (iii), Suppose $R, R_1, R_2, \cdots \in \mathcal{R}$ and $R \subseteq \cup_k R_k$. Write $R_k = \cup_{j=1}^{m_k} C_{kj}$ and $R = \cup_{i=1}^{r} D_i$ as disjoint unions with $C_{kj}, D_i \in \mathcal{S}$. For each i, j, k, set $E_{ijk} = C_{kj} \cap D_i$. Then each $E_{ijk} \in \mathcal{S}$ and, for each i, $D_i \subseteq \cup_{j,k} E_{i,j,k}$, so

$$\iota(D_i) \leq \sum_{k,j} \iota(E_{ijk}) \ .$$

Then

$$\kappa(R) = \sum_{i=1}^{r} \iota(D_i) \leq \sum_{i,j,k} \iota(E_{ijk}) = \sum_{k=1}^{\infty} \sum_{j=1}^{m_k} \sum_{i=1}^{r} \iota(E_{ijk}) \leq \sum_{k=1}^{\infty} \sum_{j=1}^{m_k} \iota(C_{kj}) = \sum_{k=1}^{\infty} \kappa(R_k) \ .$$

👍

The model for constructing an extension of a premeasure to a measure is the construction of Lebesgue measure: begin with the premeasure ι, form the induced outer measure μ^* and the σ-algebra $\mathcal{M}$ of μ^*-measurable subsets; the restriction of μ^* to $\mathcal{M}$ is the desired extension. The precise statement is the next theorem, which is the main result of this section, and another of the most important facts in measure theory:

XVII.4.5.8. THEOREM. [EXTENSION THEOREM] Let $\mathcal{S}$ be a semiring on a set X, $\mathcal{A}$ the σ-algebra generated by $\mathcal{S}$, and ι a premeasure on $\mathcal{S}$. Let μ^* be the outer measure on X induced by ι, $\mathcal{M}$ the σ-algebra of μ^*-measurable subsets of X, and $\mu = \mu^*|_{\mathcal{M}}$. Then

(i) $\mathcal{S} \subseteq \mathcal{M}$, i.e. every set in $\mathcal{S}$ is μ^*-measurable.

(ii) The restriction of μ^* to $\mathcal{S}$ is ι, i.e. μ extends ι.

Thus ι extends to a complete measure μ on $\mathcal{M}$, and hence to a measure $\mu|_{\mathcal{A}}$ on $\mathcal{A}$. If $\mathcal{B}$ is a σ-algebra with $\mathcal{A} \subseteq \mathcal{B} \subseteq \mathcal{M}$, the extension $\mu|_{\mathcal{B}}$ is the largest extension of ι to a measure on $\mathcal{B}$, i.e. any extension ν satisfies $\nu \leq \mu$, and ν agrees with μ on sets of σ-finite μ-measure. If ι is σ-finite, then μ is the unique extension of ι to a measure on $\mathcal{B}$, and $(X, \mathcal{M}, \mu)$ is the completion of $(X, \mathcal{A}, \mu|_{\mathcal{A}})$ (hence also of $(X, \mathcal{B}, \mu|_{\mathcal{B}})$).

PROOF: We first prove (ii). Let $C \in \mathcal{S}$. Since $\{C\}$ is a cover of C, we have $\mu^*(C) \leq \iota(C)$. For the opposite inequality, we may assume $\mu^*(C) < \infty$. Let $\epsilon > 0$, and let (C_n) be a sequence of elements of $\mathcal{S}$ with $C \subseteq \cup_{n=1}^{\infty} C_n$ and $\sum_{n=1}^{\infty} \iota(C_n) \leq \mu^*(C) + \epsilon$. Then, by (iii),

$$\iota(C) \leq \sum_{n=1}^{\infty} \iota(C_n) \leq \mu^*(C) + \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, $\iota(C) \leq \mu^*(C)$.

(i): Now let $C \in \mathcal{S}$, and let $A \subseteq X$ with $\mu^*(A) < \infty$. Fix $\epsilon > 0$, and let (C_n) be a sequence in $\mathcal{S}$ with $A \subseteq \cup_{n=1}^{\infty} C_n$ and $\sum_{n=1}^{\infty} \iota(C_n) \leq \mu^*(A) + \epsilon$. Then $A \cap C \subseteq \cup_{n=1}^{\infty}(C_n \cap C)$, and $C_n \cap C \in \mathcal{S}$, so

$$\mu^*(A \cap C) \leq \sum_{n=1}^{\infty} \mu^*(C_n \cap C) = \sum_{n=1}^{\infty} \iota(C_n \cap C) \ .$$

Also, $A \setminus C \subseteq \cup_{n=1}^{\infty}(C_n \setminus C)$. We have that $C_n \setminus C$ is a finite disjoint union $\cup_{k=1}^{m_n} D_{nk}$ for each n, with $D_{nk} \in \mathcal{S}$. So

$$\mu^*(A \setminus C) \leq \sum_{n=1}^{\infty} \sum_{k=1}^{m_n} \mu^*(D_{nk}) = \sum_{n=1}^{\infty} \sum_{k=1}^{m_n} \iota(D_{nk})$$

$$\mu^*(A \cap C) + \mu^*(A \setminus C) \leq \sum_{n=1}^{\infty} \iota(C_n \cap C) + \sum_{n=1}^{\infty} \sum_{k=1}^{m_n} \iota(D_{nk})$$

$$= \sum_{n=1}^{\infty} \left(\iota(C_n \cap C) + \sum_{k=1}^{m_n} \iota(D_{nk}) \right) \ .$$

We have that, for each n, C_n is the finite disjoint union of $C_n \cap C$ and the D_{nk}, so by (ii)

$$\iota(C_n) = \iota(C_n \cap C) + \sum_{k=1}^{m_n} \iota(D_{nk})$$

and thus

$$\mu^*(A \cap C) + \mu^*(A \setminus C) \leq \sum_{n=1}^{\infty} \iota(C_n) \leq \mu^*(A) + \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, $\mu^*(A \cap C) + \mu^*(A \setminus C) \le \mu^*(A)$. Thus C is μ^*-measurable.

For the last part, suppose ν is a measure extending ι to a σ-algebra $\mathcal{B}$ with $\mathcal{A} \subseteq \mathcal{B} \subseteq \mathcal{M}$. If $B \in \mathcal{B}$, $\mu(B) < \infty$, let $\epsilon > 0$ and $B \subseteq \cup_{n=1}^{\infty} C_n$ with $C_n \in \mathcal{S}$ and $\sum_{n=1}^{\infty} \iota(C_n) \le \mu(B) + \epsilon$. Then

$$\nu(B) \le \sum_{n=1}^{\infty} \nu(C_n) = \sum_{n=1}^{\infty} \iota(C_n) \le \mu(B) + \epsilon \ .$$

Since ϵ is arbitrary, $\nu(B) \le \mu(B)$. On the other hand, let $A = \cup_{n=1}^{\infty} C_n \in \mathcal{A}$. Then $\mu(A) \le \sum_{n=1}^{\infty} \iota(C_n) < \infty$. Since $\mu(A \setminus B) < \infty$, we have $\nu(A \setminus B) \le \mu(A \setminus B)$. Let $D_1 = C_1$ and $D_n = C_n \setminus \cup_{k=1}^{n-1} C_k$. Then D_n is a finite disjoint union of sets in $\mathcal{S}$, so $\nu(D_n) = \mu(D_n)$; and A is the disjoint union of the D_n, so $\nu(A) = \mu(A)$. Then

$$\nu(B) = \nu(A) - \nu(A \setminus B) \ge \mu(A) - \mu(A \setminus B) = \mu(B) \ .$$

So $\nu(B) = \mu(B)$, and thus $\mu = \nu$ for sets in $\mathcal{B}$ of finite μ-measure. Then $\nu = \mu$ also for sets of σ-finite μ-measure, which can be written as countable disjoint unions of sets of finite μ-measure; so if ι is σ-finite, so is μ and $\nu = \mu$. In general, the only possible difference between μ and ν is that there could be a set B which is not of σ-finite μ-measure, where $\mu(B) = \infty$ but $\nu(B) < \infty$. Thus $\nu \le \mu$.

For the last statement, let (C_n) be a sequence in $\mathcal{S}$ with $\cup_{n=1}^{\infty} C_n = X$ and $\iota(C_n) < \infty$ for all n. Let $M \in \mathcal{M}$. Fix $n \in \mathbb{N}$; then for each $m \in \mathbb{N}$ there is a sequence (D_{nmk}) in $\mathcal{S}$ with

$$M \cap C_n \subseteq \bigcup_{k=1}^{\infty} D_{nmk}$$

and

$$\sum_{k=1}^{\infty} \iota(D_{nmk}) < \mu(M \cap C_n) + \frac{1}{m} \ .$$

Set

$$A_{nm} = \bigcup_{k=1}^{\infty} D_{nmk} \ .$$

Then $A_{nm} \in \mathcal{A}$, $M \cap C_n \subseteq A_{nm}$, and

$$\mu(A_{nm}) < \mu(M \cap C_n) + \frac{1}{m} \ .$$

Thus if

$$A_n = C_n \cap \left[\bigcap_{m=1}^{\infty} A_{nm} \right]$$

we have $A_n \in \mathcal{A}$, $M \cap C_n \subseteq A_n$, and $\mu(A_n) = \mu(M \cap C_n)$. Thus if $B_n = A_n \setminus (M \cap C_n)$, then $B_n \in \mathcal{M}$ and $\mu(B_n) = 0$. Set $A = \cup_{n=1}^{\infty} A_n$. Then $A \in \mathcal{A}$, and we have $M \subseteq A$ and

$$B = A \setminus M = \bigcup_{n=1}^{\infty} [A_n \setminus (M \cap C_n)] = \bigcup_{n=1}^{\infty} B_n$$

so $\mu(B) = 0$. Thus M is the union of a set in $\mathcal{A}$ and a set B of μ-measure 0. Repeating the above argument for $M \cap C_n$, there is an $E \in \mathcal{A}$ with $B \subseteq E$ and $\mu(E) = 0$. Thus M is the union of a set in $\mathcal{A}$ and a subset of a null set in $\mathcal{A}$. 👍

There is an extremely important corollary of the uniqueness part:

XVII.4.5.9. Corollary. Let $\mathcal{S}$ be a semialgebra on X, and $\mathcal{A}$ the σ-algebra generated by $\mathcal{S}$. If μ and ν are measures on $\mathcal{A}$ which agree on $\mathcal{S}$ and are σ-finite on $\mathcal{S}$, then $\mu = \nu$ on $\mathcal{A}$.

Of course, it is enough to check that one of μ, ν is σ-finite on $\mathcal{S}$. Note that it is *not* sufficient to check that $\mu = \nu$ on $\mathcal{S}$ and that μ, say, is σ-finite on $\mathcal{A}$, unless we know that μ is the measure on $\mathcal{A}$ induced by $\mu|_{\mathcal{S}}$: there is an $\mathcal{S}$ on $\mathbb{R}$ which generates the Borel sets as a σ-algebra, with the property that every nonempty set in $\mathcal{S}$ has infinite Lebesgue measure (Exercise ()); Lebesgue measure is σ-finite on $\mathcal{B}$ but not on $\mathcal{S}$, and agrees on $\mathcal{S}$ with counting measure and the measure μ which is infinite on all nonempty sets (μ is the measure on $\mathcal{B}$ induced by $\lambda|_{\mathcal{S}}$).

XVII.4.5.10. Theorems XVII.4.3.4. and XVII.4.5.8. are often combined into a single theorem, which is called the *Carathéodory Extension Theorem*, and the construction called the *Carathéodory extension process*, even though Carathéodory only proved XVII.4.3.4. (in addition to giving the definition of measurable set (XVII.4.3.1.)). Theorem XVII.4.5.8. was first proved by Fréchet []; the proof using XVII.4.3.4. is due independently to Hahn [] and Kolmogorov [].

XVII.4.5.11. Theorem. [Carathéodory Extension Theorem] If ι is a premeasure on a semiring $\mathcal{S}$ of subsets of a set X, then there is an extension of ι to a complete measure μ on a σ-algebra $\mathcal{M}$ containing $\mathcal{S}$. If ι is σ-finite on $\mathcal{S}$, then the extension μ is unique if $\mathcal{M}$ is taken to be the σ-algebra generated by $\mathcal{S}$ and the null sets.

It is interesting to see what this construction gives when applied to the case where $\mathcal{S}$ is a σ-algebra and ι is a measure on $\mathcal{S}$:

XVII.4.5.12. Proposition. Let $(X, \mathcal{A}, \mu)$ be a measure space, and let μ^* be the outer measure induced by μ, $\mathcal{M}$ the σ-algebra of μ^*-measurable sets, and $\nu = \mu^*|_{\mathcal{M}}$. Then $(X, \mathcal{M}, \nu)$ is the saturation () of the completion (or the completion of the saturation) of $(X, \mathcal{A}, \mu)$. In particular, if μ is σ-finite, then $(X, \mathcal{M}, \nu)$ is the completion of $(X, \mathcal{A}, \mu)$.

XVII.4.5.13. There is an important extension of the uniqueness statement at the end of XVII.4.5.8. We first need a technical fact. Let $\mathcal{S}$ be a semiring of subsets of a set X, ι a premeasure on $\mathcal{S}$, and Y a union of countably many sets in $\mathcal{S}$. Let $\mathcal{S}_Y$ be the collection of all sets in $\mathcal{S}$ which are subsets of Y, and let ι_Y be the restriction of ι to Y.. Then $\mathcal{S}_Y$ is a semiring of subsets of Y and ι_Y is a premeasure on $\mathcal{S}_Y$. Let μ_Y^* and μ_Y° be the outer measures on Y defined by ι_Y.

XVII.4.5.14. Lemma. Using the above notation, μ_Y^* is equal to the restriction of μ^* to $\mathcal{P}(Y)$ (i.e. the notation is consistent with the notation of XVII.4.3.8.).

Proof:

XVII.4.5.15. PROPOSITION. Let $\mathcal{S}$ be a semiring of subsets of a set X and ι a premeasure on $\mathcal{S}$, and μ^* the outer measure on X induced by ι. Let $\mathcal{C}$ be the collection of subsets of X which can be covered by countably many sets in $\mathcal{S}$ of finite premeasure. Then any outer measure on X extending ι agrees with μ^* on sets in $\mathcal{C}$.

PROOF: If $C \in \mathcal{C}$, let Y be the union of a countable collection (S_n) of sets in $\mathcal{S}$ covering C with $\iota(S_n) = \mu^*(S_n) < \infty$ for all n. Then μ^*_Y is the restriction of μ^* to $\mathcal{P}(Y)$ by XVII.4.5.14.. The premeasure ι_Y is σ-finite, so there is a unique outer measure on Y extending ι_Y by XVII.4.5.8., namely μ^*_Y. Thus any outer measure ν^* on X, restricted to $\mathcal{P}(Y)$, agrees with μ^*_Y, and in particular $\nu^*(C) = \mu^*_Y(C) = \mu^*(C)$. 👍

Another Approach

XVII.4.5.16. In constructing an outer measure from a set function (e.g. a premeasure) ι on a collection $\mathcal{C}$ of subsets of a set X, we defined $\mu^*(A) = \infty$ if there is no countable cover of A by sets in $\mathcal{C}$. But we could have proceeded differently: we could have first defined μ^* in the usual way for sets with a countable cover by $\mathcal{C}$, and then for general A define

$$\mu^\circ(A) = \sup\{\mu^*(B) : B \subseteq A, B \text{ has a countable cover by } \mathcal{C}\} .$$

We then have $\mu^\circ(A) = \mu^*(A)$ if A has a countable cover by $\mathcal{C}$, and of course $\mu^\circ \leq \mu^*$ if μ^* is defined as in (). If $\mathcal{C}$ is of countable type, i.e. X is a countable union of sets in $\mathcal{C}$ (e.g. in the case of Lebesgue measure), then every subset of X has a countable cover by $\mathcal{C}$ and there is no difference between μ° and μ^* (so the following discussion is not relevant to most cases of greatest interest). In general, $\mu^\circ(A) = \mu^*(A)$ for any A with $\mu^*(A) < \infty$, and more generally for any countable union of such sets. The difference between μ° and μ^* is that there may be sets A with no countable cover by $\mathcal{C}$ for which $\mu^\circ(A) < \infty$ (for any such A, $\mu^*(A) = \infty$).

XVII.4.5.17. EXAMPLE. For a very simple example where $\mu^\circ \neq \mu^*$, let X be an uncountable set, and $\mathcal{C}$ the collection of countable subsets of X. Set $\iota(C) = 0$ for $C \in \mathcal{C}$. Then $\mu^\circ(A) = 0$ for all $A \subseteq X$, but $\mu^*(A) = \infty$ for A uncountable. Note that $\mathcal{C}$ is a σ-ring and ι is a premeasure (local measure) on $\mathcal{C}$. For an even simpler (trivial) example, let X be a nonempty set (say a one-element set) and $\mathcal{C} = \{\emptyset\}$. Then $\mu^\circ(X) = 0$ but $\mu^*(X) = \infty$.

It is slightly harder to prove that μ° is an outer measure (cf. XVII.4.1.7.):

XVII.4.5.18. PROPOSITION. This function μ° is an outer measure on X.

PROOF: Since $\emptyset \in \mathcal{C}$, $\{\emptyset\}$ is a cover of $\emptyset$, so $\mu^\circ(\emptyset) = \mu^*(\emptyset) = 0$. If $A_1 \subseteq A_2$, the supremum for calculating $\mu^\circ(A_2)$ is over a larger collection of sets than the supremum for calculating $\mu^\circ(A_1)$, so $\mu^\circ(A_1) \leq \mu^\circ(A_2)$. Finally, suppose $A = \cup_{n=1}^\infty A_n$. If $\sum_{n=1}^\infty \mu^\circ(A_n) = \infty$, then clearly $\mu^\circ(A) \leq \sum_{n=1}^\infty \mu^\circ(A_n)$. In the case that $\sum_{n=1}^\infty \mu^\circ(A_n) < \infty$, so $\mu^\circ(A_n) < \infty$ for all n, let B be a subset of A with a countable cover by $\mathcal{C}$, and for each n set $B_n = B \cap A_n$. Then B_n has a countable cover by $\mathcal{C}$, and $\mu^*(B_n) = \mu^\circ(B_n) \leq \mu^\circ(A_n) < \infty$ for each n. Fix $\epsilon > 0$, and for each n let $\{C_{nk}\}$ be a cover of B_n with

$$\sum_{k=1}^\infty \iota(C_{nk}) \leq \mu^\circ(B_n) + 2^{-n}\epsilon .$$

Then $\{C_{nk} : n, k \in \mathbb{N}\}$ is a cover of B, so

$$\mu^\circ(B) \leq \sum_{n,k} \iota(C_{nk}) \leq \sum_{n=1}^{\infty} \mu^\circ(B_n) + \epsilon \leq \sum_{n=1}^{\infty} \mu^\circ(A_n) + \epsilon \ .$$

Since ϵ is arbitrary, $\mu^\circ(B) \leq \sum_{n=1}^{\infty} \mu^\circ(A_n)$. Since $\mu^\circ(A)$ is the supremum of $\mu^\circ(B)$ over all such B, $\mu^\circ(A) \leq \sum_{n=1}^{\infty} \mu^\circ(A_n)$. 👍

The Extension Theorem holds for μ° with slight modification:

XVII.4.5.19. THEOREM. [EXTENSION THEOREM FOR μ°] Let $\mathcal{S}$ be a semiring on a set X, $\mathcal{A}$ the σ-algebra generated by $\mathcal{S}$, and ι a premeasure on $\mathcal{S}$. Let μ° be the outer measure on X induced by ι, $\mathcal{M}^\circ$ the σ-algebra of μ°-measurable subsets of X, and $\underline{\mu} = \mu^\circ|_{\mathcal{M}^\circ}$. Then

(i) $\mathcal{S} \subseteq \mathcal{M}^\circ$, i.e. every set in $\mathcal{S}$ is μ°-measurable.

(ii) The restriction of μ° to $\mathcal{S}$ is ι, i.e. $\underline{\mu}$ extends ι.

Thus ι extends to a complete measure $\underline{\mu}$ on $\mathcal{M}^\circ$, and hence to a measure $\underline{\mu}|_{\mathcal{A}}$ on $\mathcal{A}$. If ι is σ-finite, then $\underline{\mu}$ is the unique extension of ι to a measure on $\mathcal{B}$, and $(X, \mathcal{M}^\circ, \underline{\mu})$ is the completion of $(X, \mathcal{A}, \mu|_{\mathcal{A}})$.

PROOF: The proof of (ii) is identical to the proof for μ^*, since elements of $\mathcal{C}$ have countable $\mathcal{C}$-covers. We recall the argument for completeness. Let $C \in \mathcal{S}$. Since $\{C\}$ is a cover of C, we have $\mu^\circ(C) \leq \iota(C)$. For the opposite inequality, we may assume $\mu^\iota(C) < \infty$. Let $\epsilon > 0$, and let (C_n) be a sequence of elements of $\mathcal{S}$ with $C \subseteq \cup_{n=1}^{\infty} C_n$ and $\sum_{n=1}^{\infty} \iota(C_n) \leq \mu^\circ(C) + \epsilon$. Then, by (iii),

$$\iota(C) \leq \sum_{n=1}^{\infty} \iota(C_n) \leq \mu^\circ(C) + \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, $\iota(C) \leq \mu^\circ(C)$.

(i): Now let $C \in \mathcal{S}$, and let $A \subseteq X$ with $\mu^\circ(A) < \infty$. We must show

$$\mu^\circ(A) \geq \mu^\circ(A \cap C) + \mu^\circ(A \setminus C) \ .$$

We have $\mu^\circ(A \cap C), \mu^\circ(A \setminus C) < \infty$. Fix $\epsilon > 0$, and let B_1 be a subset of $A \cap C$ which has a countable $\mathcal{C}$-cover and $\mu^\circ(A \cap C) < \mu^\circ(B) + \frac{\epsilon}{4}$, and B_2 a similar subset of $A \setminus C$ with $\mu^\circ(A \setminus C) < \mu^\circ(B_2) + \frac{\epsilon}{4}$, and set $B = B_1 \cup B_2$. Then $B \subseteq A$, so $\mu^\circ(B) \leq \mu^\circ(A)$, and B has a countable $\mathcal{C}$-cover. Let (C_n) be a sequence in $\mathcal{S}$ with $B \subseteq \cup_{n=1}^{\infty} C_n$ and $\sum_{n=1}^{\infty} \iota(C_n) \leq \mu^\circ(B) + \frac{\epsilon}{2}$. Then $B_1 = B \cap C \subseteq \cup_{n=1}^{\infty}(C_n \cap C)$, and $C_n \cap C \in \mathcal{S}$, so

$$\mu^\circ(B_1) \leq \sum_{n=1}^{\infty} \mu^\circ(C_n \cap C) = \sum_{n=1}^{\infty} \iota(C_n \cap C) \ .$$

Also, $B_2 \subseteq \cup_{n=1}^{\infty}(C_n \setminus C)$. We have that $C_n \setminus C$ is a finite disjoint union $\cup_{k=1}^{m_n} D_{nk}$ for each n, with $D_{nk} \in \mathcal{S}$. So

$$\mu^\circ(B_2) \leq \sum_{n=1}^{\infty} \sum_{k=1}^{m_n} \mu^\circ(D_{nk}) = \sum_{n=1}^{\infty} \sum_{k=1}^{m_n} \iota(D_{nk})$$

$$\mu^\circ(A\cap C)+\mu^\circ(A\setminus C)\le \mu^\circ(B_1)+\mu^\circ(B_2)+\frac{\epsilon}{2}\le \sum_{n=1}^{\infty}\iota(C_n\cap C)+\sum_{n=1}^{\infty}\sum_{k=1}^{m_n}\iota(D_{nk})+\frac{\epsilon}{2}$$
$$=\sum_{n=1}^{\infty}\left(\iota(C_n\cap C)+\sum_{k=1}^{m_n}\iota(D_{nk})\right)+\frac{\epsilon}{2}\ .$$

We have that, for each n, C_n is the finite disjoint union of $C_n\cap C$ and the D_{nk}, so by (ii)

$$\iota(C_n)=\iota(C_n\cap C)+\sum_{k=1}^{m_n}\iota(D_{nk})$$

and thus

$$\mu^\circ(A\cap C)+\mu^\circ(A\setminus C)\le\sum_{n=1}^{\infty}\iota(C_n)+\frac{\epsilon}{2}<\mu^\circ(B)+\epsilon\le\mu^\circ(A)+\epsilon\ .$$

Since $\epsilon>0$ is arbitrary, $\mu^*(A\cap C)+\mu^*(A\setminus C)\le\mu^*(A)$. Thus C is μ^*-measurable.
The last statement follows immediately from XVII.4.5.8., since $\mu^\circ=\mu^*$ in this case. 👍

XVII.4.5.20. The missing thing from XVII.4.5.8. in this result is the maximality of μ. It is tempting to expect that $\underline{\mu}$ is the smallest extension of ι to $\mathcal{A}$ or $\mathcal{M}^\circ$. This is true in many cases, but not in general for $\mathcal{M}^\circ$ (XVII.4.5.24.); it is true if ι takes only finite values on $\mathcal{S}$, and more generally for locally σ-finite premeasures:

XVII.4.5.21. Proposition. Let ι be a premeasure on a semiring $\mathcal{S}$ of subsets of a set X. Let $\mathcal{C}$ be the collection of subsets of X which can be covered by countably many elements of $\mathcal{S}$. Then the following are equivalent:

(i) Every set in $\mathcal{S}$ is a countable union of elements of $\mathcal{S}$ on which ι is finite.

(ii) Every set in $\mathcal{S}$ can be covered by countably many sets in $\mathcal{S}$ on which ι is finite.

(iii) Every set in $\mathcal{C}$ can be covered by countably many sets in $\mathcal{S}$ on which ι is finite.

The premeasure ι is *locally σ-finite* if these conditions are satisfied.

Proof: (i) $\Rightarrow$ (ii) $\Longleftrightarrow$ (iii) is trivial. For (ii) $\Rightarrow$ (i), if $B\in\mathcal{S}$ is covered by (S_n), then $B=\cup_n(B\cap S_n)$, and $B\cap S_n\in\mathcal{S}$ since $\mathcal{S}$ is closed under finite intersections, and $\iota(B\cap S_n)\le\iota(S_n)<\infty$. 👍

We then have the following corollary of XVII.4.5.15.:

XVII.4.5.22. Corollary. Let ι be a locally σ-finite premeasure on a semiring $\mathcal{S}$ of subsets of a set X, and μ° the outer measure of X defined in (). Then μ° is the smallest outer measure on X extending ι.

Proof: If ν^* is an outer measure on X extending ι, then $\nu^*(C) = \mu^*(C) = \mu^\circ(C)$ for $C \in \mathcal{C}$. If A is any subset of X, and C is any set in $\mathcal{C}$ with $C \subseteq A$, we have $\nu^*(A) \geq \nu^*(C)$ by monotonicity. Thus we have

$$\nu^*(A) \geq \sup_{C \in \mathcal{C}_A} \nu^*(C) = \sup_{C \in \mathcal{C}_A} \mu^*(C) = \mu^\circ(A)$$

where $\mathcal{C}_A$ is the collection of subsets of A which are in $\mathcal{C}$. 👍

XVII.4.5.23. Corollary. Let ι be a locally σ-finite premeasure on a semiring $\mathcal{S}$ of subsets of a set X, μ° the outer measure of X defined in (), and $\underline{\mu}$ the restriction of μ° to the σ-algebra $\mathcal{M}^\circ$. If $\mathcal{A}$ is the σ-algebra generated by $\mathcal{S}$, $\mathcal{B}$ any σ-algebra with $\mathcal{A} \subseteq \mathcal{B} \subseteq \mathcal{M}^\circ$, and ν a measure on $(X, \mathcal{B})$ extending ι, then $\nu \geq \underline{\mu}|_{\mathcal{B}}$.

Proof: The premeasure ν on $\mathcal{B}$ extends to an outer measure ν^* on X, which is an outer measure extending ι, and hence $\nu^* \geq \mu^\circ$. 👍

XVII.4.5.24. Example. Consider the following very simple example. Let $X = \{1, 2\}$, $\mathcal{S} = \{\emptyset, X\}$, and set $\iota(\emptyset) = 0$, $\iota(X) = \infty$. Then $\mu^\circ(A) = \mu^*(A) = \infty$ for any nonempty $A \subseteq X$. In this case $\mathcal{M}^\circ = \mathcal{M} = \mathcal{P}(X)$ and $\underline{\mu} = \mu = \mu^\circ = \mu^*$. But $\underline{\mu}$ is not the smallest extension of ι to a measure on $(X, \mathcal{P}(X))$; in fact, there is no smallest extension, since there are extensions μ_1 and μ_2 with $\mu_1(\{1\}) = \mu_2(\{2\}) = \infty$, $\mu_1(\{2\}) = \mu_2(\{1\}) = 0$. Note that in this case $\mathcal{S}$ is a σ-algebra and ι is a measure on $(X, \mathcal{S})$.

XVII.4.5.25. There is no obvious relation between the σ-algebras $\mathcal{M}$ and $\mathcal{M}^\circ$ in general, except that both contain $\mathcal{S}$ and hence $\mathcal{A}$. One indication that there may be a difference is that there are often many more $\underline{\mu}$-null sets than μ-null sets, e.g. in XVII.4.5.17. (although in this case $\mathcal{M}^\circ = \mathcal{M} = \mathcal{P}(X)$). But they cannot be too different:

XVII.4.5.26. Proposition. Let $\mathcal{S}$ be a semiring of subsets of a set X, ι a premeasure on $\mathcal{S}$, and μ^* and μ° the extensions of ι to outer measures on X. Let $\mathcal{A}$ be the σ-algebra generated by $\mathcal{S}$, and $\mathcal{M}$ and $\mathcal{M}^\circ$ the σ-algebras of μ^*-measurable and μ°-measurable sets respectively. Let E be a subset of X which can be covered by countably many sets in $\mathcal{S}$. Then E is in $\mathcal{M}^\circ$ if and only if it is in $\mathcal{M}$.

Proof: Let (S_n) be a sequence of sets in $\mathcal{S}$ covering E, and let $Y = \cup_n S_n$. Then $Y \in \mathcal{A} \subseteq \mathcal{M} \cap \mathcal{M}^\circ$, and $E \subseteq Y$. Every subset Z of Y can be covered by countably many sets in $\mathcal{S}$, and hence $\mu^\circ(Z) = \mu^*(Z)$, i.e. using the language of XVII.4.3.8., $\mu_Y^\circ = \mu_Y^*$. Thus by XVII.4.3.8., if $Z \subseteq Y$, we have

Z is μ°-measurable

$\iff$ Z is μ_Y°-measurable

$\iff$ Z is μ_Y^*-measurable

$\iff Z$ is μ^*-measurable.

Regular Outer Measures

Not every outer measure is induced by a premeasure. The ones that are can be characterized in a simple way:

XVII.4.5.27. DEFINITION. An outer measure μ^* on a set X is *regular* if, for every $E \subseteq X$, there is a μ^*-measurable set A with $E \subseteq A$ and $\mu^*(E) = \mu^*(A)$.

Not every outer measure is regular:

XVII.4.5.28. EXAMPLES. (i) If $X = \{0, 1\}$, set $\mu^*(\emptyset) = 0$, $\mu^*(\{0\}) = \mu^*(\{1\}) = 1$, and $\mu^*(X) = \alpha$. If $1 \leq \alpha \leq 2$, μ^* is an outer measure. If $\alpha < 2$, the only μ^*-measurable sets are $\emptyset$ and X; if $1 < \alpha < 2$, μ^* is not regular.

(ii) Let $X = \mathbb{N}$. Set $\mu^*(\emptyset) = 0$, $\mu^*(E) = 1$ if E is nonempty and finite, and $\mu^*(E) = 2$ if E is infinite. The only μ^*-measurable sets are $\emptyset$ and $\mathbb{N}$, and μ^* is not regular.

XVII.4.5.29. There is a related property. If μ^* is an outer measure on X and (E_n) is an increasing sequence of subsets of X, with $E = \cup_{n=1}^{\infty} E_n$, then $\mu^*(E_1) \leq \mu^*(E_2) \leq \cdots \leq \mu^*(E)$ by monotonicity; thus

$$\mu^*(E) \geq \lim_{n\to\infty} \mu^*(E_n) = \sup_n \mu^*(E_n) \ .$$

We do not have equality in general (XVII.4.5.31.).

XVII.4.5.30. DEFINITION. Let μ^* be an outer measure on a set X. Then μ^* is *monotone regular* if, whenever (E_n) is an increasing sequence of subsets of X, we have

$$\mu^*(E) = \lim_{n\to\infty} \mu^*(E_n) = \sup_n \mu^*(E_n) \ .$$

XVII.4.5.31. EXAMPLES. The example of XVII.4.5.28.(ii) is not monotone regular: let $E_n = \{1, \ldots, n\}$. The example of XVII.4.5.28.(i) is monotone regular (as is any outer measure on a finite set) but not regular.

XVII.4.5.32. PROPOSITION. A regular outer measure is monotone regular.

PROOF: Let μ^* be a regular outer measure on X, and (E_n) an increasing sequence of subsets of X, with $E = \cup_{n=1}^{\infty} E_n$. It suffices to show that $\mu^*(E) \leq \sup_n \mu^*(E_n)$. Let A_n be a μ^*-measurable set with $E_n \subseteq A_n$ and $\mu^*(A_n) = \mu^*(E_n)$ for all n. Set $B_n = \cap_{k=n}^{\infty} A_k$. We have that $E_n \subseteq A_k$ whenever $n \leq k$, and hence $E_n \subseteq B_n \subseteq B_{n+1}$ for all n. Since $B_n \subseteq A_n$, we have $\mu^*(E_n) \leq \mu^*(B_n) \leq \mu^*(A_n) = \mu^*(E_n)$, so we have equality throughout. If $B = \cup_{n=1}^{\infty} B_n$, then $E \subseteq B$, so by () we have

$$\mu^*(E) \leq \mu^*(B) = \sup_n \mu^*(B_n) = \sup_n \mu^*(E_n) \ .$$

XVII.4.5.33. PROPOSITION. An outer measure induced by a premeasure is regular.

PROOF: Suppose the outer measure μ^* on X is induced by $\iota : \mathcal{S} \to [0, \infty]$, and let $E \subseteq X$. If $\mu^*(E) = \infty$, take $A = X$. If $\mu^*(E) < \infty$, by XVII.4.1.10. let $A \in \mathcal{S}_{\sigma\delta}$ with $E \subseteq A$ and $\mu^*(A) = \mu^*(E)$.

XVII.4.5.34. COROLLARY. Lebesgue outer measure is a regular outer measure.

For the converse, we prove a more precise statement:

XVII.4.5.35. PROPOSITION. Let μ^* be an outer measure on X, $\mathcal{M}$ the set of μ^*-measurable sets, and $\mu^\star$ the outer measure induced by $\mu^*|_{\mathcal{M}}$. Then $\mu^\star$ is a regular outer measure, $\mu^\star \geq \mu^*$, every set in $\mathcal{M}$ is $\mu^\star$-measurable, every $\mu^\star$-measurable set of σ-finite $\mu^\star$-measure is in $\mathcal{M}$, and $\mu^\star|_{\mathcal{M}} = \mu^*|_{\mathcal{M}}$; $\mu^\star = \mu^*$ if and only if μ^* is regular.

PROOF: Most of this follows immediately from previous results. By XVII.4.5.8., setting $\mathcal{S} = \mathcal{M}$ and $\iota = \mu^*|_{\mathcal{M}}$, every set in $\mathcal{M}$ is $\mu^\star$-measurable, and $\mu^\star|_{\mathcal{M}} = \mu^*|_{\mathcal{M}}$. The outer measure $\mu^\star$ is regular by XVII.4.5.33.. We have that, for any $E \subseteq X$,

$$\mu^\star(E) = \inf\{\mu^*(A) : A \in \mathcal{M}, E \subseteq A\}$$

and the infimum is attained () at some $A \in \mathcal{M}$; for this A we have $\mu^*(E) \leq \mu^*(A) = \mu^\star(E)$. Thus $\mu^\star \geq \mu^*$.

If E is $\mu^\star$-measurable and $\mu^\star(E) < \infty$, then there is a μ^*-measurable set A with $E \subseteq A$ and $\mu^*(A) = \mu^\star(E)$; then $\mu^\star(A) = \mu^*(A) = \mu^\star(E)$, so $\mu^\star(A \setminus E) = 0$. Since $\mu^*(A \setminus E) \leq \mu^\star(A \setminus E)$, $\mu^*(A \setminus E) = 0$ and $A \setminus E \in \mathcal{M}$ (). Thus $E = A \setminus (A \setminus E) \in \mathcal{M}$. The case where E has σ-finite $\mu^\star$-measure follows immediately.

Finally, if μ^* is regular, let $E \subseteq X$, and $A \in \mathcal{M}$ with $E \subseteq A$ and $\mu^*(E) = \mu^*(A)$. Then $\{A\}$ is an $\mathcal{M}$-cover of E, so $\mu^\star(E) \leq \mu^*(A) = \mu^*(E)$. Thus $\mu^\star \leq \mu^*$. So $\mu^\star = \mu^*$. 

XVII.4.5.36. EXAMPLE. [Rog70, p. 14] The σ-algebra of $\mu^\star$-measurable sets can be strictly larger than $\mathcal{M}$. Let X be a set of cardinality $\aleph_2$, and define μ^* on X by setting $\mu^*(E) = 0$ if E is countable, $\mu^*(E) = 1$ if $card(E) = \aleph_1$, and $\mu^*(E) = \infty$ if $card(E) = \aleph_2$. Then μ^* is an outer measure on X which is not regular. The σ-algebra $\mathcal{M}$ of μ^*-measurable sets is the σ-algebra of countable and cocountable sets. Construct $\mu^\star$ as above from $\mu^*|_{\mathcal{M}}$. Then, for any $E \subseteq X$, $\mu^\star(E) = 0$ if E is countable and $\mu^\star(E) = \infty$ if E is uncountable, and every subset of X is $\mu^\star$-measurable.

Putting the last two results together, we obtain:

XVII.4.5.37. PROPOSITION. An outer measure is induced by a premeasure if and only if it is regular.

As a corollary of XVII.4.5.35., we can show that Lebesgue's definition of measurability agrees with Carathéodory's for finite regular outer measures:

XVII.4.5.38. THEOREM. Let μ^* be a regular outer measure on a set X, with $\mu^*(X) < \infty$. Then $A \subseteq X$ is μ^*-measurable if and only if $\mu^*(A) + \mu^*(X \setminus A) = \mu^*(X)$.

(Of course, $\mu^*(A) + \mu^*(X \setminus A) \geq \mu^*(X)$ is automatic, so only the reverse inequality needs to be checked.) PROOF: If A is μ^*-measurable, the equality holds by definition. Conversely, suppose $A \subseteq X$ and $\mu^*(A) + \mu^*(X \setminus A) = \mu^*(X)$. Let B and C be μ^*-measurable subsets of X with $A \subseteq B$, $\mu^*(B) = \mu^*(A)$, $(X \setminus A) \subseteq C$, $\mu^*(C) = \mu^*(X \setminus A)$. We have

$$\mu^*(B \setminus C) + \mu^*(B \cap C) + \mu^*(C \setminus B) = \mu^*(B \cup C) = \mu^*(X) \ .$$

We also have

$$\mu^*(X) = \mu^*(A) + \mu^*(X \setminus A) = \mu^*(B) + \mu^*(C) = \mu^*(B \setminus C) + 2\mu^*(B \cap C) + \mu^*(C \setminus B)$$

and subtracting we get $\mu^*(B \cap C) = 0$. If $D = B \setminus A$, then $D = B \cap (X \setminus A) \subseteq (B \cap C)$, so $\mu^*(D) = 0$ and D is μ^*-measurable. Hence so is $A = B \setminus D$. 👍

This result can fail for finite outer measures which are not regular (Exercise ()). It also usually fails for outer measures which are not finite: for example, there is a nonmeasurable subset A of $\mathbb{R}$ with $\lambda^*(A) = \lambda^*(\mathbb{R} \setminus A) = \infty$ ().

Inner Measure

XVII.4.5.39. If μ^* is a finite regular outer measure on a set X, we can define the *inner measure* of a subset A of X by

$$\mu_*(A) = \mu^*(X) - \mu^*(X \setminus A) \ .$$

Then the result of XVII.4.5.38. can be rephrased:

XVII.4.5.40. COROLLARY. Let μ^* be a finite regular outer measure on a set X, and μ_* the corresponding inner measure. Then $A \subseteq X$ is μ^*-measurable if and only if $\mu^*(A) = \mu_*(A)$.

Generalizations of Regularity

XVII.4.5.41. The notion of regularity can be generalized. If $\mathcal{C}$ is a collection of subsets of a set X, and μ^* is an outer measure on X, then μ^* is *$\mathcal{C}$-regular* if every subset Y of X is contained in some $C \in \mathcal{C}$ with $\mu^*(C) = \mu^*(Y)$ (this implies that $X \in \mathcal{C}$). Normally this definition is applied only when $\mathcal{C} \subseteq \mathcal{M}$, where $\mathcal{M}$ is the set of μ^*-measurable sets. Thus μ^* is regular if and only if it is $\mathcal{M}$-regular. If μ^* is a σ-finite outer measure induced from $\iota : \mathcal{C} \to [0, \infty]$, then μ^* is $\mathcal{C}_{\sigma\delta}$-regular (XVII.4.1.10.).

XVII.4.5.42. Proposition. Let μ^* be an outer measure on a set X, $\mathcal{M}$ the set of μ^*-measurable subsets of X, and $\mathcal{A}$ a sub-σ-algebra of $\mathcal{M}$ such that $\mu^*|_{\mathcal{A}}$ is σ-finite. If μ^* is $\mathcal{A}$-regular, then $\mathcal{M}$ is the σ-algebra generated by $\mathcal{A}$ and the $\mathcal{A}$-null sets (subsets of sets in $\mathcal{A}$ of outer measure 0). In particular, if $(X, \mathcal{A}, \mu^*|_{\mathcal{A}})$ is complete and σ-finite, then $\mathcal{A} = \mathcal{M}$.

XVII.4.5.43. This does not mean that if $(X, \mathcal{A}, \mu)$ is a σ-finite complete measure space, then it is not possible to extend μ to a measure on a strictly larger σ-algebra; there are many examples where this is possible. See Exercise () for a simple example, and (), (), ... for more natural and important ones. What XVII.4.5.42. does say is that if such a μ is extended to a measure ν on a larger σ-algebra $\mathcal{B}$, and ν^* is the outer measure induced by ν, then ν^* is not $\mathcal{A}$-regular.

XVII.4.5.44. An important special case of regularity is when μ^* is an outer measure on a topological space X. Then μ^* is *Borel regular* if it is $\mathcal{B}$-regular, where $\mathcal{B}$ is the class of Borel sets in X. This definition is usually reserved for Borel outer measures, i.e. ones where all Borel sets are μ^*-measurable. The most important example is that Lebesgue outer measure is Borel regular (XVII.4.4.5., XVII.4.5.34.).

XVII.4.6. The Suslin Operation

XVII.4.6.1. There is a curious operation on sets called the *Suslin operation* (sometimes called the *A-operation*), which is reminiscent of the construction in the proof of XIII.10.4.7.. For each finite sequence $(s_1, \ldots, s_n)$ of natural numbers, let $A_{s_1,\ldots,s_n}$ be a subset of a set X. The collection of finite sequences in $\mathbb{N}$ is countable, so there are countably many such sets in all. Define

$$S(\{A_{s_1,\ldots,s_n}\}) = \bigcup_{s \in \mathcal{N}} \bigcap_{n=1}^{\infty} A_{s_1,\ldots,s_n}$$

where $\mathcal{N} = \mathbb{N}^\infty$ is the set of all sequences in $\mathbb{N}$ (). Although the operation begins with a countable collection of sets, the union is over all sequences (uncountably many) in $\mathcal{N}$.

If $s = (s_1, s_2, \ldots) \in \mathcal{N}$, write $s|n = (s_1, \ldots, s_n) \in \mathbb{N}^n$. These are called *initial segments* of s. Take $s|0$ to be the "empty string." Thus

$$S(\{A_{s_1,\ldots,s_n}\}) = \bigcup_{s \in \mathcal{N}} \bigcap_{n=1}^{\infty} A_{s|n} \ .$$

XVII.4.6.2. More generally, if $\mathcal{E}$ is a nonempty collection of subsets of a set X, and all the $A_{s_1,\dots,s_n}$ are in $\mathcal{E}$, the indexed collection $\{A_{s_1,\dots,s_n}\}$ is called a *Suslin scheme in* $\mathcal{E}$. Denote by $\mathcal{S}(\mathcal{E})$ the collection $\{S(\{A_{s_1,\dots,s_n}\})\}$, for all Suslin schemes $\{A_{s_1,\dots,s_n}\}$ in $\mathcal{E}$, along with $\emptyset$ (we will automatically have $\emptyset \in \mathcal{S}(\mathcal{E})$ in many cases, e.g. if $\emptyset$ is a countable intersection of sets in $\mathcal{E}$). The sets in $\mathcal{S}(\mathcal{E})$ are called the *$\mathcal{E}$-Suslin sets* (sometimes called the *$\mathcal{E}$-analytic sets*, but we reserve this term for sets defined differently in (); the two classes of sets coincide in most natural settings). It is obvious that if $\mathcal{E} \subseteq \mathcal{F}$, then $\mathcal{S}(\mathcal{E}) \subseteq \mathcal{S}(\mathcal{F})$.

We typically take $\mathcal{E}$ to be the collection of closed or compact sets in $\mathbb{R}^n$ (or in a topological space), or a semialgebra (algebra, σ-algebra) of sets such as the Borel sets in $\mathbb{R}^n$.

The sets in $\mathcal{S}(\mathcal{E})$ have a simpler explicit description than the sets in $\sigma(\mathcal{E})$ (cf. ()). The collection $\mathcal{S}(\mathcal{E})$ is usually different from $\sigma(\mathcal{E})$ although it has some of the same properties; it frequently happens that $\mathcal{S}(\mathcal{E})$ contains $\sigma(\mathcal{E})$ (XVII.4.6.4.(iv)).

XVII.4.6.3. A Suslin scheme $\{A_{s_1,\dots,s_n}\}$ is *monotone* (or *regular*) if $A_{s_1,\dots,s_n,s_{n+1}} \subseteq A_{s_1,\dots,s_n}$ for all $(s_1,\dots,s_{n+1})$. If $\mathcal{E}$ is closed under finite intersections (e.g. in one of the common situations described above), then for any Suslin scheme $\{A_{s_1,\dots,s_n}\}$ in $\mathcal{E}$ there is a monotone Suslin scheme $\{B_{s_1,\dots,s_n}\}$ with $S(\{B_{s_1,\dots,s_n}\}) = S(\{A_{s_1,\dots,s_n}\})$: just set

$$B_{s_1,\dots,s_n} = A_{s_1} \cap A_{s_1,s_2} \cap \cdots \cap A_{s_1,\dots,s_n}$$

for each $(s_1,\dots,s_n)$.

XVII.4.6.4. PROPOSITION. Let $\mathcal{E}$ be a collection of subsets of a set X. Then

(i) $\mathcal{E} \subseteq \mathcal{S}(\mathcal{E})$.

(ii) $\mathcal{S}(\mathcal{S}(\mathcal{E})) = \mathcal{S}(\mathcal{E})$. Thus if $\mathcal{E} \subseteq \mathcal{F} \subseteq \mathcal{S}(\mathcal{E})$, then $\mathcal{S}(\mathcal{F}) = \mathcal{S}(\mathcal{E})$.

(iii) $\mathcal{S}(\mathcal{E})$ is closed under countable unions and countable intersections.

(iv) If the complement of every set in $\mathcal{E}$ is in $\mathcal{S}(\mathcal{E})$, then $\sigma(\mathcal{E}) \subseteq \mathcal{S}(\mathcal{E})$.

PROOF: (i): If $A \in \mathcal{E}$, set $A_{s_1,\dots,s_n} = A$ for all $(s_1,\dots,s_n)$. Then $\{A_{s_1,\dots,s_n}\}$ is a Suslin scheme in $\mathcal{E}$, and $S(\{A_{s_1,\dots,s_n}\}) = A$.
(ii): Let $\phi : \mathbb{N}^2 \to \mathbb{N}$ be the bijection given by $\phi(n,m) = 2^{n-1}(2m-1)$. Let α and β be the coordinate functions of the inverse map, i.e. $\alpha(2^{n-1}(2m-1)) = n$, $\beta(2^{n-1}(2m-1)) = m$. Define a bijection $\psi : \mathcal{N} \times \mathcal{N}^\infty \to \mathcal{N}$ by

$$\psi(s,(t^{(k)}))(r) = \phi(s_r, t^{(\alpha(r))}_{\beta(r)})$$

where $t^{(k)}_j$ is the j'th term of the sequence $t^{(k)}$. Note that if $r = \phi(n,m)$, then $\psi(s,(t^{(k)}))|r$ completely determines $s|n$ and $t^{(n)}|m$, i.e. if $(p_1,\dots,p_r) \in \mathbb{N}^r$, then there are $(s_1,\dots,s_n)$ and $(t_1,\dots,t_m)$ such that whenever $\psi(s,(t^{(k)}))|r = (p_1,\dots,p_r)$, $s|n = (s_1,\dots,s_n)$ and $t^{(n)}|m = (t_1,\dots,t_m)$.

Now let $B = \cup_{s\in\mathcal{N}} \cap_n B_{s|n} \in \mathcal{S}(\mathcal{S}(\mathcal{E}))$, where $\{B_{s_1,\dots,s_n}\}$ is a Suslin scheme in $\mathcal{S}(\mathcal{E})$, and suppose for each $(s_1,\dots,s_n)$ we have $B_{s_1,\dots,s_n} = \cup_{t\in\mathcal{N}} \cap_m A^{t|m}_{s_1,\dots,s_m}$ with $A^{t|m}_{s_1,\dots,s_n} \in \mathcal{E}$. For a finite sequence $(p_1,\dots,p_r)$, let $(s_1,\dots,s_n)$ and $(t^{(n)}_1,\dots,t^{(n)}_m)$ be the initial segments determined by $(p_1,\dots,p_r)$ as above, and define

$$E_{p_1,\dots,p_r} = A^{t^{(n)}_1,\dots,t^{(n)}_m}_{s_1,\dots,s_n} .$$

Then $\{E_{p_1,\dots,p_r}\}$ is a Suslin scheme in $\mathcal{E}$; set $E = \cup_{p\in\mathcal{N}} \cap_r E_{p|r} \in \mathcal{S}(\mathcal{E})$.

We have that $x \in B$ if and only if there is an $s \in \mathcal{N}$ such that $x \in B_{s|n}$ for all n, i.e. if and only if for each n there is $(t^{(n)}) \in \mathcal{N}^\infty$ such that $x \in A_{s|n}^{t^{(n)}|m}$ for all m. Set $p = \psi(s, (t^{(n)}))$. Then, for any r, $E_{p|r} = A_{s|n}^{t^{(n)}|m}$ where $r = \phi(n, m)$, so $x \in B$ if and only if $x \in E_{p|r}$ for all r, for some $p \in \mathcal{N}$, i.e. if and only if $x \in E$. Thus $B = E \in \mathcal{S}(\mathcal{E})$. So $\mathcal{S}(\mathcal{S}(\mathcal{E})) \subseteq \mathcal{S}(\mathcal{E})$, and the opposite inclusion follows from (i).

(iii): By (ii), it suffices to show that $\mathcal{S}(\mathcal{E})$ contains all countable unions and countable intersections of sets in $\mathcal{E}$. Suppose (E_n) is a sequence of sets in $\mathcal{E}$. For each $(s_1, \dots, s_n)$, set $A_{s_1,\dots,s_n} = E_{s_1}$. Then $\{A_{s_1,\dots,s_n}\}$ is a Suslin scheme in $\mathcal{E}$, and $S(\{A_{s_1,\dots,s_n}\}) = \cup_{n=1}^\infty E_n$. Similarly, set $A_{s_1,\dots,s_n} = E_n$ for all $(s_1, \dots, s_n)$; then $S(\{A_{s_1,\dots,s_n}\}) = \cap_{n=1}^\infty E_n$.

(iv): Follows immediately from XVI.1.7.2.(b) (cf. XVII.5.3.12.), since $\mathcal{E} \subseteq \mathcal{S}(\mathcal{E}) \cap \widetilde{\mathcal{S}(\mathcal{E})}$ which is a σ-algebra. ☝

XVII.4.6.5. $\mathcal{S}(\mathcal{E})$ is not closed under complements in general, even if $\mathcal{E}$ is a σ-algebra. For example, if $\mathcal{B}$ is the σ-algebra of Borel sets in $\mathbb{R}$, then $\mathcal{S}(\mathcal{B})$ is not closed under complements ().

XVII.4.6.6. Let $\mathcal{K}$ be the collection of compact subsets of $\mathbb{R}^n$, $\mathcal{F}$ the collection of closed subsets, and $\mathcal{B}$ the collection of Borel sets. The complement of every compact set is open, hence a countable union of compact sets; thus by XVII.4.6.4.(iv) $\sigma(\mathcal{K}) = \mathcal{B} \subseteq \mathcal{S}(\mathcal{K})$. Thus by (ii) $\mathcal{S}(\mathcal{K}) = \mathcal{S}(\mathcal{F}) = \mathcal{S}(\mathcal{B})$, i.e. every $\mathcal{B}$-Suslin set is $\mathcal{K}$-Suslin. These sets are called the *Suslin sets* in $\mathbb{R}^n$. See also Exercise XVII.5.3.9..

The next theorem is the main result of this subsection.

XVII.4.6.7. Theorem. Let μ^* be an outer measure on a set X, $\mathcal{M}$ the σ-algebra of μ^*-measurable sets, and $\mu = \mu^*|_{\mathcal{M}}$. Then

(i) $\mathcal{M}$ is closed under the Suslin operation, i.e. $\mathcal{S}(\mathcal{M}) = \mathcal{M}$.

(ii) Suppose μ^* is monotone regular. Let $\mathcal{E}$ be a subset of $\mathcal{M}$ which is closed under finite unions and countable intersections, and such that $\mu(E) < \infty$ for all $E \in \mathcal{E}$. Then, for every $A \in \mathcal{S}(\mathcal{E})$ with $\mu(A) < \infty$, we have
$$\mu(A) = \sup\{\mu(E) : E \in \mathcal{E}, E \subseteq A\} .$$

Combining XVII.4.6.7. with XVII.4.5.12., we obtain:

XVII.4.6.8. Corollary. Let $(X, \mathcal{A}, \mu)$ be a complete σ-finite measure space. Then $\mathcal{A}$ is closed under the Suslin operation. ("σ-finite" can be replaced by "saturated.")

XVII.4.6.9. The conclusion of this corollary can be false if the measure is not complete. In fact, the σ-algebra of Borel sets on $\mathbb{R}$ is not closed under the Suslin operation ().

We now prove Theorem XVII.4.6.7..

PROOF: ([Rog70], [Bog07]) We first prove (i) and (ii) in the case where μ^* is monotone regular. Let $A = S(\{A_{s_1,\dots,s_n}\}) \in \mathcal{S}(\mathcal{M})$, where $\{A_{s_1,\dots,s_n}\}$ is a Suslin scheme in $\mathcal{M}$ which we may assume is monotone since $\mathcal{M}$ is closed under finite intersections. For (ii), we take the $A_{s_1,\dots,s_n}$ to be in $\mathcal{E}$. To show that $A \in \mathcal{M}$, we use the criterion of XVII.4.3.2.(ii). So let $Y \subseteq A$ and $Z \subseteq X \setminus A$ with $\mu^*(Y), \mu^*(Z) < \infty$; in (ii) we take $Y = A$ (and in this case we can take $Z = \emptyset$). For (i) we must show that $\mu^*(Y \cup Z) \geq \mu^*(Y) + \mu^*(Z)$. We will show that for any $\epsilon > 0$ there is an $E \in \mathcal{M}$, $E \subseteq A$, with $\mu^*(Y \cap E) \geq \mu^*(Y) - \epsilon$, and $E \in \mathcal{E}$ in case (ii); (ii) will then follow immediately, and (i) will also follow since then $Z \subseteq X \setminus E$, so

$$\mu^*(Y \cup Z) \geq \mu^*((Y \cap E) \cup Z) = \mu^*(Y \cap E) + \mu^*(Z) \geq \mu^*(Y) - \epsilon + \mu^*(Z)$$

and since $\epsilon > 0$ is arbitrary, $\mu^*(Y \cup Z) \geq \mu^*(Y) + \mu^*(Z)$.

Fix $\epsilon > 0$. For $m \in \mathbb{N}$, set

$$B_m = Y \cap \bigcup_{s \in \mathcal{N}_m} \bigcap_k A_{s|k}$$

where $\mathcal{N}_m = \{s \in \mathcal{N} : s_1 \leq m\}$. Then the B_m increase with m, and $\cup_m B_m = Y$. So

$$\mu^*(Y) = \sup_m \mu^*(B_m)$$

since μ^* is monotone regular. Thus there is an m_1 such that

$$\mu^*(B_{m_1}) > \mu^*(Y) - \epsilon \ .$$

Proceed inductively. Suppose $m_1, \dots, m_n$ have been defined and

$$B_{m_1,\dots,m_n} = Y \cap \bigcup_{s \in \mathcal{N}_{m_1,\dots,m_n}} \bigcap_k A_{s|k}$$

where $\mathcal{N}_{m_1,\dots,m_n} = \{s \in \mathcal{N} : s_1 \leq m_1, \dots, s_n \leq m_n\}$ and

$$\mu^*(B_{m_1,\dots,m_n}) > \mu^*(Y) - \epsilon \ .$$

For $m \in \mathcal{N}$, set

$$B_{m_1,\dots,m_n,m} = Y \cap \bigcup_{s \in \mathcal{N}_{m_1,\dots,m_n,m}} \bigcap_k A_{s|k}$$

where $\mathcal{N}_{m_1,\dots,m_n,m} = \{s \in \mathcal{N} : s_1 \leq m_1, \dots, s_n \leq m_n, s_{n+1} \leq m\}$. Then the $B_{m_1,\dots,m_n,m}$ increase in m, and $\cup_m B_{m_1,\dots,m_n,m} = B_{m_1,\dots,m_n}$, so as before there is an m_{n+1} such that

$$\mu^*(B_{m_1,\dots,m_{n+1}}) > \mu^*(Y) - \epsilon \ .$$

Now for each n set

$$E_n = \bigcup_{s \in \mathcal{N}_{m_1,\dots,m_n}} A_{s|n} \ .$$

This is a finite union, so $E_n \in \mathcal{M}$ for all n, and $E_n \in \mathcal{E}$ in case (ii). We have $B_{m_1,\dots,m_n} \subseteq Y \cap E_n$ for all n. We also have $E_{n+1} \subseteq E_n$ for all n. Set $E = \cap_n E_n$.

We claim that $\mu^*(E) \geq \mu^*(Y) - \epsilon$. This is obvious from downward continuity () in case (ii) since μ is finite on $\mathcal{E}$ and $\mu^*(E_n) \geq \mu^*(B_{m_1,\dots,m_n}) > \mu^*(Y) - \epsilon$ for all n. For case (i), define a new outer measure μ_Y^* on X by

$$\mu_Y^*(S) = \mu^*(Y \cap S)$$

for $S \subseteq X$. Then every set in $\mathcal{M}$ is μ_Y^*-measurable by (), and we have

$$\mu^*(E) \geq \mu_Y^*(E) = \inf_n \mu_Y^*(E_n) = \inf_n \mu^*(Y \cap E_n) \geq \inf_n \mu^*(B_{m_1,\dots,m_n}) \geq \mu^*(Y) - \epsilon$$

where the first equality is downward continuity for the finite measure μ_Y.

Finally, we show $E \subseteq A$. Let $x \in E$. Write

$$\mathbb{N}^n_{m_1,\dots,m_n} = \{(s_1,\dots,s_n) : s_1 \leq m_1, \dots, s_n \leq m_n\} \subseteq \mathbb{N}^n$$

for each n. If $k > n$, say $(s_1,\dots,s_n) \in \mathbb{N}^n_{m_1,\dots,m_n}$ is *extendible to* k if there are $s_{n+1},\dots,s_k$ such that $(s_1,\dots,s_n,s_{n+1},\dots,s_k) \in \mathbb{N}^k_{m_1,\dots,m_k}$ and $x \in A_{s_1,\dots,s_k}$. Since $x \in E_k$ for all k, there is for every k an s_1 for which (s_1) is extendible to k. Since there are only finitely many $s_1 \leq m_1$, there is an s_1 such that (s_1) is extendible to arbitrarily large k. Similarly, for this s_1 there is an s_2 such that (s_1,s_2) is extendible to arbitrarily large k. Continuing inductively, a sequence $s = (s_1, s_2, \dots)$ is generated such that $x \in A_{s|n}$ for all n, i.e. $x \in \cap_n A_{s|n} \subseteq A$.

This completes the proof of (ii), and of (i) if μ^* is monotone regular.

For (i) in the case of general μ^*, let A, Y, Z be as above. Form the outer measure μ_W^*, where $W = Y \cup Z$. Then every set in $\mathcal{M}$ is μ_W^*-measurable. We also have that $\mu_W^*(X \setminus W) = 0$, hence $X \setminus W$ and also W are μ_W^*-measurable. Let ι be the restriction of μ_W^* to the μ_W^*-measurable sets, and ν^* the outer measure on X induced by ι. Then ν^* is a regular outer measure, hence monotone regular (XVII.4.5.32.), and every μ_W^*-measurable set is ν^*-measurable (XVII.4.5.35.); in particular, W and all sets in $\mathcal{M}$ are ν^*-measurable. So

$$\nu^*(W) = \iota(W) = \mu_W^*(W) = \mu(W) \ .$$

We also have $\nu^*(S) \geq \mu_W^*(S)$ for all $S \subseteq X$ (XVII.4.5.35.); in particular, $\nu^*(Y) \geq \mu_W^*(Y) = \mu^*(Y)$ and $\nu^*(Z) \geq \mu_W^*(Z) = \mu^*(Z)$. By the first part of the proof, A is ν^*-measurable, so

$$\mu^*(Y \cup Z) = \mu^*(W) = \nu^*(W) = \nu^*(W \cap A) + \nu^*(W \cap A^c) = \nu^*(Y) + \nu^*(Z) \geq \mu^*(Y) + \mu^*(Z)$$

and it follows that A is μ^*-measurable.

This completes the proof of XVII.4.6.7.. 👍

XVII.4.7. Local Measures on σ-Rings and δ-Rings

In some situations it is useful to consider "measures" defined on σ-rings or, more generally, δ-rings; in fact, some authors such as [Hal50] define measures using σ-rings instead of σ-algebras. The theory is largely identical with a few modest technical complications, especially after the extension theory of this chapter has been developed. The primary utility of the increased generality comes with considering signed and complex measures (); for ordinary measures there is little advantage. Although many authors call these more general functions "measures," we will reserve the term *measure* for ones defined on σ-algebras to avoid any confusion, and use the term "local measure" for the more general version (the term is nonstandard but will be justified in XVII.4.7.2.), but we will typically use the letters μ, ν, etc. for local measures as well as measures. ✋

XVII.4.7.1. DEFINITION. Let X be a set, and $\mathcal{D}$ a δ-ring of subsets of X. A premeasure (XVII.4.5.6.) on $\mathcal{D}$ is called a *local measure* on $\mathcal{D}$. A local measure is *finite* if it does not take the value $+\infty$.

A local measure on a δ-ring $\mathcal{D}$ is thus a function $\mu : \mathcal{D} \to [0, +\infty]$ with $\mu(\emptyset) = 0$ and which is countably additive on sequences of pairwise disjoint sets which are "uniformly bounded" by a set in $\mathcal{D}$. If $\mathcal{D}$ is a σ-ring, a local measure is unrestrictedly countably additive, thus is indistinguishable from a measure except that unrestricted complements are not allowed; in fact, the difference only occurs in situations where X is not a countable union of sets in $\mathcal{D}$, and thus essentially does not happen if μ is finite (XVII.4.7.3.).

XVII.4.7.2. If μ is a local measure on a δ-ring $\mathcal{D}$, The Extension Theorems XVII.4.5.8. and XVII.4.5.19. give two canonical extensions of μ to a measure on the σ-algebra $\mathcal{A}$ generated by $\mathcal{D}$ (and the proof of the Extension Theorem simplifies greatly in this case). It is better to work with the extension $\underline{\mu}$ of XVII.4.5.19.. Since $\mathcal{D}$ is a hereditary subset of $\mathcal{A}$ (XVI.1.4.8.), μ is thus the restriction of an honest measure to a hereditary subset of its σ-algebra, justifying the term "local measure." Here the canonical extension $\underline{\mu}$ can be replaced by any extension of μ to $\mathcal{A}$. Conversely, any such restriction of a measure to a hereditary subset of its σ-algebra is a local measure. In particular, if μ is a local measure on $\mathcal{D}$, and $Y \in \mathcal{D}$, then the restriction of μ to the σ-algebra $\mathcal{D}_Y$ of elements of $\mathcal{D}$ which are subsets of Y is a measure on $(Y, \mathcal{D}_Y)$, further justifying the term "local measure."

XVII.4.7.3. If μ is a local measure on a δ-ring $\mathcal{D}$, the canonical extension $\underline{\mu}$ to the generated σ-algebra $\mathcal{A}$ is often not finite even if μ is finite (consider counting measure on the δ-ring of finite subsets of an infinite set; see XVII.4.7.4. for a more interesting example). The local measure μ is not necessarily bounded ($\underline{\mu}$ will be finite if and only if μ is bounded), so there may be no finite measure on $\mathcal{A}$ extending μ. But if $\mathcal{D}$ is a σ-ring and μ is finite, then $\underline{\mu}$ is a finite measure on $\mathcal{A}$ extending μ and there is a $Y \in \mathcal{D}$ with $\underline{\mu}(X \setminus Y) = 0$ (Exercise XVII.5.3.12.), and thus μ is effectively just a measure on $\mathcal{D}_Y$.

XVII.4.7.4. EXAMPLE. Let $\mathcal{D}$ be the set of bounded Lebesgue measurable sets in $\mathcal{D}$. Then $\mathcal{D}$ is a δ-ring, and the restriction of Lebesgue measure on $\mathbb{R}$ to $\mathcal{D}$ is a finite local measure. This $\mathcal{D}$ could be replaced by the set of bounded Borel sets, or the collection of Lebesgue measurable sets (or Borel sets) of finite Lebesgue measure. In each case the (unique) extension is Lebesgue measure.

Canonical Local Measures Associated With a Measure

XVII.4.7.5. Let $(X, \mathcal{A}, \mu)$ be a measure space. There are two obvious local measures associated with μ. Let $\mathcal{F}_\mu = \{A \in \mathcal{A} : \mu(A) < +\infty\}$. Then $\mathcal{F}_\mu$ is a δ-ring, and the restriction of μ to $\mathcal{F}_\mu$ is finite. We can also let $\mathcal{S}_\mu$ be the set of sets in $\mathcal{A}$ of σ-finite measure; then $\mathcal{S}_\mu$ is a σ-ring, equal to $\mathcal{A}$ if and only if μ is σ-finite. We of course have $\mathcal{F}_\mu \subseteq \mathcal{S}_\mu$. The σ-algebra generated by $\mathcal{S}_\mu$ (and, *a fortiori*, $\mathcal{F}_\mu$) is not all of $\mathcal{A}$ in general (we could even have $\mathcal{S}_\mu = \{\emptyset\}$ in extreme cases). For integration purposes, the local measure $\mu|_{\mathcal{S}_\mu}$ carries all the information of μ. Note that if μ is a finite local measure on a δ-ring $\mathcal{D}$, and ν is an extension of μ (canonical or not) to the σ-algebra $\mathcal{A}$ generated by $\mathcal{D}$, then $\mathcal{F}_\nu$ may be strictly larger than $\mathcal{D}$: for example, if $\mathcal{D}$ is the set of bounded Borel sets in $\mathbb{R}$, so that $\mathcal{A}$ is the σ-algebra of Borel sets $\mathcal{B}$, and μ is the restriction of Lebesgue measure to $\mathcal{D}$, then λ is the unique extension of μ to $\mathcal{B}$, but $\mathcal{F}_\lambda$ is the set of Borel sets of finite Lebesgue measure, which is strictly larger than $\mathcal{D}$.

XVII.4.8. Radon Measures on $\mathbb{R}$

XVII.4.9. Lebesgue Measure and Radon Measures on $\mathbb{R}^n$

XVII.4.10. Nonmeasurable Subsets of $\mathbb{R}$

An interesting and rather subtle question is whether every subset of $\mathbb{R}$ is Lebesgue measurable. Using the Axiom of Choice, we construct a family of nonmeasurable subsets. This construction is due to Vitali.

XVII.4.10.1. Define a relation R on $\mathbb{R}$ by xRy if $y-x \in \mathbb{Q}$. It is easily checked that R is an equivalence relation. If $a \in \mathbb{R}$, then the equivalence class of a is

$$[a] = a + \mathbb{Q} = \{a + q : q \in \mathbb{Q}\} .$$

Thus the equivalence classes are countable and dense. (They are exactly the cosets of $\mathbb{Q}$ in the additive group $\mathbb{R}$.) As for any equivalence relation, the equivalence classes are pairwise disjoint and their union is $\mathbb{R}$.

XVII.4.10.2. Definition. (AC) Let P be a subset of $(0,1)$ which contains exactly one element of each equivalence class of R. If $q \in \mathbb{Q}$, set $P_q = P + q$.

Since each equivalence class is dense, it has nonempty intersection with $(0,1)$. The existence of such a set P is then guaranteed by the Axiom of Choice. (Any other actual interval could be used in place of $(0,1)$.)

XVII.4.10.3. Proposition. The sets $\{P_q : q \in \mathbb{Q}\}$ are pairwise disjoint, and $\cup_{q\in\mathbb{Q}} P_q = \mathbb{R}$.

Proof: If $x \in (P+q_1) \cap (P+q_2)$, then $x = p_1 + q_1 = p_2 + q_2$ for $p_1, p_2 \in P$. Then $p_2 - p_1 = q_1 - q_2 \in \mathbb{Q}$, so $p_1 R p_2$ and hence $p_1 = p_2$ since P contains only one element from any equivalence class. Thus also $q_1 = q_2$. If $x \in \mathbb{R}$, then xRp for some $p \in P$. Set $q = x - p \in \mathbb{Q}$; then $x = p + q \in P_q$. 👍

Now let $J = \mathbb{Q} \cap (-1,1)$, and set $N = \cup_{q\in J} P_q$.

XVII.4.10.4. Proposition. We have $(0,1) \subseteq N \subseteq (-1,2)$. Thus $1 \le \lambda^*(N) \le 3$.

Proof: Since $P \subseteq (0,1)$, it is obvious that $P_q \subseteq (-1,2)$ for any $q \in J$. For the other containment, let $x \in (0,1)$. Then $x = p + q$ for some $p \in P$, $q \in \mathbb{Q}$ by XVII.4.10.3.. Then $q = x - p \in (-1,1)$, so $x \in N$. 👍

XVII.4.10.5. Theorem. P is not Lebesgue measurable.

Proof: Suppose P is measurable. Then P_q is measurable for all q, and $\lambda(P_q) = \lambda(P)$; so N is measurable. If $\lambda(P) = 0$, then $\lambda(N) = \sum_{q\in J} \lambda(P_q) = 0$, contradicting XVII.4.10.4.. And if $\lambda(P) > 0$, then $\lambda(N) = \sum_{q\in J} \lambda(P_q) = \infty$ since J is infinite, again contradicting XVII.4.10.4.. 👍

In fact, we can do better:

XVII.4.10.6. PROPOSITION. If A is a Lebesgue measurable subset of P, then $\lambda(A) = 0$.

PROOF: Let $B = \cup_{q\in J}(A+q)$. The sets $A+q$ are pairwise disjoint since $A \subseteq P$. Since $\lambda(A+q) = \lambda(A)$ for all q, and J is infinite, we would have $\lambda(B) = \infty$ if $\lambda(A) > 0$. But $B \subseteq N \subseteq (-1, 2)$, so $\lambda(B) \leq 3$. Thus we must have $\lambda(A) = 0$ (and hence $\lambda(B) = 0$). 👍

XVII.4.10.7. THEOREM. (AC) Let $Y \subseteq \mathbb{R}$. If $\lambda^*(Y) > 0$, then Y contains a subset which is not Lebesgue measurable.

PROOF: For $q \in \mathbb{Q}$, let $Y_q = Y \cap P_q$. Then the Y_q are pairwise disjoint and $Y = \cup_{q\in\mathbb{Q}} Y_q$ by XVII.4.10.3.. If Y_q is measurable, then $\lambda(Y_q) = 0$ by XVII.4.10.6.. Thus, if all the Y_q are measurable, then $\lambda^*(Y) \leq \sum_{q\in\mathbb{Q}} \lambda^*(Y_q) = 0$. 👍

This result is only interesting if Y is Lebesgue measurable, since it is trivial otherwise. The important consequence is that every measurable set of positive measure contains a nonmeasurable subset.

XVII.4.10.8. Homeomorphisms of $\mathbb{R}$ do not necessarily preserve Lebesgue measurability (XVII.5.2.3.), i.e. Lebesgue measurability of subsets of $\mathbb{R}$ is not a topological property, although it is a metric property (in fact, see XIX.5.1.12..) Note that the property of being a Borel set is a topological property.

XVII.4.10.9. The Axiom of Choice was used in an essential way in the definition of P, so all results of this subsection depend on AC. In fact, R. SOLOVAY showed [] that (assuming that the existence of an inaccessible cardinal is consistent with ZFC; cf. ()) the existence of a nonmeasurable subset of $\mathbb{R}$ cannot be proved in ZF, i.e. it is consistent with ZF to assume that every subset of $\mathbb{R}$ is Lebesgue measurable. Specifically, he showed that if an inaccessible cardinal exists, then there is a model for ZF in which every subset of $\mathbb{R}$ is Lebesgue measurable; this model satisfies DC, but of course not AC. Thus even ZF+DC is not sufficient to prove the existence of a subset of $\mathbb{R}$ which is not Lebesgue measurable.

But the full Axiom of Choice is not needed to obtain a set which is not Lebesgue measurable. The argument only requires a choice function for the set of cosets of $\mathbb{Q}$ in $\mathbb{R}$, hence existence of a choice function for $\mathcal{P}(\mathbb{R})$ suffices, which will be automatic if $\mathbb{R}$ can be well ordered. Thus the Continuum Hypothesis is sufficient (but not necessary) to obtain Vitali's example (). For another example of a Lebesgue nonmeasurable set based on the CH, see XVIII.3.3.1..

Actually, assuming AC and some weak version of the CH, there is no finite continuous probability measure at all on $([0,1], \mathcal{P}([0,1]))$. See II.10.3. for a discussion. It is also known that ZF+(Hahn-Banach Theorem) suffices to prove existence of a Lebesgue nonmeasurable set [], and the Hahn-Banach Theorem is strictly weaker than the Axiom of Choice ().

Bernstein's Nonmeasurable Set

There is another construction of a nonmeasurable subset of $\mathbb{R}$, due to F. BERNSTEIN. This construction uses more machinery than VITALI'S, but works in great generality.

XVII.4.10.10. The general setting is an outer measure μ^* on a set X, for which there is a collection $\mathcal{C} = \{C_i : i \in I\}$ of subsets of X, with the following properties:

(i) $|I| \leq 2^{\aleph_0}$.

(ii) $|C_i| = 2^{\aleph_0}$ for all i.

(iii) $\mu^*(C_i) > 0$ for all i.

(iv) If A is any μ^*-measurable subset of X with $\mu^*(A) > 0$, then $C_i \subseteq A$ for some i.

Actually, $2^{\aleph_0}$ can be replaced by any other infinite cardinal here; the case of $2^{\aleph_0}$ is just the important one for applications.

XVII.4.10.11. Lebesgue outer measure on $\mathbb{R}$ has such a $\mathcal{C}$: the collection of closed subsets of $\mathbb{R}$ with positive Lebesgue measure. There are $2^{\aleph_0}$ closed subsets of $\mathbb{R}$ in all () (and $2^{\aleph_0}$ closed intervals, each of positive measure). Each closed set of positive measure is uncountable, hence has cardinality $2^{\aleph_0}$ by (). Condition (iv) is satisfied by XVII.4.4.5..

XVII.4.10.12. THEOREM. Let μ^* be an outer measure on a set X for which there is a $\mathcal{C}$ satisfying (i)–(iv). If Y is any subset of X with $\mu^*(Y) > 0$, there is a subset of Y which is not μ^*-measurable.

PROOF: Put a well ordering on I such that the set of predecessors of any $i \in I$ has cardinality strictly less than $2^{\aleph_0}$ (the Axiom of Choice guarantees that this can be done, by putting I in one-one correspondence with the cardinal $card(I)$). Inductively choose for each i two distinct elements x_i and y_i of C_i such that x_i and y_i are also distinct from the set $\{x_j, y_j : j < i\}$; this is possible since the cardinality of this set is strictly smaller than the cardinality of C_i. Let $A = \{x_i : i \in I\}$.

Let $Y \subseteq X$ with $\mu^*(Y) > 0$. To show that Y contains a subset which is not μ^*-measurable, we may assume that Y is μ^*-measurable (since otherwise Y itself is the desired subset). We claim $A \cap Y$ is not μ^*-measurable. If $A \cap Y$ (and hence also $Y \setminus A$) is μ^*-measurable, we cannot have $\mu^*(A \cap Y) > 0$, since then $C_i \subseteq (A \cap Y)$ for some i; but $y_i \in C_i \setminus A$, a contradiction. Thus $\mu^*(A \cap Y) = 0$. Similarly, we cannot have $\mu^*(Y \setminus A) > 0$, so $\mu^*(Y \setminus A) = 0$. But then $\mu^*(Y) = \mu^*(A \cap Y) + \mu^*(Y \setminus A) = 0$, contradicting the assumption that $\mu^*(Y) > 0$. 👍

Note that AC is used twice: well ordering I and choosing the x_i and y_i.

XVII.4.10.13. This result applies more generally to any purely nonatomic Borel regular Borel outer measure on a Polish space, whose restriction to the Borel sets is σ-finite: an infinite Polish space has $2^{\aleph_0}$ Borel sets (), and an uncountable Borel set in a Polish space has cardinality $2^{\aleph_0}$ (). Compare with XIII.13.9.14..

XVII.5. Measurable Functions

A crucial companion notion to measure spaces is measurable functions. Although they can be defined more generally (XVI.1.6.2.), we will restrict to real-valued or extended real-valued functions, which are by far the most important case.

XVII.5.1. Measurable Functions on a Measure Space

XVII.5.1.1. If $(X, \mathcal{A}, \mu)$ is a measure space, we say a real-valued function on X is *μ-measurable* if it is $\mathcal{A}$-measurable in the sense of XVI.2.2.2., i.e. $f^{-1}(B) \in \mathcal{A}$ for every Borel set B in $\mathbb{R}$. This definition has nothing specifically to do with μ, but only the σ-algebra $\mathcal{A}$ (which recall is part of the definition of μ). There is a useful slight variation:

XVII.5.1.2. Definition. Let μ^* be an outer measure on a set X, and $\mathcal{A}$ the σ-algebra of μ^*-measurable subsets of X. A real-valued function is *μ^*-measurable* if it is $\mathcal{A}$-measurable in the sense of XVI.2.2.2..

XVII.5.1.3. Proposition XVI.2.2.4. can be rephrased in this context, using XVII.4.3.2.: f is μ^*-measurable if and only if, for every $Y \subseteq X$ with $\mu^*(Y) < \infty$, and every $r \in \mathbb{R}$,

$$\mu^*(Y) \geq \mu^*(Y \cap \{x \in X : f(x) \leq r\}) + \mu^*(Y \cap \{x \in X : f(x) > r\}) \ .$$

A similar statement holds for the other criteria in XVI.2.2.4..

There is a useful variation (cf. [Fed69, 2.3.2(7)]):

XVII.5.1.4. Proposition. Let μ^* be an outer measure on a set X, and $f : X \to \mathbb{R}$. The following are equivalent:

(i) f is μ^*-measurable.

(ii) For every $Y \subseteq X$, $\mu^*(Y) < \infty$, and $a, b \in \mathbb{R}$, $a < b$,

$$\mu^*(Y) \geq \mu^*(Y \cap \{x \in X : f(x) \leq a\}) + \mu^*(Y \cap \{x \in X : f(x) \geq b\}) \ .$$

(iii) There is a dense subset D of $\mathbb{R}$ such that, for every $Y \subseteq X$, $\mu^*(Y) < \infty$, and $a, b \in D$, $a < b$,

$$\mu^*(Y) \geq \mu^*(Y \cap \{x \in X : f(x) \leq a\}) + \mu^*(Y \cap \{x \in X : f(x) \geq b\}) \ .$$

In (ii) and (iii), the inequalities can be replaced by strict inequalities.

Proof: (i) $\Rightarrow$ (ii) by XVI.2.2.4. and monotonicity, and (ii) $\Rightarrow$ (iii) is trivial.

(iii) $\Rightarrow$ (i): Fix D, Y, and $r \in \mathbb{R}$, and set $A = \{x \in X : f(x) \leq r\}$. For each $k \in \mathbb{N}$, set

$$B_k = Y \cap \left\{ x \in X : r + \frac{1}{k+1} \leq f(x) \leq r + \frac{1}{k} \right\} \ .$$

We claim that if K is any finite subset of $\mathbb{N}$ consisting entirely of even numbers or entirely of odd numbers, then

$$\mu^* \left(\bigcup_{k \in K} B_k \right) \geq \sum_{k \in K} \mu^*(B_k) \ .$$

The proof is by induction on $|K|$. If $|K| = 1$ the statement is trivial. Now suppose $|K| > 1$ and j is the largest number in K. Set $C_K = \cup_{k\in K} B_k$, $u = \sup\{f(x) : x \in B_j\}$, and $v = \inf\{f(x) : x \in \cup_{k\in K\setminus\{j\}} B_k\}$. Then $u < v$. Let $a, b \in D$, $u < a < b < v$. Then

$$\mu^*(C_K) \geq \mu^*(C_K \cap \{x \in X : f(x) \leq a\}) + \mu^*(C_K \cap \{x \in X : f(x) \geq b\})$$

$$\geq \mu^*(B_j) + \mu^*(\cup_{k\in K\setminus\{j\}} B_k) \geq \mu^*(B_j) + \sum_{k\in K\setminus\{j\}} \mu^*(B_k) \ .$$

Thus we have

$$\sum_{k=1}^{\infty} \mu^*(B_k) \leq \mu^*\left(\bigcup_{k\ odd} B_k\right) + \mu^*\left(\bigcup_{k\ even} B_k\right) \leq 2\mu^*(Y) < \infty$$

so, if $\epsilon > 0$, there is an n such that

$$\epsilon > \sum_{k=n}^{\infty} \mu^*(B_k) \geq \mu^*\left(\bigcup_{k=n}^{\infty} B_k\right) = \mu^*\left(Y \cap \left\{x \in X : r < f(x) \leq r + \frac{1}{n}\right\}\right)$$

so

$$\mu^*(Y \setminus A) \leq \mu^*\left(Y \cap \left\{x \in X : r < f(x) \leq r + \frac{1}{n}\right\}\right) + \mu^*\left(Y \cap \left\{x \in X : f(x) \geq r + \frac{1}{n}\right\}\right)$$

$$< \mu^*\left(Y \cap \left\{x \in X : f(x) \geq r + \frac{1}{n}\right\}\right) + \epsilon \ .$$

If $c, d \in D$, $r < c < d < r + \frac{1}{n}$,

$$\mu^*(Y \cap A) + \mu^*(Y \setminus A) - \epsilon < \mu^*(Y \cap A) + \mu^*\left(Y \cap \left\{x \in X : r < f(x) \leq r + \frac{1}{n}\right\}\right)$$

$$\leq \mu^*(Y \cap \{x \in X : f(x) \leq c\}) + \mu^*(Y \cap \{x \in X : f(x) \geq d\}) \leq \mu^*(Y) \ .$$

Since $\epsilon > 0$ is arbitrary, the result follows. 👍

XVII.5.1.5. If the outer measure μ^* is monotone regular (XVII.4.5.30.), the proof simplifies greatly, since then for any ϵ there is automatically an n with

$$\mu^*(Y \setminus A) < \mu^*\left(Y \cap \left\{x \in X : f(x) \geq r + \frac{1}{n}\right\}\right) + \epsilon \ .$$

XVII.5.2. Lebesgue Measurable Functions

The most important class of functions from $\mathbb{R}$ to $\mathbb{R}$ for advanced analysis purposes is the class of Lebesgue measurable functions:

XVII.5.2.1. Definition. A function $f : \mathbb{R} \to \mathbb{R}$ is *Lebesgue measurable* if it is λ^*-measurable in the sense of XVII.5.1.2., i.e. if $f^{-1}(B)$ is a Lebesgue measurable set for every Borel set $B \subseteq \mathbb{R}$.

XVII.5.2.2. There is a subtlety in this definition. Note that the criterion for a function to be Lebesgue measurable is that the preimage of every *Borel* set be Lebesgue measurable, not that the preimage of every Lebesgue measurable set is Lebesgue measurable; in fact the preimage of a Lebesgue measurable set under a Lebesgue measurable function is not necessarily Lebesgue measurable (XVII.5.2.3.). In other words, a Lebesgue measurable function from $\mathbb{R}$ to $\mathbb{R}$ is an $(\mathcal{L}, \mathcal{B})$-measurable function in the sense of XVI.1.6.2., not necessarily an $(\mathcal{L}, \mathcal{L})$-measurable function. This may seem like a curious definition, but experience has shown that it is the most useful and appropriate one; too small a class of functions is $(\mathcal{L}, \mathcal{L})$-measurable (not even every strictly increasing continuous function is $(\mathcal{L}, \mathcal{L})$-measurable! See XVII.5.2.3..) The definition is much more natural if it is regarded as a special case of XVI.2.2.2..

XVII.5.2.3. Proposition. (AC) The preimage of a Lebesgue measurable set under a Lebesgue measurable function is not necessarily Lebesgue measurable. In fact, there is a strictly increasing continuous function (homeomorphism) $f : \mathbb{R} \to \mathbb{R}$ and a measurable subset $A \subseteq \mathbb{R}$ such that $f^{-1}(A)$ is not Lebesgue measurable.

Proof: Let K be the Cantor set, and K_α the generalized Cantor set of positive measure from (). There is a strictly increasing continuous function $f : \mathbb{R} \to \mathbb{R}$ with $f(K_\alpha) = K$. By XVII.4.10.7., there is a nonmeasurable subset B of K_α. Let $A = f(B)$; since $A \subseteq K$ and $\lambda(K) = 0$, A is measurable and $\lambda(A) = 0$. But $B = f^{-1}(A)$ is nonmeasurable.

A Criterion for Lebesgue Measurability

We have the following special case of XVI.2.2.4.:

XVII.5.2.4. Proposition. Let $f : \mathbb{R} \to \mathbb{R}$ a function. Then f is Lebesgue measurable if and only if any of the following conditions are satisfied:

(i) $f^{-1}(U) \in \mathcal{L}$ for every open set $U \subseteq \mathbb{R}$.

(ii) $f^{-1}(E) \in \mathcal{L}$ for every closed set $E \subseteq \mathbb{R}$.

(iii) $f^{-1}(U) \in \mathcal{L}$ for every open interval $U \subseteq \mathbb{R}$.

(iv) $f^{-1}((-\infty, a)) \in \mathcal{L}$ for every $a \in \mathbb{R}$.

(v) $f^{-1}((-\infty, a]) \in \mathcal{L}$ for every $a \in \mathbb{R}$.

(vi) $f^{-1}((a, +\infty)) \in \mathcal{L}$ for every $a \in \mathbb{R}$.

(vii) $f^{-1}([a, +\infty)) \in \mathcal{L}$ for every $a \in \mathbb{R}$.

(viii) $f^{-1}((-\infty, a)) \in \mathcal{L}$ for every $a \in \mathbb{Q}$.

(ix) $f^{-1}((-\infty, a]) \in \mathcal{L}$ for every $a \in \mathbb{Q}$.

(x) $f^{-1}((a, +\infty)) \in \mathcal{L}$ for every $a \in \mathbb{Q}$.

(xi) $f^{-1}([a, +\infty)) \in \mathcal{L}$ for every $a \in \mathbb{Q}$.

This proposition is one of the reasons why Lebesgue measurability is defined as it was.

XVII.5.2.5. Corollary. Every continuous function from $\mathbb{R}$ to $\mathbb{R}$ is Lebesgue measurable (in fact, Borel measurable).

Pointwise Limits

Because $(\mathbb{R}, \mathcal{L}, \lambda)$ is complete, we have:

XVII.5.2.6. Proposition. Let $f, g : \mathbb{R} \to \mathbb{R}$. If $f = g$ a.e. and f is Lebesgue measurable, so is g.

Proof: Let $C = \{t \in \mathbb{R} : f(t) \neq g(t)\}$. Then by assumption C is a subset of a λ-null set, hence λ-null by completeness. Let $a \in \mathbb{R}$. Then $A := \{t : g(t) < a\}$ differs from $\{t : f(t) < a\} \in \mathcal{L}$ by a subset of C, which is in $\mathcal{L}$ by completeness, so $A \in \mathcal{L}$. 👍

We can then give a generalization of XVI.2.2.9.:

XVII.5.2.7. Proposition. Let (f_n) be a sequence of Lebesgue measurable functions, with $f_n \to f$ pointwise a.e. Then f is Lebesgue measurable.

Proof: Let $C = \{t : f_n(t) \not\to f(t)\}$. By assumption, C is λ-null. For each n, set

$$g_n(t) = \begin{cases} f_n(t) & \text{if} \quad t \notin C \\ 0 & \text{if} \quad t \in C \end{cases}.$$

Then $g_n = f_n$ a.e., so is Lebesgue measurable, and $g_n \to g$ pointwise, where

$$g(t) = \begin{cases} f(t) & \text{if} \quad t \notin C \\ 0 & \text{if} \quad t \in C \end{cases}.$$

By XVI.2.2.9., g is Lebesgue measurable, and $f = g$ a.e., so f is Lebesgue measurable by XVII.5.2.6.. 👍

Other Properties

XVII.5.2.8. We summarize the other important properties of Lebesgue measurable functions:

A sum or product of Lebesgue measurable functions is Lebesgue measurable (XVI.2.4.11.).

The supremum or infimum of a pointwise bounded sequence of Lebesgue measurable functions is Lebesgue measurable (XVI.2.2.7.).

If f is Lebesgue measurable and g is Borel measurable (e.g. continuous), then $g \circ f$ is Lebesgue measurable (XVI.2.4.8.). [**Caution:** $f \circ g$ is not necessarily Lebesgue measurable!] In particular, if f is Lebesgue measurable, so are f_+, f_-, and $|f|$. If $f \geq 0$, then $\sqrt{f}$ is also Lebesgue measurable. ✋

Lebesgue Measurability vs. Borel Measurability

XVII.5.2.9. Since $\mathcal{B} \subseteq \mathcal{L}$, every Borel measurable function () is Lebesgue measurable. In particular, every continuous function is Lebesgue measurable.

Of course, not every Lebesgue measurable function is Borel measurable (e.g. χ_A for $A \in \mathcal{L} \setminus \mathcal{B}$). However:

XVII.5.2.10. PROPOSITION. Let f be a Lebesgue measurable function. Then there is a Borel measurable function g with $f = g$ a.e. If f is bounded below [resp. bounded above], we may additionally require that $g \leq f$ [resp. $g \geq f$].

PROOF: First suppose $f = \sum_{k=1}^{n} \alpha_k \chi_{A_k}$ is a simple function. By adding a constant, we may assume f is nonnegative. For each k there is an F_σ $E_k \subseteq A_k$ with $\lambda(A_k \setminus E_k) = 0$ (). Then $g = \sum_{k=1}^{n} \alpha_k \chi_{E_k}$ is a nonnegative Borel measurable simple function with $g \leq f$ and $g = f$ a.e.

Now suppose f is nonnegative. Let (f_n) be a sequence of simple functions with $0 \leq f_n \leq f$ for all n and $f_n \to f$ pointwise, so $f = \sup f_n$ (). Let g_n be a nonnegative Borel measurable simple function with $g_n \leq f_n$ and $g_n = f_n$ on the complement of a null set C_n. Set $g = \sup g_n$. Then g is Borel measurable (), $g \leq f$ since $g_n \leq f_n \leq f$ for all n, and $g = f$ on the complement of the null set $C = \cup_n C_n$.

If f is bounded below, then by adding a constant f is nonnegative, so the previous argument proves the last statement; for the parenthetical part consider $-f$.

Finally, for a general f let f_+ and f_- be the positive and negative parts of f. Then f_+ and f_- are Lebesgue measurable (). Let g_+ and g_- be Borel measurable functions equal to f_+ and f_- a.e. respectively. Then $g = g_+ - g_-$ is Borel measurable and equal to $f = f_+ - f_-$ a.e. 👍

It is unclear whether the inequalities can be satisfied in general if f is unbounded (they can be easily satisfied if g is allowed to take the values $\pm\infty$).

See XVIII.6.7.3. for an alternate proof using the Radon-Nikodym Theorem.

XVII.5.3. Exercises

XVII.5.3.1. (a) There is a sequence (S_i) of pairwise disjoint Borel subsets of $[1, \infty)$, each of infinite Lebesgue measure. [Let (N_i) be a sequence of pairwise disjoint infinite subsets of $\mathbb{N}$, e.g. by identifying $\mathbb{N}$ with $\mathbb{N} \times \mathbb{N}$. Let $S_i = \cup_{n \in N_i} [n, n+1)$.]

(b) Let $\mathcal{F}$ be the set of finite subsets of $\mathbb{N}$. $\mathcal{F}$ is countable; let i be a bijection from $\mathcal{F}$ to $\mathbb{N}$.

(c) Arrange the bounded open intervals in $\mathbb{R}$ with rational endpoints into a sequence (J_n), with each interval appearing infinitely often in the sequence.

(d) For each n, let

$$A_n = J_n \cup \left[\bigcup_{n \in F} S_{i(F)} \cap [n, \infty) \right]$$

(i.e. the union runs over all sets $F \in \mathcal{F}$ with $n \in F$) and let $\mathcal{S}$ be the set of finite intersections of the A_n and their complements. Then $\mathcal{S}$ is a semialgebra (). Show that every nonempty set in $\mathcal{S}$ has infinite Lebesgue measure. [If $E = A_{n_1} \cap \cdots \cap A_{n_k} \cap A_{m_1}^c \cap \cdots \cap A_{m_r}^c$, if $n_i = m_j$ for some i, j, then $E = \emptyset$, and otherwise $S_{i(\{n_1, \ldots, n_k\})} \cap [p, \infty) \subseteq E$, where $p = \max\{n_1, \ldots, n_k\}$. Note that $S_i \cap [p, \infty)$ has infinite Lebesgue measure

for every i and p.] If $\mathcal{A}$ is the algebra generated by $\mathcal{S}$, then $\mathcal{A}$ consists of finite disjoint unions of sets in $\mathcal{S}$ (), and hence every nonempty set in $\mathcal{A}$ has infinite Lebesgue measure.

(e) If J is a bounded open interval with rational endpoints, then there is an infinite sequence (n_k) such that $J_{n_k} = J$ for all k. Then $\cap_{k=1}^{\infty} A_{n_k} = J$. Thus J is in the σ-algebra generated by $\mathcal{S}$ (or $\mathcal{A}$). Since such intervals generate $\mathcal{B}$ as a σ-algebra, the σ-algebra generated by $\mathcal{S}$ (or $\mathcal{A}$) is $\mathcal{B}$.

(f) The restriction of λ to $\mathcal{S}$ (or $\mathcal{A}$) is not σ-finite, and λ is not the measure induced on $\mathcal{B}$ from $\lambda|_{\mathcal{S}}$ or $\lambda|_{\mathcal{A}}$ by the Carathéodory extension process.

(g) If $(X, \mathcal{B}, \mu)$ is a measure space with $\mu(X) = \infty$, is there always an algebra $\mathcal{A}$ in $\mathcal{B}$ which generates $\mathcal{B}$ as a σ-algebra, with the property that $\mu(A) = \infty$ for every nonempty $A \in \mathcal{A}$?

XVII.5.3.2. Let $X = \{x_1, x_2, x_3\}$ be a set with three elements. If $A \subseteq X$, let $\mu^*(A) = 0$ if $A = \emptyset$, $\mu^*(A) = 1$ if $|A| = 1$ or if $|A| = 2$, and $\mu^*(A) = 2$ if $|A| = 3$.

(a) Show that μ^* is an outer measure on X which is not regular.

(b) If $A = \{x_1, x_2\}$, show that $\mu^*(A) + \mu^*(X \setminus A) = \mu^*(X)$, but A is not μ^*-measurable. [Consider $Y = \{x_1, x_3\}$.]

XVII.5.3.3. Prove the following generalization of (). Let μ^* be an outer measure on a set X, and $\mathcal{M}$ the σ-algebra of μ^*-measurable sets.

(a) If (A_n) is a pairwise disjoint sequence of sets in $\mathcal{M}$ with $A = \cup_{n=1}^{\infty} A_n$, and Y is any subset of X, then $\mu^*(Y \cap A) = \sum_{n=1}^{\infty} \mu^*(Y \cap A_n)$.

(b) If $B_1 \subseteq B_2 \subseteq \cdots$ is an increasing sequence in $\mathcal{M}$ with $B = \cup_{n=1}^{\infty} B_n$, and Y is any subset of X, then $\mu^*(Y \cap B) = \sup_n \mu^*(Y \cap B_n)$.

(c) If $C_1 \supseteq C_2 \supseteq \cdots$ is a decreasing sequence in $\mathcal{M}$ with $C = \cap_{n=1}^{\infty} C_n$, and Y is any subset of X with $\mu^*(Y \cap C_1) < \infty$, then $\mu^*(Y \cap C) = \inf_n \mu^*(Y \cap C_n)$.

XVII.5.3.4. If μ^* is an outer measure on X and $A, Y \subseteq X$ with A μ^*-measurable, show that

$$\mu^*(A \cup Y) + \mu^*(A \cap Y) = \mu^*(A) + \mu^*(Y) \ .$$

XVII.5.3.5. Let μ^* be a regular outer measure on a set X. If $A, B \subseteq X$ with $A \cup B$ μ^*-measurable and $\mu^*(A \cup B) = \mu^*(A) + \mu^*(B) < \infty$, show that A and B are μ^*-measurable.

XVII.5.3.6. Let X and Y be sets, $f : X \to Y$ a function, and μ^* an outer measure on X. For $B \subseteq Y$, set $\nu^*(B) = \mu^*(f^{-1}(B))$. Show that ν^* is an outer measure on Y. This outer measure is usually denoted $f_*(\mu^*)$.

XVII.5.3.7. Let $\{\mu_i^*\}$ be a collection of outer measures on a set X, and let $\mu^* = \sup \mu_i^*$. Show that μ^* is an outer measure.

XVII.5.3.8. Let $X = (0,2]$, $\mathcal{A} = \{\emptyset, (0,1], (1,2], (0,2]\}$. Let μ be the restriction of Lebesgue measure to $\mathcal{A}$, and μ^* the induced outer measure on X.

(a) Describe $\mu^*(Y)$ for a general $Y \subseteq X$, and compare it to $\lambda^*(Y)$. Find the σ-algebra of μ^*-measurable subsets of X.

(b) Show that $(X, \mathcal{A}, \mu)$ is a finite complete measure space, but that μ extends to a measure (e.g. λ) on a strictly larger σ-algebra. Show that λ^* is not $\mathcal{A}$-regular.

XVII.5.3.9. Let $\mathcal{U}$ be the collection of open sets in $\mathbb{R}^n$, and let $\mathcal{Q}$ be the set of bounded open intervals with rational endpoints. Show that $\mathcal{S}(\mathcal{U}) = \mathcal{S}(\mathcal{Q})$ and that this collection of sets is the same as $\mathcal{S}(\mathcal{K})$, $\mathcal{S}(\mathcal{F})$, and $\mathcal{S}(\mathcal{B})$ of XVII.4.6.6.. These sets are usually just called the *Suslin subsets* of $\mathbb{R}^n$.

XVII.5.3.10. Show that the collection $\mathcal{S}(\mathcal{Q})$ of Suslin subsets of $\mathbb{R}^n$ (Exercise XVII.5.3.9.) has cardinality $2^{\aleph_0}$. [Show that there are exactly $2^{\aleph_0}$ Suslin schemes in $\mathcal{Q}$.] Since $\mathcal{B} \subseteq \mathcal{S}(\mathcal{Q})$, this gives a cleaner proof than () that $\mathcal{B}$ has cardinality $2^{\aleph_0}$.

XVII.5.3.11. Let $\mathcal{E}$ be a nonempty collection of subsets of a set X.

(a) If $\mathcal{A} = \mathcal{S}(\mathcal{E}) \cap \widetilde{\mathcal{S}(\mathcal{E})}$ is nonempty, it is a σ-algebra and the largest σ-algebra contained in $\mathcal{S}(\mathcal{E})$ (cf. XVI.1.7.2.).

(b) Show that $\mathcal{S}(\mathcal{E}) \cap \widetilde{\mathcal{S}(\mathcal{E})}$ can be empty.

XVII.5.3.12. Let μ be a finite local measure on a σ-ring $\mathcal{D}$ of subsets of X, and let $\mathcal{A}$ be the σ-algebra generated by $\mathcal{D}$.

(a) Show that μ is bounded on $\mathcal{D}$.

(b) Let $M = \sup\{\mu(A) : A \in \mathcal{D}\}$. For each n let $A_n \in \mathcal{D}$ with $\mu(A_n) \geq M - \frac{1}{n}$, and let $Y = \cup_n A_n \in \mathcal{D}$. Show that $\mu(Y) = M$.

(c) For $A \in \mathcal{A}$, define $\nu(A) = \mu(A \cap Y)$. Show that ν is a (finite) measure on $(X, \mathcal{A})$ extending μ.

In probability, $\mathbf{P}$ is usually used for a measure instead of μ. Thus $\mathbf{P}(E)$ is the probability (measure) of E, and $\mathbf{E}(\mathbf{X}) = \int \mathbf{X}\, d\mathbf{P}$ is the expectation (integral) of $\mathbf{X}$.

XVII.6. Measures on Metric Spaces

Many important outer measures (e.g. Lebesgue outer measure) are defined on metric spaces, and behave nicely relative to the topology of the space.

XVII.6.1. Metric Outer Measures and Borel Measures

XVII.6.1.1. DEFINITION. Let (X, ρ) be a metric space, and let μ^* be an outer measure on X. The outer measure μ^* is a *metric outer measure* on X (with respect to ρ) if, whenever $A, B \subseteq X$ and $\rho(A, B) > 0$ (), we have $\mu^*(A \cup B) = \mu^*(A) + \mu^*(B)$.

XVII.6.1.2. EXAMPLE. By Exercise (), Lebesgue outer measure is a metric outer measure on $\mathbb{R}$ with the usual metric.

XVII.6.1.3. PROPOSITION. Let (X, ρ) be a metric space, and μ^* an outer measure on X for which every closed set is μ^*-measurable. Then μ^* is a metric outer measure.

PROOF: If $A, B \subseteq X$ with $\rho(A, B) > 0$, then $B \cap \bar{A} = \emptyset$. Since $\bar{A}$ is closed, we have

$$\mu^*(A \cup B) = \mu^*((A \cup B) \cap \bar{A}) + \mu^*((A \cup B) \cap (\bar{A})^c) = \mu^*(A) + \mu^*(B) \ .$$

The main theorem of this subsection is the converse:

XVII.6.1.4. THEOREM. Let (X, ρ) be a metric space, and μ^* a metric outer measure on X with respect to ρ. Then every Borel set in X is μ^*-measurable.

PROOF: Since the collection of μ^*-measurable sets is a σ-algebra, it suffices to show that every closed set F in X is μ^*-measurable. Fix $E \subseteq X$ with $\mu^*(E) < \infty$, and let $A = E \cap F$, $B = E \cap F^c$. It suffices to show that $\mu^*(E) \geq \mu^*(A) + \mu^*(B)$.

For $n \in \mathbb{N}$, set

$$B_n = \left\{ x \in B : \rho(x, F) \geq \frac{1}{n} \right\} \ .$$

We have $B = \cup_{n=1}^{\infty} B_n$ since F is closed; and we have $\mu^*(A \cup B_n) = \mu^*(A) + \mu^*(B_n)$ for each n since μ^* is a metric outer measure.

If μ^* were known to be monotone regular, the proof would be trivial:

$$\mu^*(E) = \mu^*(A \cup B) = \sup_n \mu^*(A \cup B_n) = \sup_n [\mu^*(A) + \mu^*(B_n)] = \mu^*(A) + \sup_n \mu^*(B_n) = \mu^*(A) + \mu^*(B) \ .$$

In general, we must show that μ^* has enough vestiges of monotone regularity to get the conclusion.

For each n let $D_n = B_{n+1} \setminus B_n$. We have $\rho(D_{n+1}, B_n) \geq \frac{1}{n} - \frac{1}{n+1} = \frac{1}{n(n+1)}$ by the triangle inequality, and thus $\mu^*(B_n \cup D_{n+1}) = \mu^*(B_n) + \mu^*(D_{n+1})$ for all n; since $B_n \cup D_{n+1} \subseteq B_{n+2}$, we have $\mu^*(B_n) + \mu^*(D_{n+1}) \leq \mu^*(B_{n+2})$ for all n (this also holds for $n = 0$ if we set $B_0 = \emptyset$). Inductively, we get

$$\sum_{k=1}^{n} \mu^*(D_{2k-1}) \leq \mu^*(B_{2n}) \leq \mu^*(E) < \infty$$

for all n. Similarly,

$$\sum_{k=1}^{n} \mu^*(D_{2k}) \leq \mu^*(B_{2n+1}) \leq \mu^*(E) < \infty$$

for all n. Thus $\sum_{k=1}^{\infty} \mu^*(D_k)$ converges; hence, for any $\epsilon > 0$ there is an n such that $\sum_{k=n+1}^{\infty} \mu^*(D_k) < \epsilon$. By countable subadditivity we then have for this n that

$$\mu^*(B) \leq \mu^*(B_n) + \sum_{k=n+1}^{\infty} \mu^*(D_k) < \mu^*(B_n) + \epsilon \ .$$

Thus $\mu^*(B) = \sup_n \mu^*(B_n)$. We then have

$$\mu^*(E) \geq \sup_n \mu^*(A \cup B_n) = \sup_n [\mu^*(A) + \mu^*(B_n)] = \mu^*(A) + \sup_n \mu^*(B_n) = \mu^*(A) + \mu^*(B) \ .$$

Borel Measures

XVII.6.1.5. DEFINITION. Let X be a topological space. A *Borel measure* on X is a measure on $(X, \mathcal{B})$, where $\mathcal{B}$ is the σ-algebra of Borel subsets of X.

XVII.6.1.6. Suppose X is a metrizable topological space, and ρ is a metric on X giving the topology. If μ^* is an outer measure on X which is a metric outer measure with respect to ρ, then μ^* defines a Borel measure on X by XVII.6.1.4.. Conversely, a Borel measure μ on X defines a (regular) outer measure μ^* on X by

$$\mu^*(Y) = \inf\{\mu(B) : B \text{ Borel}, Y \subseteq B\} = \min\{\mu(B) : B \text{ Borel}, Y \subseteq B\}$$

for $Y \subseteq X$ (this makes no reference to ρ, and works whether or not X is metrizable) which is a metric outer measure for ρ by XVII.6.1.3.. Thus every Borel measure on a metric space arises this way from a (regular) metric outer measure.

Borel measures on metric spaces are not regular in general (XVII.6.1.13.). But they are under a mild hypothesis:

XVII.6.1.7. DEFINITION. Let X be a topological space and μ a Borel measure on X. Then μ is *locally finite* if every (Borel) set in X of finite measure is contained in an open set of finite measure.

XVII.6.1.8. Some references define a locally finite measure to be a (Borel) measure for which every point has a neighborhood of finite measure. We will call such a measure *neighborhood-finite*. In good cases the notions are the same (XVII.6.1.14.). Our definition turns out to be more useful.

XVII.6.1.9. EXAMPLES. (i) Any finite Borel measure is locally finite.

(ii) Lebesgue measure on $\mathbb{R}^n$ is locally finite.

(iii) Counting measure on $\mathbb{Q}$ with its usual metric is not locally finite (every nonempty open set has infinite measure). So a σ-finite Borel measure on a separable metric space need not be locally finite.

(iv) Let $X = \{p\}$ and μ the measure on X with $\mu(X) = \infty$. Then μ is locally finite but not neighborhood-finite: $\{p\}$ is an infinite atom.

(v) Let $\mathcal{H}$ be a nonseparable Hilbert space. Let $\{\xi_i : i \in I\}$ be an orthonormal basis for $\mathcal{H}$ and $Y = \{3\xi_i : i \in I\}$. Then Y is a closed subset of $\mathcal{H}$, and any two points of Y are distance $3\sqrt{2} > 4$ apart. Define a Borel measure on $\mathcal{H}$ by setting $\mu(A) = 0$ if A is a (Borel) set which is the union of a subset of Y and a set which can be covered by countably many open balls of radius 1, and $\mu(A) = \infty$ otherwise. It is easily checked that μ is a measure, and it is neighborhood-finite since every open ball of radius ≤ 1 has measure 0. Y is a Borel set of finite measure; but if U is an open set of finite measure containing Y, then $U = A \cup V$, where $A \subseteq Y$ and V can be covered by a sequence (B_n) of open balls of radius 1. We have that $W := U \setminus Y \subseteq V$, and since the interior of Y is empty $Y \subseteq \bar{W} \subseteq \bar{V}$. For each $i \in I$ let $n(i)$ be the first n such that the distance from $3\xi_i$ to B_n is less than 1. If $i \neq j$, $n(i) \neq n(j)$ since $\|3\xi_i - 3\xi_j\| > 4$, so $i \mapsto n(i)$ is an injective map from I to $\mathbb{N}$, contradicting that I is uncountable. Thus μ is not locally finite.

A locally finite Borel measure on a reasonable space is regular in the following sense:

XVII.6.1.10. THEOREM. Let X be a topological space in which every open set is an F_σ (e.g. a metrizable space), μ a locally finite Borel measure on X, and $\epsilon > 0$. Then for every Borel set A in X with $\mu(A) < \infty$, there is a closed set $E \subseteq A$ and an open set U containing A with $\mu(U \setminus E) < \epsilon$.

PROOF: First assume μ is finite. Let $\mathcal{A}$ be the collection of all subsets of X for which the conclusion holds for every $\epsilon > 0$. If V is an open set and $\epsilon > 0$, there is an increasing sequence (F_n) of closed sets with $\cup_n F_n = V$, so $\mu(U) = \sup_n \mu(F_n)$. So if $\mu(V) < \infty$, there is an n with $\mu(F_n) > \mu(V) - \epsilon$. Thus, taking $U = V$ and $E = F_n$ for sufficiently large n, we have $V \in \mathcal{A}$.

We now show that $\mathcal{A}$ is a σ-algebra. $\mathcal{A}$ is obviously closed under complements. Every clopen set Z is in $\mathcal{A}$ (with $E = U = Z$), and in particular $X, \emptyset \in \mathcal{A}$. If (A_n) is a sequence in $\mathcal{A}$ and $A = \cup_n \mathcal{A}_n$, for each k there are F_k and U_k with $F_k \subseteq A_k \subseteq U_k$, F_k closed, U_k open, and $\mu(U_k \setminus F_k) < 2^{-k}\epsilon$. Set $U = \cup_k U_k$ and, for each m,

$$E_m = \cup_{k=1}^m F_k \ .$$

We have $E_m \subseteq A \subseteq U$ for all m, U is open, E_m is closed, and

$$\mu\left(U \setminus \bigcup_{k=1}^{\infty} F_k\right) = \mu\left(\bigcup_{k=1}^{\infty} [U_k \setminus F_k]\right) \leq \sum_{k=1}^{\infty} \mu(U_k \setminus F_k) < \epsilon$$

and, since

$$U \setminus \bigcup_{k=1}^{\infty} F_k = \bigcap_{m=1}^{\infty} U \setminus E_m$$

we have $\mu(U \setminus E_m) < \epsilon$ for some sufficiently large m.

Thus all Borel sets are in $\mathcal{A}$, and the result is proved if μ is finite.

Now suppose μ is locally finite and B is a Borel set in X with $\mu(B) < \infty$. There is an open set W with $B \subseteq W$ and $\mu(W) < \infty$. Replacing X by W and μ by $\mu|_W$, if $\epsilon > 0$ there is a relatively open set U and a relatively closed set E in W with $E \subseteq B \subseteq U$ and $\mu(U \setminus E) < \epsilon$. Then U is open in X. W is an F_σ in X, so there is an increasing sequence (F_n) of closed sets in X with $W = \cup_n F_n$. Set $E_n = E \cap F_n$. We have $E = G \cap W$ for some closed set G in X; then

$$E_n = (E \cap F_n) = (G \cap W) \cap F_n = G \cap F_n$$

since $F_n \subseteq W$; thus each E_n is closed in X, and $E = \cup_n E_n$. And we have

$$U \setminus E = \bigcap_{n=1}^{\infty} E \setminus E_n$$

so we have

$$\mu(U \setminus E_n) < \epsilon$$

for some sufficiently large n. 👍

XVII.6.1.11. Conversely, a Borel measure which is regular in this sense is obviously locally finite (the U must have finite measure).

There is a consequence (of the finite part) for general Borel measures (cf. [Fed69, 2.2.2]):

XVII.6.1.12. Corollary. Let μ be a Borel measure on a metric space X and A a Borel set in X.

(i) If $\mu(A) < \infty$, then for any $\epsilon > 0$ there is a closed set $E \subseteq A$ with $\mu(A \setminus E) < \epsilon$.

(ii) If A can be covered by countably many open sets of finite measure, then for any $\epsilon > 0$ there is an open set U with $A \subseteq U$ and $\mu(U \setminus A) < \epsilon$.

In particular, if X can be covered by countably many open sets of finite measure, then μ is locally finite.

Proof: (i): Define a new Borel measure ν on X by $\nu(B) = \mu(A \cap B)$ for Borel sets B. Then ν is a finite Borel measure. Apply XVII.6.1.10. to ν to get E (and U). Then

$$\mu(A \setminus E) = \nu(A \setminus E) \leq \nu(U \setminus E) < \epsilon \ .$$

(ii): Let (V_n) be a sequence of open sets covering A with $\mu(V_n) < \infty$ for all n. By (i), for each n there is a closed set $E_n \subseteq V_n \setminus A$ with $\mu([V_n \setminus A] \setminus E_n) < 2^{-n}\epsilon$. Set $U = \cup_n (V_n \setminus E_n)$. Then U is open and, since $A \cap V_n \subseteq V_n \setminus E_n$, $A \subseteq U$. We have

$$U \setminus A = \bigcup_{n=1}^{\infty} [V_n \setminus E_n] \setminus A = \bigcup_{n=1}^{\infty} [V_n \setminus A] \setminus E_n$$

so

$$\mu(U \setminus A) \leq \sum_{n=1}^{\infty} \mu([V_n \setminus A] \setminus E_n) < \sum_{n=1}^{\infty} 2^{-n}\epsilon = \epsilon \ .$$

XVII.6.1.13. EXAMPLE. Here is an interesting example due to DIEUDONNÉ [**?**] which shows the result can fail even for a finite Borel measure on a compact Hausdorff space, if open sets are not always F_σ's.

Let X be the set of ordinals less than or equal to the first uncountable ordinal ω_1, and let $X_0 = X \setminus \{\omega_1\}$. Then X is a compact Hausdorff space in the order topology, and X_0 is a dense open set. Let $\mathcal{F}_0$ be the set of all uncountable (relatively) closed subsets of X_0. Define a measure μ on the Borel sets of X by

$$\mu(B) = \begin{cases} 1 & \text{if} \quad F \subseteq A \text{ for some } F \in \mathcal{F}_0 \\ 0 & \text{otherwise} \end{cases} \ .$$

Suppose (F_n) is a sequence in $\mathcal{F}_0$. If $F = \cap_n F_n$, we claim $F \in \mathcal{F}_0$. F is closed in X_0. If F is countable, then $F \subseteq [0, \alpha_0]$ for some $\alpha_0 < \omega_1$. There is a countable $\alpha_1 > \alpha_0$ such that $(\alpha_0, \alpha_1]$ contains infinitely many elements of F_n for each n: for each n there is a countable $\alpha_{1,n}$ such that $(\alpha_0, \alpha_{1,n}]$ contains infinitely many elements of F_n since F_n is uncountable and $[0, \alpha_0]$ is countable. Set $\alpha_1 = \sup_n \alpha_{1,n}$. Repeating the argument inductively, there is an increasing sequence (α_m) of countable ordinals such that there are infinitely many elements of each F_n in $(\alpha_{m-1}, \alpha_m]$ for each m. Set $\beta = \sup_m \alpha_m$. Then β is countable, and is in F_n for each n since F_n is closed in X_0. Thus $\beta \in F$, a contradiction. So F is uncountable.

Now let $\mathcal{A}$ be the collection of all subsets A of X for which either A or A^c contains a set in $\mathcal{F}_0$ (they cannot both since $\mathcal{F}_0$ is closed under countable intersections). Clearly $\mathcal{A}$ contains $\emptyset$ and X and is closed under complements. If (A_n) is a sequence in $\mathcal{A}$, then if some A_n contains a set in $\mathcal{F}_0$ so does $A = \cup_n A_n$, and otherwise each A_n^c contains an F_n, so $A^c = \cap_n A_n$ contains $\cap_n F_n \in \mathcal{F}_0$. If F is a closed set in X, then if F is uncountable it contains $F \cap X_0 \in \mathcal{F}_0$, and if F is countable F^c contains $[\alpha, \omega_1) \in \mathcal{F}_0$ for some α. It follows that every Borel set is in $\mathcal{A}$.

We claim μ is a Borel measure on X. We have $\mu(\emptyset) = 0$ and $\mu(X) = 1$. To show that μ is countably additive, let (B_n) be a sequence of pairwise disjoint Borel sets and set $B = \cup_n B_n$. At most one B_n can contain a set in $\mathcal{F}_0$. If one does, then so does B, and $\mu(B) = 1 = \sum_n \mu(B_n)$. If none contain one, then B_n^c contains an $F_n \in \mathcal{F}_0$ for each n, so B^c contains $\cap_n F_n$ and therefore B contains no set in $\mathcal{F}_0$ and $\mu(B) = 0 = \sum_n \mu(B_n)$. However, μ is not regular, since $\mu(\{\omega_1\}) = 0$, but $\mu(U) = 1$ for every open neighborhood of ω_1.

Finally, we fill in a loose end:

XVII.6.1.14. PROPOSITION. Let X be a topological space and μ a Borel measure on X.

(i) If X is T_1 (or, more generally, $T_{1/2}$ (XIII.7.10.26.)) and μ is locally finite and has no infinite atoms, then μ is neighborhood-finite.

(ii) If X is second countable and regular (i.e. separable and metrizable) and μ is neighborhood-finite, then μ is locally finite and σ-finite (and in particular has no infinite atoms).

PROOF: (i) If $p \in X$, then $\{p\}$ is closed, hence Borel, and has finite measure.

(ii) We show that X can be covered by countably many open sets of finite measure (so in particular μ is σ-finite). Let $\mathcal{U} = \{U_n : n \in \mathbb{N}\}$ be a countable base for the topology. For each $p \in X$, there is a neighborhood V of p with $\mu(V) < \infty$, and there is an n such that $p \in U_n \subseteq V$ since $\mathcal{U}$ is a base; so the U_n with $\mu(U_n) < \infty$ cover X. Then μ is locally finite by XVII.6.1.12.. 👍

XVII.6.1.15. We call a Borel measure on a metric space *bounded-finite* if every bounded Borel set has finite measure. Some references define "locally finite" to mean "bounded-finite." But bounded-finite is an unnecessarily strong restriction in many cases. A bounded-finite measure is obviously neighborhood-finite, hence locally finite in the separable case. But a neighborhood-finite measure need not be bounded-finite: for example, there is a bounded metric ρ on $\mathbb{R}$ equivalent to the usual metric, and Lebesgue measure is neighborhood-finite but not bounded-finite on $(\mathbb{R}, \rho)$. In a metric space in which every closed bounded set is compact (e.g. $\mathbb{R}^n$ with the usual metric), a neighborhood-finite measure is bounded-finite. In particular, on a compact metric space, a neighborhood-finite measure is finite. ✋

Tight and Radon Measures

Locally finite Borel measures are regular: the measure of a Borel set can be approximated by the measures of closed subsets. It is often better to be able to approximate by the measures of *compact* subsets, and this is possible under fairly mild hypotheses.

XVII.6.1.16. DEFINITION. A Borel measure μ on a (Hausdorff) topological space X is *tight* if for every $\epsilon > 0$ there is a compact subset K of X with $\mu(X \setminus K) < \epsilon$.

This definition is usually reserved for finite measures.

XVII.6.1.17. DEFINITION. Let X be a Hausdorff topological space. A finite Borel measure μ on X is a *Radon measure* if for every Borel set $A \subseteq X$ and every $\epsilon > 0$ there is a compact $K \subseteq A$ and an open set U with $A \subseteq U$ and $\mu(U \setminus K) < \epsilon$.

XVII.6.1.18. The same definition makes sense for general Borel measures if $\mu(A)$ is required to be finite, but Radon measures are conventionally assumed to be finite (so the finiteness assumption does not have to be repeatedly specified). We will have occasion to use the definition for locally finite measures, which we will call "locally finite Radon measures."

We summarize some obvious connections between the definitions:

XVII.6.1.19. PROPOSITION. Let μ be a finite Borel measure on a Hausdorff topological space X. Then

(i) The measure μ is Radon if and only if it is regular and tight.

(ii) If X is metrizable, then μ is Radon if and only if it is tight (XVII.6.1.10.).

(iii) If X is compact, then μ is tight.

(iv) If X is compact and metrizable, then μ is Radon.

PROOF: Only (i) needs proof. If μ is Radon, it is obviously regular and tight. Conversely, if μ is regular and tight, Let A be a Borel set in X and $\epsilon > 0$. Let K be a compact set with $\mu(X \setminus K) < \epsilon/2$, and E and U closed and open sets with $E \subseteq A \subseteq U$ and $\mu(U \setminus E) < \epsilon/2$. Then $E \cap K$ is compact, and

$$\mu(U \setminus (E \cap K)) = \mu(U \setminus E) + \mu(E \setminus (E \cap K)) \leq \mu(U \setminus E) + \mu(X \setminus K) < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \ .$$

XVII.6.1.20. EXAMPLE. Every finite Borel measure on a metric space is regular (XVII.6.1.10.), but not necessarily tight. Let X be a nonmeasurable subset of $[0,1]$ with $\lambda^*(X) = \lambda^*([0,1] \setminus X) = 1$ (). Give X the induced metric. If A is a Borel set in X, then $A = B \cap X$ for some Borel set B in $[0,1]$. Set $\mu(A) = \lambda(B)$ (i.e. $\mu = \lambda|_X$ in the sense of ()). If K is a compact subset of X, then K is compact in $[0,1]$, hence measurable, and $\lambda([0,1] \setminus K) \geq \lambda^*([0,1] \setminus X) = 1$, and thus $\mu(K) = \lambda(K) = 0$. Since $\mu(X) = 1$, μ is not tight (hence not Radon).

However, finite Borel measures on complete separable metric spaces are always Radon. We first need a lemma which is an extension of XVII.6.1.10. in this case:

XVII.6.1.21. LEMMA. Let X be a separable metric space, and μ a locally finite Borel measure on X. Then, for every Borel set $A \subseteq X$ with $\mu(A) < \infty$, and $\epsilon > 0$, there is a totally bounded closed set $E \subseteq A$ and an open set U containing A with $\mu(U \setminus E) < \epsilon$.

PROOF: Given A and ϵ, by XVII.6.1.10. there is a closed set $F \subseteq A$ and open U containing A with $\mu(U \setminus F) < \epsilon/2$, so it suffices to show there is a totally bounded closed set $E \subseteq F$ with $\mu(F \setminus E) < \epsilon/2$. Since F is itself a separable metric space and $\mu|_F$ is finite, and a relatively closed subset of F is closed in X, by replacing X by F and μ by $\mu|_F$ (and $\epsilon/2$ by ϵ), it suffices to show:

> If X is a separable metric space and μ a finite Borel measure on X, then for every $\epsilon > 0$ there is a totally bounded closed subset E of X with $\mu(X \setminus E) < \epsilon$.

To prove this, fix a dense sequence (x_k) in X and $\epsilon > 0$. For fixed $n \in \mathbb{N}$, let B_{nk} be the open ball of radius $1/n$ centered at x_k. Then the B_{nk} cover X. For $m \in \mathbb{N}$ set $V_{nm} = \cup_{k=1}^{m} B_{nk}$. Then (V_{nm}) is an increasing sequence of open, hence Borel, sets with union X, so

$$\mu(X) = \mu\left(\bigcup_{m=1}^{\infty} V_{nm}\right) = \sup_m \mu(V_{nm})$$

so there is an m with $\mu(V_{nm}) > \mu(X) - 2^{-n}\epsilon$. Let V_n be V_{nm} for such an m (say the first such m). We then have $\mu(X \setminus V_n) < 2^{-n}\epsilon$.
Let $V = \cap_n V_n$. Then V is a Borel set, and is totally bounded; and

$$\mu(X \setminus V) \leq \sum_{n=1}^{\infty} \mu(X \setminus V_n) < \sum_{n=1}^{\infty} 2^{-n}\epsilon = \epsilon \ .$$

Set $E = \bar{V}$. Since the closure of a totally bounded set is totally bounded (XIII.11.14.32.), E has the desired properties.

XVII.6.1.22. THEOREM. Every locally finite Borel measure on a Polish space is a locally finite Radon measure.

PROOF: Let X be a Polish space, and μ a locally finite Borel measure on X. Fix a complete metric on X. If A is a Borel set in X with $\mu(A) < \infty$, and $\epsilon > 0$, there are a totally bounded closed set E and open set U with $E \subseteq A \subseteq U$ and $\mu(U \setminus E) < \epsilon$. Since X is complete and E is closed, E is also complete, and since it is totally bounded it is compact. 👍

XVII.6.2. Method II Construction of Outer Measures

The standard construction of an outer measure from a set function (e.g. a premeasure) described in XVII.4.1.5. is sometimes called the *Method I* construction, particularly in Geometric Measure Theory. On a metric space, there is another construction of outer measures which is more roundabout, but gives interesting examples such as Hausdorff measures.

It is customary in Geometric Measure Theory to use upper-case script letters such as $\mathscr{M}$ to denote outer measures. (The reader is also cautioned that in much of the literature for Geometric Measure Theory, an outer measure is called a "measure." The outer measures of Geometric Measure Theory are typically metric outer measures and are applied only to Borel sets, where they are indeed countably additive.)

Method II uses covers of sets which are "fine" in the sense that every point is contained in a set in the cover of arbitrarily small diameter:

XVII.6.2.1. Definition. Let (X, ρ) be a metric space, and $E \subseteq X$. A *Vitali cover* of E is a collection $\mathcal{V}$ of subsets of X such that, for every $x \in E$ and $\epsilon > 0$, there is a $V \in \mathcal{V}$ with $x \in V$ and $diam(V) < \epsilon$.

XVII.6.2.2. The notion of Vitali cover depends on ρ. It is easily checked that if σ is another metric on X uniformly equivalent to ρ, then a collection $\mathcal{V}$ of subsets of X is a Vitali cover for E with respect to ρ if and only if it is a Vitali cover with respect to σ. However, this is not necessarily true if ρ and σ are just equivalent (). To denote the dependence on ρ where necessary, we will use the terminology "ρ-Vitali cover."

XVII.6.2.3. The sets in a Vitali cover are not required to be of any particular form. But note that if $\mathcal{V}$ is a Vitali cover of E, then

$$\bar{\mathcal{V}} = \{\bar{V} : V \in \mathcal{V}\}$$

is a Vitali cover of E consisting of closed sets. Thus we may work with Vitali covers consisting of closed sets, which is often convenient.

XVII.6.2.4. Examples. (i) The power set of X is a Vitali cover of any subset of X.

(ii) The collection of open balls in (X, ρ) is a Vitali cover of any subset E of X.

(iii) The collection of closed balls in (X, ρ) is a Vitali cover of any subset E of X.

(iv) In (ii) and (iii), we may restrict to balls of rational radius and/or with centers in E.

(v) If $\mathcal{V}$ is a Vitali cover of E and $\delta > 0$, then

$$\mathcal{V}_\delta = \{V \in \mathcal{V} : diam(V) < \delta\}$$

$$\bar{\mathcal{V}}_\delta = \{V \in \mathcal{V} : diam(V) \leq \delta\}$$

are also Vitali covers of E.

(vi) A Vitali cover of E is also a Vitali cover of any subset of E. In particular, a Vitali cover of X is a Vitali cover of any subset of X.

XVII.6.2.5. Fix a metric space (X, ρ) and a Vitali cover $\mathcal{V}$ of X. We may assume $\emptyset \in \mathcal{V}$. Let ι be a function from $\mathcal{V}$ to $[0, +\infty]$ with $\iota(\emptyset) = 0$. For any $\delta > 0$, define $\mathscr{M}^\iota_\delta$ to be the outer measure on X defined by the restriction of ι to $\mathcal{V}_\delta$ (XVII.6.2.4.(v)) as in (), i.e. for $E \subseteq X$ define

$$\mathscr{M}^\iota_\delta(E) = \inf\left\{\sum_{k=1}^{\infty} \iota(V_k) : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \in \mathcal{V}, diam(V_k) < \delta\right\}$$

(with $\mathscr{M}^\iota_\delta(E) = +\infty$ if there are no countable covers of E by sets in $\mathcal{V}_\delta$). As usual, since $\emptyset \in \mathcal{V}$ and $\iota(\emptyset) = 0$, finite as well as countably infinite covers are allowed in computing $\mathscr{M}^\iota_\delta$.

As δ decreases, there are fewer such covers, so $\mathscr{M}^\iota_\delta$ increases. Define

$$\mathscr{M}^\iota = \sup_{\delta > 0} \mathscr{M}^\iota_\delta$$

and note that $\mathscr{M}^\iota$ is an outer measure by (). $\mathscr{M}^\iota$ is called the *outer measure defined by* $\mathcal{V}$ *and* ι *by Method II.*

The outer measure $\mathscr{M}^\iota$ does depend on $\mathcal{V}$ in general, but the standard notation does not reflect this since in reasonable cases (e.g. ()) it is independent of $\mathcal{V}$. It is most common to take $\mathcal{V}$ to be the entire power set of X.

XVII.6.2.6. Use of a strict inequality in the diameters of the sets used is arbitrary. We could have also used the covers $\bar{\mathcal{V}}_\delta$ to obtain outer measures $\bar{\mathscr{M}}^\iota_\delta$, where

$$\bar{\mathscr{M}}^\iota_\delta(E) = \inf\left\{\sum_{k=1}^{\infty} \iota(V_k) : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \in \mathcal{V}, diam(V_k) \leq \delta\right\}$$

and then obtained

$$\mathscr{M}^\iota = \sup_{\delta > 0} \bar{\mathscr{M}}^\iota_\delta$$

since we have

$$\mathscr{M}^\iota_{\delta'}(E) \leq \bar{\mathscr{M}}^\iota_\delta(E) \leq \mathscr{M}^\iota_\delta(E)$$

for any E and any $0 < \delta < \delta'$.

XVII.6.2.7. In the most commonly used special case where $\mathcal{V} = \mathcal{P}(X)$, we may also restrict to covers by closed sets:

$$\mathscr{M}^\iota_\delta(E) = \inf\left\{\sum_{k=1}^{\infty} \iota(V_k) : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \text{ closed}, diam(V_k) < \delta\right\}$$

since $diam(\bar{A}) = diam(A)$ for any $A \subseteq X$. In some cases, one can also restrict to covers by open sets (cf. XVII.6.3.6.).

XVII.6.2.8. It is the passage to the limit as $\delta \to 0$ which gives Method II outer measures some nice properties making them useful. The idea is very similar to the way arc length for curves is defined: short chords and a passage to a limit are necessary to truly give an appropriate notion of length for curves. See () for more on this.

The first example of a nice property of Method II outer measures is:

XVII.6.2.9. PROPOSITION. For any $\mathcal{V}$ and ι, $\mathscr{M}^\iota$ is a metric outer measure.

PROOF: Suppose $A, B \subseteq X$ and $\rho(A,B) > 0$. If $\delta < \frac{\rho(A,B)}{2}$, then covers of A and B by sets in $\mathcal{V}_\delta$ are disjoint, so any cover of $A \cup B$ by sets in $\mathcal{V}_\delta$ breaks into a disjoint union of a cover of A and a cover of B, and every pair of covers of A and B arises this way. It follows that

$$\mathscr{M}^\iota_\delta(A \cup B) = \mathscr{M}^\iota_\delta(A) + \mathscr{M}^\iota_\delta(B)$$

by taking infima. Then taking supremum over such small δ gives

$$\mathscr{M}^\iota(A \cup B) = \mathscr{M}^\iota(A) + \mathscr{M}^\iota(B) \ .$$

XVII.6.2.10. So by XVII.6.1.4., $\mathscr{M}^\iota$ defines a Borel measure on X, also denoted $\mathscr{M}^\iota$.

XVII.6.3. Hausdorff Measure

Perhaps the most important example of the Method II construction of outer measures is Hausdorff measure. Hausdorff measure is most commonly considered on $\mathbb{R}^n$, but it can be equally well defined (with slight additional technicalities) on any metric space. It gives a metric notion of "dimension" for subsets of the space, which need not be an integer. Actually, we will get a more refined and flexible notion of metric dimension than just a number.

To make the construction work on a metric space (X, ρ), we need to be able to cover subsets of X with countable collections of balls of arbitrarily small radius. Thus it follows easily that X must be separable. So throughout this section all metric spaces will be assumed *separable*.

We first consider a class of functions:

XVII.6.3.1. DEFINITION. Let $\mathcal{H}$ be the set of all nondecreasing, right continuous functions from $[0, +\infty]$ to $[0, +\infty]$. Let $\mathcal{H}_0$ be the set of functions $h \in \mathcal{H}$ with $h(0) = 0$ (and hence $\lim_{t \to 0+} h(t) = 0$).

If (X, ρ) is any metric space, we will define a Hausdorff measure on (X, ρ) corresponding to each $h \in \mathcal{H}$. (Unfortunately, there are many h's in the standard notation for Hausdorff measure, which must be carefully distinguished; it will be impossible to stick to the recommendations of II.1.3.14. if standard notation is used.)

XVII.6.3.2. DEFINITION. Let (X, ρ) be a metric space, and $h \in \mathcal{H}$. Define the *Hausdorff measure* $\mathscr{H}^h$ on X by $\mathscr{H}^h = \mathscr{M}^\iota$, the Method II outer measure on X using $\mathcal{V} = \mathcal{P}(X)$ and $\iota(V) = h(diam(V))$ (set $\iota(\emptyset) = 0$). Thus $\mathscr{H}^h = \sup_{\delta > 0} \mathscr{H}^h_\delta$, where for $E \neq \emptyset$ we have

$$\mathscr{H}^h_\delta(E) = \inf \left\{ \sum_{k=1}^{\infty} h(diam((V_k)) : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \subseteq X, diam(V_k) < \delta \right\}$$

(with $\mathscr{H}^h_\delta(E) = +\infty$ if there are no countable covers of E by sets of diameter $< \delta$).

We will use the notation $\mathscr{H}^h$ for both the outer measure and the associated Borel measure. When the dependence on the metric ρ is relevant, we will write $\mathscr{H}^h_\rho$.

The most important case is when h is a power function:

XVII.6.3.3. DEFINITION. Let $s > 0$. Then *s-dimensional Hausdorff measure* $\mathscr{H}^{(s)}$ on a metric space (X, ρ) is $\mathscr{H}^h$, where $h(t) = t^s$. In other words, $\mathscr{H}^{(s)} = \sup_{\delta>0} \mathscr{H}^{(s)}_\delta$, where for $E \neq \emptyset$ we have

$$\mathscr{H}^{(s)}_\delta(E) = \inf\left\{\sum_{k=1}^{\infty}[diam((V_k)]^s : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \subseteq X, diam(V_k) < \delta\right\}$$

(with $\mathscr{H}^{(s)}_\delta(E) = +\infty$ if there are no countable covers of E by sets of diameter $< \delta$).

We also define $\mathscr{H}^{(0)}$ to be $\mathscr{H}^h$, where h is the constant function 1.

XVII.6.3.4. PROPOSITION. The measure $\mathscr{H}^{(0)}$ is counting measure on X.

PROOF: Suppose E is a finite subset of X with n elements. If δ is smaller than the minimum distance between distinct points of E, any cover of E by sets of diameter $< \delta$ must have at least n elements, so $\mathscr{H}^{(0)}_\delta(E) = n$. A similar argument applies in the case where E is infinite: for any n, we have $\mathscr{H}^{(0)}_\delta(E) > n$ for sufficiently small δ. 👍

XVII.6.3.5. In the definition of Hausdorff measure, we can also use the outer measures $\bar{\mathscr{H}}^h_\delta$, where

$$\bar{\mathscr{H}}^h_\delta(E) = \inf\left\{\sum_{k=1}^{\infty} h(diam((V_k)) : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \subseteq X, diam(V_k) \leq \delta\right\}$$

(cf. XVII.6.2.6.).

In computing $\mathscr{H}^h_\delta(E)$, we may restrict to covers by closed sets by XVII.6.2.7.. We may also use open covers (this is the place where right continuity of h is used):

XVII.6.3.6. PROPOSITION. Let (X, ρ) be a metric space, $h \in \mathcal{H}$, and $\delta > 0$. Then

$$\mathscr{H}^h_\delta(E) = \inf\left\{\sum_{k=1}^{\infty} h(diam((V_k)) : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \subseteq X \text{ open}, diam(V_k) < \delta\right\}$$

for any $E \subseteq X$.

PROOF: We clearly have

$$\mathscr{H}^h_\delta(E) \leq \inf\left\{\sum_{k=1}^{\infty} h(diam((V_k)) : E \subseteq \cup_{k=1}^{\infty} V_k, V_k \subseteq X \text{ open}, diam(V_k) < \delta\right\} .$$

For the reverse inequality, there is nothing to prove if $\mathscr{H}^h_\delta(E) = +\infty$, so assume $\mathscr{H}^h_\delta(E) < +\infty$. Let $\epsilon > 0$, and fix a cover $\{V_k\}$ of E with $diam(V_k) < \delta$ for all k and

$$\sum_{k=1}^{\infty} h(diam(V_k)) < \mathscr{H}^h_\delta(E) + \frac{\epsilon}{2} .$$

For each k, let U_k be an open set containing V_k such that $diam(U_k) < \delta$ and $h(diam(U_k)) \le h(diam(V_k)) + \frac{\epsilon}{2^{k+1}}$; U_k can be taken to be

$$U_k = \{x \in X : \rho(x, V_k) < r\}$$

for some sufficiently small $r > 0$, using the right continuity of h. Then

$$\sum_{k=1}^{\infty} h(diam(U_k)) \le \sum_{k=1}^{\infty} h(diam(V_k)) + \frac{\epsilon}{2} < \mathscr{H}^h_\delta(E) + \epsilon$$

and since $\epsilon > 0$ is arbitrary, we obtain the reverse inequality. 👍

XVII.6.3.7. The Hausdorff measures $\mathscr{H}^h$, even the s-dimensional Hausdorff measures $\mathscr{H}^{(s)}$, depend strongly on the choice of metric. If σ is uniformly equivalent to ρ, ...

Spherical Measures

XVII.6.3.8. Many slight variations on Hausdorff measure are possible. One variation is to take $\mathcal{V}$ to be the set of balls in (X, ρ) (in metric spaces such as $\mathbb{R}^n$ where each closed ball is the closure of an open ball of the same diameter, it does not matter whether one uses open balls, closed balls, or arbitrary balls in between; note that in a general metric space the diameter of a ball of radius r may be strictly smaller than $2r$). The measures made in the same way are sometimes called *spherical measures* and denoted $\mathscr{S}^h$ or $\mathscr{S}^{(s)}$. The measure $\mathscr{S}^h$ is not the same as $\mathscr{H}^h$ since a *set* of diameter d is not necessarily contained in a *ball* of diameter d (cf. (); it is clearly contained in a ball of diameter $\le 2d$). We have $\mathcal{H}^h(E) \le \mathscr{S}^h(E)$ for any h and E. For power functions we have

$$\mathscr{H}^{(s)}(E) \le \mathscr{S}^{(s)}(E) \le 2^s \mathscr{H}^{(s)}(E)$$

for any s and E. The relation for general h is not so simple unless $\lim_{t \to 0+} \dfrac{h(2t)}{h(t)}$ exists.

XVII.6.3.9. There is also a question of what should be considered the "size" of a ball in a general metric space: note that in a general metric space the diameter of a ball of radius r may be strictly smaller than $2r$ (this is not an issue in Euclidean space, but is even in subsets of Euclidean space with the induced metric). It is more convenient in general metric spaces to take $\iota(B) = 2r$ instead of $diam(B)$ for a ball of radius r. This will give "radius-based spherical measure"; we could also consider diameter-based spherical measure, which gives an alternate theory not as nicely behaved in general. Similarly, for other measures such as packing measure we will only consider radius-based versions. Thus, to make $\mathscr{S}^h$, we take for $\delta > 0$

$$\mathscr{S}^h_\delta(E) = \sum_{k=1}^{\infty} h(2r_k)$$

where the infimum is over all countable covers (B_k) of E by balls of radius $r_k \le \delta$, and

$$\mathscr{S}^h(E) = \inf_{\delta > 0} \mathscr{S}^h_\delta(E) \ .$$

We will remain with diameter-based Hausdorff measure.

XVII.6.3.10. A variation of spherical measure is *center-based spherical measure*, requiring the centers of the balls to be contained in the subset E. Specifically for $\delta > 0$ let

$$\mathscr{C}_\delta^{(s)} = \inf \sum_{k=1}^{\infty} (2r_k)^s$$

where the infimum is over all countable covers of E with balls centered in E, of diamerer $\leq \delta$, and

$$\tilde{\mathscr{C}}^{(s)}(E) = \inf_{\delta>0} \mathscr{C}_\delta^{(s)}(E) \ .$$

There is a subtlety, however (cf. [Edg08, 1.4.1]): $\tilde{\mathscr{C}}^{(s)}$ is not necessarily monotone, hence not an outer measure. This is easily fixed, however: write

$$\mathscr{C}^{(s)}(E) = \sup_{A \subseteq E} \tilde{\mathscr{C}}^{(s)}(A) \ .$$

The relations between these outer measures for power functions are:

XVII.6.3.11. Proposition. Let (X, ρ) be a metric space, and $E \subseteq X$. If $s \geq 0$, then

$$\mathscr{H}^{(s)}(E) \leq \mathscr{S}^{(s)}(E) \leq \mathscr{C}^{(s)}(E) \leq 2^s \mathscr{S}^{(s)}(E) \ .$$

[Note that the inequality $\mathscr{S}^{(s)}(E) \leq 2^s \mathscr{H}^{(s)}(E)$ of XVII.6.3.8. is for diameter-based spherical measure and not radius-based spherical measure; this inequality holds for radius-based spherical measure in Euclidean space but not in general metric spaces.]

XVII.6.3.12. Hausdorff measures are rarely finite or even σ-finite. They are, however, often semifinite: $\mathscr{H}^{(s)}(X, \rho)$ is always semifinite if (X, ρ) is complete and separable, a surprisingly recent result [How95] (special cases have long been known, cf. [Bes52], [Dav52], [Lar67b]). The case of $\mathscr{H}^h$ for more general h has been shown to be semifinite if (X, ρ) is metrically finite-dimensional (XVII.6.7.20.) [Lar67b] or if h satisfies a growth condition [How95], but this is false in general [DR69].

Hausdorff Dimension

As s increases, the Hausdorff measure $\mathscr{H}^{(s)}(E)$ of a subset E of a metric space (X, ρ) jumps suddenly down from $+\infty$ to 0. The critical value where this occurs is called the *Hausdorff dimension* of E. More generally, there are typically functions $h \in \mathcal{H}$ whose rate of convergence to 0 describe the boundary between infinite and zero Hausdorff measure.

XVII.6.3.13. Proposition. Suppose $g, h \in \mathcal{H}$ and $\lim_{t \to 0+} \frac{g(t)}{h(t)} = 0$. Let (X, ρ) be a metric space, and $E \subseteq X$.

(i) If $\mathscr{H}^h(E) < +\infty$, then $\mathscr{H}^g(E) = 0$.

(ii) If $\mathscr{H}^g(E) > 0$, then $\mathscr{H}^h(E) = +\infty$.

PROOF: Statement (ii) is the contrapositive of (i). To prove (i), let $\epsilon > 0$, and choose $\eta > 0$ such that $g(t) \leq \frac{\epsilon}{\mathscr{H}^h(E)+1} h(t)$ for $t < \eta$. If $0 < \delta < \eta$, there is a cover (V_k) of E with $diam(V_k) < \delta$ for all k, such that

$$\sum_{k=1}^{\infty} h(diam(V_k)) < \mathscr{H}^h_\delta(E) + 1 \leq \mathscr{H}^h(E) + 1$$

and for this cover we have

$$\sum_{k=1}^{\infty} g(diam(V_k)) \leq \frac{\epsilon}{\mathscr{H}^h(E) + 1} \sum_{k=1}^{\infty} h(diam(V_k)) < \epsilon$$

so we have $\mathscr{H}^g_\delta(E) < \epsilon$. Taking the supremum over such δ, we have $\mathscr{H}^g(E) \leq \epsilon$. Since $\epsilon > 0$ is arbitrary, $\mathscr{H}^g(E) = 0$. 👍

XVII.6.3.14. COROLLARY. Let $0 \leq s < t$. Let (X, ρ) be a metric space, and $E \subseteq X$. Then
(i) If $\mathscr{H}^{(s)}(E) < +\infty$, then $\mathscr{H}^{(t)}(E) = 0$.
(ii) If $\mathscr{H}^{(t)}(E) > 0$, then $\mathscr{H}^{(s)}(E) = +\infty$.

XVII.6.3.15. COROLLARY. Let (X, ρ) be a metric space, and E an infinite subset of X. Then

$$\sup\{s \geq 0 : \mathscr{H}^{(s)}(E) = \infty\} = \inf\{t > 0 : \mathscr{H}^{(t)}(E) = 0\}$$

(set $\inf(\emptyset) = +\infty$).

XVII.6.3.16. DEFINITION. The common value in XVII.6.3.15. is called the *Hausdorff dimension* of E in (X, ρ), denoted $dim_H(E)$. We also define the Hausdorff dimension of a finite set to be 0.

XVII.6.3.17. So the Hausdorff dimension of E is the critical value s where the Hausdorff measure $\mathscr{H}^{(s)}(E)$ jumps from $+\infty$ to 0. Examples show that if $s = dim_H(E)$, then $\mathscr{H}^{(s)}(E)$ can be 0, $+\infty$, or any finite positive number.

XVII.6.3.18. If only power functions are considered, for a given E there is an exact boundary between the functions h for which $\mathscr{H}^h(E) = +\infty$ and the h for which $\mathscr{H}^h(E) = 0$. But if all functions in $\mathcal{H}$ are considered, there is not such a clean boundary. Still, if there is an $h \in \mathcal{H}$ for which $0 < \mathscr{H}^h(E) < +\infty$, it can be considered a reasonable boundary: for any $g \in \mathcal{H}$ with $\lim_{t \to 0+} \frac{g(t)}{h(t)} = 0$, we have $\mathscr{H}^g(E) = 0$, and for any $g \in \mathcal{H}$ with $\lim_{t \to 0+} \frac{g(t)}{h(t)} = +\infty$, we have $\mathscr{H}^g(E) = +\infty$. Such an h is not generally unique, however; but dividing $\mathcal{H}$ into those h for which $\mathscr{H}^h(E) < +\infty$ and those h for which $\mathscr{H}^h(E) = +\infty$ (or, almost equivalently, those h for which $\mathscr{H}^h(E) = 0$ and those h for which $\mathscr{H}^h(E) > 0$) is an illuminating partition.

XVII.6.3.19. Because of XVII.6.3.8., the same phenomenon works for spherical measures (either radius-based or diameter-based) and, for diameter-based spherical measure, gives the same s as the transition point. Thus Hausdorff dimension can be calculated using diameter-based spherical measures, i.e. covering with balls. For more general h the phenomenon is not quite the same or so simple. And in general metric spaces, if one uses radius-based spherical measure, even the Hausdorff dimension can be different (it is smaller in general). Not a problem, of course, in Euclidean space.

XVII.6.4. Hausdorff Measure on $\mathbb{R}^n$

XVII.6.4.1. Hausdorff measures and Hausdorff dimension were originally defined and studied for subsets of $\mathbb{R}^n$, and are still of most interest there.

Unfortunately, there is no consistency in references about the exact definition of Hausdorff measure in $\mathbb{R}^n$. It appears that most references define the measures in the same way up to a constant factor, which can vary from reference to reference. There are two predominant definitions used in the literature: the "unnormalized Hausdorff measure," primarily used in the theory of fractals, and the "normalized Hausdorff measure," primarily used in Geometric Measure Theory (only s-dimensional Hausdorff measure can be reasonably normalized, and usually only integer values of s are used). The normalized version has nicer properties for most purposes in analysis, since it exactly coincides with Lebesgue measure and arc length/surface area/surface measure in appropriate dimensions. Thus we will concentrate on the normalized case. The distinction is not important for many purposes: the crucial distinction is often simply whether a set has zero, infinite, or finite nonzero measure. For example, both versions give the same Hausdorff dimension for subsets of $\mathbb{R}^n$.

Unnormalized Hausdorff Measure

XVII.6.4.2. Definition. Let $h \in \mathcal{H}$. Unnormalized Hausdorff h-measure $\mathscr{H}^h$ on $\mathbb{R}^n$ is $\mathscr{H}^h$ on $\mathbb{R}^n$ with the usual Euclidean metric ρ_2. If $0 \leq s$, unnormalized s-dimensional Hausdorff measure $\mathscr{H}^{(s)}$ on $\mathbb{R}^n$ is $\mathscr{H}^{(s)}$ for $(\mathbb{R}^n, \rho_2)$.

As usual, we will use the same notation for the outer measure and the Borel measure.

Normalized Hausdorff Measure

XVII.6.4.3. Definition. If $0 \leq s$, normalized s-dimensional Hausdorff measure $\mathscr{L}^{(s)}$ on $\mathbb{R}^n$ is $\alpha_s \mathscr{H}^{(s)}$ for $(\mathbb{R}^n, \rho_2)$, where

$$\alpha_s = \frac{\pi^{s/2}}{2^s \Gamma(\frac{s}{2}+1)}$$

is a normalizing constant (Γ is the Gamma function ().)

XVII.6.4.4. If s is an integer, α_s is the s-dimensional "volume" of a ball in $\mathbb{R}^s$ of diameter 1 (radius $\frac{1}{2}$). Thus $\alpha_1 = 1$, $\alpha_2 = \frac{\pi}{4}$, $\alpha_3 = \frac{1}{8}\left(\frac{4}{3}\pi\right) = \frac{\pi}{6}$, etc.; see ().

XVII.6.4.5. The notation $\mathscr{L}^{(s)}$ for normalized Hausdorff measure is nonstandard; it is most commonly called $\mathscr{H}^{(s)}$. But this notation is also used by some authors to mean unnormalized Hausdorff measure, which is consistent with its use in general metric spaces, so we use $\mathscr{H}^{(s)}$ to mean unnormalized Hausdorff measure.

We have chosen the notation $\mathscr{L}^{(s)}$ for normalized Hausdorff measure since for appropriate s it coincides with usual Lebesgue measure or standard variants. Note that we do not define normalized Hausdorff measure for general $h \in \mathcal{H}$.

XVII.6.4.6. Hausdorff measure on $\mathbb{R}^n$ can be defined in other ways too. For example, in [**?**] it is defined using the metric ρ_∞ (). Hausdorff measure defined in this way is not a constant multiple of the usual Hausdorff measure in most cases, but it is an equivalent measure and gives the same theory of Hausdorff dimension, and is technically simpler in some respects.

XVII.6.5. Hausdorff Measure and Hausdorff Dimension for Self-Similar Sets

XVII.6.6. Packing Measure and other Geometric Measures

Hausdorff measure, or more precisely spherical measure (XVII.6.3.8.) which is equivalent and hence gives the same dimension, uses good coverings by balls. There is a "dual" notion which uses dense packings by disjoint balls, not surprisingly called packing measure. Packing measure is a much more recent development than Hausdorff measure, being defined by TRICOT in 1982 [].

The definition of packing measure involves yet another level of approximation:

XVII.6.6.1. DEFINITION. Let (X, ρ) be a metric space, and $s \geq 0$. Let $E \subseteq X$. For each $\delta > 0$ set

$$\mathscr{P}_\delta^{(s)}(E) = \sup\left\{\sum_{k=1}^{\infty}(2r_k)^s\right\}$$

where the supremum is over all sequences (B_k) of pairwise disjoint open balls of radii $r_k \leq \delta$ with centers in E (empty balls are allowed with radius 0, i.e. finite sequences of B_k are allowed). Set

$$\mathscr{P}_0^{(s)}(E) = \inf_{\delta>0} \mathscr{P}_\delta^{(s)}(E)$$

(note that $\mathscr{P}_\delta^{(s)}(E)$ decreases as δ decreases) and

$$\mathscr{P}^{(s)}(E) = \inf\left\{\sum_{k=1}^{\infty} \mathscr{P}_0^{(s)}(E_k) : E \subseteq \bigcup_{k=1}^{\infty} E_k\right\}$$

i.e. $\mathscr{P}^{(s)}$ is the outer measure defined by the set function $\mathscr{P}_0^{(s)}$ (). $\mathscr{P}^{(s)}$ is called *s-dimensional packing measure* on (X, ρ).

XVII.6.6.2. Note that "packing measure" is actually an outer measure. But it is easily seen to be a metric outer measure, so all Borel sets are measurable and it is truly a measure on Borel sets. $\mathscr{P}_\delta^{(s)}$ is an outer measure for any $\delta > 0$, but $\mathscr{P}_0^{(s)}$ is not an outer measure in general (), so the last step is necessary even though it makes packing measure harder to compute. Roughly speaking, the last step allows not just packings by disjoint balls with centers in E, but "packings" by "almost disjoint" balls with centers close to E, which can be taken to be in E:

XVII.6.6.3. PROPOSITION. Let (X,ρ) be a metric space, and $E \subseteq X$. Then, for any s,

$$\inf\left\{\sum_{k=1}^{\infty} \mathscr{P}_0^{(s)}(E_k) : E \subseteq \bigcup_{k=1}^{\infty} E_k\right\} = \inf\left\{\sum_{k=1}^{\infty} \mathscr{P}_0^{(s)}(E_k) : E \subseteq \bigcup_{k=1}^{\infty} E_k, E_k \subseteq E\right\} .$$

PROOF: Let $E \subseteq \bigcup_{k=1}^{\infty} E_k$, and let $\tilde{E}_k = E \cap E_k$ for each k. Then $\mathscr{P}_0^{(s)}(\tilde{E}_k) \leq \mathscr{P}_0^{(s)}(E_k)$ since $\mathscr{P}_0^{(s)}$ is monotone, and $E \subseteq \bigcup_{k=1}^{\infty} \tilde{E}_k$. 👍

XVII.6.6.4. A routine argument shows that disjoint closed balls can be used instead of disjoint open balls in the definition of packing measure, since the diameter of an open ball is the supremum of the diameters of the closed balls contained in it, and two open balls are disjoint if and only if all pairs of closed balls contained in them are disjoint. It also suffices to use finite packings rather than sequences. Packing measures on separable complete metric spaces are semifinite [JP95], but not generally σ-finite.

It is also easily verified that $\mathscr{P}^{(0)}$ is counting measure on $(X, \mathcal{P}(X))$.

XVII.6.6.5. PROPOSITION. Let (X,ρ) be a metric space, $E \subseteq X$, and $s \geq 0$. Then $\mathscr{P}_0^{(s)}(E) = \mathscr{P}_0^{(s)}(\bar{E})$ (where $\bar{E}$ is the closure of E).

PROOF: Any δ-packing of $\bar{E}$ can be approximated by a δ'-packing of E, for any $\delta' < \delta$. 👍

XVII.6.6.6. This shows why $\mathscr{P}_0^{(s)}$ is not an outer measure: if E is a countable dense set in X, then $\mathscr{P}_0^{(s)}(E) = \mathscr{P}_0^{(s)}(X)$, which is not necessarily zero. But $\mathscr{P}_0^{(s)}(pt) = 0$. So $\mathscr{P}_0^{(s)}$ is not countably subadditive in general.

Packing measure behaves in a similar way to Hausdorff measure as s varies:

XVII.6.6.7. PROPOSITION. Let $0 \leq s < t$. Let (X,ρ) be a metric space, and $E \subseteq X$. Then
(i) If $\mathscr{P}^{(s)}(E) < +\infty$, then $\mathscr{P}^{(t)}(E) = 0$.
(ii) If $\mathscr{P}^{(t)}(E) > 0$, then $\mathscr{P}^{(s)}(E) = +\infty$.

PROOF: If (B_k) is a sequence of pairwise disjoint balls of radius $\leq \delta$ with centers in E, then $\sum_{k=1}^{\infty}(diam(B_k))^t \leq (2\delta)^{t-s}\sum_{k=1}^{\infty}(diam(B_k))^s$. Taking the infimum over all such sequences, we obtain $\mathscr{P}_\delta^{(t)}(E) \leq (2\delta)^{t-s}\mathscr{P}_\delta^{(s)}(E)$. Taking the infimum over all δ, if $\mathscr{P}_0^{(s)}(E) < +\infty$, then $\mathscr{P}_0^{(t)}(E) = 0$. Now suppose $\mathscr{P}^{(s)}(E) < +\infty$. Then there is a sequence (E_k) with $E \subseteq \cup_{k=1}^{\infty} E_k$ and $\sum_{k=1}^{\infty} \mathscr{P}_0^{(s)}(E_k) < +\infty$. Then $\mathscr{P}_0^{(s)}(E_k) < +\infty$ for all k, so $\mathscr{P}_0^{(t)}(E_k) = 0$ for all k, and thus

$$\mathscr{P}^{(t)}(E) \leq \sum_{k=1}^{\infty} \mathscr{P}_0^{(t)}(E) = 0 .$$

Statement (ii) is the contrapositive of (i). 👍

XVII.6.6.8. Corollary. Let (X, ρ) be a metric space, and E an infinite subset of X. Then

$$\sup\{s \geq 0 : \mathscr{P}^{(s)}(E) = \infty\} = \inf\{t > 0 : \mathscr{P}^{(t)}(E) = 0\}$$

(set $\inf(\emptyset) = +\infty$).

XVII.6.6.9. Definition. The common value in XVII.6.6.8. is called the *packing dimension* of E in (X, ρ), denoted $dim_P(E)$. We also define the packing dimension of a finite set to be 0.

XVII.6.6.10. So the packing dimension of E is the critical value s where the packing measure $\mathscr{P}^{(s)}(E)$ jumps from $+\infty$ to 0. Examples show that if $s = dim_P(E)$, then $\mathscr{P}^{(s)}(E)$ can be 0, $+\infty$, or any finite positive number.

XVII.6.6.11. We have that $dim_H(E) \leq dim_P(E)$ for any $E \subseteq X$ (XVII.6.6.18.). The Hausdorff and packing dimensions of a subset can differ (XVII.6.9.2.(d)), although for well-behaved subsets they frequently coincide; when they do, the "fractal dimension" of the set is well defined as the common value.

XVII.6.6.12. We can also consider "diameter-based packing measure." This is the same as radius-based packing measure on $\mathbb{R}^n$, but different in general metric spaces and can even yield a different packing dimension.

Packing Measure of Subsets

XVII.6.6.13. There is a potential ambiguity in packing measure: is the packing measure or packing dimension of a subset E of X the same whether E is regarded as a subset of X or just as a metric space with the restricted metric? More generally, if Y is a subset of X with the restricted metric, and $E \subseteq Y$, is the packing measure or packing dimension of E as a subset of Y the same as it is as a subset of X?

XVII.6.6.14. We may define some other variations of packing measure by using other types of "packing" (cf. [Edg98,]). If (X, ρ) is a metric space and $E \subseteq X$, we can describe a potential finite packing as a finite set $\{(x_j, r_j) : 1 \leq j \leq n\}$, where the $x_j \in E$ and $r_j > 0$, corresponding to the set $\{\bar{B}_{r_j}(x_j) : 1 \leq j \leq n\}$.

XVII.6.6.15. Fix $s > 0$ and define radius-based "packing" measures using (finite) "packings" of various forms:

$\mathscr{P}^{(s)}_{max}(E)$ by using "packings" for which $\rho(x_j, x_k) > \max(r_j, r_k)$ for all j, k.

$\mathscr{P}^{(s)}_{sub}(E)$ by using "packings" for which $\bar{B}_{r_j}(x_j) \cap \bar{B}_{r_k}(x_k) \cap E = \emptyset$ for all j, k.

$\mathscr{P}^{(s)}_{rad}(E)$ by using "packings" for which $\bar{B}_{r_j}(x_j) \cap \bar{B}_{r_k}(x_k) = \emptyset$ for all j, k.

$\mathscr{P}^{(s)}_{sum}(E)$ by using "packings" for which $\rho(x_j, x_k) > r_j + r_k$ for all j, k.

In each case, one takes for $\delta > 0$ the supremum of the sums $\sum_j (2r_j)^s$ over all "packings" with all $r_j < \delta$, then the inf for $\delta > 0$, and then the inf over all countable coverings of E.

A "packing" of any of these kinds is a "packing" of the kinds above it ("packings" of the last two kinds are true packings). The measure $\mathscr{P}^{(s)}_{rad}$ is just the previously-defined s-dimensional packing measure. As E varies, $\mathscr{P}^{(s)}_{sub}$ is not clearly an outer measure since a variable E is used in its definition, but if E is fixed, by XVII.6.6.3. $\mathscr{P}^{(s)}_{sub}(E)$ is the s-dimensional packing measure of the metric space $(E, \rho|_E)$. We have the inequalities

$$\mathscr{P}^{(s)}_{sum}(E) \leq \mathscr{P}^{(s)}_{rad}(E) \leq \mathscr{P}^{(s)}_{sub}(E) \leq \mathscr{P}^{(s)}_{max}(E) \leq 2^s \mathscr{P}^{(s)}_{sum}(E)$$

for any E. It follows that the packing dimension of E from any of these is the same.

In particular, although the s-dimensional radius-based packing *measure* of E as a subset of X may (potentially) differ from its packing *measure* as a metric space on its own, the radius-based packing *dimension* of E is the same whether regarded as a subset of X or as a metric space on its own.

The corresponding situation about diameter-based packing dimension is unclear. For one thing, the diameter of a ball B in X may be much larger than the diameter of the relative ball $B \cap E$.

XVII.6.6.16. We could also normalize packing measure on $\mathbb{R}^n$ as with Hausdorff measure. This is rarely done, however; the principal use of packing measure (at present) is to define and work with packing dimension, which is independent of normalization.

Relation Between Hausdorff and Packing Dimension

XVII.6.6.17. PROPOSITION. Let (X, ρ) be a metric space, and $E \subseteq X$. If $s \geq 0$, then

$$\mathscr{H}^{(s)}(E) \leq \mathscr{S}^{(s)}(E) \leq \mathscr{C}^{(s)}(E) \leq \mathscr{P}^{(s)}(E) \ .$$

PROOF: The first two inequalities were noted in XVII.6.3.11.. For the last inequality, it suffices to show that $\tilde{\mathscr{C}}^{(s)}(E) \leq \mathscr{P}^{(s)}_0(E)$ for all $E \subseteq X$. Fix E; we may assume $\mathscr{P}^{(s)}_0(E) < \infty$. Then, for some $\delta > 0$, $\mathscr{P}^{(s)}_\delta(E) < \infty$. Set $\mathcal{V} = \{\bar{B}_r(x) : x \in E, 0 < r < \delta\}$. By (), there is a disjoint family $\{\bar{B}_{r_j}(x_j)\}$ in $\mathcal{V}$ with

$$E \setminus \bigcup_{j=1}^{k} \bar{B}_{r_j}(x_j) \subseteq \bigcup_{j=k+1}^{\infty} \bar{B}_{3r_j}(x_j)$$

for all k.

Since $\{\bar{B}_{r_j}(x_j)\}$ is a packing of E by balls of radius $< \delta$,

$$\sum_{j=1}^{\infty} (2r_j)^s \leq \mathscr{P}^{(s)}_\delta(E) < \infty \ .$$

For each k,

$$\{\bar{B}_{r_j}(x_j) : 1 \leq j \leq k\} \cup \{\bar{B}_{3rj}(x_j) : j > k\}$$

is a cover of E with balls of radius $< 3\delta$, so

$$\mathscr{C}^{(s)}_{3\delta}(E) \leq \sum_{j=1}^{k}(2r_j)^s + \sum_{j=k+1}^{\infty}(6r_j)^s$$

for every k. Letting $k \to \infty$, we obtain

$$\mathscr{C}^{(s)}_{3\delta}(E) \leq \sum_{j=1}^{\infty}(2r_j)^s \leq \mathscr{P}^{(s)}_{\delta}(E) \ .$$

Letting $\delta \to 0$, the result follows. 👍

XVII.6.6.18. COROLLARY. Let (X, ρ) be a metric space, and $E \subseteq X$. Then

$$dim_H(E) \leq dim_P(E) \ .$$

Integralgeometric Measure

We now restrict to an integer value of s, which we will denote k. Another related measure on $\mathbb{R}^n$ "averages" over projections onto k-dimensional subspaces. For "nice" subspaces such as k-dimensional smooth submanifolds, this measure agrees with k-dimensional Hausdorff measure. This measure was defined by J. FAVARD in 1932 [].

XVII.6.6.19. If $0 \leq k \leq n$, let $Gr_k(\mathbb{R}^n)$ be the Grassmannian () of k-dimensional subspaces of $\mathbb{R}^n$, a manifold of dimension $k(n-k)$. Points of $Gr_k(\mathbb{R}^n)$ can be identified with the rank k orthogonal projections on $\mathbb{R}^n$. We can regard $Gr_k(\mathbb{R}^n)$ as the homogeneous space

$$O(n)/[O(k) \times O(n-k)]$$

and it thus has a unique Radon probability measure μ invariant under the natural action of O_n. (In fact μ is a smooth measure given by integration of a differential form.)

If $E \subseteq \mathbb{R}^n$ and P is a rank k projection on $\mathbb{R}^n$, for y in the range of P let $N(P|_E, y)$ be the number of points in $E \cap P^{-1}(\{y\})$. If E is a Borel set, then $N(P|_E, y)$ is a measurable function of y ().

XVII.6.6.20. DEFINITION. If E is a Borel set in $\mathbb{R}^n$, define the k-dimensional *integralgeometric measure* of E by

$$\mathscr{I}^{(k)}(E) = \frac{1}{\beta(n,k)} \int_{P \in Gr_k(\mathbb{R}^n)} \int_{P(\mathbb{R}^n)} N(P|_E, y)\, d\lambda^{(k)}(y)\, d\mu(P)$$

where $\lambda^{(k)}$ is k-dimensional Lebesgue measure on the range of P which is isomorphic to $\mathbb{R}^k$, and $\beta(n,k)$ is a normalizing constant

$$\beta(n,k) = \frac{\Gamma([k+1]/2)\Gamma([n-k+1]/2)}{\sqrt{\pi}\,\Gamma([n+1]/2)} \ .$$

Extend $\mathscr{I}^{(k)}$ to an outer measure on $\mathbb{R}^n$ in the usual way.

Note that $Gr_0(\mathbb{R}^n)$ and $Gr_n(\mathbb{R}^n)$ are one-point spaces, and it is easy to see that $\mathscr{I}^{(0)}$ is counting measure and $\mathscr{I}^{(n)} = \mathscr{L}^{(n)}$.

Many more similar measures are discussed in [Fed69, 2.10].

$\mathscr{H}$ is Hausdorff measure
$\mathscr{P}$ is packing measure
$\mathscr{I}$ is integralgeometric measure
$\mathscr{L}$ is Lebesgue measure

XVII.6.7. Metric Dimensions

Hausdorff and packing dimensions are two important examples of fractal dimensions for metric spaces. There are several more that have been considered in the literature, and two particularly important ones, Assouad dimension and metric dimension, and various box-counting dimensions. These fractal dimensions do not arise from measures in general, although see XVII.6.7.18.. It should be noted that these various notions of fractal dimension are *metric* invariants and not *topological* invariants, and must be carefully distinguished from topological dimension as discussed in () (although there are connections, e.g. XVII.6.7.23., XVII.6.7.25.).

Doubling and Homogeneous Metrics

XVII.6.7.1. Definition. A metric space (X, ρ) is *doubling* if there is a constant $K \in \mathbb{N}$ such that, for every $r > 0$, every open ball of radius r can be covered by at most K open balls of radius $r/2$.

XVII.6.7.2. If (X, ρ) is doubling, then any open ball of radius r can be covered by at most K^n open balls of radius $r/2^n$, for any n. It follows that every bounded set in X is totally bounded in a "uniform" way.

There is a (very!) closely related notion, based on packing:

XVII.6.7.3. Definition. If $C > 0$ and $s \geq 0$, a metric space (X, ρ) is (C, s)-*homogeneous* if for every $x \in X$, $r > 0$, and $\lambda > 1$, at most $C\lambda^s$ points can be placed in $B_{\lambda r}(x)$ which are at least r apart. (X, ρ) is s-*homogeneous* if it is (C, s)-homogeneous for some $C > 0$. (X, ρ) is *homogeneous* if it is s-homogeneous for some s.

XVII.6.7.4. The C in the definition is necessary: a finite metric space (X, ρ) is 0-homogeneous, but the smallest C necessary is $card(X)$.

XVII.6.7.5. The number of points a distance at least r apart which can be placed in $B_{\lambda r}(x)$ is roughly the number of disjoint open balls of radius $r/2$ which can be packed into $B_{\lambda r}(x)$ (it is not exactly the same since balls centered at points of $B_{\lambda r}(x)$ can overlap the boundary). In packing problems, closed balls are usually used. Since any closed ball is contained in an open ball with the same center and slightly larger radius, these quantities are "asymptotically" the same.

XVII.6.7.6. The connection between packing and covering is that if P is a set of points in a set S which are at least r apart, and $\mathcal{U}$ is a covering of S by open balls of radius $r/2$, then each ball in $\mathcal{U}$ contains at most one point of P, so $card(P) \leq card(\mathcal{U})$. Conversely, if P is a set of points of S at least r apart of maximum size, then the open balls of radius r centered at points of P cover S.

XVII.6.7.7. PROPOSITION. A metric space is doubling if and only if it is homogeneous.

PROOF: If (X, ρ) is (C, s)-homogeneous, $x \in X$, and $r > 0$, let P be a set of maximum cardinality of points of $B_{2r}(x)$ of distance at least r apart. Then the open balls of radius r centered at points of P cover $B_{2r}(x)$; thus there is a cover of cardinality $card(P) \leq C \cdot 2^s$, so (X, ρ) is doubling with $K = C \cdot 2^s$.

Conversely, suppose (X, ρ) is doubling with constant K. We may assume $K \geq 2$. We claim (X, ρ) is (C, s)-homogeneous, where $C = K^2$ and $s = \log_2 K$. Let $x \in X$ and $r > 0$. If $\lambda > 1$, choose n so that $2^{n-1} < \lambda \leq 2^n$. Then $B_{\lambda r}(x)$ can be covered by $K \cdot K^n = K^2 \cdot K^{n-1}$ open balls of radius $r/2$, so there can be no more than $K^2 \cdot K^{n-1}$ points in $B_{\lambda r}$ of distance at least r apart. And

$$K^2 \cdot K^{n-1} = K^2(2^s)^{n-1} = K^2(2^{n-1})^s < K^2\lambda^s \ .$$

XVII.6.7.8. There are several other equivalent conditions, described in the Appendix to [Luu98], which has a detailed discussion of Assouad dimension.

Assouad Dimension

The following definition was made in [Ass79] (with different notation):

XVII.6.7.9. DEFINITION. A metric space (X, ρ) which is homogeneous or, equivalently, doubling, has *finite Assouad dimension*, and the *Assouad dimension* of (X, ρ) is

$$dim_A(X, \rho) = \inf\{s : (X, \rho) \text{ is } s\text{-homogeneous}\} \ .$$

If (X, ρ) does not have finite Assouad dimension, we write $dim_A(X, \rho) = \infty$.

We often slightly abuse notation by writing $dim_A X$, although the Assouad dimension depends (greatly!) on the metric ρ.

The next proposition summarizes the most important basic properties of Assouad dimension.

XVII.6.7.10. PROPOSITION. Let (X, ρ) be a metric space. Then

(i) If $Y \subseteq X$, then $dim_A(Y, \rho|_Y) \leq dim_A(X, \rho)$, and $dim_A(Y, \rho|_Y) = dim_A(X, \rho)$ if Y is dense in X.

(ii) $dim_A(X, \rho) = dim_A(\bar{X}, \bar{\rho})$, where $(\bar{X}, \bar{\rho})$ is the completion of (X, ρ).

(iii) If $Y_1, \ldots, Y_n \subseteq X$, then $dim_A(Y_1 \cup \cdots \cup Y_n) = \max_{k=1}^n dim_A(Y_k)$.

(iv) If σ is a metric on X biLipschitz equivalent to ρ, i.e. there are constants $0 < a < b$ such that $a\rho \leq \sigma \leq b\rho$, then $dim_A(X, \sigma) = dim_A(X, \rho)$.

(v) If $dim_A(X, \rho) < \infty$, then X is separable and every bounded subset of X is totally bounded. If (X, ρ) is complete, then every closed bounded subset of X is compact, and X is locally compact and σ-compact.

XVII.6.7.11. Properties (i) and (iii) show that Assouad dimension behaves quite differently from topological dimension, cf. ().

XVII.6.7.12. Example. Let $X = \left\{\frac{1}{n} : n \in \mathbb{N}\right\} \cup \{0\} \subseteq \mathbb{R}$ with the induced metric ρ, i.e. $\rho\left(\frac{1}{n}, \frac{1}{m}\right) = \left|\frac{1}{n} - \frac{1}{m}\right|$. For any $t > 1$, the set of points at least $1/t^2$ apart of maximum size is $\{0\} \cup \left\{\frac{1}{n} : n \leq t\right\}$. It follows that $dim_A(X, \rho) = \frac{1}{2}$.

Assouad dimension behaves as expected for Euclidean space:

XVII.6.7.13. Proposition. Let X be a subset of $\mathbb{R}^n$ with nonempty interior (e.g. $\mathbb{R}^n$ itself). Then $dim_A(X) = n$.

Proof: $\mathbb{R}^n$ is n-homogeneous (), so $dim_A(X) \leq n$ (XVII.6.7.10.(i)). It suffices to show that an open cube E in $\mathbb{R}^n$ has Assouad dimension $\geq n$. By XVII.6.7.10.(iv) we may use $\|\cdot\|_\infty$, which is biLipschitz equivalent to the Euclidean norm. But for any $m \in \mathbb{N}$ and $r > 0$ we can put more than m^n points (in fact $(2m-1)^n$) of $\|\cdot\|_\infty$-distance at least r apart in an open cube of radius mr, so E cannot be s-homogeneous for any $s < n$. ☝

Doubling and Homogeneous Measures

There is a measure version of the metric notions of doubling and homogeneity:

XVII.6.7.14. Definition. Let (X, ρ) be a metric space, and μ a Borel measure on X.
(i) The measure μ on X is *doubling* for ρ if there is a $K \in \mathbb{N}$ such that

$$\mu(B_{2r}(x)) \leq K\mu(B_r(x))$$

for all $x \in X$ and $r > 0$, and $0 < \mu(B) < \infty$ for some (hence every) ball B.
(i) If $C > 0$, $s \geq 0$, the measure μ on X is (C, s)-*homogeneous* for ρ if

$$\mu(B_{\lambda r}(x)) \leq C\lambda^s\mu(B_r(x))$$

for all $x \in X$ and $\lambda > 1$, and $0 < \mu(B) < \infty$ for some (hence every) ball B. The measure μ is *s-homogeneous* if it is (C, s)-homogeneous for some C, and is *homogeneous* if it is s-homogeneous for some s.

XVII.6.7.15. A Borel measure is doubling if and only if it is homogeneous; the proof is virtually identical to the proof of ().

XVII.6.7.16. If (X, ρ) has a (C, s)-homogeneous measure, then it is (C, s)-homogeneous. The converse is false in general: $\mathbb{Q}$ with the metric from $\mathbb{R}$ is 1-homogeneous, but there is no doubling measure on $\mathbb{Q}$ (or on any countable metric space with no isolated points). However:

XVII.6.7.17. THEOREM. [LS98] Let $C > 1$ and $0 < s < t$. Then there is a $C' > 1$ such that every complete (C, s)-homogeneous metric space has a (C', t)-homogeneous measure.

XVII.6.7.18. COROLLARY. Let (X, ρ) be a complete metric space. Then

$$dim_A(X, \rho) = \inf\{s : X \text{ has a } s\text{-homogeneous measure}\} .$$

Metric Dimension

XVII.6.7.19. One feature of Assouad dimension is that it uses both large and small balls. This is an advantage in some contexts, but a defect in other contexts where only small balls are relevant (and there are also contexts where only large balls are important, e.g. [LeC73] and coarse geometry/topology ()). We can restrict to small balls in various ways:

XVII.6.7.20. DEFINITION. Let (X, ρ) be a metric space.

(i) [ML92] The *metric dimension* $dim_m(X, \rho)$ is the infimum of all s for which there is an $R > 0$ for which there is a $C > 0$ such that every ball of radius R is (C, s)-homogeneous (equivalently, there is a K such that every ball of radius R is doubling with constant K). If $dim_m(X, \rho) < \infty$, then (X, ρ) is *metrically finite-dimensional*.

(ii) [Lar67a] The *dimension number* $dim\text{-}n(X, \rho)$ is the infimum of all s such that every point of X has a neighborhood U with $dim_A(U) \leq s$.

There is inconsistency in the literature about this definition: some references define metric dimension differently. Our definition of metrically finite-dimensional is called "finite structural dimension" in [How95].

XVII.6.7.21. It is clear that, for any (X, ρ),

$$dim\text{-}n(X, \rho) \leq dim_m(X, \rho) \leq dim_A(X, \rho) .$$

These dimensions behave somewhat more like topological or Hausdorff dimension since they involve only small subsets of X.

The difference between metric dimension and Assouad dimension can be dramatic:

XVII.6.7.22. EXAMPLES. (i) Let X be an infinite set with the discrete metric. Then $dim_A(X) = \infty$ but $dim_m(X) = 0$.

(ii) Let (X, ρ) be a metric space with ρ unbounded. Let $\tilde{\rho}$ be either $\min(\rho, 1)$ or $\frac{\rho}{\rho+1}$ (). Then $\dim_A(X, \tilde{\rho}) = \infty$, but $dim_m(X, \tilde{\rho}) = dim_m(X, \rho)$.

XVII.6.7.23. PROPOSITION. Let (X, ρ) be a metric space. Then

$$dim(X) \leq dim_H(X, \rho) \leq dim_P(X, \rho) \leq dim_m(X, \rho) \leq dim_A(X, \rho) \ .$$

Examples show that these can all be different.

XVII.6.7.24. EXAMPLE. The packing dimension of any countable metric space is 0. If (X, ρ) is the metric space of XVII.6.7.12., then

$$0 = dim_P(X, \rho) < dim_m(X, \rho) = \frac{1}{2} \ .$$

Relation with Topological Dimension

If (X, ρ) is a metric space, then $dim_A(X, \rho) \geq dim(X)$ (XVII.6.7.23.). Since $dim(X)$ is a topological invariant of X, we have $dim_A(X, \sigma) \geq dim(X)$ for every metric σ equivalent to ρ. Can we find a σ which gives equality (as we can for dim_H or dim_P ())?

XVII.6.7.25. THEOREM. [Luu98, 4.3] Let X be a separable metrizable (second countable regular) topological space. Then there is a totally bounded metric σ on X compatible with its topology, with

$$dim(X) = dim_H(X, \sigma) = dim_P(X, \sigma) = dim_m(X, \sigma) = dim_A(X, \sigma)$$

(such a metric is called *flat*).

The proof is a combination of XIII.19.5.15. with the construction of a flat metric on the Menger compactum.

BiLipschitz Embedding in Euclidean Space

XVII.6.7.26. If ρ is a metric on a set X, then so is ρ^q for $0 < q < 1$ (), and ρ^q is uniformly equivalent to ρ. If (X, ρ) is (C, s)-homogeneous, then (X, ρ^q) is $(C, s/q)$-homogeneous, and conversely; Thus

$$dim_A(X, \rho^q) = \frac{1}{q} dim_A(X, \rho) \ .$$

It makes sense that the fractal dimension of (X, ρ^q) should be larger than (X, ρ) since (X, ρ^q) is "more fractal" than (X, ρ). However, it follows that if (X, ρ) has finite Assouad dimension, so does (X, ρ^q).

XVII.6.7.27. THEOREM. ([Ass79], cf. [Luu98, A13]) Let (X, ρ) be a metric space. The following are equivalent:

(i) $dim_A(X, \rho) < \infty$.

(ii) For some q, $0 < q < 1$, there is an n and a biLipschitz embedding of (X, ρ^q) into $\mathbb{R}^n$.

(iii) For every q, $0 < q < 1$, there is an n and a biLipschitz embedding of (X, ρ^q) into $\mathbb{R}^n$.

XVII.6.7.28. There is an (X, ρ) with $dim_A(X, \rho) < \infty$ for which there is no biLipschitz embedding of (X, ρ) into a Euclidean space, cf. [Luu98, A15].

Other Fractal Dimensions

XVII.6.7.29. There are some other notions of fractal dimension generally intermediate between Hausdorff and packing dimension, e.g. upper and lower box-counting dimension and modified upper and lower box-counting dimensions (sometimes called *Minkowski dimensions*), which do not arise from measures and which are not as nicely behaved, and some others which are more subtle and variable. These are defined and discussed in [Fal14].

XVII.6.8. Radon Measures on Metric Spaces

XVII.6.9. Exercises

XVII.6.9.1. (a) Let ρ be a metric on $\mathbb{R}^n$ coming from a norm. Show that $\mathscr{H}_\rho^{(n)}$ is a scalar multiple $\alpha\mathscr{L}^{(n)}$, where α is the reciprocal of the Lebesgue measure of the unit ball for ρ.

(b) Show that unless ρ is a constant multiple of the usual Euclidean distance, $\mathscr{H}_\rho^{(s)}$ for $0 < s < n$ is not a constant multiple of $\mathscr{L}^{(s)}$. [For $s = 1$ consider horizontal and diagonal line segments.]

XVII.6.9.2. [Edg98] (a) If F is a closed set in $\mathbb{R}^n$ and $\mathscr{P}^{(n)}(F) = 0$, then F is nowhere dense.

(b) If $A \subseteq \mathbb{R}^n$ and $dim_P(A) < n$, fix s with $dim_P(A) < s < n$. Show that A can be covered by a sequence (F_k) of closed sets with $\mathscr{P}^{(s)}(F_k) < \infty$ for all k (in fact one can do much better!) [Use that if $B \subseteq \mathbb{R}^n$, then $\mathscr{P}_0^{(s)}(B) = \mathscr{P}_0^{(s)}(\bar{B})$ (XVII.6.6.5.).]

(c) Show that if $A \subseteq \mathbb{R}^n$ and $dim_P(A) < n$, then A is meager in $\mathbb{R}^n$.

(d) Let L be the set of Liouville numbers in $\mathbb{R}$. Then $dim_P(L) = 1$ although $dim_H(L) = 0$ (III.8.2.37.).

(e) If $A \subseteq \mathbb{R}^n$ and $\mathscr{P}^{(n)}(A) = 0$, is A necessarily meager in $\mathbb{R}^n$?

XVII.6.9.3. [Mor09, p. 19] **A Triangular Cantor Set.** In $\mathbb{R}^2$, let T_1 be a solid equilateral triangle of side 1. Let T_2 be the union of the three corner solid equilateral triangles of T_1 of side 1/3, and for each n, T_{n+1} the union of all solid corner triangles of the triangles in T_n of 1/3 the side length. Set $T = \cap_n T_n$. See Figure XVII.1 (the edge segments between the triangles are not part of T).
(a) Show that T is homeomorphic to the Cantor set. [Use ().] In particular, $dim(T) = 0$.

(b) Show that $\mathscr{L}^{(1)}(T) = 1$, and hence $dim_H(T) = 1$. [Use self-similarity.]

(c) Describe a homeomorphism of $\mathbb{R}^2$ sending T onto the usual Cantor set as a subset of the x-axis (cf. XIII.19.5.43.).

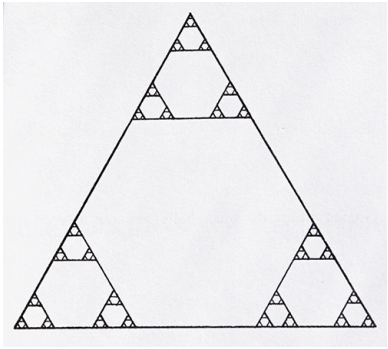

Figure XVII.1: A triangular Cantor set

XVII.7. Measures on Product Spaces

In this section, we will discuss a natural way of constructing a Cartesian product of two or more measure spaces.

XVII.7.1. Product σ-Algebras

XVII.7.1.1. Suppose $(X, \mathcal{A})$ and $(Y.\mathcal{B})$ are measurable spaces. If $A \subseteq X$ and $B \subseteq Y$, then $A \times B$ is called a *rectangle* in $X \times Y$. If $A \in \mathcal{A}$ and $B \in \mathcal{B}$, then $A \times B$ is called a *measurable rectangle* (technically, $(\mathcal{A}, \mathcal{B})$-*measurable rectangle*). It is natural that such subsets of $X \times Y$ should be regarded as measurable sets.

XVII.7.1.2. Definition. The *product σ-algebra* of $(\mathcal{A}, \mathcal{B})$, denoted $\mathcal{A} \otimes \mathcal{B}$, is the σ-algebra on $X \times Y$ generated by the measurable rectangles.

Although some authors use the notation $\mathcal{A} \times \mathcal{B}$ for the product σ-algebra, we will use the symbol $\otimes$ since $\mathcal{A} \otimes \mathcal{B}$ is much larger than just the set of measurable rectangles in general; we will use $\mathcal{A} \times \mathcal{B}$ to denote the set of measurable rectangles. (The symbol $\otimes$ is normally used for "tensor product" in abstract algebra; there is a close analogy between our use of the symbol here and algebraic tensor products.)

XVII.7.1.3. Examples.

(i) Let $X = Y = \{0, 1\}$, with $\mathcal{A} = \mathcal{B} = \mathcal{P}(\{0, 1\})$. Then $X \times Y = \{(0, 0), (0, 1), (1, 0), (1, 1)\}$. Each singleton in $X \times Y$ is a (measurable) rectangle. The set $\{(0, 0), (1, 1)\}$ is not a (measurable) rectangle in $X \times Y$, but it is a union of two rectangles, hence is in $\mathcal{A} \otimes \mathcal{B}$; thus $\mathcal{A} \otimes \mathcal{B}$ is strictly larger than $\mathcal{A} \times \mathcal{B}$. In fact, $\mathcal{A} \otimes \mathcal{B} = \mathcal{P}(X \times Y)$.

(ii) If X and Y are sets, and at least one is countable, then it is easily checked that $\mathcal{P}(X) \otimes \mathcal{P}(Y) = \mathcal{P}(X \times Y)$ (Exercise ().) In particular, $\mathcal{P}(\mathbb{N}) \otimes \mathcal{P}(\mathbb{N}) = \mathcal{P}(\mathbb{N}^2)$. But this result does not hold if X and Y are of large cardinality (Exercise ()).

(iii) If $\mathcal{B}$ is the σ-algebra of Borel sets in $\mathbb{R}$, then $\mathcal{B} \otimes \mathcal{B} = \mathcal{B}^{(2)}$, the σ-algebra of Borel sets in $\mathbb{R}^2$. Neither inclusion is completely obvious. To show that $\mathcal{B} \otimes \mathcal{B} \subseteq \mathcal{B}^{(2)}$, it suffices to show that every measurable rectangle is in $\mathcal{B}^{(2)}$. But $\mathcal{B}_x = \{B \times \mathbb{R} : B \in \mathcal{B}\}$ is a σ-algebra which is generated by $\{U \times \mathbb{R} : U \text{ open}\}$, and $U \times \mathbb{R}$ is open in $\mathbb{R}^2$, hence in $\mathcal{B}^{(2)}$; thus $\mathcal{B}_x \subseteq \mathcal{B}^{(2)}$. Similarly, $B^y = \{\mathbb{R} \times B : B \in \mathcal{B}\} \subseteq \mathcal{B}^{(2)}$. So if $A, B \in \mathcal{B}$, then $A \times B = (A \times \mathbb{R}) \cap (\mathbb{R} \times B) \in \mathcal{B}^{(2)}$, so $\mathcal{B} \otimes \mathcal{B} \subseteq \mathcal{B}^{(2)}$. For the other inclusion, it suffices to show that every open set in $\mathbb{R}^2$ is in $\mathcal{B} \otimes \mathcal{B}$. But it is a simple exercise () that every nonempty open set in $\mathbb{R}^2$ is a (countable) union of open rectangles of the form $(a, b) \times (c, d)$ with $a, b, c, d \in \mathbb{Q}$. (This example generalizes to the Borel sets in any product of second countable topological spaces; see ().)

Although the set of measurable rectangles is not a σ-algebra or even an algebra because it is not closed under complements or finite unions (except in trivial cases), we have:

XVII.7.1.4. PROPOSITION. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measurable spaces. Then the set

$$\mathcal{A} \times \mathcal{B} = \{A \times B : A \in \mathcal{A}, B \in \mathcal{B}\}$$

of measurable rectangles is a semialgebra.

PROOF: We have $X \times Y$ and $\emptyset = \emptyset \times \emptyset$ in $\mathcal{A} \times \mathcal{B}$. If $\{A_k \times B_k : 1 \leq k \leq n\}$ is a finite collection in $\mathcal{A} \times \mathcal{B}$, then

$$\bigcap_{k=1}^{n} (A_k \times B_k) = \left(\bigcap_{k=1}^{n} A_k \right) \times \left(\bigcap_{k=1}^{n} B_k \right) \in \mathcal{A} \times \mathcal{B}$$

so $\mathcal{A} \times \mathcal{B}$ is closed under finite intersections (in fact, the same argument shows that $\mathcal{A} \times \mathcal{B}$ is closed under countable intersections). And if $A \times B \in \mathcal{A} \times \mathcal{B}$, then

$$(A \times B)^c = (A \times B^c) \cup (A^c \times Y)$$

so $(A \times B)^c$ is a disjoint union of two sets in $\mathcal{A} \times \mathcal{B}$. 👍

XVII.7.1.5. PROPOSITION. Let $(X, \mathcal{A})$, $(Y, \mathcal{B})$, and $(Z, \mathcal{C})$ be measurable spaces. Let π_X and π_Y be the projections from $X \times Y$ to X and Y respectively, i.e. $\pi_X(x, y) = x$, $\pi_Y(x, y) = y$. Then

(i) π_X is an $(\mathcal{A} \otimes \mathcal{B}, \mathcal{A})$-measurable function and π_Y is an $(\mathcal{A} \otimes \mathcal{B}, \mathcal{B})$-measurable function.

(ii) If $f : Z \to (X \times Y)$ is a function, then f is $(\mathcal{C}, \mathcal{A} \otimes \mathcal{B})$-measurable if and only if $\pi_X \circ f : Z \to X$ is $(\mathcal{C}, \mathcal{A})$-measurable and $\pi_Y \circ f : Z \to Y$ is $(\mathcal{C}, \mathcal{B})$-measurable.

PROOF: (i): If $A \in \mathcal{A}$, then $\pi_X^{-1}(A) = A \times Y \in \mathcal{A} \otimes \mathcal{B}$, so π_X is measurable. The argument for π_Y is similar. (ii): If f is measurable, then $\pi_X \circ f$ and $\pi_Y \circ f$ are measurable by XVI.1.6.3.. Conversely, if $\pi_X \circ f$ is measurable, then $f^{-1}(A \times Y) = [\pi_X \circ f]^{-1}(A) \in \mathcal{C}$ for all $A \in \mathcal{A}$. Similarly, if $\pi_Y \circ f$ is measurable, then $f^{-1}(X \times B) \in \mathcal{C}$ for all $B \in \mathcal{B}$. Since $\{A \times Y : A \in \mathcal{A}\} \cup \{X \times B : B \in \mathcal{B}\}$ generates $\mathcal{A} \otimes \mathcal{B}$ as a σ-algebra, f is measurable by XVI.1.6.10.. 👍

XVII.7.2. Product Measures

Now suppose that $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ are measure spaces. We want to obtain a reasonable measure $\mu \times \nu$ on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$. It is natural to want the measure of a measurable rectangle $A \times B$ to be $\mu(A)\nu(B)$. It turns out that it is possible to obtain such a measure through the Caratheodory extension process.

XVII.7.2.6. THEOREM. Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces. For $A \times B$ in the semialgebra $\mathcal{C}$ of measurable rectangles (XVII.7.1.4.), set $\iota(A \times B) = \mu(A)\nu(B)$ (where $0 \cdot \infty = \infty \cdot 0 = 0$ by convention). Then ι is a premeasure on $\mathcal{C}$, and hence ι extends to a measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$ denoted $\mu \times \nu$ by the Caratheodory extension process. If μ and ν are σ-finite, then $\mu \times \nu$ is the unique extension of ι to a measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$, and is also σ-finite.

PROOF: We verify that ι satisfies (i), (ii′), and (iii) of XVII.4.5.2. and XVII.4.5.6. (note that (ii′) $\Rightarrow$ (ii) since $\emptyset \in \mathcal{A} \times \mathcal{B}$). Condition (i) is obvious. We prove (ii′) and (iii) simultaneously since the arguments are almost identical (we could simplify the argument slightly by using the somewhat nontrivial result XVII.4.5.6. to avoid proving (iii), but this is not necessary). Suppose $A_1 \times B_1, A_2 \times B_2, \cdots$ is a sequence of measurable rectangles and

$$\bigcup_{k=1}^{\infty} (A_k \times B_k) \supseteq A \times B \in \mathcal{A} \times \mathcal{B}$$

(for (ii′), assume the $A_k \otimes B_k$ are pairwise disjoint and $\cup_{k=1}^{\infty}(A_k \times B_k) = A \times B$). We must show $\mu(A)\nu(B) \leq \sum_{k=1}^{\infty} \mu(A_k)\nu(B_k)$, with equality for (ii′). We may assume A and B are nonempty. Set

$$\phi = \mu(A)\chi_B, \quad \psi = \sum_{k=1}^{\infty} \mu(A_k)\chi_{B_k}$$

(where the convention $\infty \cdot 0 = 0$ is followed). Then ϕ and ψ are extended real-valued measurable functions on $(Y, \mathcal{B})$. We claim $\phi \leq \psi$, with equality in (ii′). If $y \notin B$, then $\phi(y) = 0$, and in case (ii′) also $\psi(y) = 0$. If $y \in B$, set

$$I_y = \{k \in I : y \in B_k\} \subseteq \mathbb{N} .$$

If $x \in A$, then $(x, y) \in A \times B$, so $(x, y) \in A_k \times B_k$ for at least one k (exactly one k in case (ii′)), i.e. $x \in A_k$ for at least one $k \in I_y$ (exactly one in case (ii′)). Thus A is contained in the union of $\{A_k : k \in I_y\}$. In case (ii′), if $x \notin A$, then for every $k \in I_y$ $(x, y) \notin A_k \times B_k$; since $y \in B_k$, we have $x \notin A_k$ for every $k \in I_y$, i.e. A is the disjoint union of $\{A_k : k \in I_y\}$. Thus

$$\phi(y) = \mu(A) \leq \sum_{k \in I_y} \mu(A_k) = \sum_{k \in I_y} \mu(A_k)\chi_{B_k}(y)$$

$$= \sum_{k \in \mathbb{N}} \mu(A_k)\chi_{B_k}(y) = \psi(y)$$

(with equality in case (ii′)), where the first equality in the last line is because the additional terms are zero. Thus $\phi \leq \psi$, with equality in case (ii′). So

$$\mu(A)\nu(B) = \int_Y \phi \, d\nu \leq \int_Y \psi \, d\nu = \int_Y \left[\sum_{k=1}^{\infty} \mu(A_k)\chi_{B_k} \right] d\nu$$

$$= \sum_{k=1}^{\infty} \mu(A_k) \left[\int_Y \chi_{B_k} \, d\nu \right] = \sum_{k=1}^{\infty} \mu(A_k)\nu(B_k)$$

(with equality in case (ii′)), where interchange of the sum and integral is justified by the MCT (XVIII.1.5.5.). Thus ι satisfies (ii′) and (iii) and is a premeasure.

The other conclusions then follow from XVII.4.5.8.. 👍

XVII.7.2.7. DEFINITION. The measure $\mu \times \nu$ is called the *product measure* of μ and ν.

Completeness

XVII.7.2.8. There is a slight ambiguity in XVII.7.2.7.. By the Extension Theorem, the σ-algebra $\mathcal{M}$ of $(\mu \times \nu)$-measurable sets contains the σ-algebra $\mathcal{A} \otimes \mathcal{B}$. But $(X \times Y, \mathcal{M}, \mu \times \nu)$ is a complete measure space and $\mathcal{M}$ is strictly larger than $\mathcal{A} \otimes \mathcal{B}$ in general. By slight abuse of notation, we will write $\mu \times \nu$ for the measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$ and $\overline{\mu \times \nu}$ for the measure on $\mathcal{M}$, and we will write $\mathcal{A} \bar{\otimes} \mathcal{B}$ for $\mathcal{M}$; we will sometimes use the notation $\mu \times \nu$ for both the measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$ and its extension on $(X \times Y, \mathcal{M})$ when a distinction is unimportant.

If μ and ν are σ-finite, then $(X \times Y, \mathcal{M}, \overline{\mu \times \nu})$ is precisely the completion of $(X \times Y, \mathcal{A} \otimes \mathcal{B}, \mu \times \nu)$ (XVII.4.5.8.). If $(X, \bar{\mathcal{A}}, \bar{\mu})$ and $(Y, \bar{\mathcal{B}}, \bar{\nu})$ are the completions of $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ respectively, then the outer measures induced by ι on $\mathcal{A} \times \mathcal{B}$ and $\bar{\iota}$ on $\bar{\mathcal{A}} \times \bar{\mathcal{B}}$ coincide (Exercise XVIII.3.3.2.); so if $\bar{\mathcal{M}}$ is the σ-algebra of $(\bar{\mu} \times \bar{\nu})$-measurable sets, then $\bar{\mathcal{M}} = \mathcal{M}$. Thus in the σ-finite case we can also identify the completion of $(X \times Y, \bar{\mathcal{A}} \otimes \bar{\mathcal{B}}, \bar{\mu} \times \bar{\nu})$ with $(X \times Y, \mathcal{M}, \overline{\mu \times \nu})$, i.e. the completions of $(X \times Y, \mathcal{A} \otimes \mathcal{B}, \mu \times \nu)$ and $(X \times Y, \bar{\mathcal{A}} \otimes \bar{\mathcal{B}}, \bar{\mu} \times \bar{\nu})$ coincide, and in particular $\mathcal{A} \bar{\otimes} \mathcal{B} = \bar{\mathcal{A}} \bar{\otimes} \bar{\mathcal{B}}$.

Products of Finitely Many Spaces

XVII.7.2.9. The results about products of two measure spaces can easily be generalized to products of finitely many. If $(X_1, \mathcal{A}_1), \cdots, (X_n, \mathcal{A}_n)$ are measurable spaces, then a set of the form $A_1 \times \cdots \times A_n$ with $A_i \subseteq X_i$, is called a *rectangle*, a *measurable rectangle* if $A_i \in \mathcal{A}_i$ for each i. Then $\mathcal{A}_1 \otimes \cdots \otimes \mathcal{A}_n$ is the σ-algebra generated by the measurable rectangles in $X_1 \times \cdots \times X_n$. If $I = \{1, \ldots, n\}$, $\mathcal{A}_1 \otimes \cdots \otimes \mathcal{A}_n$ is often denoted $\bigotimes_{i \in I} \mathcal{A}_i$ or $\bigotimes_{i=1}^{n} \mathcal{A}_i$.

The next proposition shows that the product σ-algebra can be defined also by successive products of two σ-algebras, using any convenient grouping:

XVII.7.2.10. Proposition. Let $(X, \mathcal{A})$, $(Y, \mathcal{B})$, and $(Z, \mathcal{C})$ be measurable spaces. If $X \times Y \times Z$ is identified with $(X \times Y) \times Z$ and $X \times (Y \times Z)$ in the standard way, we have $\mathcal{A} \otimes \mathcal{B} \otimes \mathcal{C} = (\mathcal{A} \otimes \mathcal{B}) \otimes \mathcal{C} = \mathcal{A} \otimes (\mathcal{B} \otimes \mathcal{C})$.

The proof is routine, and is left as an exercise.

XVII.7.2.11. Corollary. Let $(X_1, \mathcal{A}_1), \ldots, (X_n, \mathcal{A}_n)$ be measurable spaces, and let I_1, I_2 be disjoint subsets of $I = \{1, \ldots, n\}$ with $I = I_1 \cup I_2$. If $\prod_{i \in I} X_i$ is identified with $\left(\prod_{i \in I_1} X_i\right) \times \left(\prod_{i \in I_2} X_i\right)$ in the standard way, then

$$\bigotimes_{i \in I} \mathcal{A}_i = \left(\bigotimes_{i \in I_1} \mathcal{A}_i\right) \otimes \left(\bigotimes_{i \in I_2} \mathcal{A}_i\right).$$

There is then an analog of XVII.7.1.5.. This can be proved directly in the same way as XVII.7.1.5., or by repeated application of XVII.7.1.5. and XVII.7.2.10..

XVII.7.2.12. Theorem. Let $(X_1, \mathcal{A}_1), \ldots, (X_n, \mathcal{A}_n)$ and $(Z, \mathcal{C})$ be measurable spaces. Let π_k $(1 \leq k \leq n)$ be the projections from $X_1 \times \cdots \times X_n$ to X_k, i.e. $\pi_k(x_1, \ldots, x_n) = x_k$. Then

(i) π_k is an $(\mathcal{A}_1 \otimes \cdots \otimes \mathcal{A}_n, \mathcal{A}_k)$-measurable function.

(ii) If $f : Z \to (X_1 \times \cdots \times X_n)$ is a function, then f is $(\mathcal{C}, \mathcal{A}_1 \otimes \cdots \otimes \mathcal{A}_n)$-measurable if and only if $\pi_k \circ f : Z \to X$ is $(\mathcal{C}, \mathcal{A}_k)$-measurable for each k, $1 \leq k \leq n$.

We also have the analog of XVII.7.1.4., which can also either be proved directly in the same way as XVII.7.1.4. or by repeated application of XVII.7.1.4. and XVII.7.2.10..

XVII.7.2.13. PROPOSITION. Let $(X_1, \mathcal{A}_1), \ldots, (X_n, \mathcal{A}_n)$ be measurable spaces. Then the set $\mathcal{C} = \{A_1 \times \cdots \times A_n : A_i \in \mathcal{A}_i\}$ of measurable rectangles is a semialgebra.

XVII.7.2.14. If $(X_1, \mathcal{A}_1, \mu_1), \cdots, (X_n, \mathcal{A}_n, \mu_n)$ are measure spaces, we can form a product measure $\mu_1 \times \cdots \times \mu_n$ on $(\prod_{i=1}^n X_i, \bigotimes_{i=1}^n \mathcal{A}_i)$ such that $(\mu_1 \times \cdots \times \mu_n)(A_1 \times \cdots \times A_n) = \mu_1(A_1)\mu_2(A_2)\cdots\mu_n(A_n)$ for any $A_i \in \mathcal{A}_i$. The proof of the next theorem is an adaptation of the proof of () and is left as an exercise ().

XVII.7.2.15. THEOREM. Let $\{(X_i, \mathcal{A}_i, \mu_i) : 1 \leq i \leq n\}$ be measure spaces. For $\prod_{i=1}^n A_i$ in the semialgebra $\mathcal{C}$ of measurable rectangles (XVII.7.2.13.), set $\tau(\prod_{i=1}^n A_i) = \mu_1(A_1)\cdots\mu_n(A_n)$. Then τ is a premeasure on $\mathcal{C}$, and hence τ extends to a measure on $(\prod_{i=1}^n X_i, \bigotimes_{i=1}^n \mathcal{A}_i)$ denoted $\mu_1 \times \cdots \times \mu_n$ or $\times_{i=1}^n \mu_i$, by the Caratheodory extension process. If all μ_i are σ-finite, then $\times_{i=1}^n \mu_i$ is the unique extension of τ to a measure on $(\prod_{i=1}^n X_i, \bigotimes_{i=1}^n \mathcal{A}_i)$.

The next fact is immediate from the uniqueness in the σ-finite case, but holds in general. The proof in the general case is routine but somewhat tedious, and the result in the non-σ-finite case is of limited interest, so we omit the details.

XVII.7.2.16. PROPOSITION. Let $(X_1, \mathcal{A}_1, \mu_1), \ldots, (X_n, \mathcal{A}_n, \mu_n)$ be measure spaces, and let I_1, I_2 be disjoint subsets of $I = \{1, \ldots, n\}$ with $I = I_1 \cup I_2$. If $\prod_{i \in I} X_i$ is identified with $\left(\prod_{i \in I_1} X_i\right) \times \left(\prod_{i \in I_2} X_i\right)$ in the standard way, then

$$\times_{i \in I} \mu_i = (\times_{i \in I_1} \mu_i) \times (\times_{i \in I_2} \mu_i) .$$

XVII.7.3. Lebesgue Measure on $\mathbb{R}^n$

XVII.7.4. Infinite Product Spaces

It is also possible to define an infinite Cartesian product of measure spaces provided that all (or all but finitely many) of the measures are probability measures.

XVII.7.4.1. Suppose that $\{(X_i, \mathcal{A}_i) : i \in I\}$ is an indexed collection of measurable spaces. A *rectangle* in $\prod_i X_i$ is a finite set $I_0 = \{i_1, \ldots, i_n\}$ of coordinates, and for each i_k a subset A_{i_k} of X_{i_k}. The corresponding set

$$\{(\cdots x_i \cdots) \in \prod_i X_i : x_{i_k} \in A_{i_k} \text{ for all } k, 1 \leq k \leq n\}$$

is often denoted $A_{i_1} \times \cdots \times A_{i_n}$, although it should more correctly be denoted $\prod_{i \in I_0} A_i \times \prod_{i \notin I_0} X_i$. Such a rectangle is a *measurable rectangle* if each A_{i_k} is in $\mathcal{A}_{i_k}$.

If A_i is a subset of X_i for each i, then the subset

$$\prod_i A_i = \{(\cdots x_i \cdots) \in \prod_i X_i : x_i \in A_i \text{ for all } i \in I\}$$

is called a *box*, and, if each $A_i \in \mathcal{A}_i$, a *measurable box*. Note that a [measurable] box is not a [measurable] rectangle in general if I is infinite, unless $A_i = X_i$ for all but finitely many i.

XVII.7.4.2. DEFINITION. The *product σ-algebra* $\bigotimes_{i \in I} \mathcal{A}_i$ is the σ-algebra on $\prod_i X_i$ generated by the measurable rectangles.

XVII.7.4.3. PROPOSITION. If I is countable, then every measurable box is in $\bigotimes_i \mathcal{A}_i$.

XVII.7.4.4. This statement is false in general if I is uncountable. We say that a subset A of $\prod_i X_i$ *depends only on the coordinates in $J \subseteq I$* if, whenever $x = (\cdots x_i \cdots)$ and $y = (\cdots y_i \cdots)$ are elements of $\prod_i X_i$, and $x_j = y_j$ for all $j \in J$, then $x \in A$ if and only if $y \in A$. A subset A of $\prod_i X_i$ *depends on finitely many* [*countably many*] *coordinates* if it depends only on some finite [countable] set of coordinates. Thus every rectangle depends only on finitely many coordinates.

XVII.7.4.5. PROPOSITION. Every set in $\bigotimes_i \mathcal{A}_i$ depends only on countably many coordinates.

PROOF: It is easily checked that the collection of all sets which depend on only countably many coordinates is a σ-algebra. 👍

XVII.7.4.6. COROLLARY. A nonempty measurable box $\prod_i A_i$ is in $\bigotimes_i \mathcal{A}_i$ if and only if $A_i = X_i$ for all but countably many i.

Infinite product measures are particularly important in probability. The next example is a good illustration of an infinite product measure which has a nice probabilistic interpretation.

XVII.7.4.7. EXAMPLE. Let $X = \{0,1\}$, and for each n let $(X_n, \mathcal{A}_n) = (X, \mathcal{P}(X))$. Put a measure μ on $(X, \mathcal{P}(X))$ by $\mu(\{0\}) = \mu(\{1\}) = 1/2$, and let μ_n be the corresponding measure on $(X_n, \mathcal{A}_n)$. Let $X^{\mathbb{N}} = \prod_{n\in\mathbb{N}} X_n$, $\mathcal{A}^{\mathbb{N}} = \bigotimes_{n\in\mathbb{N}} \mathcal{A}_n$, and $\mu^{\mathbb{N}} = \times_{n\in\mathbb{N}}\mu_n$. $(X, \mathcal{P}(X), \mu)$ is not a very interesting or complicated measure space, but $(X^{\mathbb{N}}, \mathcal{A}^{\mathbb{N}}, \mu^{\mathbb{N}})$ is quite interesting and nontrivial. Elements of $X^{\mathbb{N}}$ are, of course, all sequences of 0's and 1's.

If instead of $\{0,1\}$ we take $X = \{H,T\}$, we may interpret $(X, \mathcal{P}(X), \mu)$ as the sample space of the experiment of tossing a fair coin once. Then $(X^{\mathbb{N}}, \mathcal{A}^{\mathbb{N}}, \mu^{\mathbb{N}})$ can be interpreted as the sample space of the experiment of tossing a fair coin infinitely many times. Probabilists use this measure space to analyze such things as the likelihood of long runs and other details in a sequence of coin tosses. This is a good example of a *stochastic process*, the study of which is an entire branch of probability theory.

This example also has other interpretations not closely connected with probability. The product measure can be interpreted as a measure on the Cantor set () or as Haar measure on a certain compact topological group (). There is also a close connection with Lebesgue measure on the unit interval ().

The example could be modified by taking $\mu_\alpha(\{0\}) = \alpha$, $\mu_\alpha(\{1\}) = 1-\alpha$ for some fixed α, $0 < \alpha < 1$ (the original μ is $\mu_{1/2}$.) The measure μ_α could be interpreted probabilistically (using $\{H,T\}$ for $\{0,1\}$) as tossing an unfair coin with probability of heads equal to α. It turns out that the $\mu_\alpha^{\mathbb{N}}$ are mutually singular continuous probability measures on $(X^{\mathbb{N}}, \mathcal{A}^{\mathbb{N}})$ as α ranges over $(0,1)$ (). One could even similarly define μ_0 and μ_1; $\mu_0^{\mathbb{N}}$ is then the point mass at the constant sequence of 0's, and $\mu_1^{\mathbb{N}}$ the point mass at the constant sequence of 1's.

XVII.7.4.8. One might try to construct the infinite product of $\{(X_i, \mathcal{A}_i, \mu_i) : i \in I\}$ (where $\mu_i(X_i) = 1$ for all i) as follows. For each finite subset F of I, let $\mathcal{A}_F$ be the σ-algebra on $X = \prod_i X_i$ generated by the measurable rectangles depending only on F, and μ_F the measure on $(X, \mathcal{A}_F)$ which is effectively $\times_{i\in F}\mu_i$ using the obvious identification of $\mathcal{A}_F$ with $\otimes_{i\in F}\mathcal{A}_i$ on $\prod_{i\in F} X_i$. Then $\mathcal{B} = \cup_F \mathcal{A}_F$ is an algebra of subsets of X, and the μ_F give a well-defined function ι from $\mathcal{B}$ to $[0,1]$. The σ-algebra generated by $\mathcal{B}$ is $\otimes_{i\in I}\mathcal{A}_i$, and $\times_i\mu_i$ is an extension of ι to $\otimes_{i\in I}\mathcal{A}_i$, so one might try to obtain $\times_{i\in I}\mu_i$ directly from ι by the Caratheodory extension process.

The difficulty in this approach is showing that ι is a premeasure on $\mathcal{B}$. This is not automatic: it is not true in general that if $(X, \mathcal{A}_n, \nu_n)$ is a compatible family of probability measures on an increasing sequence $(\mathcal{A}_n)$ of σ-algebras, that the function ι defined by the ν_n on the algebra $\cup_n\mathcal{A}_n$ is a premeasure. For example, let $X = \mathbb{N}$, $\mathcal{A}_n$ the σ-algebra of all subsets of $\{1,\dots,n\}$ and their complements in $\mathbb{N}$, and ν_n the measure on $(\mathbb{N}, \mathcal{A}_n)$ with $\nu_n(A) = 0$ if $A \subseteq \{1,\dots,n\}$ and $\nu_n(A) = 1$ if $\mathbb{N} \setminus A \subseteq \{1,\dots,n\}$. Then the function ι is not a premeasure on $\cup_n\mathcal{A}_n$.

XVII.7.5. Exercises

XVII.7.5.1. Let X and Y be sets, and $E \subseteq X \times Y$. For each $x \in X$, set

$$E_x = \{y \in Y : (x,y) \in E\} \subseteq Y$$

$$\mathcal{S}_X(E) = \{E_x : x \in X\} \subseteq \mathcal{P}(Y)\ .$$

$\mathcal{S}_X(E)$ is the set of "vertical cross-sections" of the set E. The *X-variety* of E is $var_X(E) = card(\mathcal{S}_X(E))$, the "number" of different sets occurring as vertical cross sections of E. Similarly, for $y \in Y$ define

$$E^y = \{x \in X : (x,y) \in E\} \subseteq X$$

$$\mathcal{S}_Y(E) = \{E^y : y \in Y\} \subseteq \mathcal{P}(X)$$

and the *Y-variety* of E to be $var_Y(E) = card(\mathcal{S}_Y(E))$.

(a) Prove that $\mathcal{C}_X = \{E \subseteq X \times Y : var_X(E) \leq 2^{\aleph_0}\}$ is a σ-algebra of subsets of $X \times Y$ containing $\mathcal{P}(X) \otimes \mathcal{P}(Y)$. Similarly, $\mathcal{C}_Y = \{E \subseteq X \times Y : var_Y(E) \leq 2^{\aleph_0}\}$ is a σ-algebra containing $\mathcal{P}(X) \otimes \mathcal{P}(Y)$.

(b) If $card(X) > 2^{\aleph_0}$ and $card(Y) \geq 2^{\aleph_0}$, then $\mathcal{P}(X) \otimes \mathcal{P}(Y) \neq \mathcal{P}(X \times Y)$. [Let $\kappa = \min(card(X), 2^{2^{\aleph_0}})$. Construct an $E \subseteq X \times Y$ with $var_X(E) = \kappa$. (What is really needed is a function from X to $\mathcal{P}(Y)$ whose range has cardinality greater than $2^{\aleph_0}$; AC is needed in general to insure that $card(X)$ is comparable with $2^{2^{\aleph_0}}$.)]

(c) Is it true that $\mathcal{P}(X) \otimes \mathcal{P}(Y) = \mathcal{C}_X \cap \mathcal{C}_Y$ for all X, Y?

(d) Is $\mathcal{P}(\mathbb{R}) \otimes \mathcal{P}(\mathbb{R}) = \mathcal{P}(\mathbb{R}^2)$? [Unfair question: it cannot be answered in ZFC! The CH, or, more generally, Martin's Axiom (II.10.5.6.), implies a positive answer, but (if ZFC is consistent) there are models of ZFC where the answer is negative. See ().]

XVII.7.5.2. ([GP10], attributed to von Neumann) Let $R = \prod_{k=1}^n [a_k, b_k]$ be a closed rectangle in $\mathbb{R}^n$. Note that $\lambda(R) \leq \prod_{k=1}^n (b_k - a_k)$ is immediate from the definition. The aim of this problem is to show the opposite inequality.

(a) Suppose $R_1, \ldots, R_m$ are open rectangles covering R (note that any cover of R by open rectangles has a finite subcover). Let $R_j = \prod_{k=1}^n (a_k^{(j)}, b_k^{(j)})$. If $S \subseteq \mathbb{R}^n$, let $\#(S)$ be the number of points with integer coordinates in S. If $\alpha > 0$ is large enough that $\alpha(b_k - a_k) > 1$ and $\alpha(b_k^{(j)} - a_k^{(j)}) > 1$ for all k and j, then

$$\prod_{k=1}^n (\alpha b_k - \alpha a_k - 1) \leq \#(\alpha R) \leq \sum_{j=1}^m \#(\alpha R_j) \leq \sum_{j=1}^m \prod_{k=1}^n (\alpha b_k^{(j)} - \alpha a_k^{(j)} + 1) \ .$$

(b) Let $\alpha \to +\infty$ to conclude that

$$\prod_{k=1}^n (b_k - a_k) \leq \sum_{j=1}^m \prod_{k=1}^n (b_k^{(j)} - a_k^{(j)}) \ .$$

Taking the infimum over all such open covers, conclude that

$$\prod_{k=1}^n (b_k - a_k) \leq \lambda(R) \ .$$

XVII.7.5.3. Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces, with completions $(X, \bar{\mathcal{A}}, \bar{\mu})$ and $(Y, \bar{\mathcal{B}}, \nu)$ respectively, and let ι and $\bar{\iota}$ be the induced premeasures on $\mathcal{A} \times \mathcal{B}$ and $\bar{\mathcal{A}} \times \bar{\mathcal{B}}$, i.e. $\iota(A \times B) = \mu(A)\mu(B)$ for $A \in \mathcal{A}$, $B \in \mathcal{B}$ and $\bar{\iota}(C \times D) = \bar{\mu}(C)\bar{\nu}(D)$ for $C \in \bar{\mathcal{A}}$, $D \in \bar{\mathcal{B}}$. Let θ^* and $\bar{\theta}^*$ be the outer measures on $X \times Y$ induced by ι and $\bar{\iota}$ respectively.

(a) If $C \in \bar{\mathcal{A}}$ and $D \in \bar{\mathcal{B}}$, show that there are $A \in \mathcal{A}$ and $B \in \mathcal{B}$ such that $C \subseteq A$, $D \subseteq B$, and $\iota(A \times B) = \bar{\iota}(C \times D)$.

(b) Show that $\bar{\theta}^* = \theta^*$.

XVII.8. The Besicovitch Covering Theorem

The Besicovitch Covering Theorem is a more flexible version of the Vitali Covering Theorem () which applies to arbitrary locally finite Borel measures on subsets of $\mathbb{R}^n$ and, more generally, on metric spaces which have a certain "finite-dimensionality."

This theorem was first stated in [Bes45] for $\mathbb{R}^2$ and soon extended to $\mathbb{R}^n$ [Mor47], and a very general version was given (somewhat cryptically) in [Fed69]. Our treatment is adapted from [Fed69], [FL94], and [Mor09]. Other relevant references include [KP86], [EoGKP88], [Pre83], and [Sul94] (there is a large additional literature on this and related matters). Our main interest is the $\mathbb{R}^n$ case, but there is no additional work in proving a very general version, even more general than the one in [Fed69]. The results are related to sphere-packing problems and sphere-of-influence graphs (cf. [FL94], [Sul94], [MQ94].

XVII.8.1. Controlled Metrics

We fix a metric space (X, ρ). We really want to work with closed balls in (X, ρ), but we must refer to the center and radius of a ball, neither of which is unique in general, so instead we work with pairs $(x, r) \in X \times (0, \infty)$, where (x, r) corresponds to the closed ball $\bar{B}_r(x)$ (i.e. to each (x, r) we associate a closed ball with specified center and radius). In many cases (e.g. in $\mathbb{R}^n$) this correspondence is a bijection.

XVII.8.1.1. Definition. If $\tau \geq 1$, a subset $\mathcal{P} = \{(x_i, r_i) : i \in I\}$ of $X \times (0, \infty)$ is *τ-controlled* if, for every $i \neq j$, either $\rho(x_i, x_j) > r_i \geq r_j/\tau$ or $\rho(x_i, x_j) > r_j \geq r_i/\tau$.

If $0 < R \leq \infty$ and $\tau \geq 1$, and $(x, r) \in X \times (0, \infty)$ with $r \leq R$, an *(R, τ)-controlled expansion* of (x, r) is a τ-controlled set $\mathcal{P} = \{(x_i, r_i) : i \in I\}$ such that

(i) $r/\tau \leq r_i \leq R$ for all $i \in I$.

(ii) For each $i \in I$, $\bar{B}_{r_i}(x_i) \cap \bar{B}_r(x) \neq \emptyset$.

(iii) $x \notin \bar{B}_{r_i}(x_i)$ (i.e. $r_i < \rho(x, x_i)$) for all $i \in I$.

A *strictly controlled expansion* of $(x, r) \in X \times (0, \infty)$ is a 1-controlled expansion in which $r_i = r$ for all i.

The metric ρ is *(R, τ)-controlled* ($\tau \geq 1$) if there is an $M \in \mathbb{N}$ such that, whenever $(x, r) \in X \times (0, \infty)$, $r < R$, and $\mathcal{C} = \{(x_i, r_i) : i \in I\}$ is an (R, τ)-controlled expansion of (x, r), then $card(I) \leq M - 1$. The metric ρ is *controlled* if it is (R, τ)-controlled for some $R > 0$ and $\tau > 1$.

The metric ρ is *strictly controlled* if there is an R and $M \in \mathbb{N}$ such that, whenever $(x, r) \in X \times (0, \infty)$, $r < R$, and $\mathcal{C} = \{(x_i, r) : i \in I\}$ is a strictly controlled expansion of (x, r), then $card(I) \leq M$.

XVII.8.1.2. The definition of a controlled metric is a little difficult to digest. Strictly controlled is easier to understand: it means that for any closed ball B in X of (specified) radius $r \leq R$, there are at most M closed balls of (specified) radius r intersecting B, including B, with no ball containing the (specified) center of any other ball. The variations with $\tau > 1$ and allowing the r_i to be greater than r are needed for technical reasons. ("Strictly controlled" should perhaps be called "strictly 1-controlled"; one could also make a definition of a strictly τ-controlled metric for $\tau > 1$, but this does not seem to be useful.)

Being controlled is a metric property. Even replacing a metric with a uniformly equivalent metric need not preserve control (Exercise XVII.8.4.8.).

XVII.8.1.3. PROPOSITION. (i) Any subspace of a controlled metric space is controlled (with the restriction metric).

(ii) A metric space is controlled (resp. strictly controlled) if and only if its completion is controlled (resp. strictly controlled).

Although checking that a metric is controlled can be difficult, there are important special cases which cover most situations of interest.

XVII.8.1.4. EXAMPLE. Let (X, ρ) be an ultrametric space (). Then any for any two closed balls, either the balls are disjoint or one is contained in the other. An ultrametric space is $(\infty, 1)$-controlled, with $M = 1$. But if $\tau > 1$, the situation is dicier: a τ-controlled expansion P of (x, r) would consist of a set of "almost disjoint" balls of radius greater than r/τ contained in $\bar{B}_r(x)$. These need not be bounded in number (XVII.8.4.8.). However, the p-adic numbers $\mathbb{Q}_p$, or any finite-dimensional ultranormed vector space over $\mathbb{Q}_p$, is (∞, τ)-controlled with $M = 1$ for $\tau > 1$ sufficiently close to 1.

XVII.8.1.5. If $\tau \geq \tau' \geq 1$, an (R, τ)-controlled metric is (R, τ')-controlled for any R, and is strictly controlled. The main difference between "controlled" and "strictly controlled," besides the presence of $\tau > 1$ (which is relatively harmless (XVII.8.1.12.)), is that for controlled expansions the r_i are allowed to be much larger than r, and there is no control (pun intended) over the ratios r_i/r and thus no ball of controlled size containing all the (x_i, r_i). This turns out to be a considerable technical difficulty (cf. Exercise XVII.8.4.4.) and can only be overcome if the metric space has enough "approximately interpolating" points.

The most important example is:

XVII.8.1.6. THEOREM. Let $(X, \|\cdot\|)$ be a finite-dimensional normed vector space, and ρ the induced metric on X. Then ρ is controlled.

Even if one is only interested in the case $X = \mathbb{R}^n$, one must essentially prove this theorem as part of the (standard) proof of the Besicovitch Covering Theorem; in fact, proving this theorem is arguably the most delicate part of the proof of the Besicovitch Covering Theorem. The proof relates this problem to the sphere-packing problem, and thus is geometric in nature. Our exposition of the proof is adapted from [FL94]. See [Sul94] for an alternate argument for $\mathbb{R}^n$ based on the Law of Cosines, although the reduction to $\tau = 1$ there is incomplete and flawed (the remark on p. 200 contains an incorrect statement and an inadequately justified statement; the paper does not have a proof that $\beta_n(\epsilon) < \infty$ for any $\epsilon > 0$). See [Fed69, 2.8] for another argument (cf. Exercise XVII.8.4.2.).

XVII.8.1.7. For the proof, we introduce some notation. For $\tau \geq 1$ let $M(X, \tau)$ be the smallest M such that every (∞, τ)-controlled expansion of a (closed) ball in X has cardinality $\leq M - 1$. By homogeneity and translation-invariance, $M(X, \tau)$ is the smallest M such that every (∞, τ)-controlled expansion of the closed unit ball in X has cardinality $\leq M - 1$. To prove the theorem we must show that $M(X, \tau)$ is finite for some $\tau > 1$. $M(X, \tau)$ is an increasing function of τ. Set $M(X) = M(X, 1)$.

XVII.8.1.8. For technical reasons, we slightly modify the definition of a controlled expansion, replacing all strict inequalities with nonstrict ones. If $\tau \geq 1$, a *τ-satellite configuration* is a set of closed balls $\{(x_i, r_i) : 0 \leq i\}$ with each $r_i \geq 1/\tau$, $x_0 = 0$, $r_0 = 1$, such that $\bar{B}_{r_i}(x_i) \cap \bar{B}_1(0) \neq \emptyset$ for all i, $\rho(x_i, 0) = \|x_i\| \geq \max(r_i, 1)/\tau$ and, for $i \neq j$, either $\rho(x_i, x_j) = \|x_i - x_j\| \geq r_i \geq r_j/\tau$ or $\rho(x_i, x_j) \geq r_j \geq r_i/\tau$. Let $\tilde{M}(X, \tau)$ be the maximum cardinality of a τ-satellite configuration. A τ-controlled expansion of the unit ball, along with the unit ball itself, is a τ-satellite configuration; thus $M(X, \tau) \leq \tilde{M}(X, \tau)$. $\tilde{M}(X, \tau)$ is an increasing function of τ. Set $\tilde{M}(X) = \tilde{M}(X, 1)$.

XVII.8.1.9. We also consider the sphere-packing constant $\theta(X)$, the largest number of points of distance at least 1 apart which can be put into the closed ball of radius 2 around the origin in X with one of the points at the origin. If we consider the closed balls of radius 1 around such a collection, we obtain a 1-satellite configuration; thus $\theta(X) \leq \tilde{M}(X)$.

XVII.8.1.10. PROPOSITION. If X is a normed vector space of dimension d, then $\theta(X) \leq 5^d$ (and in particular is finite).

PROOF: If $\{x_i : 1 \leq i \leq m\}$ is a set of points of distance ≥ 1 apart in $\bar{B}(0, 2)$, then the open balls of radius $1/2$ around the x_i form a pairwise disjoint set of balls of radius $1/2$ in the ball of radius $5/2$ around 0, of cardinality m. Identifying X with $\mathbb{R}^d$ and taking λ to be Lebesgue measure on $\mathbb{R}^d$, we have

$$m\lambda(B_{1/2}(0)) \leq \lambda(B_{5/2}(0)) = 5^d \lambda(B_{1/2}(0)) \ .$$

XVII.8.1.11. PROPOSITION. Let $(X, \|\cdot\|)$ be a finite-dimensional normed vector space. Then there is an ϵ, $0 < \epsilon < 1$, such that $\theta(X)$ is the largest number of points of distance $\geq 1 - \epsilon$ apart which can be put into the closed ball $B = \bar{B}_2(0)$, with one point at the origin.

PROOF: Suppose not. Set $m = \theta(X) + 1$. Then for each n there are points $x_1^{(n)}, \ldots, x_m^{(n)}$ in B of distance $\geq 1 - \frac{1}{n}$ apart, with $x_1^{(n)} = 0$. By compactness of B, passing to subsequences we may assume that for each i, $x_i^{(n)} \to x_i$ for some $x_i \in B$. Then the x_i are a set of points of B of distance ≥ 1 apart, of cardinality m, with $x_1 = 0$, a contradiction. 

Theorem XVII.8.1.6. is a corollary of the following result:

XVII.8.1.12. THEOREM. Let $(X, \|\cdot\|)$ be a finite-dimensional normed vector space. Let $\epsilon > 0$ be as in XVII.8.1.11.. Then, if $1 \leq \tau < 1 + \frac{\epsilon}{4}$, we have

$$\theta(X) = \tilde{M}(X) = \tilde{M}(X, \tau) \ .$$

In particular, $M(X, \tau) \leq \theta(X) \leq 5^{dim(X)} < \infty$.

PROOF: By XVII.8.1.9., we only need to show that $\tilde{M}(X,\tau) \leq \theta(X)$. To understand the proof, first consider the case where $\tau = 1$ (1-satellite configuration), which gives the inequality $\tilde{M}(X) \leq \theta(X)$. The general proof needs some estimates to handle the case where $\tau > 1$. The two estimates needed are

$$1 - \frac{1}{\tau} = \frac{\tau - 1}{\tau} \leq \tau - 1 < \frac{\epsilon}{4} < \epsilon$$

$$2\tau^2\left(1 - \frac{1}{\tau}\right) \leq 2\tau^2(\tau - 1) < 2\left(1 + \frac{\epsilon}{4}\right)^2 \frac{\epsilon}{4} < 2\left(\frac{5}{4}\right)^2 \frac{\epsilon}{4} = \frac{25}{32}\epsilon < \epsilon$$

since $\epsilon < 1$.

Suppose $\{(x_i, r_i) : 0 \leq i \leq m\}$ is a τ-satellite configuration. For each i set

$$y_i = \begin{cases} x_i & \text{if} \quad \|x_i\| \leq 2 \\ \frac{2}{\|x_i\|} x_i & \text{if} \quad \|x_i\| > 2 \end{cases}$$

i.e. the x_i outside the ball of radius 2 around 0 are radially projected onto the sphere of radius 2. We claim that $\|y_i - y_j\| \geq 1 - \epsilon$ for all $i \neq j$. This is obvious if $\|x_i\|$ and $\|x_j\|$ are ≤ 2.

If $\|x_i\| > 2$, $(y_i, 1) \subseteq (x_i, r_i)$ since $(x_i, r_i) \cap (0, 1) \neq \emptyset$. If $\|x_i\| > 2$, $\|x_j\| \leq 2$, and $\|x_i - x_j\| \geq r_i$, we have $\|y_i - y_j\| = \|y_i - x_j\| \geq 1$. $\|x_i\| > 2$, $\|x_j\| \leq 2$, and $\|x_i - x_j\| < r_i$, we have $\|x_i - x_j\| \geq r_j \geq r_i/\tau$, so

$$2\tau \geq \|x_j\|\tau \geq r_j$$

so $2\tau^2 \geq r_i$. Thus

$$r_i - r_i/\tau = r_i\left(1 - \frac{1}{\tau}\right) \leq 2\tau^2\left(1 - \frac{1}{\tau}\right) < \epsilon$$

and

$$\|y_i - y_j\| = \|y_i - x_j\| \geq \|x_i - x_j\| - \|x_i - y_i\| \geq r_i/\tau - (r_i - 1) = 1 - (r_i - r_i/\tau) > 1 - \epsilon \ .$$

Now consider the case $\|x_i\| \geq \|x_j\| > 2$. Set $s = \|x_j\|$ and $z = \frac{s}{\|x_i\|} x_i$ (z is the point on the ray from 0 to x_i of norm s). We have

$$\|x_i - x_j\| \leq \|x_i - z\| + \|z - x_j\| = (\|x_i\| - s) + \|z - x_j\| \ .$$

If $a \in (x_i, r_i) \cap (0, 1)$, we have

$$\|x_i\| \leq \|x_i - a\| + \|a\| \leq r_i + 1$$

so

$$\|z - x_j\| \geq (s + \|x_i - x_j\|) - \|x_i\| \geq (s + \|x_i - x_j\|) - (r_i + 1) = (s - 1) + (\|x_i - x_j\| - r_i) \ .$$

We have $y_i = \frac{2}{s} z$ and $y_j = \frac{2}{s} x_j$, so if $\|x_i - x_j\| \geq r_i$ we have

$$\|y_i - y_j\| = \frac{2}{s}\|z - x_j\| \geq \frac{2}{s}(s - 1) = 2 - \frac{2}{s} > 1$$

since $s > 2$. If $\|x_i - x_j\| < r_i$, then $\|x_i - x_j\| \geq r_j \geq r_i/\tau$ so

$$r_i - \|x_i - x_j\| \leq r_i - r_j \leq \tau r_j - r_j = r_j(\tau - 1) \leq \tau s(\tau - 1) \ .$$

We have $2\tau(\tau-1) \leq 2\tau^2(\tau-1) < \epsilon$, so

$$\|y_i - y_j\| \geq \frac{2}{s}[(s-1) - (\|x_i - x_j\| - r_i)] \geq \left(2 - \frac{2}{s}\right) - 2\tau(\tau-1) > 1 - \epsilon \ .$$

Thus, since $y_0 = 0$, $m \leq \theta(X)$. 👍

XVII.8.1.13. It is generally difficult to find $M(X)$ for a given normed vector space; the bound $M(X) \leq 5^{dim(X)}$ is usually crude. $M(\mathbb{R}^2)$ with the usual metric is 19 (Exercise XVII.8.4.3.). Exact values for $M(\mathbb{R}^n)$ for $n > 2$ do not appear to be known. However, for our purposes the value does not matter; we only need to know it is finite.

XVII.8.1.14. There are many other metric spaces of interest which are controlled besides subsets of Euclidean space (or finite-dimensional normed vector spaces); cf. Exercise XVII.8.4.2..

Finite-Dimensionality

XVII.8.1.15. PROPOSITION. (i) If (X, ρ) is a controlled metric space, then $dim(X) < \infty$ ().
(ii) If X is a separable metrizable (second countable regular) topological space and $dim(X) < \infty$, then there is a controlled metric on X giving its topology.

PROOF: (i) Let M be a constant for (X, ρ) as in the definition (for some R and $\tau > 1$). If $\mathcal{U}$ is an open cover of X, then $\mathcal{U}$ has a refinement $\mathcal{C}$ which is a Besicovitch cover. By (), $\mathcal{C}$ has a subcover $\mathcal{D}$ which can be split into at most M pieces $\mathcal{D}_i$, each of which consists of pairwise disjoint sets. Thus the nuclear dimension () of X is $\leq M - 1$.
(ii) X can be embedded in $\mathbb{R}^n$ for some n (XIII.22.6.3.). Apply XVII.8.1.3.(i). 👍

XVII.8.1.16. The upper bound of $M-1$ in (i) for $dim(X)$ is generally crude: $dim(X)$ is typically more on the order of $\log M$ or even smaller (cf. XVII.8.4.7.).

XVII.8.1.17. Not every metric on a finite-dimensional metric space, even a compact one, is controlled (XVII.8.4.8.).

XVII.8.2. The Besicovitch Partition Theorem

We first obtain a version of the Besicovitch Covering Theorem which has no reference to Borel measures. Actually the definition of a controlled metric was made specifically so this result holds.

There is inconsistency in the literature about names: some authors call this the Besicovitch Covering Theorem. ✋

Besicovich Coverings

XVII.8.2.1. DEFINITION. Let (X, ρ) be a metric space, and $A \subseteq X$. A *Besicovitch covering* (sometimes called a *fine covering*) of A in X is a collection $\mathcal{C} = \{(x_i, r_i) : i \in I\} \subseteq X \times (0, \infty)$ of closed balls in X such that for every $x \in A$ and $\epsilon > 0$, there is a δ with $0 < \delta \leq \epsilon$ with $(x, \delta) \in \mathcal{C}$.

In other words, for every $x \in A$, there are balls *centered at* x of arbitrarily small radius in the cover $\mathcal{C}$. This is stronger than the notion of a Vitali cover ().

Only small balls are needed, and we can restrict to small balls:

XVII.8.2.2. PROPOSITION. Let $\mathcal{C}$ be a Besicovitch covering of a subset A in a metric space (X, ρ).

(i) For any $\epsilon > 0$, the collection $\mathcal{C}_\epsilon$ of balls $(x, r) \in \mathcal{C}$ with $r < \epsilon$ is also a Besicovitch covering of A in X.

(ii) If W is an open subset of X containing A, then the set $\mathcal{C}_W$ of balls $(x, r) \in \mathcal{C}$ with $\bar{B}_r(x) \subseteq W$ is also a Besicovitch covering of A in X.

(iii) The subset $\mathcal{C}'$ of $\mathcal{C}$ consisting of balls in $\mathcal{C}$ with centers in A is also a Besicovitch covering of A.

XVII.8.2.3. Thus we may assume a Besicovitch covering of A in X has any or all of these properties. But it is convenient not to require them in the definition of Besicovitch covering.

The Partition Theorem

XVII.8.2.4. THEOREM. [BESICOVITCH PARTITION THEOREM] Let (X, ρ) be a metric space. If ρ is controlled with constants $M \in \mathbb{N}$, $R > 0$, and $\tau > 1$, $A \subseteq X$, and $\mathcal{C}$ is a Besicovitch covering of A, then there are M pairwise disjoint subcollections $\mathcal{D}_1, \ldots, \mathcal{D}_M$ of $\mathcal{C}$ such that $\cup_i \mathcal{D}_i$ covers A and each $\mathcal{D}_i$ consists of pairwise disjoint balls.

While a proof of this theorem using Zorn's Lemma can be given (cf. [Fed69, 2.8]), it is more illuminating to give a (semi)constructive proof by transfinite induction, along the lines of the argument outlined in [Mor09].

PROOF: We choose a set of balls by transfinite induction. We want at each step to choose the next ball to be the "largest" remaining ball; but since there may not be a largest ball, we will choose one which is "almost the largest." First well order the balls (x_α, r_α) in $\mathcal{C}$. By transfinite induction, we will select a ball, place it in a row, discard some other balls, and reindex the remaining balls.

Let $s = \sup\{r_\alpha : (x_\alpha, r_\alpha) \in \mathcal{C}\}$. At the first step, select the first (x_α, r_α) with $r_\alpha > s/\tau$, put it in the first row, and discard all balls (x_β, r_β) with $x_\beta \in \bar{B}_{r_\alpha}(x_\alpha)$. Reindex the remaining balls, calling the chosen ball B_0. Note that the remaining balls (B_0 along with the ones not discarded) still cover A.

Suppose $B_0, \ldots, B_\alpha$ have been chosen and put in rows, and some other ones discarded, so that

The balls already chosen form an (R, τ)-controlled set.

The chosen balls in each row are pairwise disjoint.

No chosen ball is disjoint from all the previously chosen balls in any higher row.

All remaining balls (x, r) not chosen have $r/\tau \leq r_\beta$ for all $\beta \leq \alpha$, and x not in any chosen ball.

The remaining balls (chosen or not) cover A.

Let s_α be the supremum of the radii of the remaining balls not chosen. Choose $B_{\alpha+1}$ to be the first remaining ball not yet chosen with radius greater than s_α/τ. By construction, the center $x_{\alpha+1}$ of $B_{\alpha+1}$ is not in any previously chosen ball; and $B_{\alpha+1}$ along with the previously chosen balls still form a τ-controlled set. Put $B_{\alpha+1}$ in the first row for which it is disjoint from the balls already in that row, or put it in a new row if there is no existing row for which this holds. Discard any succeeding balls whose center is in $\bar{B}_{r_\alpha}(x_\alpha)$. The remaining balls (chosen or not) still cover A. Reindex the remaining balls.

If α is a limit ordinal and B_β have been chosen for all $\beta < \alpha$. Set $t = \inf_{\beta<\alpha} r_\beta$. There are two cases:

(1) $t > 0$. Then the previously chosen B_β, along with the remaining balls, cover A: if $x \in A \setminus \cup_{\beta<\alpha} B_\beta$ and $(x, r) \in \mathcal{C}$ with $r < t$, then (x, r) has not been discarded. In this case we can choose B_α and discard and reindex the same way as above.

(2) $t = 0$. If $(x, r) \in \mathcal{C}$, choose $\beta < \alpha$ with $r_\beta/\tau < r$; then (x, r) must have been either chosen or discarded by the β'th step. Thus x is in one of the previously chosen balls, and the already chosen balls cover A. In fact, in this case there are no remaining balls not chosen, and the process terminates.

Continue transfinitely until there are no remaining balls not either chosen or discarded. (This will happen when (2) occurs.)

At the end of the process, we have balls from $\mathcal{C}$ in rows with the following properties:

All the balls cover A.

If (x, r) is a chosen ball and (y, s) a previously chosen ball, then $r/\tau \leq s$.

All the balls in each row are pairwise disjoint.

No ball in any row is disjoint from all the previously chosen balls in any previous row.

There could *a priori* be infinitely many rows, even uncountably many. But the key fact is:

XVII.8.2.5. LEMMA. There are at most M rows.

PROOF: Suppose there is a chosen ball B, of radius r, which is put in the $M+1$ row. Then in each preceding row k, there is a previously chosen ball B_k not disjoint from B; the radius of B_k is at least r/τ. Then, since all balls have radius no more than R, the balls $B_1, \ldots, B_M$ form an (R, τ)-controlled expansion of B of cardinality M, contradicting the choice of M, R, and τ. 👍

We let $\mathcal{D}_i$ be the set of balls in the i'th row (some $\mathcal{D}_i$ may be empty if there are less than M rows). This completes the proof of Theorem XVII.8.3.1.. 👍

XVII.8.3. The Besicovitch Covering Theorem

Informally, the Besicovitch Covering Theorem says that if μ is a locally finite Borel measure on a controlled metric space (X, ρ), $A \subseteq X$ of finite measure, and $\mathcal{C}$ a Besicovitch covering of A in X, then there is a sequence of pairwise disjoint closed balls in $\mathcal{C}$ which cover μ-almost all of A. We use the outer measure μ^* defined by μ (XVII.6.1.6.): if $Y \subseteq X$, set

$$\mu^*(Y) = \inf\{\mu(B) : B \text{ Borel}, Y \subseteq B\} = \min\{\mu(B) : B \text{ Borel}, Y \subseteq B\} .$$

We need this outer measure since A is not necessarily a Borel set in X.

XVII.8.3.1. Theorem. [Besicovitch Covering Theorem] Let (X, ρ) be a controlled metric space and μ a locally finite Borel measure () on X, $A \subseteq X$ with $\mu^*(A) < \infty$, and $\mathcal{C}$ a Besicovitch covering of A in X. Assume that

(i) There is a largest open set W in X with $\mu(W) = 0$.

((i) is automatic if (X, ρ) is separable). Then there is a countable subset $\mathcal{B} = \{(x_n, r_n)\}$ of $\mathcal{C}$ with the $\bar{B}_{r_n}(x_n)$ pairwise disjoint, such that

$$\mu^*\left(A \setminus \bigcup_{\mathcal{B}} \bar{B}_{r_n}(x_n)\right) = 0 .$$

($\mathcal{B}$ will usually be countably infinite, i.e. a sequence.) For any $\epsilon > 0$, we may choose $\mathcal{B}$ so that

$$\sum_{B \in \mathcal{B}} \mu(B) < \mu^*(A) + \epsilon .$$

Proof: We may assume $\mu^*(A) > 0$ since otherwise there is nothing to prove. Fix an $M \in \mathbb{N}$, $R > 0$, and $\tau > 1$ for ρ as in the definition of a controlled metric (XVII.8.1.1.). We may assume all balls $(x, r) \in \mathcal{C}$ have $x \in A$ and $r < R$ (XVII.8.2.2.).

To see that (i) is automatic if (X, ρ) is separable (second countable), let $\mathcal{U}$ be a countable base for the topology, and let W be the union of all $U \in \mathcal{U}$ with $\mu(U) = 0$.

Suppose (i) holds. Then any closed ball whose center is not in W has positive measure. We have

$$\mu^*(A) = \mu^*(A \cap W) + \mu^*(A \cap W^c) = \mu^*(A \cap W^c)$$

since W is measurable, and $\mathcal{C}$ is a Besicovitch covering of $A \cap W^c$. So it suffices to obtain the conclusion for $A \cap W^c$, i.e. replacing A by $A \cap W^c$ and $\mathcal{C}$ by the subset consisting of all $(x, r) \in \mathcal{C}$ with $x \in A \cap W^c$, we may assume that all balls in $\mathcal{C}$ have strictly positive measure.

Let $\epsilon > 0$. Since μ is a locally finite Borel measure on X and $\mu(A) < \infty$, there is an open set V in X with $A \subseteq V$ and $\mu(V) < \mu^*(A) + \epsilon$ (). We may assume all $(x, r) \in \mathcal{C}$ have $\bar{B}_r(x) \subseteq V$ (XVII.8.2.2.).

By Theorem XVII.8.2.4. there are subsets $\mathcal{D}_1, \ldots, \mathcal{D}_M$ of $\mathcal{C}$ so that $\cup_i \mathcal{D}_i$ covers A and each $\mathcal{D}_i$ consists of pairwise disjoint balls. Each $\mathcal{D}_i$ is countable since all the balls are contained in V and have positive measure.

For each i, $1 \le i \le M$, let D_i be the union of the balls in $\mathcal{D}_i$. We have $A \subseteq \cup_i D_i$, so

$$\mu^*(A) \le \sum_{i=1}^{M} \mu^*(A \cap D_i)$$

and thus there is an i for which

$$\mu^*(A \cap D_i) \ge \frac{1}{M} \mu^*(A) \ .$$

Fix such an i, and, changing notation, let $B_1, B_2, \ldots$ be an enumeration of the balls in row i. Let Z be a Borel set containing $A \cap D_i$ with $\mu(Z) = \mu^*(A \cap D_i)$. By regularity, there is a closed set E with $E \subseteq Z$ and with

$$\mu(E) > \frac{1}{M+1} \mu^*(A) \ .$$

Since the B_k are disjoint and cover almost all of E, we have

$$\mu(E) = \sum_{k=1}^{\infty} \mu(E \cap B_k)$$

so there is an n such that

$$\sum_{k=1}^{n} \mu(E \cap B_k) > \frac{1}{M+1} \mu^*(A) \ .$$

Put $B_1, \ldots, B_n$ into $\mathcal{B}$.

Set $F = B_1 \cup \cdots \cup B_n$. Then F is a closed set, and

$$\mu^*(A \cap F) \ge \mu(E \cap F) > \frac{1}{M+1} \mu^*(A) \ .$$

Set $A_1 = A \setminus F$. Since F is measurable,

$$\mu^*(A) = \mu^*(A \cap F) + \mu(A_1)$$

so

$$\mu^*(A_1) < \frac{M}{M+1} \mu^*(A) \ .$$

Set $V_1 = V \cap F^c$. Then V_1 is an open set of finite measure disjoint from $B_1, \ldots, B_n$, and $A_1 \subseteq V_1$. Let $\mathcal{C}_1$ be the set of balls in $\mathcal{C}$ contained in V_1; then $\mathcal{C}_1$ is a Besicovitch covering of A_1. Repeat the construction with $\mathcal{C}_1$, A_1, V_1 in place of $\mathcal{C}$, A, V, to obtain a closed set F_1 which is a finite union of disjoint balls in $\mathcal{C}_1$, with

$$\mu^*(A_1 \cap F_1) > \frac{1}{M+1} \mu^*(A_1) \ .$$

Put these balls into $\mathcal{B}$, and set $A_2 = A_1 \setminus F_1 = A \setminus (F \cup F_1)$; then

$$\mu^*(A_2) < \frac{1}{M+1} \left(\frac{M}{M+1} \right) \mu^*(A) \ .$$

Repeat the process inductively; after n steps we have that the part A_n of A not covered by $\mathcal{B}$ has

$$\mu^*(A_n) < \frac{1}{M+1}\left(\frac{M}{M+1}\right)^{n-1}\mu^*(A)\ .$$

Since

$$\frac{M}{M+1} < 1$$

at the end of the process (it might end after finitely many steps if $\mu^*(A_n) = 0$ for some n) we have a countable set $\mathcal{B}$ of pairwise disjoint balls in $\mathcal{C}$ which covers almost all of A. Since all the balls in $\mathcal{B}$ are contained in V, the last assertion follows. 👍

Euclidean Space

The hypotheses of the theorem are satisfied if X is a subset of $\mathbb{R}^n$ (or a finite-dimensional normed vector space) with the metric induced by the norm (XVII.8.1.6.). Thus we obtain the common version of the theorem:

XVII.8.3.2. Corollary. [Besicovitch Covering Theorem, Euclidean Version] Let $X \subseteq \mathbb{R}^n$ with the induced metric and μ a locally finite Borel measure on X, $A \subseteq X$ with $\mu^*(A) < \infty$, and $\mathcal{C}$ a Besicovitch covering of A in X. Then there is a countable subset $\mathcal{B} = \{(x_n, r_n)\}$ of $\mathcal{C}$ with the $\bar{B}_{r_n}(x_n)$ pairwise disjoint, such that

$$\mu^*\left(A \setminus \bigcup_{\mathcal{B}} \bar{B}_{r_n}(x_n)\right) = 0\ .$$

($\mathcal{B}$ will usually be countably infinite, i.e. a sequence.) For any $\epsilon > 0$, we may choose $\mathcal{B}$ so that

$$\sum_{B\in\mathcal{B}} \mu(B) < \mu^*(A) + \epsilon\ .$$

XVII.8.3.3. Actually the X can be eliminated since any (locally finite) Borel measure on a subset of a topological space can be converted to a (locally finite) Borel measure on the whole space ().

XVII.8.3.4. Example. Here is an example illustrating why assumption (i) (or something similar) in the statement of XVII.8.3.1. is necessary. Let X be a set of measurable cardinality (), ρ the discrete metric, μ a nonatomic $\{0,1\}$-valued measure on $(X, \mathcal{P}(X))$, and $\mathcal{C}$ the collection of all balls of radius $< \frac{1}{2}$ (each such ball is actually a singleton). The metric ρ is controlled (with, say, constants $R = 1/2$, $M = 1$, $\tau = 3/2$). But (i) is not satisfied. If $A = X$, the process in the proof can be carried out, and there is only one $\mathcal{D}_i$, but it contains uncountably many balls. Actually, the conclusion of the theorem holds except that $\mathcal{B}$ is necessarily uncountable (in fact, it must be all the singleton subsets).

XVII.8.3.5. The proof uses the AC. But if $card(\mathcal{C}) \leq 2^{\aleph_0}$ (e.g. if (X, ρ) is separable), then one only needs that $\mathbb{R}$ can be well ordered (i.e. that $2^{\aleph_0}$ is an aleph), which is weaker than the full AC (e.g. the CH suffices).

XVII.8.4. Exercises

XVII.8.4.1. (a) Verify the assertions in Example XVII.8.1.4..

(b) Show that the following version of the Besicovitch Partition Theorem holds:

THEOREM. Let (X, ρ) be an ultrametric space, $A \subseteq X$, and $\mathcal{C}$ a Besicovitch covering of A. Then there is a subset $\mathcal{D}$ of $\mathcal{C}$ consisting of pairwise disjoint balls which covers A.

[In the proof of XVII.8.2.4., fix $\tau > 1$ and at each stage throw away not only any remaining balls (not yet chosen) with center in $B_{\alpha+1}$, but also any remaining balls of larger radius. All balls go in the first row.]

(c) Show that the statement of the Besicovitch Covering Theorem holds if (X, ρ) is an ultrametric space, with a simplified proof, even with "almost all" replaced by "all."

XVII.8.4.2. [Fed69, 2.8] Let (X, ρ) be a metric space. If $\zeta \in \mathbb{N}$, $0 < \eta \leq \frac{1}{3}$, and $0 < R \leq \infty$, and $A \subseteq X$, say (X, ρ) is R, η, ζ-*directionally limited at* A if, whenever $a \in A$, $P \subseteq B_R(a) \setminus \{a\}$, and $b, c \in P$ with $b \neq c$ and $\rho(a, b) \geq \rho(a, c)$, and

$$\rho(a, c) + \rho(c, b) - \rho(a, b) \geq \eta\rho(a, b)$$

then $card(P) \leq \zeta$.

(a) Show that if X is a finite-dimensional normed vector space, then X is $\infty, 1/3, \zeta$-directionally limited at X for some $\zeta \in \mathbb{N}$.

(b) Show that if X is a Riemannian manifold and K is a compact subset, then X is R, η, ζ-directionally limited at K for some R, η, ζ.

(c) Show that if (X, ρ) is R, η, ζ-directionally limited at A, and $Y \subseteq X$, then $(Y, \rho|_Y)$ is R, η, ζ-directionally limited at $A \cap Y$.

(d) Show that if (X, ρ) is R, η, ζ-directionally limited at A, then its completion $(\bar{X}, \bar{\rho})$ is R, η, ζ-directionally limited at $\bar{A}$.

(e) If (X, ρ) is R, η, ζ-directionally limited on every ball of radius R in X, and if $\tau > 1$ satisfies

$$\eta + \tau/(2 - \eta) + \tau(\tau - 1) < 1$$

then (X, ρ) is (R, τ)-controlled, with constant $M = 2\zeta + 1$.

(f) In (e), show that any $\tau > 1$ which is sufficiently close to 1 satisfies the condition. If $\eta = 1/3$, the restriction is

$$1 < \tau < \frac{1}{5} + \sqrt{\frac{53}{75}} \approx 1.04 \ .$$

Parts (a) and (e) give an alternate proof of Theorem XVII.8.1.6.. The *directionally limited* definition here is a less restrictive version of the one in [Fed69]: the definition there presupposes the existence of interpolating points; in the absence of such points the restriction is vacuous (always satisfied) and the condition essentially forces the metric to be discrete (in the presence of the interpolating points the two definitions are the same by the argument in the proof of [Fed69, 2.8.11]).

XVII.8.4.3. [Sul94] For each n let $M(n) = M(n,1)$ be the best constant for strict control of $\mathbb{R}^n$ ().
(a) [Rei48] Show that $M(2) = 19$. See Figure XVII.2 (from [Sul94]).
(b) Show that

$$67 \leq M(3) \leq 87$$

$$226 \leq M(4) \leq 331$$

$$681 \leq M(5) \leq 1159$$

and that $M(n)$ grows exponentially in n.

It is conjectured in [Sul94] that $M(3) = 67$ and that $M(4)$ and $M(5)$ are close to the lower bounds 226 and 681 respectively. The value of $M(n)$ is closely related to sphere-packing problems.

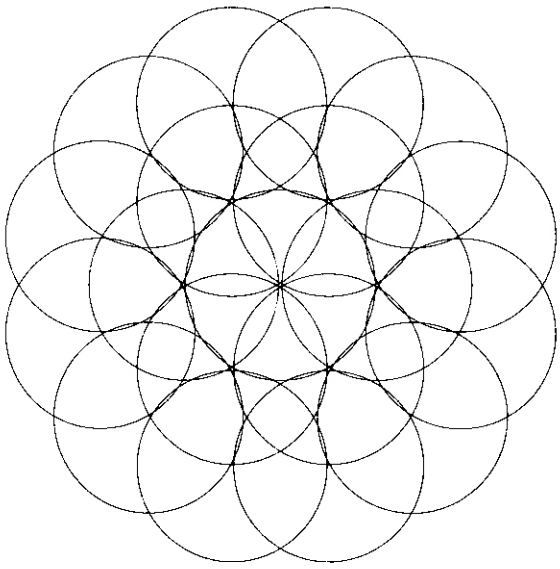

Figure XVII.2: A (strictly) controlled expansion consisting of 19 balls (disks) in $\mathbb{R}^2$

XVII.8.4.4. (a) Show that a metrically finite-dimensional metric space () is strictly controlled.
(b) Try to prove that a metrically finite-dimensional metric space is controlled. What goes wrong? (See XVII.8.1.5..)

In fact, metrically finite-dimensional metric spaces are not controlled in general [LDR19].

XVII.8.4.5. Show that a metric space satisfying the conclusion of the Besicovitch Partition Theorem is topologically finite-dimensional. [See the proof of XVII.8.1.15.(i).]

XVII.8.4.6. (a) Show that the proof of Theorem XVII.8.2.4. works verbatim if the cover $\mathcal{C}$ of A is not necessarily a Besicovitch cover, but merely a cover containing a ball centered at each point of A, of uniformly bounded radius.

(b) In verifying the hypotheses of this version, it suffices to take $A = X$. [If $\mathcal{C}$ is such a cover, for each $x \in \bar{A} \setminus A$ add a ball centered at x contained in a ball in $\mathcal{C}$ of almost the largest radius possible, and for points of $X \setminus \bar{A}$ an almost largest ball centered at x disjoint from $\bar{A}$.]

(c) Show that a metric space satisfying the conclusion of this more general version of the Besicovitch Partition Theorem is controlled. [Let A be the set of centers of a controlled expansion.]

XVII.8.4.7. Let $1 \leq N \leq \infty$, and let X be a countable dense subset of $[0,1]^N$, with the restriction of a metric giving the topology of $[0,1]^N$. Then X is homeomorphic to $\mathbb{Q}$ (), and in particular zero-dimensional, but its completion is N-dimensional. The metric is not controlled if $N = \infty$ (XVII.8.1.3., XVII.8.1.15.).

XVII.8.4.8. Let $X = \prod_{n=1}^{\infty} \{1, \ldots, n\}$. Then X consists of all sequences in $\mathbb{N}$ for which the n'th term is $\leq n$ for all n. If x and y are such sequences, set $\rho(x,y) = \frac{1}{n}$ if x and y first differ in the n'th term. Then ρ is an ultrametric on X. The ρ-topology on X is the product topology, where each coordinate has the discrete topology; thus (X, ρ) is compact and zero-dimensional (and homeomorphic to the Cantor set, cf. ()). Since $\frac{n}{n+1}$ becomes arbitrarily close to 1, (X, ρ) is not (R, τ)-controlled for any $R > 0$ and $\tau > 1$.

XVII.9. Signed and Complex Measures

In this section we examine the theory of measures which are not necessarily nonnegative or even real-valued. It turns out that the theory of such measures can be nicely reduced to the theory of ordinary (nonnegative) measures.

The only insurmountable difficulty comes with trying to make sense of the expression $\infty - \infty$. It will be implicit in our definitions that this possibility will never arise, which will entail that our measures do not take both values $\pm\infty$. In most applications, we will only consider real-valued measures, i.e. ones not taking either value $\pm\infty$. For complex measures we will not be able to satisfactorily allow any type of infinite value. There is an alternate approach to avoiding the $\infty - \infty$ problem, using local measures only defined on δ-rings ().

XVII.9.1. Signed Measures

XVII.9.1.1. DEFINITION. Let $(X, \mathcal{A})$ be a measurable space. A *signed measure* on $(X, \mathcal{A})$ is a function $\nu : \mathcal{A} \to [-\infty, +\infty]$ such that

(i) $\nu(\emptyset) = 0$.

(ii) If $\{A_n\}$ is a sequence of pairwise disjoint sets in $\mathcal{A}$, then either

$$\sum_{\nu(A_n)>0} \nu(A_n) < +\infty \quad \text{or} \quad \sum_{\nu(A_n)<0} \nu(A_n) > -\infty$$

(so $\sum_n \nu(A_n)$ is well defined), and

$$\nu\left(\bigcup_{n=1}^{\infty} A_n\right) = \sum_{n=1}^{\infty} \nu(A_n) \ .$$

The signed measure ν is *finite* if $\nu(A) \in \mathbb{R}$ for all $A \in \mathcal{A}$.

Note that, as with measures, the countable additivity of (ii) includes finite additivity (taking the remaining sets to be $\emptyset$). In particular, there cannot be disjoint sets $A_1, A_2 \in \mathcal{A}$ with $\nu(A_1) = +\infty$ and $\nu(A_2) = -\infty$.

XVII.9.1.2. EXAMPLES. (i) Any measure is a signed measure.

(ii) If μ_1 and μ_2 are (ordinary) measures on a measurable space $(X, \mathcal{A})$, at least one of which is finite, then $\mu_1 - \mu_2$ is a well-defined signed measure on $(X, \mathcal{A})$. More generally, any (finite) linear combination of measures, all but at most one of which are finite, is a signed measure. Any (finite) linear combination of finite signed measures is a (finite) signed measure.

(iii) Let $(X, \mathcal{A}, \mu)$ be an (ordinary) measure space, and $f \in \mathcal{L}^1(X, \mathcal{A}, \mu)$. For $A \in \mathcal{A}$, let

$$\nu(A) = \int_A f \, d\mu \ .$$

It is easy to check (cf. ()) that ν is a finite signed measure.

A signed measure of the form in (ii) can be regarded as "trivial", since its structure is completely determined and easy to describe in terms of the properties of μ_1 and μ_2. The main result of this section is that every signed measure is of this form, with the positive and negative pieces supported on disjoint sets:

XVII.9.1.3. THEOREM. [JORDAN DECOMPOSITION THEOREM] Let ν be a signed measure on a measure space $(X, \mathcal{A})$. Then there are unique measures ν^+ and ν^- on $(X, \mathcal{A})$, with $\nu = \nu^+ - \nu^-$ and $\nu^+ \perp \nu^-$. At least one of ν^+ and ν^- is a finite measure.

Thus the theory of signed measures turns out to be "trivial." (However, the *proof* that the theory is actually trivial is definitely nontrivial!)

It is useful to rephrase this theorem in a somewhat different way. We first make some definitions:

XVII.9.1.4. DEFINITION. Let ν be a signed measure on a measurable space $(X, \mathcal{A})$. A set $P \in \mathcal{A}$ is a *positive set* for ν if $\nu(A) \geq 0$ for every $A \in \mathcal{A}$, $A \subseteq P$. Similarly, $N \in \mathcal{A}$ is a *negative set* for ν if $\nu(A) \leq 0$ for all $A \in \mathcal{A}$, $A \subseteq N$. A set $E \in \mathcal{A}$ is a *null set* for ν if it is both positive and negative, i.e. $\nu(A) = 0$ for all $A \in \mathcal{A}$, $A \subseteq E$.

Note that a set $E \in \mathcal{A}$ with $\nu(E) = 0$ is not necessary a null set: such an E could be a disjoint union $A \cup B$, where $\nu(A) > 0$ and $\nu(B) = -\nu(A)$. Similarly, an $E \in \mathcal{A}$ with $\nu(E) > 0$ is not necessarily a positive set.

It is obvious that any (measurable) subset of a positive set is positive, and a finite or countable union of positive sets is positive (Exercise ()). The same holds for negative sets and null sets.

XVII.9.1.5. DEFINITION. Let ν be a signed measure on a measurable space $(X, \mathcal{A})$. A *Hahn decomposition* for ν is a pair (P, N), where $P, N \in \mathcal{A}$, $N = X \setminus P$, P is positive for ν, and N is negative for ν.

We can then rephrase the Jordan Decomposition Theorem in the following way:

XVII.9.1.6. THEOREM. [HAHN DECOMPOSITION THEOREM] Let ν be a signed measure on a measurable space $(X, \mathcal{A})$. Then there is a Hahn decomposition for ν. If (P, N) and (P', N') are Hahn decompositions for ν, then $P \triangle P'$ and $N \triangle N'$ are null sets for ν, i.e. the Hahn decomposition of ν is unique up to null sets.

XVII.9.1.7. To see that the Hahn Decomposition Theorem is equivalent to the Jordan Decomposition Theorem (we will only need one direction of this equivalence), suppose (P, N) is a Hahn decomposition for ν. For $A \in \mathcal{A}$, set $\nu^+(A) = \nu(A \cap P)$ and $\nu^-(A) = -\nu(A \cap N)$. Then it is easily checked that ν^+ and ν^- are measures, $\nu^+ \perp \nu^-$, and $\nu = \nu^+ - \nu^-$. These measures do not change if P and N are changed by null sets. At least one of P and N must have finite measure. Conversely, let $\nu = \mu_1 - \mu_2$, where μ_1 and μ_2 are measures with $\mu_1 \perp \mu_2$. Let $P \in \mathcal{A}$ with $\mu_2(P) = 0$ and $\mu_1(X \setminus P) = 0$; such a P is unique up to null sets. Then $(P, X \setminus P)$ is a Hahn decomposition for ν. Another Hahn decomposition for ν not differing from this one by null sets would give a pair (ν^+, ν^-) different from (μ_1, μ_2).

XVII.9.1.8. EXAMPLE. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f \in \mathcal{L}^1(X, \mathcal{A}, \mu)$, and for $A \in \mathcal{A}$ set $\nu(A) = \int_A f \, d\mu$ as in XVII.9.1.2.. A Hahn decomposition for ν is precisely a pair (P, N), where $N = X \setminus P$, $f \geq 0$ a.e. on P, and $f \leq 0$ a.e. on N. One Hahn decomposition is given by $P = \{x : f(x) \geq 0\}$ and $N = \{x : f(x) < 0\}$. The Jordan decomposition of ν is $\nu = \nu^+ - \nu^-$, where $\nu^+(A) = \int_A f_+ \, d\mu$ and $\nu^-(A) = \int_A f_- \, d\mu$ for $A \in \mathcal{A}$ and f_+, f_- the positive and negative parts of f ().

The proof of Theorem XVII.9.1.6. (and therefore Theorem XVII.9.1.3.) will consist of a series of lemmas, all of which would be easy corollaries of the theorem. Our proof is based on [Dos80] [note that the argument of [Dos80] is incomplete as written since it assumes the conclusion of XVII.9.1.14. without comment.]

The first result about signed measures is that a signed measure cannot take both the values $+\infty$ and $-\infty$:

XVII.9.1.9. LEMMA. Let ν be a signed measure on $(X, \mathcal{A})$. Then there do not exist $A, B \in \mathcal{A}$ with $\nu(A) = +\infty$ and $\nu(B) = -\infty$.

PROOF: It follows immediately from XVII.9.1.1.(ii) that there do not exist *disjoint* sets $A_1, A_2 \in \mathcal{A}$ with $\nu(A_1) = +\infty$ and $\nu(A_2) = -\infty$. Suppose $\nu(A) = +\infty$ and $\nu(B) = -\infty$. Then $A \cap B$, $A \setminus B$, and $B \setminus A$ are pairwise disjoint, and:

At least one of $A \cap B$ and $A \setminus B$ has measure $+\infty$.

At least one of $A \cap B$ and $B \setminus A$ has measure $-\infty$.

Thus there are disjoint sets with measure $+\infty$ and $-\infty$, a contradiction. 👍

XVII.9.1.10. LEMMA. Let ν be a signed measure on $(X, \mathcal{A})$, and $A, B \in \mathcal{A}$ with $B \subseteq A$. If $\nu(A) \in \mathbb{R}$ (i.e. $|\nu(A)| < \infty$), then $\nu(B) \in \mathbb{R}$.

PROOF: We have $\nu(A) = \nu(B) + \nu(A \setminus B)$, and the sum on the right is well defined. If $\nu(B) = +\infty$, then we cannot have $\nu(A \setminus B) = -\infty$, and hence we would have to have $\nu(A) = +\infty$. The argument if $\nu(B) = -\infty$ is similar. 👍

The next result is an exact analog of ().

XVII.9.1.11. LEMMA. Let ν be a signed measure on a measurable space $(X, \mathcal{A})$.

(i) If $E_1, E_2, \cdots \in \mathcal{A}$ with $E_1 \subseteq E_2 \subseteq \cdots$, then $\lim_{n\to\infty} \nu(E_n)$ exists as an extended real number and equals $\nu(\cup_{n=1}^{\infty} E_n)$.

(ii) If $E_1, E_2, \cdots \in \mathcal{A}$ with $E_1 \supseteq E_2 \supseteq \cdots$, and $\nu(E_n) \in \mathbb{R}$ for some n, then $\lim_{n\to\infty} \nu(E_n)$ exists as a real number and equals $\nu(\cap_{n=1}^{\infty} E_n)$.

PROOF: (i): Let $A_1 = E_1$ and $A_n = E_n \setminus E_{n-1}$ for $n > 1$. Then the A_n are pairwise disjoint, $E_n = \cup_{k=1}^{n} A_k$ for all n, $\cup_{n=1}^{\infty} A_n = \cup_{n=1}^{\infty} E_n$, and the series $\sum_{k=1}^{\infty} \nu(A_k)$ converges to $\nu(\cup_{n=1}^{\infty} E_n)$. So

$$\nu\left(\bigcup_{n=1}^{\infty} E_n\right) = \sum_{k=1}^{\infty} \nu(A_k) = \lim_{n\to\infty} \sum_{k=1}^{n} \nu(A_k) = \lim_{n\to\infty} \nu\left(\bigcup_{k=1}^{n} A_k\right) = \lim_{n\to\infty} \nu(E_n) \ .$$

(ii): We may assume $\nu(E_1) \in \mathbb{R}$. Set $E = \cap_{n=1}^{\infty} E_n$, $B_n = E_1 \setminus E_n$, and $B = \cup_{n=1}^{\infty} B_n = E_1 \setminus E$. Then by (i)

$$\nu(B) = \lim_{n\to\infty} \nu(B_n) = \lim_{n\to\infty} \nu(E_1 \setminus E_n) \ .$$

Thus, since $\nu(E_1) \in \mathbb{R}$,

$$\lim_{n\to\infty} \nu(E_1 \setminus E_n) = \lim_{n\to\infty} [\nu(E_1) - \nu(E_n)]$$

exists and hence $\lim_{n\to\infty} \nu(E_n)$ exists and equals $\nu(E_1) - \lim_{n\to\infty} \nu(B_n)$, and we have

$$\nu(E) = \nu(E_1) - \nu(B) = \nu(E_1) - \lim_{n\to\infty} \nu(B_n) = \lim_{n\to\infty} \nu(E_n) \ .$$

Furthermore, since $E \subseteq E_1$ and $\nu(E_1) \in \mathbb{R}$, we have $\nu(E) \in \mathbb{R}$ by XVII.9.1.10.. 👍

XVII.9.1.12. LEMMA. Let ν be a signed measure on a measurable space $(X, \mathcal{A})$ not taking the value $+\infty$, and let $\epsilon > 0$. Then for every $A \in \mathcal{A}$ there is a set $A_\epsilon \in \mathcal{A}$ with $A_\epsilon \subseteq A$, $\nu(A_\epsilon) \geq \nu(A)$, and $\nu(B) > -\epsilon$ for all $B \in \mathcal{A}$, $B \subseteq A_\epsilon$.

PROOF: Fix $\epsilon > 0$ and $A \in \mathcal{A}$. If $\nu(A) \leq 0$, we may take $A_\epsilon = \emptyset$. Assume $\nu(A) > 0$ (in particular, $\nu(A) \in \mathbb{R}$). Suppose the conclusion is false. Then there is a $B_1 \in \mathcal{A}$, $B_1 \subseteq A$, with $\nu(B_1) \leq -\epsilon$ (otherwise we could take $A_\epsilon = A$). Then $\nu(A \setminus B_1) = \nu(A) - \nu(B_1) \geq \nu(A) + \epsilon$. There is a $B_2 \in \mathcal{A}$, $B_2 \subseteq (A \setminus B_1)$, with $\nu(B_2) \leq -\epsilon$ (otherwise we could take $A_\epsilon = A \setminus B_1$). Proceeding in this way, we generate a sequence (B_n) of pairwise disjoint sets in $\mathcal{A}$ with $B_n \subset A$ and $\nu(B_n) \leq -\epsilon$ for all n. If $B = \cup_{n=1}^{\infty} B_n$, then $B \in \mathcal{A}$, $B \subseteq A$, and $\nu(B) = -\infty$, contradicting XVII.9.1.10.. 👍

XVII.9.1.13. LEMMA. Let ν be a signed measure on a measurable space $(X, \mathcal{A})$ not taking the value $+\infty$. If $A \in \mathcal{A}$, then A contains a subset P with $P \in \mathcal{A}$, $\nu(P) \geq \nu(A)$, and P a positive set for ν.

PROOF: Let $A \in \mathcal{A}$. If $\nu(A) \leq 0$ (in particular, if $\nu(A) = -\infty$), we may take $P = \emptyset$. Assume $\nu(A) > 0$ (in particular, $\nu(A) \in \mathbb{R}$). Generate a decreasing sequence (A_n) of subsets of A by setting $A_0 = A$ and $A_{n+1} = (A_n)_\epsilon$ (XVII.9.1.12.) with $\epsilon = \frac{1}{n+1}$. Set $P = \cap_{n=1}^{\infty} A_n$. Then $P \in \mathcal{A}$, $P \subseteq A$, and

$$\nu(P) = \lim_{n\to\infty} \nu(A_n) \geq \nu(A)$$

by XVII.9.1.11.(ii) and the fact that $\nu(A_n) \geq \nu(A)$ for all n. Also, if $B \in \mathcal{A}$, $B \subseteq P$, then $B \subseteq A_n$ for each n, and so $\nu(B) > -\frac{1}{n}$ for all $n \geq 1$. Hence $\nu(B) \geq 0$. Thus P is positive for ν. 👍

We can now prove that a signed measure which does not take an infinite value is actually bounded on that side.

XVII.9.1.14. LEMMA. Let ν be a signed measure on a measurable space $(X, \mathcal{A})$. If ν does not take the value $+\infty$, then $\{\nu(A) : A \in \mathcal{A}\}$ is bounded above. If ν does not take the value $-\infty$, then $\{\nu(A) : A \in \mathcal{A}\}$ is bounded below.

PROOF: We prove only the first statement; the second follows by replacing ν by $-\nu$.

Suppose for each n there is a set $A_n \in \mathcal{A}$ with $\nu(A_n) > n$. By XVII.9.1.13. there is a set $P_n \in \mathcal{A}$ with $\nu(P_n) \geq \nu(A_n) > n$ which is positive for ν. Set $P = \cup_{n=1}^{\infty} P_n$. Then $P \in \mathcal{A}$ and is positive for ν; thus $\nu(P) \geq \nu(P_n) > n$ for all n, i.e. $\nu(P) = +\infty$. 👍

We can now prove Theorem XVII.9.1.6..

PROOF: Replacing ν by $-\nu$ if necessary, we may assume that ν does not take the value $+\infty$. Let $M = \sup\{\nu(A) : A \in \mathcal{A}\}$. Then $0 \leq M < +\infty$ by XVII.9.1.14. ($M \geq 0$ since $\nu(\emptyset) = 0$). Let (A_n) be a sequence of sets in $\mathcal{A}$ with $\sup_n \nu(A_n) = M$. By XVII.9.1.13., for each n there is a set $P_n \in \mathcal{A}$ with $\nu(P_n) \geq \nu(A_n)$ which is positive for ν. Then $\sup_n \nu(P_n) = M$. Set $P = \cup_{n=1}^{\infty} P_n$. Then P is a positive set for ν, and $\nu(P) \geq \nu(P_n)$ for all n; thus $\nu(P) = M$. Let $N = X \setminus P$. If $B \in \mathcal{A}$, $B \subseteq N$, then

$$M + \nu(B) = \nu(P \cup B) \leq M$$

and hence $\nu(B) \leq 0$; thus N is a negative set for ν, and (P, N) is a Hahn decomposition for ν.

To show uniqueness, if (P', N') is another Hahn decomposition, let A be a subset of $P \setminus P'$. Then $\nu(A) \geq 0$ since $A \subseteq P$, and $\nu(A) \leq 0$ since $A \subseteq N'$. Hence $P \setminus P'$ is a null set. Similarly, $P' \setminus P$, $N \setminus N'$, and $N' \setminus N$ are null sets.

This completes the proof of XVII.9.1.6.. 👍

The proof actually shows the following:

XVII.9.1.15. COROLLARY. Let ν be a signed measure on a measurable space $(X, \mathcal{A})$. If $L = \inf\{\nu(A) : A \in \mathcal{A}\}$ and $M = \sup\{\nu(A) : A \in \mathcal{A}\}$, then:

(i) At least one of L and M is finite (note that $L \leq 0$ and $M \geq 0$ since $\nu(\emptyset) = 0$).

(ii) A pair (P, N) of sets in $\mathcal{A}$ is a Hahn decomposition for ν if and only if $N = X \setminus P$, $\nu(P) = M$, and $\nu(N) = L$.

(iii) There exists at least one pair (P, N) as in (ii).

See [Kön97] for a detailed discussion of signed premeasures and versions of the Carathéodory Extension Theorem.

The Total Variation of a Signed Measure

XVII.9.1.16. DEFINITION. Let ν be a signed measure on a measurable space $(X, \mathcal{A})$, with Jordan decomposition $\nu = \nu^+ - \nu^-$. The measure $|\nu| = \nu^+ + \nu^-$ is called the *total variation measure*, or *total variation*, of ν.

The next proposition is nearly trivial (given our previous results). Part (ii) is preparation for the definition of the total variation of a complex measure (XVII.9.2.6.), which is less trivial. This part is strongly reminiscent of the definition of the total variation of a function (). (This similarity is no accident! See ().)

XVII.9.1.17. PROPOSITION. Let ν be a signed measure on a measurable space $(X, \mathcal{A})$. If $E \in \mathcal{A}$, then

(i) $|\nu(E)| \leq |\nu|(E)$.

(ii) $|\nu|(E) = \sup(\sum_{n=1}^{\infty} |\nu(E_n)|)$, where the supremum runs over all measurable partitions $\{E_n\}$ of E.

PROOF: (i) is obvious. For (ii), let S be the supremum. If $\{E_n\}$ is a measurable partition of E, then since $|\nu|$ is a measure,

$$\sum_{n=1}^{\infty} |\nu(E_n)| \leq \sum_{n=1}^{\infty} |\nu|(E_n) = |\nu| \left(\bigcup_{n=1}^{\infty} E_n \right) = |\nu|(E)$$

using (i), so $S \leq |\nu|(E)$. On the other hand, if (P, N) is a Hahn decomposition for ν, we have

$$|\nu|(E) = \nu^+(E) + \nu^-(E) = |\nu(E \cap P)| + |\nu(E \cap N)| \leq S \ .$$

An easy consequence of (ii) is:

XVII.9.1.18. COROLLARY. Let ν_1 and ν_2 be signed measures on a measurable space $(X, \mathcal{A})$. Suppose $\nu_1 + \nu_2$ is well defined as a signed measure (i.e. both ν_1 and ν_2 are bounded above or both are bounded below, e.g. if at least one is finite). Then $|\nu_1 + \nu_2| \leq |\nu_1| + |\nu_2|$ (i.e. $|\nu_1 + \nu_2|(E) \leq |\nu_1|(E) + |\nu_2|(E)$ for all $E \in \mathcal{A}$).

Note that there is no simple way to obtain a Hahn decomposition for $\nu_1 + \nu_2$ from Hahn decompositions for ν_1 and ν_2 in general.

XVII.9.2. Complex Measures

XVII.9.2.1. DEFINITION. If $(X, \mathcal{A})$ is a measurable space, a *complex measure* on $(X, \mathcal{A})$ is a function $\nu : \mathcal{A} \to \mathbb{C}$ such that

(i) $\nu(\emptyset) = 0$.

(ii) If $A_1, A_2, \ldots$ is a sequence of pairwise disjoint sets in $\mathcal{A}$, then $\sum_{n=1}^{\infty} \nu(A_n)$ converges to $\nu(\cup_{n=1}^{\infty} A_n)$.

XVII.9.2.2. EXAMPLES. (i) Any finite signed measure (in particular, any finite measure) is a complex measure.
(ii) If ν_1 and ν_2 are finite signed measures on $(X, \mathcal{A})$, then $\nu = \nu_1 + i\nu_2$ is a complex measure on $(X, \mathcal{A})$. More generally, any (finite) complex linear combination of complex measures on $(X, \mathcal{A})$ is a complex measure on $(X, \mathcal{A})$.

The following converse to (ii) essentially reduces the theory of complex measures to the theory of finite signed measures, and hence to the theory of ordinary finite measures:

XVII.9.2.3. PROPOSITION. Let ν be a complex measure on a measurable space $(X, \mathcal{A})$. For $E \in \mathcal{A}$, define $\nu_{re}(E) = Re(\nu(E))$ and $\nu_{im}(E) = Im(\nu(E))$. Then ν_{re} and ν_{im} are finite signed measures on $(X, \mathcal{A})$, called the *real* and *imaginary parts* of ν respectively.

Conversely, if ν_1 and ν_2 are finite signed measures on $(X, \mathcal{A})$, and $\nu = \nu_1 + i\nu_2$, then $\nu_{re} = \nu_1$, $\nu_{im} = \nu_2$.

XVII.9.2.4. To a complex measure ν there are thus four canonically associated finite measures ν_{re}^+, ν_{re}^-, ν_{im}^+, and ν_{im}^-. Note, however, that there may be overlap between the supports of $\nu_{re}^\pm$ and $\nu_{im}^\pm$, i.e. the measures $|\nu_{re}|$ and $|\nu_{im}|$ may not be mutually singular. Thus there is no analog of a Hahn decomposition of X into "real" and "imaginary" subsets for ν in general.

XVII.9.2.5. There is a slight difficulty in making a good definition of the total variation of a complex measure. A reasonable approach is to take the measure

$$|\nu_{re}| + |\nu_{im}| = \nu_{re}^+ + \nu_{re}^- + \nu_{im}^+ + \nu_{im}^-$$

but this measure does not have all the desirable properties of a total variation. Instead it is customary to take the following definition:

XVII.9.2.6. DEFINITION. Let ν be a complex measure on a measurable space $(X, \mathcal{A})$. If $E \in \mathcal{A}$, define $|\nu|(E) = \sup(\sum_{n=1}^\infty |\nu(E_n)|)$, where the supremum runs over all measurable partitions $\{E_n\}$ of E.

XVII.9.2.7. THEOREM. Let ν be a complex measure on a measurable space $(X, \mathcal{A})$. Then

(i) $|\nu|$ is a measure on $(X, \mathcal{A})$.

(ii) If $E \in \mathcal{A}$, then $|\nu(E)| \le |\nu|(E)$.

(iii) If $E \in \mathcal{A}$, then

$$\max(|\nu_{re}|(E), |\nu_{im}|(E)) \le |\nu|(E) \le |\nu_{re}|(E) + |\nu_{im}|(E) \ .$$

In particular, $|\nu|$ is a finite measure, and since

$$\frac{1}{2}\big[|\nu_{re}|(E) + |\nu_{im}|(E)\big] \le \max(|\nu_{re}|(E), |\nu_{im}|(E))$$

we have

$$\frac{1}{2}\big[|\nu_{re}|(E) + |\nu_{im}|(E)\big] \le |\nu|(E) \le |\nu_{re}|(E) + |\nu_{im}|(E) \ .$$

PROOF: (ii): This is trivial since $\{E\}$ is a measurable partition of E.
(iii): Note that if $x, y \in \mathbb{R}$, then

$$\frac{1}{2}\big[|x| + |y|\big] \le \max(|x|, |y|) \le |x + iy| \le |x| + |y|$$

(). If $\{E_n\}$ is a measurable partition of E, then

$$\max\left(\sum_{n=1}^\infty |\nu_{re}(E_n)|, \sum_{n=1}^\infty |\nu_{im}(E_n)|\right) \le \sum_{n=1}^\infty \big[\max(|\nu_{re}(E_n)|, |\nu_{im}(E_n)|)\big]$$

$$\le \sum_{n=1}^\infty |\nu(E_n)| \le \sum_{n=1}^\infty \big[|\nu_{re}(E_n)| + |\nu_{im}(E_n)|\big] = \sum_{n=1}^\infty |\nu_{re}(E_n)| + \sum_{n=1}^\infty |\nu_{im}(E_n)|$$

and the result follows by taking the supremum over all measurable partitions of E and applying XVII.9.1.17.(ii). In particular, since $|\nu_{re}|(E)$ and $|\nu_{im}|(E)$ are finite, so is $|\nu|(E)$.

(i): It is obvious that $|\nu|(\emptyset) = 0$. Let $\{A_m\}$ be a pairwise disjoint sets in $\mathcal{A}$, and let $A = \cup_{m=1}^{\infty} A_m$. Fix $\epsilon > 0$. Let $\{E_n\}$ be a measurable partition of A with $\sum_{n=1}^{\infty} |\nu(E_n)| > |\nu|(A) - \epsilon$ ($|\nu|(A)$ is finite by (iii)). Set $A_{n,m} = E_n \cap A_m$ for each n, m. Then

$$|\nu|(A) - \epsilon \le \sum_{n=1}^{\infty} |\nu(E_n)| = \sum_{n=1}^{\infty} \left| \sum_{m=1}^{\infty} \nu(A_{n,m}) \right|$$

$$\le \sum_{n=1}^{\infty} \left[\sum_{m=1}^{\infty} |\nu(A_{n,m})| \right] = \sum_{m=1}^{\infty} \left[\sum_{n=1}^{\infty} |\nu(A_{n,m})| \right] \le \sum_{m=1}^{\infty} |\nu|(A_m)$$

(the equality in the last line uses ().) Since $\epsilon > 0$ is arbitrary, $|\nu|(A) \le \sum_{m=1}^{\infty} |\nu|(A_m)$. Conversely, if $\epsilon > 0$, for each m let $\{E_{n,m}\}$ be a measurable partition of A_m with

$$\sum_{n=1}^{\infty} |\nu(E_{n,m})| > |\nu|(A_m) - 2^{-m}\epsilon \ .$$

Then $\{E_{n,m}\}$ is a measurable partition of A, so

$$\left(\sum_{m=1}^{\infty} |\nu|(A_m) \right) - \epsilon = \sum_{m=1}^{\infty} [|\nu|(A_m) - 2^{-m}\epsilon] < \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} |\nu(E_{n,m})| \le |\nu|(A) \ .$$

Since $\epsilon > 0$ is arbitrary, $\sum_{m=1}^{\infty} |\nu|(A_m) \le |\nu|(A)$. 👍

XVII.9.2.8. PROPOSITION. Let ν_1 and ν_2 be complex measures on $(X, \mathcal{A})$, and let $\alpha \in \mathbb{C}$. Then

(i) $|\nu_1 + \nu_2| \le |\nu_1| + |\nu_2|$ (i.e. $|\nu_1 + \nu_2|(E) \le |\nu_1|(E) + |\nu_2|(E)$ for all $E \in \mathcal{A}$).

(ii) $|\alpha\nu_1| = |\alpha||\nu_1|$.

XVII.9.3. Integration With Respect to Signed and Complex Measures

There is nothing difficult or complicated about extending integration to the case of signed or complex measures; we need only make the right definitions, which are fairly obvious, guided by the desire to preserve linearity.

The only slight difficulty is deciding what should be meant by an integrable function. But the definition here is fairly obvious too, because of the following fact:

XVII.9.3.1. PROPOSITION. (i) Let ν be a signed measure on a measurable space $(X, \mathcal{A})$, and $f : X \to \mathbb{R}$ an $\mathcal{A}$-measurable function. Then $f \in \mathcal{L}^1(X, \mathcal{A}, |\nu|)$ if and only if $f \in \mathcal{L}^1(X, \mathcal{A}, \nu^+)$ and $f \in \mathcal{L}^1(X, \mathcal{A}, \nu^-)$.
(ii) Let ν be a complex measure on a measurable space $(X, \mathcal{A})$, and $f : X \to \mathbb{C}$ an $\mathcal{A}$-measurable function. Then $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, |\nu|)$ if and only if $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, |\nu_{re}|)$ and $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, |\nu_{im}|)$.

PROOF: Part (i) is obvious since $\int_X |f|\, d|\nu| = \int_X |f|\, d\nu^+ + \int_X |f|\, d\nu^-$, and (ii) follows easily from the same argument and XVII.9.2.7.(iii). 👍

XVII.9.3.2. DEFINITION. Let ν be a signed measure or complex measure on a measurable space $(X, \mathcal{A})$, and f a real- or complex-valued $\mathcal{A}$-measurable function. Then $f \in \mathcal{L}^1(X, \mathcal{A}, \nu)$ [$\mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$ if f is complex-valued] if $|f| \in \mathcal{L}^1(X, \mathcal{A}, |\nu|)$.

We then make the following obvious definition:

XVII.9.3.3. DEFINITION. (i) Let ν be a signed measure on a measurable space $(X, \mathcal{A})$, and $f \in \mathcal{L}^1(X, \mathcal{A}, \nu)$ or $\mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$. Then

$$\int_X f \, d\nu = \int_X f \, d\nu^+ - \int_X f \, d\nu^- \ .$$

(ii) Let ν be a complex measure on a measurable space $(X, \mathcal{A})$, and $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$. Then

$$\int_X f \, d\nu = \int_X f \, d\nu_{re} + i \int_X f \, d\nu_{im} \ .$$

(iii) If $A \in \mathcal{A}$, then in either of the above cases $\int_A f \, d\nu = \int_X f \chi_A \, d\nu$.

XVII.9.3.4. The integrals defined in this way have almost all the properties of integrals with respect to ordinary measures; the only obvious exceptions are positivity and monotonicity. It thus only makes sense to integrate $\mathcal{L}^1$-functions, not arbitrary nonnegative measurable functions.

We list the important properties of this extended integral. The proofs are simple applications of the results for nonnegative measures, and are mostly omitted.

XVII.9.3.5. PROPOSITION. Let ν be a signed or complex measure on a measurable space $(X, \mathcal{A})$. If $f, g \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$, then

$$\int_A (f + g) \, d\nu = \int_A f \, d\nu + \int_A g \, d\nu$$

for all $A \in \mathcal{A}$. If $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$ and $\alpha \in \mathbb{C}$, then

$$\int_A \alpha f \, d\nu = \alpha \int_A f \, d\nu$$

for all $A \in \mathcal{A}$.

For the proof of the last statement, see Exercise XVII.9.5.2..

XVII.9.3.6. If ν is a signed or complex measure and $f \in \mathcal{L}_1(\nu)$, then in general

$$\left| \int_X f \, d\nu \right| \not\leq \int |f| \, d\nu$$

(the right side is not necessarily nonnegative or even real). However, we have:

XVII.9.3.7. PROPOSITION. Let ν be a signed or complex measure on a measurable space $(X, \mathcal{A})$, and let $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$. Then

$$\left| \int_A f \, d\nu \right| \leq \int_A |f| \, d|\nu|$$

for any $A \in \mathcal{A}$.

Because of the lack of monotonicity, there are no versions of the Monotone Convergence Theorem or Fatou's Lemma for signed or complex measures. But the Dominated Convergence Theorem holds with an identical statement:

XVII.9.3.8. THEOREM. [DOMINATED CONVERGENCE THEOREM] Let ν be a signed or complex measure on a measurable space $(X, \mathcal{A})$. Let (f_n) be a sequence of functions in $\mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$ converging pointwise a.e. to a function f. If there is a $g \in \mathcal{L}^1_+(X, \mathcal{A}, \nu)$ with $|f_n| \leq g$ a.e. for all n, then

$$\int_X f \, d\nu = \lim_{n \to \infty} \int_X f_n \, d\nu \ .$$

There is a version for infinite series. We omit the general statement, but note the following important special case:

XVII.9.3.9. PROPOSITION. Let ν be a signed or complex measure on a measurable space $(X, \mathcal{A})$, and let $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$. Let $\{A_n\}$ be a sequence of pairwise disjoint sets in $\mathcal{A}$, with $A = \cup_{n=1}^{\infty} A_n$. Then the series

$$\sum_{n=1}^{\infty} \int_{A_n} f \, d\nu$$

converges absolutely to $\int_A f \, d\nu$.

XVII.9.3.10. As a consequence, if ν is a complex measure on $(X, \mathcal{A})$, and $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$, and σ is defined on $\mathcal{A}$ by $\sigma(A) = \int_A f \, d\nu$, then σ is also a complex measure on A. In this case, we have that $|\sigma|(A) = \int_A |f| \, d|\nu|$ (**??**).

XVII.9.4. Another Approach via Local Measures

There is another way to avoid the $\infty - \infty$ problem: considering signed and complex local measures defined on δ-rings () rather than σ-algebras. This approach allows for a more general theory which is important, for example, in the general form of the Riesz Representation Theorem ().

XVII.9.4.1. DEFINITION. Let X be a set, and $\mathcal{D}$ a δ-ring of subsets of X. A *(finite) signed local measure* on $(X, \mathcal{D})$ is a function $\nu : \mathcal{D} \to \mathbb{R}$ such that

(i) $\nu(\emptyset) = 0$.

(ii) If $\{A_n\}$ is a sequence of pairwise disjoint sets in $\mathcal{D}$ with $A := \cup_{n=1}^{\infty} A_n \in \mathcal{D}$, then

$$\nu\left(\bigcup_{n=1}^{\infty} A_n\right) = \sum_{n=1}^{\infty} \nu(A_n)$$

(in particular, the infinite series in (ii) converges).

XVII.9.4.2. We could allow ν to take either the value $+\infty$ or $-\infty$, but not both; but the utility of this generalization is modest at best since working on δ-rings is primarily designed to eliminate infinite values of the measure, so we will stick to finite signed local measures, and the "finite" will be understood. Note that in the definition, the series $\sum_{n=1}^{\infty} \nu(A_n)$ necessarily converges absolutely under the hypotheses, since

$$A_+ = \cup\{A_n : \nu(A_n) \geq 0\} \quad \text{and} \quad A_- = \cup\{A_n : \nu(A_n) < 0\}$$

are in $\mathcal{D}$.

XVII.9.4.3. EXAMPLES. (i) A finite signed measure on $(X, \mathcal{A})$ is a signed local measure, with $\mathcal{D} = \mathcal{A}$.

(ii) More generally, let μ be a signed measure on $(X, \mathcal{A})$, not necessarily finite. Set $\mathcal{D} = \{A \in \mathcal{A} : \mu(A) \in \mathbb{R}\}$. Then $\mathcal{D}$ is a δ-ring, and $\nu = \mu|_{\mathcal{D}}$ is a signed local measure (XVII.9.1.10.).

(iii) Here is an example not of the form in (ii), which illustrates the main point in passing to signed local measures. Let $\mathcal{D}$ be the collection of Lebesgue measurable sets in $\mathbb{R}$ of finite Lebesgue measure, and for $A \in \mathcal{D}$ set

$$\nu(A) = \lambda(A \cap [0, \infty)) - \lambda(A \cap (-\infty, 0)) \ .$$

Then $\mathcal{D}$ is a δ-ring of subsets of $\mathbb{R}$, and ν is a signed local measure on $\mathcal{D}$. This $\mathcal{D}$ can be replaced by the δ-ring of bounded Lebesgue measurable sets or the δ-ring of bounded Borel sets (or Borel sets of finite Lebesgue measure). Note that there is no way to work with a signed measure in this case which avoids the $\infty - \infty$ problem.

(iv) A local measure on a δ-ring $\mathcal{D}$ is a signed local measure. Such a local measure extends canonically to a measure on the σ-algebra generated by $\mathcal{D}$, so there is little advantage to considering local measures on δ-rings. But Example (iii) shows that this is not true for signed local measures in general.

(v) Since we are only considering finite signed local measures, any linear combination of signed local measures on the *same* δ-ring $\mathcal{D}$ is a signed local measure on $\mathcal{D}$. In particular, the difference of two finite local measures on $\mathcal{D}$ is a local signed measure on $\mathcal{D}$.

XVII.9.4.4. If ν is a signed local measure on a δ-ring $\mathcal{D}$ of subsets of X, and $Y \in \mathcal{D}$, then the restriction of ν to the σ-algebra $\mathcal{D}_Y$ is a finite signed measure on $(Y, \mathcal{D}_Y)$. Thus, although the strict analog of XVII.9.1.14. is false in general for signed local measures, i.e. a signed local measure need not be bounded, as shown by Example XVII.9.4.3.(iii), a signed local measure is "locally bounded," and locally has all the other properties of a signed measure.

Jordan and Hahn Decompositions of Signed Local Measures

XVII.9.4.5. If ν is a signed local measure on a δ-ring $\mathcal{D}$, and $Y \in \mathcal{D}$, then ν defines a finite signed measure on $(Y, \mathcal{D}_Y)$, hence there is a Jordan decomposition for $\nu_Y := \nu|_{\mathcal{D}_Y}$, i.e. there are unique finite measures ν_Y^+ and ν_Y^- on $(Y, \mathcal{D}_Y)$ with $\nu_Y = \nu_Y^+ - \nu_Y^-$. If $Y, Z \in \mathcal{D}$, $Y \subseteq Z$, then ν_Y is the restriction of ν_Z to $\mathcal{D}_Y$, and it follows that $\nu_Y^\pm$ is the restriction of $\nu_Z^\pm$ to $\mathcal{D}_Y$. Since $\mathcal{D}$ is a directed set under inclusion, the $\nu_Y^\pm$ define finite local measures $\nu^\pm$ on $\mathcal{D}$ with $\nu = \nu^+ - \nu^-$. Thus a signed local measure has a well-defined and unique Jordan decomposition as a difference of finite local measures.

Both ν^+ and ν^- extend canonically to measures on the σ-algebra generated by $\mathcal{D}$. But the extensions are not finite in general, and ν may not extend as the difference due to the $\infty - \infty$ problem (cf. Example XVII.9.4.3.(iii)).

XVII.9.4.6. Although Jordan decomposition works nicely for signed local measures, Hahn decomposition is much more problematic since the Hahn decomposition of a signed measure is only uniquely determined up to null sets. And even if the Hahn decompositions (A_Y, B_Y) of the ν_Y can be chosen consistently, so a Hahn decomposition (A, B) can be defined as $A = \cup_Y A_Y$, $B = \cup_Y B_Y$, the A and B are only locally $\mathcal{D}$-measurable in general, and are only uniquely defined up to "locally null sets."

The Total Variation of a Signed Local Measure

XVII.9.4.7. If ν is a signed local measure on a δ-ring $\mathcal{D}$, with Jordan decomposition $\nu^+ - \nu^-$, we can define the total variation $|\nu|$ to be $\nu^+ + \nu^-$. Then $|\nu|$ is a finite local measure on $\mathcal{D}$. The exact analog of XVII.9.1.17. holds, with the same proof.

Complex Local Measures

XVII.9.4.8. The extension of the definition of signed local measures to complex measures presents no difficulty: just change $\mathbb{R}$ to $\mathbb{C}$ in Definition XVII.9.4.1.. The real and imaginary parts of a complex local measure are signed local measures.

XVII.9.4.9. The total variation of a complex local measure can be defined exactly as in XVII.9.2.6., and XVII.9.2.7. holds with trivial modifications of the proof (left to the reader).

Integration With Respect to Signed and Complex Local Measures

XVII.9.5. Exercises

XVII.9.5.1. (a) Let $(X, \mathcal{A}, \mu)$ be a measure space, and $f \in \mathcal{L}^1_{\mathbb{R}}(X, \mathcal{A}, \mu)$. Define $\nu(A) = \int_A f\, d\mu$ as in XVII.9.1.2. and XVII.9.1.8.. Show that, for all $A \in \mathcal{A}$, $|\nu|(A) = \int_A |f|\, d\mu$.

(b) Show the same for $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \mu)$. [Hint: for $n \in \mathbb{N}$ and $1 \leq k \leq n$, consider the set

$$A_{n,k} = \left\{ x \in A : \frac{2\pi(k-1)}{n} \leq arg(f(x)) < \frac{2\pi k}{n} \right\} .]$$

XVII.9.5.2. (a) Let ν be a complex measure on a measurable space $(X, \mathcal{A})$, and $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$. Show that

$$\int_A f\, d\nu = \left[\int_A Re(f)\, d\nu_{re} - \int_A Im(f)\, d\nu_{im}\right] + i\left[\int_A Re(f)\, d\nu_{im} + \int_A Im(f)\, d\nu_{re}\right]$$

for any $A \in \mathcal{A}$.

(b) Show that if $\alpha \in \mathbb{C}$, then

$$\int_X \alpha f\, d\nu = \alpha \int_X f\, d\nu\ .$$

XVII.9.5.3. Let ν be a signed measure on a measurable space $(X, \mathcal{A})$, and $f \in \mathcal{L}^1_{\mathbb{R}}(X, \mathcal{A}, \nu)$. Define a signed measure σ by $\sigma(A) = \int_A f\, d\nu$ for $A \in \mathcal{A}$ ().

(a) Find a Hahn decomposition for σ, and the Jordan decomposition.

(b) Show that $|\sigma|(A) = \int_A |f|\, d|\nu|$ for $a \in \mathcal{A}$.

XVII.9.5.4. Let ν be a complex measure on $(X, \mathcal{A})$, and $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$. Define a complex measure σ by $\sigma(A) = \int_A f\, d\nu$ for $A \in \mathcal{A}$ (). If g is an $\mathcal{A}$-measurable function, show that g is σ-integrable if and only if fg is ν-integrable, and that

$$\int_A g\, d\sigma = \int_A fg\, d\nu$$

for all $A \in \mathcal{A}$.

XVII.9.5.5. Try to extend the theory of complex measures to include measures of the form $\nu_1 + i\nu_2$, where ν_1 and ν_2 are signed measures, not necessarily finite. Try to give a definition as in XVII.9.1.1. and XVII.9.2.1. which covers this case (clumsy and unnatural, isn't it?) Discuss the properties which can and cannot be established in this case, and the difficulties and limitations of such a theory.

XVII.9.5.6. A finitely additive signed measure on an algebra can be finite but unbounded, and can fail to have a Hahn decomposition.

(a) Let $\mathcal{A}$ be the algebra of finite/cofinite subsets of $\mathbb{N}$. If $A \in \mathcal{A}$ is finite, let $\nu(A)$ be the number of elements in A; if A is cofinite, let $\nu(A) = -n$, where n is the number of elements in A^c. Show that ν is a finitely additive signed measure on $(\mathbb{N}, \mathcal{A})$.

(b) Show that there is no Hahn decomposition for ν.

XVII.9.5.7. **Products of Signed Measures.** Let μ and ν be finite signed measures on measurable spaces $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ respectively, with Hahn decompositions (P_μ, N_μ) and (P_ν, N_ν) and Jordan decompositions μ^+, μ^-, ν^+, ν^-. Let

$$(\mu \times \nu)^+ = (\mu^+ \times \nu^+) + (\mu^- \times \nu^-)$$
$$(\mu \times \nu)^- = (\mu^+ \times \nu^-) + (\mu^- \times \nu^+)$$

be corresponding measures on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$.

(a) Show that $(\mu \times \nu)^+$ and $(\mu \times \nu)^-$ are mutually singular finite measures on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$.

(b) Define $\mu \times \nu = (\mu \times \nu)^+ - (\mu \times \nu)^-$. Show that $\mu \times \nu$ is a finite signed measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$ with Hahn decomposition

$$([P_\mu \times P_\nu] \cup [N_\mu \times N_\nu], [P_\mu \times N_\nu] \cup [N_\mu \times P_\nu])$$

satisfying $(\mu \times \nu)(A \times B) = \mu(A)\nu(B)$ for $A \in \mathcal{A}$, $B \in \mathcal{B}$. Show that this measure is the unique finite signed measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$ with this property.

(c) Discuss the difficulties in defining $\mu \times \nu$ if μ and ν are signed measures which are not finite.

XVII.9.5.8. Products of Complex Measures. Let $\mu = \mu_{re} + i\mu_{im}$ and $\nu = \nu_{re} + i\nu_{im}$ be complex measures on measurable spaces $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ respectively. Let

$$(\mu \times \nu)_{re} = (\mu_{re} \times \nu_{re}) - (\mu_{im} \times \nu_{im})$$

$$(\mu \times \nu)_{im} = (\mu_{re} \times \nu_{im}) + (\mu_{im} \times \nu_{re})$$

be corresponding signed measures on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$, defined as in XVII.9.5.7..

(a) Show that $(\mu \times \nu)_{re}$ and $(\mu \times \nu)_{im}$ are finite signed measures on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$.

(b) Show that $\mu \times \nu = (\mu \times \nu)_{re} + i(\mu \times \nu)_{im}$ is a complex measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$ satisfying $(\mu \times \nu)(A \times B) = \mu(A)\nu(B)$ for $A \in \mathcal{A}$, $B \in \mathcal{B}$. Show that this measure is the unique complex measure on $(X \times Y, \mathcal{A} \otimes \mathcal{B})$ with this property.

XVII.9.5.9. Make an appropriate definition of signed and complex premeasures (XVII.4.5.2.) on semirings, and prove analogs of Carathéodory's Theorem (XVII.4.3.4.) and the Extension Theorem (XVII.4.5.8.) in this case. Use this to give an alternate proof of XVII.9.5.7. (and XVII.9.5.8.) which does not use Jordan decomposition.

XVII.9.6. Signed and Complex Measures on σ-Rings

There is no particular advantage in considering ordinary measures on σ-rings instead of σ-algebras, since an ordinary measure on a σ-ring can be extended in a canonical way to the σ-algebra it generates (). But there is utility in considering signed and complex measures on σ-rings, since they arise naturally and cannot generally be extended to the generated σ-algebra, essentially because of the $\infty - \infty$ problem. In this section, we describe the theory of such measures, which of course includes the theory of ordinary measures on σ-rings. We concentrate on the crucial case of Borel measures on locally compact Hausdorff spaces.

XVII.10. Limits of Measures

In this section, we discuss the following question: if (μ_i) is a sequence (or net) of measures, and $\mu_i \to \mu$, is μ a measure?

XVII.10.1. General Considerations

We must first make sense of what it means to say that $\mu_i \to \mu$. There is one obvious minimal sense to interpret this:

XVII.10.1.1. Definition. Let X be a set, $\mathcal{A}$ a collection of subsets of X, and Y a topological space. Then a sequence (or net) (f_i) of functions from $\mathcal{A}$ to Y *converges setwise* to the function $f : \mathcal{A} \to Y$ if $f_i(A) \to f(A)$ for all $A \in \mathcal{A}$. In particular, if (μ_i) is a sequence (or net) of measures on a measurable space $(X, \mathcal{A})$, and $\mu : \mathcal{A} \to [0, \infty]$, then $\mu_i \to \mu$ setwise if $\mu_i(A) \to \mu(A)$ for all $A \in \mathcal{A}$. Setwise convergence of a sequence (or net) (ν_i) of complex measures to a function $\nu : \mathcal{A} \to \mathbb{C}$ is defined in the same way.

In other words: a measure on $(X, \mathcal{A})$ may be thought of as an element of the product space $[0, \infty]^{\mathcal{A}}$, the set of all functions from $\mathcal{A}$ to $[0, \infty]$. Then $\mu_i \to \mu$ setwise if $\mu_i \to \mu$ in the product topology. Similarly, a complex measure on $(X, \mathcal{A})$ is an element of $\mathbb{C}^{\mathcal{A}}$, and setwise convergence is convergence in the product topology.

There are stronger notions of convergence; see, for example, Exercise XVII.10.4.1..

So the basic question is:

XVII.10.1.2. Question. If (μ_i) is a sequence (or net) of measures (ordinary or complex), and $\mu_i \to \mu$ setwise, is μ is also a measure (or complex measure)?

This question can be rephrased: is the set of measures a closed subset of $[0, \infty]^{\mathcal{A}}$? Is the set of complex measures a closed subset of $\mathbb{C}^{\mathcal{A}}$?

The following simple examples show that the answer is no in general.

XVII.10.1.3. Examples. (i) On $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$, let μ_n be counting measure on $\{m : m > n\}$, regarded as a measure on $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$ by setting $\mu_n(E) = 0$ if $E \subseteq \{1, \dots, n\}$. Then each μ_n is a σ-finite measure, $(\mu_n(E))$ is decreasing for each E, and $\mu(E) = \lim_{n\to\infty} \mu_n(E)$ exists for each $E \subseteq \mathbb{N}$. But $\mu(E) = 0$ if E is finite, and $\mu(\mathbb{N}) = \infty$ (in fact, $\mu(E) = \infty$ if E is any infinite set), so μ is not a measure.

(ii) Again on $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$, let δ_n be the unit point mass at n, i.e. for $E \subseteq \mathbb{N}$, $\delta_n(E) = 1$ if $n \in E$ and $\delta_n(E) = 0$ if $n \notin E$. Each δ_n gives a point of $\{0, 1\}^{\mathcal{P}(\mathbb{N})}$, which is compact in the product topology; thus there is a subnet of the sequence (δ_n) which converges setwise to a function $\mu : \mathcal{P}(\mathbb{N}) \to \{0, 1\}$. But $\mu(E) = 0$ for all finite E, while $\mu(\mathbb{N}) = 1$, and thus μ cannot be a measure.

Example (ii) is rather generic: there are grave difficulties in taking limits of nets of measures which are not sequences. But, rather remarkably, often (i.e. under mild hypotheses) it will turn out that limits of *sequences* of measures are measures.

A setwise limit of measures is always at least a finitely additive measure:

XVII.10.1.4. PROPOSITION. Let $(X, \mathcal{A})$ be a measurable space. Then the set of finitely additive measures on $(X, \mathcal{A})$ is closed under setwise limits (i.e. is a closed subset of $[0, \infty]^{\mathcal{A}}$). The set of finitely additive complex measures is a closed subset of $\mathbb{C}^{\mathcal{A}}$.

This is an immediate consequence of ().

So the whole difficulty is with countable additivity.

XVII.10.2. Monotone and Dominated Convergence

The first result is an analog of the Monotone Convergence Theorem:

XVII.10.2.1. THEOREM. Let (μ_i) be a net of measures on a measurable space $(X, \mathcal{A})$. If $(\mu_i(A))$ is increasing for each $A \in \mathcal{A}$, then $\mu = \lim \mu_i = \sup \mu_i$ (defined by $\mu(A) = \sup_i \mu_i(A)$ for $A \in \mathcal{A}$) is a measure on $(X, \mathcal{A})$.

PROOF: We only need to show countable additivity. Suppose (A_n) is a pairwise disjoint sequence in $\mathcal{A}$, and set $A = \cup_{n=1}^{\infty} A_n$. We have

$$\sum_{n=1}^{\infty} \mu(A_n) = \sup_N \sum_{n=1}^{N} \mu(A_n) = \sup_N \left[\mu \left(\bigcup_{n=1}^{N} A_n \right) \right] \leq \mu(A)$$

by finite additivity and monotonicity. To show the reverse inequality, first suppose $\mu(A) < \infty$. Let $\epsilon > 0$ and choose i_0 such that $\mu_{i_0}(A) > \mu(A) - \epsilon$. Then we have

$$\mu(A) - \epsilon < \mu_{i_0}(A) = \sum_{n=1}^{\infty} \mu_{i_0}(A_n) \leq \sum_{n=1}^{\infty} \mu(A_n) \ .$$

Since $\epsilon > 0$ is arbitrary, $\mu(A) \leq \sum_{n=1}^{\infty} \mu(A_n)$.

Now suppose $\mu(A) = \infty$. Fix $M > 0$, and choose i_0 such that $\mu_{i_0}(A) > M$. We then have

$$M < \mu_{i_0}(A) = \sum_{n=1}^{\infty} \mu_{i_0}(A_n) \leq \sum_{n=1}^{\infty} \mu(A_n)$$

so $\sum_{n=1}^{\infty} \mu(A_n) = +\infty$. 👍

This implies that arbitrary sums of measures are measures (finite sums of measures are obviously measures ()).

XVII.10.2.2. COROLLARY. Let $\{\mu_i : i \in I\}$ be a set of measures on a measurable space $(X, \mathcal{A})$. For each $A \in \mathcal{A}$, define

$$\mu(A) = \sum_{i \in I} \mu_i(A) = \sup \left\{ \sum_{i \in F} \mu_i(A) : F \subseteq I \text{ finite} \right\} \ .$$

Then μ is a measure on $(X, \mathcal{A})$.

There is also a version of the Dominated Convergence Theorem:

XVII.10.2.3. THEOREM. Let (ν_i) be a net of complex measures on a measurable space $(X, \mathcal{A})$, converging setwise to a function ν. If there is a finite measure μ such that $|\nu_i| \leq \mu$ for all i, then ν is a complex measure.

(Of course, this theorem applies in the case the ν_i are ordinary measures uniformly dominated by a finite measure μ.)

In fact, this result holds in greater generality. We make some definitions:

XVII.10.2.4. DEFINITION. Let $(\nu_i)_{i\in I}$ be a net of complex measures on a measurable space $(X, \mathcal{A})$, and μ a measure on $(X, \mathcal{A})$. Then (ν_i) is *uniformly absolutely continuous* with respect to μ if for every $\epsilon > 0$ there is a $\delta > 0$ and an $i_0 \in I$ such that, for all $A \in \mathcal{A}$ with $\mu(A) < \delta$,

$$|\nu_i(A)| < \epsilon \text{ for all } i \geq i_0 \ .$$

The term "uniformly absolutely continuous" is appropriate for this notion, in analogy with the characterization of absolute continuity of measures in ().

Under the hypotheses of XVII.10.2.5., (ν_i) is uniformly absolutely continuous with respect to μ (take $\delta = \epsilon$). Thus Theorem XVII.10.2.5. is a special case of the following result:

XVII.10.2.5. THEOREM. Let (ν_i) be a net of complex measures on a measurable space $(X, \mathcal{A})$, converging setwise to a function $\nu : \mathcal{A} \to \mathbb{C}$. If there is a finite measure μ such that (ν_i) is uniformly absolutely continuous with respect to μ, then ν is a complex measure.

We can even go to one step greater generality:

XVII.10.2.6. DEFINITION. Let $(\nu_i)_{i\in I}$ be a net of complex measures on a measurable space $(X, \mathcal{A})$. Then (ν_i) is *uniformly countably additive* if, whenever (A_n) is a sequence of pairwise disjoint sets in $\mathcal{A}$ with $A = \cup_{n=1}^{\infty} A_n$, and $\epsilon > 0$, there is an $N_0 \in \mathbb{N}$ and an $i_0 \in I$ such that

$$\left|\nu_i(A) - \nu_i\left(\cup_{n=1}^{N} A_n\right)\right| < \epsilon$$

for all $N \geq N_0$ and $i \geq i_0$.

XVII.10.2.7. PROPOSITION. Let $(\nu_i)_{i\in I}$ be a net of complex measures on a measurable space $(X, \mathcal{A})$. Then (ν_i) is uniformly countably additive if and only if, whenever (B_n) is a decreasing sequence in $\mathcal{A}$ with $\cap_{n=1}^{\infty} B_n = \emptyset$, we have $\lim_{n\to\infty} \nu_i(B_n) = 0$ uniformly in i, i.e. for every $\epsilon > 0$ there is an $n_0 \in \mathbb{N}$ and $i_0 \in I$ such that

$$|\nu_i(B_n)| < \epsilon$$

for all $n \geq n_0$ and $i \geq i_0$.

PROOF: If (ν_i) is uniformly countably additive and (B_n) is decreasing with empty intersection, set $A_n = B_n \setminus B_{n+1}$. Conversely, if (A_n) is a pairwise disjoint sequence, let $B_n = \cup_{k\geq n} A_k$.

XVII.10.2.8. Corollary. Let $(\nu_i)_{i\in I}$ be a net of complex measures on a measurable space $(X, \mathcal{A})$. If (ν_i) is uniformly countably additive, then whenever (A_n) is a pairwise disjoint sequence in $\mathcal{A}$ we have $\lim_{n\to\infty} \nu_i(A_n) = 0$ uniformly in i.

The converse is also true for a *sequence* of complex measures, and is a key step in the direct proof of the Nikodým Convergence Theorem (Exercise XVII.10.4.2.).
Proof: Set $B_n = \cup_{k=n}^{\infty} A_k$. Then $\nu_i(B_n) \to 0$ uniformly in i, and $|\nu_i(A_n)| \leq |\nu_i(B_n)| + |\nu_i(B_{n+1})|$ for all n and i. 👍

XVII.10.2.9. Proposition. Let (ν_i) be a net of complex measures on a measurable space $(X, \mathcal{A})$. If there is a finite measure μ such that (ν_i) is uniformly absolutely continuous with respect to μ, then (ν_i) is uniformly countably additive.

The converse is true for a setwise convergent sequence of complex measures (XVII.10.3.8.).
Proof: Use XVII.10.2.7.. Let $\epsilon > 0$, and fix δ_0 and i_0 as in Definition XVII.10.2.4.. Let (B_n) be a decreasing sequence in $\mathcal{A}$ with $\cap_{n=1}^{\infty} B_n = \emptyset$. Fix n_0 such that $\mu(B_n) < \delta$ for all $n \geq n_0$. Then, for all $n \geq n_0$ and $i \geq i_0$, $|\nu_i(B_n)| < \epsilon$. 👍

We then obtain the most general version of the Dominated Convergence Theorem for measures (note that there is no actual domination in this version!)

XVII.10.2.10. Theorem. Let (ν_i) be a net of complex measures on a measurable space $(X, \mathcal{A})$, converging setwise to a function $\nu : \mathcal{A} \to \mathbb{C}$. If (ν_i) is uniformly countably additive, then ν is a complex measure.

Proof: We again need only show countable additivity. Since ν is finite-valued, it suffices to show () that if (B_n) is a decreasing sequence in $\mathcal{A}$ with $\cap_{n=1}^{\infty} B_n = \emptyset$, we have $\lim_{n\to\infty} \nu(B_n) = 0$. Let $\epsilon > 0$, and fix a corresponding n_0 and i_0 as in the definition of uniform countable additivity (XVII.10.2.6.). Then, if $n \geq n_0$, then $|\nu_i(B_n)| < \epsilon$ for all $i \geq i_0$, and thus $|\nu(A_n)| \leq \epsilon$. 👍

XVII.10.3. The Nikodým and Vitali-Hahn-Saks Theorems

We now restrict attention to sequences of measures. There is a circle of results due to Nikodým, Vitali, Hahn, and Saks (there were other contributors too) which say that under certain mild restrictions, the setwise limit of a sequence of complex measures is a complex measure, and that the convergence is "almost uniform."

These results are closely interconnected, and can be largely deduced from each other; various schemes for proving them are found in the literature. Even the names of the results are not uniform in references; what is called the "Vitali-Hahn-Saks Theorem" in some references is called the "Nikodým Convergence Theorem" in others, reflecting the close connections. We have tried to use names accurately reflecting the actual work of the originators. ✋

The first observation is that a sequence of complex measures is dominated by a single measure:

XVII.10.3.1. PROPOSITION. Let (ν_n) be a sequence of complex measures on a measurable space $(X, \mathcal{A})$. Then there is a finite measure μ on $(X, \mathcal{A})$ such that $\nu_n \ll \mu$ for all n.

PROOF: We may assume all the ν_n are nonzero. For $A \in \mathcal{A}$, set

$$\mu(A) = \sum_{n=1}^{\infty} \frac{|\nu_n|(A)}{2^n |\nu_n|(X)} \ .$$

By XVII.10.2.2., μ is a measure. It is obvious that μ is finite and $\nu_n \ll \mu$ for all n. 👍

The next theorem is the main result of this section. VITALI proved the first version as a special case of his convergence theorem (), and HAHN obtained the result for Lebesgue-Stieltjes measures. The general result is due to SAKS. Our proof, also due to SAKS (cf. [DS88]), uses the Baire Category Theorem and is strongly reminiscent of the proof of the Uniform Boundedness Theorem ().

XVII.10.3.2. THEOREM. [VITALI-HAHN-SAKS] Let μ be a measure, and (ν_n) a sequence of complex measures, on a measurable space $(X, \mathcal{A})$. If (ν_n) converges setwise to a function $\nu : \mathcal{A} \to \mathbb{C}$, and $\nu_n \ll \mu$ for all n, then (ν_n) is uniformly absolutely continuous with respect to μ.

PROOF: Let $\Sigma(\mu)$ be the metric space of μ. Then each ν_n gives a continuous function from $\Sigma(\mu)$ to $\mathbb{C}$, converging pointwise to $\nu : \Sigma(\mu) \to \mathbb{C}$. Fix $\epsilon > 0$. For each m and n, set

$$E_{m,n} = \{A \in \mathcal{A} : |\nu_n(A) - \nu_m(A)| \leq \epsilon\}$$

(regarded as a subset of $\Sigma(\mu)$) and set $F_k = \bigcap_{m,n \geq k} E_{m,n}$. Then F_k is a closed subset of $\Sigma(\mu)$ for each k, and since (ν_n) converges pointwise, $\cup_{k=1}^{\infty} F_k = \Sigma(\mu)$. Thus, since $\Sigma(\mu)$ is complete (), F_k has a nonempty interior for some k by the Baire Category Theorem, i.e. there is a k, an $A \in \mathcal{A}$, and an $r > 0$ such that

$$\{B \in \mathcal{A} : \mu(A \triangle B) < r\} \subseteq F_k \ .$$

There is a δ, $0 < \delta < r$, such that $|\nu_n(B)| < \epsilon$ for $1 \leq n \leq k$ whenever $B \in \mathcal{A}$ and $\mu(B) < \delta$ (). Then, if $B \in \mathcal{A}$, $\mu(B) < \delta$, we have that $A \cup B$ and $A \setminus B$ are in F_k, so for $n \geq k$ we have

$$\nu_n(B) = \nu_k(B) + (\nu_n(B) - \nu_k(B))$$

$$= \nu_k(B) + (\nu_n(A \cup B) - \nu_k(A \cup B)) - (\nu_n(A \setminus B) - \nu_k(A \setminus B))$$

and thus $|\nu_n(B)| < 3\epsilon$ for all n. 👍

XVII.10.3.3. COROLLARY. [NIKODÝM CONVERGENCE THEOREM] Let (ν_n) be a sequence of complex measures on a measurable space $(X, \mathcal{A})$, converging setwise to a function $\nu : \mathcal{A} \to \mathbb{C}$. Then (ν_n) is uniformly countably additive, and ν is a complex measure.

PROOF: There is a finite measure μ on $\mathcal{A}$ with $\nu_n \ll \mu$ for all n by XVII.10.3.1.. Then (ν_n) is uniformly absolutely continuous with respect to μ by XVII.10.3.2., and hence is uniformly countably additive by XVII.10.2.9.. Then ν is a measure by XVII.10.2.10.. 👍

XVII.10.3.4. The Nikodým Convergence Theorem was proved before the general theorem XVII.10.3.2. was obtained. See [Swa94] for a direct proof of the Nikodým Convergence Theorem using a matrix version () of the "gliding hump" argument (cf. Exercise ()). The Vitali-Hahn-Saks Theorem can then be derived from the Nikodým Convergence Theorem (). There is a direct proof of the Nikodým Convergence Theorem for ordinary (finite) measures not using the Baire Category Theorem; see Exercise XVII.10.4.3..

There are versions of these results for finitely additive measures and for vector measures; see [DU77].

A nice consequence of the Nikodým Convergence Theorem is the following result, which is a close analog of the Uniform Boundedness Principle:

XVII.10.3.5. THEOREM. [NIKODÝM BOUNDEDNESS THEOREM] Let (ν_n) be a sequence of complex measures on a measurable space $(X, \mathcal{A})$. If $\{\nu_n(A) : n \in \mathbb{N}\}$ is bounded for each $A \in \mathcal{A}$, then the ν_n are uniformly bounded, i.e. there is an M such that $|\nu_n(A)| \leq M$ for all n and for all $A \in \mathcal{A}$.

For the proof, we need a lemma:

XVII.10.3.6. LEMMA. Let (ν_n) be a sequence of complex measures on a measurable space $(X, \mathcal{A})$. If $\{\nu_n(A) : n \in \mathbb{N}\}$ is bounded for each $A \in \mathcal{A}$, then (ν_n) is uniformly bounded if and only if, for every sequence (A_n) of pairwise disjoint sets in $\mathcal{A}$, the set $\{\nu_n(A_n)\}$ is bounded.

PROOF: The condition is obviously necessary. For sufficiency, suppose (ν_n) is not uniformly bounded. Let $N_0 = \sup_n\{|\nu_n(X)|\}$. Let $E_1 \in \mathcal{A}$ with $|\nu_{n_1}(E_1)| > 1 + N_0$ for some n_1; then, if $F_1 = X \setminus E_1$, $|\nu_{n_1}(F_1)| \geq |\nu_{n_1}(E_1)| - |\nu_{n_1}(X)| > 1$. Either $\{|\nu_n(A \cap E_1)| : A \in \mathcal{A}, n \in \mathbb{N}\}$ or $\{|\nu_n(A \cap F_1)| : A \in \mathcal{A}, n \in \mathbb{N}\}$ is unbounded; set $B_1 = E_1$ in the first case, and $B_1 = F_1$ in the second case, and let A_{n_1} be the other (i.e. $A_{n_1} = X \setminus B_1$). Let $N_1 = \sup_n\{|\nu_n(B_1)|\}$. Let $E_2 \in \mathcal{A}$, $E_2 \subseteq B_1$, with $|\nu_{n_2}(E_2)| > 2 + N_1$ for some n_2; we may assume $n_2 \neq n_1$ since $\{\nu_{n_1}(A) : A \in \mathcal{A}\}$ is bounded [by $|\nu_{n_1}|(X)$]. Then, if $F_2 = B_1 \setminus E_2$, $|\nu_{n_2}(F_2)| > 2$. Let $B_2 = E_2$ if $\{|\nu_n(A \cap E_2)| : A \in \mathcal{A}, n \in \mathbb{N}\}$ is unbounded and $B_2 = F_2$ if $\{|\nu_n(A \cap F_2)| : A \in \mathcal{A}, n \in \mathbb{N}\}$ is unbounded, and set $A_{n_2} = B_1 \setminus B_2$. Continue inductively to obtain a sequence (n_k) in $\mathbb{N}$ and a pairwise disjoint sequence (A_{n_k}) in $\mathcal{A}$ such that $|\nu_{n_k}(A_{n_k})| > k$. Set $A_n = \emptyset$ for n not equal to any n_k. 👍

XVII.10.3.7. **Remark:** The hypothesis that (ν_n) be setwise bounded is omitted from the statement of this result in [Swa94, p. 68]. This hypothesis is easily seen to be necessary: let X be a singleton and $\nu_n(X) = n$. Also, the proof only requires that $\mathcal{A}$ be an algebra and that the ν_n be finitely additive if the additional hypothesis is added that each ν_n is bounded, which is not automatic in this case (Exercise XVII.9.5.6.). (Without this hypothesis, the result fails: let ν_1 be a finitely additive signed measure which is finite but not bounded, and $\nu_n = 0$ for $n > 1$.)

We now prove XVII.10.3.5..

PROOF: By XVII.10.3.6. and (), it suffices to show that if (A_n) is a pairwise disjoint sequence in $\mathcal{A}$ and (α_n) is a sequence in $\mathbb{C}$ with $\alpha_n \to 0$, that $\alpha_n\nu_n(A_n) \to 0$. But $(\alpha_n\nu_n)$ is a sequence of complex measures on $(X, \mathcal{A})$ converging setwise to the zero measure; hence by XVII.10.3.3. the sequence $(\alpha_n\nu_n)$ is uniformly countably additive, giving the conclusion from XVII.10.2.8.. 👍

As a related matter, we have the following converse to XVII.10.2.9.:

XVII.10.3.8. THEOREM. Let (ν_n) be a sequence of complex measures on a measurable space $(X, \mathcal{A})$, and μ a measure on $(X, \mathcal{A})$ such that $\nu_n \ll \mu$ for all n. If (ν_n) is uniformly countably additive, then (ν_n) is uniformly absolutely continuous with respect to μ.

PROOF: If (ν_n) is not uniformly absolutely continuous with respect to μ, we will construct a pairwise disjoint sequence (A_k) in $\mathcal{A}$ and indices n_k such that $\nu_{n_k}(A_k)$ does not approach 0, contradicting XVII.10.2.8..

If (ν_n) is not uniformly absolutely continuous with respect to μ, there is an $\epsilon > 0$ such that for all $\delta > 0$, there is a $B \in \mathcal{A}$ with $\mu(B) < \delta$ and $|\nu_n(B)| \geq \epsilon$ for infinitely many n. Fix such an ϵ. Choose $B_1 \in \mathcal{A}$ and n_1 with $|\nu_{n_1}(B_1)| \geq \epsilon$ and $\mu(B_1) < 1$. Since $\nu_{n_1} \ll \mu$, there is a $\delta_1 > 0$ such that $|\nu_{n_1}(B)| < \epsilon/2$ whenever $\mu(B) < \delta_1$. There is a $B_2 \in \mathcal{A}$ and an $n_2 > n_1$ such that $|\nu_{n_2}(B_2)| \geq \epsilon$ and $\mu(B_2) < \delta_1/2$. Continuing inductively, construct sets $B_k \in \mathcal{A}$, numbers δ_k, and a strictly increasing sequence (n_k) of indices, such that, for all k, $\delta_{k+1} < \delta_k/2$, $|\nu_{n_k}(B_k)| \geq \epsilon$, $\mu(B_{k+1}) < \delta_k/2$, and $|\nu_{n_k}(B)| < \epsilon/2$ whenever $\mu(B) < \delta_k$.

Set $C_k = \cup_{n=k+1}^{\infty} B_n$ for each k. Then

$$\mu(C_k) \leq \sum_{n=k+1}^{\infty} \mu(B_n) < \sum_{n=1}^{\infty} \frac{\delta_k}{2^n} = \delta_k$$

so that $|\nu_{n_k}(B_k \cap C_k)| < \epsilon/2$ for each k. Thus, if $A_k = B_k \setminus C_k$, the A_k are pairwise disjoint and, for all k,

$$|\nu_{n_k}(A_k)| \geq |\nu_{n_k}(B_k)| - |\nu_{n_k}(B_k \cap C_k)| > \epsilon - \frac{\epsilon}{2} = \frac{\epsilon}{2} \ .$$

XVII.10.4. Exercises

XVII.10.4.1. Let (ν_n) be a sequence of complex measures on a measurable space $(X, \mathcal{A})$ which is a Cauchy sequence with respect to the total variation norm (). Give a direct proof (not using the Nikodým Convergence Theorem) that (ν_n) converges setwise to a complex measure.

XVII.10.4.2. (a) Prove the converse of XVII.10.2.8.. [If (B_n) is a decreasing sequence with $\cap_{n=1}^{\infty} B_n = \emptyset$ but $|\nu_n(B_n)| > \delta$ for all n, for some δ, choose n_1 with $\nu_1(B_{n_1}) < \delta/2$, and for each k choose n_{k+1} with $\nu_{n_k}(B_{n_{k+1}}) < \delta/2$. If $A_{n_k} = B_{n_k} \setminus B_{n_{k+1}}$, the A_{n_k} are pairwise disjoint and $|\nu_{n_k}(A_{n_k})| > \delta/2$ for all k.]
(b) Use (a) and () to give a direct proof of XVII.10.3.3. (cf. [Swa94, p. 68]).

XVII.10.4.3. [Doo94, III.10] Give a direct proof that if (μ_n) is a sequence of finite measures on a measurable space $(X, \mathcal{A})$, converging setwise to a function $\mu : \mathcal{A} \to [0, \infty)$, then μ is a measure (i.e. countably additive), as follows:
(a) Suppose (B_n) is a decreasing sequence in $\mathcal{A}$ with $\cap_{n=1}^{\infty} B_n = \emptyset$ but

$$\lim_{n \to \infty} \mu(B_n) = \epsilon > 0$$

(why does the limit exist?) Let $n_1 = m_1 = 1$ and inductively choose $n_{k+1} > n_k$ and $m_{k+1} > m_k$ with $\mu_{n_{k+1}}(B_{m_k}) > \frac{7\epsilon}{8}$ and $\mu_{n_{k+1}}(B_{m_{k+1}}) < \frac{\epsilon}{8}$.

(b) Let $A_k = B_{m_k} \setminus B_{m_{k+1}}$ for each k. Show that if $j > k$ is odd, then

$$\mu_{n_j}(\cup\{A_n : n \text{ even}, n \geq k\}) > \frac{3\epsilon}{4}$$

and if $j > k$ is even, then

$$\mu_{n_j}(\cup\{A_n : n \text{ odd}, n \geq k\}) > \frac{3\epsilon}{4} \ .$$

(c) Conclude that $\mu(B_{m_k}) \geq \frac{3\epsilon}{2}$ for all k, a contradiction.

Chapter XVIII

Modern Integration

There are four general approaches to integration: the Riemann integral and the "modern" approaches of Lebesgue, Daniell, and Denjoy-Perron-Henstock-Kurzweil. In this chapter, we discuss the last three; Riemann integration is treated in Chapter IX.

We begin with Lebesgue integration. The name "Lebesgue integral" has two standard meanings in mathematics: the Lebesgue integral on $\mathbb{R}$, or $\mathbb{R}^n$, with respect to Lebesgue measure, and the "abstract Lebesgue integral" on a general measure space.

Many general measure theory texts follow what I call the "reinventing the wheel" plan: first develop Lebesgue measure and integration, then redo everything in general, in many cases just referring back to the Lebesgue case for proofs of results. This approach is certainly defensible pedagogically, and is preferred by many people, but it is not to my personal taste; I much prefer to start out with general measure and integration theory, spending considerable time discussing and emphasizing the critical special case of Lebesgue measure and integration on $\mathbb{R}$ (and then $\mathbb{R}^n$) as I go, as well as discussing other special cases such as probability spaces.

XVIII.1. The Lebesgue Integral

This section treats the heart of modern integration theory, the general integral first defined by LEBESGUE and subsequently refined by other authors.

The term "Lebesgue integral" is commonly used to mean two different things:

(i) Lebesgue's generalization of the Riemann integral for functions from $\mathbb{R}$ to $\mathbb{R}$.

(ii) The general integral for real-valued functions on a measure space, often called the *abstract Lebesgue integral*.

As the integral is normally done today, the Lebesgue integral on $\mathbb{R}$ is just the special case of the general abstract Lebesgue integral for the measure space $(\mathbb{R}, \mathcal{M}, \lambda)$, and it is no easier and even no different to develop this special case than the general integral. Thus we will work generally and point out the few important special properties of the Lebesgue integral on $\mathbb{R}$ as we go. We will usually suppress the name "Lebesgue" from the general abstract integral, except when this integral must be distinguished from integrals defined in other ways, and mostly reserve it for the special case of Lebesgue measure on $\mathbb{R}$ (or $\mathbb{R}^n$).

If $(X, \mathcal{A}, \mu)$ is a measure space, we want to assign an extended real number to any extended real-valued measurable function f, and $E \in \mathcal{A}$, called the *integral of f over E* and denoted $\int_E f\, d\mu$, in such a way that the integral has standard nice properties we would like and expect. It turns out not to be possible to do this for every extended real-valued measurable function in general (because of the obstacle of defining $\infty - \infty$), but only for nonnegative functions and general functions whose positive and negative parts are not "too large" ("integrable" functions). We will build up the integral in three steps (the process is called *bootstrapping*):

(i) Simple functions.

(ii) Nonnegative extended real-valued measurable functions.

(iii) Integrable functions.

XVIII.1.1. Properties of the Integral

We can give a list of properties we want the integral to have. This list might be regarded as a "wish list" at the moment, but we will be able to get almost everything on the list.

XVIII.1.1.1. Let $(X, \mathcal{A}, \mu)$ be a measure space. We would like the assignment $(f, E) \mapsto \int_E f\, d\mu$ to have the following properties:

(i) [MONOTONICITY] If $f \le g$, then $\int_E f\, d\mu \le \int_E g\, d\mu$ for any E.

(ii) [LINEARITY] $\int_E (f+g)\, d\mu = \int_E f\, d\mu + \int_E g\, d\mu$ for any f, g, E.

(iii) [HOMOGENEITY] $\int_E \alpha f\, d\mu = \alpha \int_E f\, d\mu$ for any $f, E, \alpha \in \mathbb{R}$ (where we always interpret $0 \cdot \infty = 0$).

(iv) [ADDITIVITY] If (E_k) are pairwise disjoint in $\mathcal{A}$ and $E = \cup_k E_k$, then $\int_E f\, d\mu = \sum_{k=1}^{\infty} \int_{E_k} f\, d\mu$.

(v) If $f = g$ a.e. (μ-a.e.), then $\int_E f\, d\mu = \int_E g\, d\mu$ for any E.

(vi) If $\mu(E) = 0$, then $\int_E f\,d\mu = 0$ for any f.

(vii) [CONTINUITY] If $f_n \to f$ pointwise, then $\int_E f_n\,d\mu \to \int_E f\,d\mu$ for any E.

(viii) [NORMALIZATION] $\int_E 1\,d\mu = \mu(E)$ for any E.

XVIII.1.1.2. Actually, (ii) and (iii) together are usually called "linearity," and can be replaced by the single condition

(ii′) $\int_E (\alpha f + g)\,d\mu = \alpha \int_E f\,d\mu + \int_E g\,d\mu$ for any f, g, E, and $\alpha \in \mathbb{R}$.

We have used "linearity" for (ii) instead of "additivity" to distinguish it from (iii), although the way we will proceed it will turn out that (iii), at least for finitely many sets, is a consequence of (ii).

XVIII.1.1.3. We will be able to get everything on this list except Continuity, although in several others we will have to make modest restrictions to avoid the $\infty - \infty$ problem. Continuity in the general form of (vii) is simply not possible in general (XVIII.1.7.1.); however, the major convergence theorems of integration theory (MCT, DCT) will show that continuity holds under some reasonable additional assumptions.

XVIII.1.2. Integral of Simple Functions

Recall the definition of a simple function (). To avoid verbosity, we will restrict the definition to only include functions which are nonnegative and measurable:

XVIII.1.2.1. DEFINITION. Let $(X, \mathcal{A})$ be a measurable space. A *simple function* on $(X, \mathcal{A})$ is a nonnegative real-valued measurable function which takes only finitely many values.

If ϕ is a simple function on $(X, \mathcal{A})$ taking exactly the values $\alpha_1, \ldots, \alpha_n$, for each k set

$$A_k = \{x \in X : \phi(x) = \alpha_k\}\ .$$

Then $\{A_1, \ldots, A_n\}$ is a partition of X into nonempty measurable subsets (), and

$$\phi = \sum_{k=1}^{n} \alpha_k \chi_{A_k}$$

is the *canonical representation* of ϕ.

In some references, a term with $\alpha_k = 0$ is deleted from the canonical representation, but we prefer to keep such a term to force $\{A_1, \ldots, A_n\}$ to be a partition of X. This will have no practical effect.

XVIII.1.2.2. Any nonnegative (finite) linear combination of indicator functions of measurable sets is a simple function. A sum

$$\phi = \sum_{j=1}^{m} \beta_j \chi_{B_j}$$

may not be a canonical representation of ϕ for four reasons:

(1) The B_j may not be disjoint.

(2) The β_j may not all be distinct.

(3) We may not have $\cup_j B_j = X$.

(4) Some of the B_j may be empty.

(3) and (4) are easy to remedy: for (3), set $B_{m+1} = X \setminus \cup_{j=1}^m B_j$ and $\beta_{m+1} = 0$, and for (4), just delete any terms with $B_j = \emptyset$. The others can also be systematically fixed: for (1), let $A_1, \ldots, A_n$ consist of all nonempty finite intersections of the B_j and their complements (i.e. the nonempty sets in the partition of $\cup_{j=1}^m B_j$ generated by the B_j), and if $A_k = B_{j_1} \cap \cdots \cap B_{j_r} \cap B^c_{j_{r+1}} \cap \cdots B^c_{j_s}$, set $\alpha_k = \beta_{j_1} + \cdots + \beta_{j_r}$. Then for (2) just combine together terms with equal β_j, using that $\chi_{A \cup B} = \chi_A + \chi_B$ if A and B are disjoint. If these corrections are done in the order (1), (3), (4), (2), each only needs to be done once and the representation is converted into canonical form.

A representation in which all the B_j are disjoint, but (2), (3), (4) are allowed, is said to be in *semicanonical form*.

XVIII.1.2.3. Note that if ϕ is simple and $E \in \mathcal{A}$, then $\phi\chi_E$ is also simple: if $\phi = \sum_{j=1}^m \beta_j \chi_{B_j}$, then $\phi\chi_E = \sum_{j=1}^m \beta_j \chi_{B_j \cap E}$. If the representation of ϕ is in semicanonical form, so is this representation of $\phi\chi_E$; but the representation of $\phi\chi_E$ is not necessarily in canonical form even if the representation of ϕ is.

The Integral of a Simple Function

We can define the integral of a simple function in the only way possible if we hope to have linearity and normalization:

XVIII.1.2.4. Definition. Let $(X, \mathcal{A}, \mu)$ be a measure space, and ϕ a simple function on $(X, \mathcal{A})$. Write $\phi = \sum_{k=1}^n \alpha_k \chi_{A_k}$ in canonical form. Then

$$\int_X \phi \, d\mu = \sum_{k=1}^n \alpha_k \mu(A_k)$$

where $0 \cdot \infty$ is always interpreted to be 0, and $r \cdot \infty = \infty$ if $r > 0$. If $E \in \mathcal{A}$, set

$$\int_E \phi \, d\mu = \int_X \phi\chi_E \, d\mu \ .$$

A few simple properties are immediate from the definition:

XVIII.1.2.5. Proposition. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $E \in \mathcal{A}$.
(i) If ϕ is a simple function on $(X, \mathcal{A})$, and $r \geq 0$, then

$$\int_E r\phi \, d\mu = r \int_E \phi \, d\mu \ .$$

(ii) If ϕ and ψ are simple functions and $\phi = \psi$ a.e. on E (i.e. $\phi\chi_E = \psi\chi_E$ a.e.), then

$$\int_E \phi\, d\mu = \int_E \psi\, d\mu \ .$$

(iii) If $\mu(E) = 0$, then $\int_E \phi\, d\mu = 0$ for any simple function ϕ.

PROOF: (i): If $r > 0$ and $\phi\chi_E = \sum_{k=1}^n \alpha_k \chi_{A_k}$ is the canonical representation, then the canonical representation of $r\phi\chi_E$ is $\sum_{k=1}^n \alpha_k \chi_{A_k}$. And if $r = 0$, both sides are 0 (recall the convention that $0 \cdot \infty = 0$).
(ii): If $\phi\chi_E = \sum_{k=1}^n \alpha_k \chi_{A_k}$ and $\psi\chi_E = \sum_{j=1}^m \beta_j \chi_{B_j}$ are the canonical representations, then each α_k corresponds to a unique β_{j_k} unless $\mu(A_k) = 0$ in which case the term $\alpha_k \mu(A_k)$ can be deleted from the sum, and conversely; thus once zero terms are deleted the terms in the sums are in one-one correspondence. For each k the sets A_k and B_{j_k} differ by a null set, so $\mu(A_k) = \mu(B_{j_k})$ (). Thus the remaining terms are numerically identical.
(iii): If $\mu(E) = 0$, then in the canonical representation $\phi\chi_E = \sum_{k=1}^n \alpha_k \chi_{A_k}$, in any term with $\alpha_k > 0$ we have $A_k \subseteq E$, so $\mu(A_k) = 0$. Thus all the terms in $\sum_{k=1}^n \alpha_k \mu(A_k)$ are zero. 👍

The key technical fact giving reasonable properties of the integral defined this way is that the formula in the definition holds for any representation of ϕ, not just the canonical one:

XVIII.1.2.6. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and ϕ a simple function on $(X, \mathcal{A})$. If $\phi = \sum_{j=1}^m \beta_j \chi_{B_j}$ is any representation of ϕ, then

$$\int_X \phi\, d\mu = \sum_{j=1}^m \beta_j \mu(B_j) \ .$$

PROOF: We must observe that the sum does not change as the four corrections of XVIII.1.2.2. are made to convert the given representation of ϕ to the canonical one. Corrections (3) and (4) obviously do not affect the sum (using the convention $0 \cdot \infty = 0$ for (3)), and correction (2) is easily seen to also leave the sum unchanged if the B_j are disjoint (using finite additivity of μ).

Correction (1) requires a little more work. We disjointize B_1 and B_2 into $B_1 \cap B_2$, $B_1 \setminus B_2$, and $B_2 \setminus B_1$. Observe that

$$\beta_1\chi_{B_1} + \beta_2\chi_{B_2} = \beta_1\chi_{B_1\setminus B_2} + \beta_2\chi_{B_2\setminus B_1} + (\beta_1 + \beta_2)\chi_{B_1\cap B_2}$$

and that

$$\beta_1\mu(B_1 \setminus B_2) + \beta_2\mu(B_2 \setminus B_1) + (\beta_1 + \beta_2)\mu(B_1 \cap B_2)$$
$$= \beta_1[\mu(B_1 \setminus B_2) + \mu(B_1 \cap B_2)] + \beta_2[\mu(B_1 \setminus B_2) + \mu(B_1 \cap B_2)] = \beta_1\mu(B_1) + \beta_2\mu(B_2)$$

by finite additivity of μ; thus the sum for the beginning representation equals the sum obtained by disjointizing B_1 and B_2. We can then successively disjointize any two nondisjoint remaining sets in the new representation in the same way without affecting the sum or the previous disjointizations. After a finite number of steps the representation is converted to semicanonical form and the sum is unchanged. 👍

Most of the important properties of the integral for simple functions follow easily. First is a formula for the integral of a simple function over a subset:

XVIII.1.2.7. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $\phi = \sum_{k=1}^{n} \alpha_k \chi_{A_k}$ a simple function on $(X, \mathcal{A})$ (not necessarily in canonical form). If $E \in \mathcal{A}$, then

$$\int_E \phi \, d\mu = \int_X \phi\chi_E \, d\mu = \sum_{k=1}^{n} \alpha_k \mu(A_k \cap E) \ .$$

Linearity and (finite) additivity also follow easily:

XVIII.1.2.8. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, and ϕ and ψ simple functions on $(X, \mathcal{A})$. If $E \in \mathcal{A}$, then

$$\int_E (\phi + \psi) \, d\mu = \int_E \phi \, d\mu + \int_E \psi \, d\mu \ .$$

Proof: If $\phi\chi_E = \sum_{k=1}^{n} \alpha_k \chi_{A_k}$ and $\psi\chi_E = \sum_{j=1}^{m} \beta_j \chi_{B_j}$ are representations (not necessarily canonical), then

$$(\phi + \psi)\chi_E = \sum_{k=1}^{n} \alpha_k \chi_{A_k} + \sum_{j=1}^{m} \beta_j \chi_{B_j}$$

is a representation. 👍

Note that the representation of $(\phi + \psi)\chi_E$ in the proof is almost necessarily non-canonical, so the proposition is necessary to establish linearity of the integral for simple functions.

XVIII.1.2.9. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, and ϕ a simple function on $(X, \mathcal{A})$. If $D_1, \ldots, D_n \in \mathcal{A}$ are pairwise disjoint and $E = D_1 \cup \cdots \cup D_n$, then

$$\int_E \phi \, d\mu = \sum_{k=1}^{n} \left[\int_{D_k} \phi \, d\mu \right] \ .$$

Proof: We have $\phi\chi_E = \phi\chi_{D_1} + \cdots + \phi\chi_{D_n}$. 👍

Finite additivity can be extended to countable additivity (XVIII.1.2.12.).

We can also obtain monotonicity:

XVIII.1.2.10. COROLLARY. Let $(X, \mathcal{A}, \mu)$ be a measure space, and ϕ and ψ simple functions on $(X, \mathcal{A})$. If $E \in \mathcal{A}$ and $\phi \leq \psi$ a.e. on E, then

$$\int_E \phi \, d\mu \leq \int_E \psi \, d\mu \ .$$

PROOF: By modifying ϕ on a null set (cf. XVIII.1.2.5.(ii)), we may assume $\phi\chi_E \leq \psi\chi_E$ everywhere. Let $\phi\chi_E = \sum_{k=1}^n \alpha_k \chi_{A_k}$ and $\psi\chi_E = \sum_{j=1}^m \beta_j \chi_{B_j}$ be canonical representations. Then

$$\phi\chi_E = \sum_{j=1}^m \sum_{k=1}^n \alpha_k \chi_{A_k \cap B_j}$$

$$\psi\chi_E = \sum_{j=1}^m \sum_{k=1}^n \beta_j \chi_{A_k \cap B_j}$$

are semicanonical representations; and whenever $A_k \cap B_j \neq \emptyset$, we have $\alpha_k \leq \beta_j$ since $\phi\chi_E \leq \psi\chi_E$. Thus

$$\int_E \phi \, d\mu = \sum_{j=1}^m \sum_{k=1}^n \alpha_k \mu(A_k \cap B_j) \leq \sum_{j=1}^m \sum_{k=1}^n \beta_j \mu(A_k \cap B_j) = \int_E \psi \, d\mu \ .$$

We also have the following slight extension of the Baby Monotone Convergence Theorem (), which will be used to establish the full Monotone Convergence Theorem and other continuity properties of the integral:

XVIII.1.2.11. PROPOSITION. [JUNIOR MONOTONE CONVERGENCE THEOREM] Let $(X, \mathcal{A}, \mu)$ be a measure space, and ϕ a simple function on $(X, \mathcal{A})$. If $E_1, E_2, \ldots$ is an increasing sequence of sets in $\mathcal{A}$, and $E = \cup_{n=1}^\infty E_n$, then

$$\int_E \phi \, d\mu = \lim_{n\to\infty} \left[\int_{E_n} \phi \, d\mu \right] = \sup_n \left[\int_{E_n} \phi \, d\mu \right] \ .$$

PROOF: Let $\phi = \sum_{k=1}^m \alpha_k \chi(A_k)$ be a representation (not necessarily canonical). Fix k. Then we have $A_k \cap E_1 \subseteq A_k \cap E_2 \subseteq \cdots$ and $A_k \cap E = \cup_{n=1}^\infty [A_k \cap E_n]$, so by the Baby MCT we have

$$\alpha_k \mu(A_k \cap E) = \lim_{n\to\infty} \alpha_k \mu(A_k \cap E_n) = \sup_n \alpha_k \mu(A_k \cap E_n) \ .$$

This is true for all k, and since the sum is finite, we have

$$\sum_{k=1}^m \alpha_k \mu(A_k \cap E) = \lim_{n\to\infty} \left[\sum_{k=1}^m \alpha_k \mu(A_k \cap E_n) \right] = \sup_n \left[\sum_{k=1}^m \alpha_k \mu(A_k \cap E_n) \right] \ .$$

XVIII.1.2.12. COROLLARY. Let $(X, \mathcal{A}, \mu)$ be a measure space, and ϕ a simple function on $(X, \mathcal{A})$. If $D_1, \ldots, D_n, \ldots \in \mathcal{A}$ are pairwise disjoint and $E = \cup_{k=1}^{\infty} D_k$, then

$$\int_E \phi \, d\mu = \sum_{k=1}^{\infty} \left[\int_{D_k} \phi \, d\mu \right] .$$

PROOF: For each n set $E_n = D_1 \cup \cdots \cup D_n$. Then the E_n are increasing and $E = \cup_n E_n$, so by XVIII.1.2.11. and XVIII.1.2.9. we have

$$\int_E \phi \, d\mu = \lim_{n\to\infty} \left(\int_{E_n} \phi \, d\mu \right) = \lim_{n\to\infty} \left(\sum_{k=1}^{n} \left[\int_{D_k} \phi \, d\mu \right] \right) = \sum_{k=1}^{\infty} \left[\int_{D_k} \phi \, d\mu \right] .$$

XVIII.1.3. The Integral of a Nonnegative Measurable Function

We can now define the integral of a general nonnegative measurable function:

XVIII.1.3.1. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a nonnegative extended real-valued measurable function on $(X, \mathcal{A})$. Define

$$\int_X f \, d\mu = \sup \left\{ \int_X \phi \, d\mu : \phi \text{ simple}, \, \phi \le f \right\} .$$

If $E \in \mathcal{A}$, define

$$\int_E f \, d\mu = \int_X f \chi_E \, d\mu .$$

Note that if f itself is a simple function, then this definition of $\int_E f \, d\mu$ agrees with the previous definition (cf. XVIII.1.2.10.); thus the definitions are consistent and unambiguous.

XVIII.1.3.2. The following properties of the integral are immediate:

(i) $0 \le \int_E f \, d\mu \le \infty$ for any f and E.

(ii) If $f \le g$ on E, then $\int_E f \, d\mu \le \int_E g \, d\mu$.

(iii) If $\alpha \ge 0$, then $\int_E \alpha f \, d\mu = \alpha \int_E f \, d\mu$ (using $0 \cdot \infty = 0$ and $\alpha \cdot \infty = \infty$ if $\alpha > 0$). In particular, $\int_E 0 \, d\mu = 0$ for any E.

(iv) If $\mu(E) = 0$, then $\int_E f \, d\mu = 0$ for any f (cf. XVIII.1.2.5.).

XVIII.1.3.3. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f and g nonnegative extended real-valued measurable functions on $(X, \mathcal{A})$. If $f = g$ a.e. (μ-a.e.) on E, then

$$\int_E f \, d\mu = \int_E g \, d\mu \ .$$

PROOF: If $f\chi_E = g\chi_E$ on $X \setminus C$, where $C \in \mathcal{A}$ and $\mu(C) = 0$, and ϕ is a simple function with $\phi \leq f\chi_E$, then $\psi = \phi\chi_{X\setminus C}$ is a simple function with $\psi \leq g\chi_E$, and $\psi = \phi$ a.e., so $\int_X \psi \, d\mu = \int_X \phi \, d\mu$ by XVIII.1.2.5.. Thus $\int_E f \, d\mu \leq \int_E g \, d\mu$. Symmetrically, $\int_E g \, d\mu \leq \int_E f \, d\mu$. 👍

Combining this with XVIII.1.3.2.(ii), we obtain:

XVIII.1.3.4. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f and g nonnegative extended real-valued measurable functions on $(X, \mathcal{A})$. If $f \leq g$ a.e. (μ-a.e.) on E, then

$$\int_E f \, d\mu \leq \int_E g \, d\mu \ .$$

XVIII.1.3.5. We have thus established all the desired properties of the integral (for nonnegative functions) from XVIII.1.1.1. except for the crucial properties of linearity, additivity, and continuity. These are trickier to show; we will first prove one of the important continuity properties, the Monotone Convergence Theorem, and use it to obtain linearity and additivity (and much more).

Integrable Functions

The integral of a nonnegative extended real-valued measurable function can be ∞ (even the integral of a simple function can be infinite). But functions with finite integral are the most interesting ones:

XVIII.1.3.6. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a nonnegative extended real-valued measurable function on $(X, \mathcal{A})$. Then f is *μ-integrable* if

$$\int_X f \, d\mu < \infty \ .$$

If $E \in \mathcal{A}$, then f is μ-integrable on E if $\int_E f \, d\mu < \infty$.

XVIII.1.3.7. Note that a μ-integrable function is by definition measurable. We often write "integrable" in place of "μ-integrable" when the μ is understood. But note that, although measurability of a function f depends only on $\mathcal{A}$ and not on μ, integrability of f depends on μ.

When μ is Lebesgue measure λ on $\mathbb{R}$ (or a subset), we will say f is *Lebesgue integrable* if it is λ-integrable. We usually, but not always, write "Lebesgue integrable" in this context to distinguish the notion from Riemann integrability (or other types of integrability on $\mathbb{R}$ such as H-K integrability).

XVIII.1.3.8. A nonnegative measurable function dominated by an integrable function is integrable. A nonnegative measurable function equal almost everywhere to an integrable function is integrable (XVIII.1.3.3.).

If μ is finite, any bounded nonnegative measurable function on $(X, \mathcal{A})$ is integrable; but if μ is infinite, even a (nonzero) constant function is not integrable.

An integrable function can be unbounded. It can even take the value ∞ on a null set, e.g. $f = \infty \cdot \chi_A$, where $\mu(A) = 0$. But an integrable function must be finite a.e., hence equal a.e. to a real-valued measurable function:

XVIII.1.3.9. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a nonnegative extended real-valued measurable function on $(X, \mathcal{A})$. Set $A = \{x \in X : f(x) = \infty\}$. If f is integrable, then $\mu(A) = 0$.

PROOF: If $\phi_n = n\chi_A$, then ϕ_n is a simple function and $\phi_n \leq f$. Thus

$$n\mu(A) = \int_X \phi_n \, d\mu \leq \int_X f \, d\mu$$

for all n, which implies $\mu(A) = 0$. 👍

Similarly, if f is integrable, the support () of f has "almost finite measure" (it need not actually have finite measure; cf. ()):

XVIII.1.3.10. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a nonnegative extended real-valued measurable function on $(X, \mathcal{A})$. Fix $\epsilon > 0$, and set $A_\epsilon = \{x \in X : f(x) \geq \epsilon\}$. Then

$$\mu(A_\epsilon) \leq \frac{1}{\epsilon} \int_X f \, d\mu \ .$$

In particular, if f is integrable, then $\mu(A_\epsilon) < \infty$ for all $\epsilon > 0$.

PROOF: Set $\phi_\epsilon = \epsilon\chi_{A_\epsilon}$. Then ϕ_ϵ is a simple function and $\phi_\epsilon \leq f$. Thus

$$\epsilon\mu(A_\epsilon) = \int_X \phi_\epsilon \, d\mu \leq \int_X f \, d\mu \ .$$

👍

XVIII.1.3.11. COROLLARY. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a nonnegative extended real-valued measurable function on $(X, \mathcal{A})$. If $E \in \mathcal{A}$ and $\int_E f \, d\mu = 0$, then $f = 0$ a.e. on E.

PROOF: If $A = \{x \in E : f(x) > 0\}$, then $A = \cup_{n=1}^\infty A_n$, where $A_n = \left\{x \in E : f(x) \geq \frac{1}{n}\right\}$, and

$$\mu(A_n) \leq n \int_E f \, d\mu = 0 \ .$$

👍

XVIII.1.3.12. Proposition XVIII.1.3.10. is not only interesting for ϵ small; it is of interest for arbitrary positive ϵ. In fact, as $\epsilon \to \infty$ we obtain XVIII.1.3.9.. The proposition says that an integrable function is small except on a set of reasonable finite measure, and not too large except on a set of small measure.

XVIII.1.3.13. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a nonnegative integrable function on $(X, \mathcal{A})$. Then the support of f is a set of σ-finite measure.

Proof: If $E = \{x \in X : f(x) > 0\}$ is the support of f, then $E = \cup_{n=1}^{\infty} A_{1/n}$. 👍

XVIII.1.3.14. Thus, although integration is defined on arbitrary measure spaces, it is only a nontrivial theory if there are sufficiently many sets of finite measure (e.g. if the measure is semifinite). If there are no sets of nonzero finite measure, then the only nonnegative integrable functions are ones equal to 0 almost everywhere.

Integration for Counting Measure

By far the most important example of the integral we have constructed is the Lebesgue integral on $\mathbb{R}$, discussed in Section XVIII.1.6.. But another illuminating example is counting measure on $\mathbb{N}$.

XVIII.1.3.15. Consider the measure space $(\mathbb{N}, \mathcal{P}(\mathbb{N}), \mu)$, where μ is counting measure on $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$. A real-valued function on $\mathbb{N}$ is just a sequence, and every such function is measurable since the σ-algebra is $\mathcal{P}(\mathbb{N})$. An extended real-valued function is one where some terms of the sequence are allowed to be ∞. A simple function is a sequence of nonnegative real numbers where only finitely many distinct numbers occur; such a function is integrable if and only if only finitely many terms are nonzero, and the integral is just the sum of the terms.

Thus if $x = (x_1, x_2, \dots)$ is a nonnegative sequence, then $\int_{\mathbb{N}} x \, d\mu$ is just the unordered sum

$$\sum_{n \in \mathbb{N}} x_n$$

which converges if and only if all terms are finite and the infinite series

$$\sum_{n=1}^{\infty} x_n$$

converges ().

We will see () that a general function (sequence) (x_n) is integrable with respect to μ if and only if the infinite series

$$\sum_{n=1}^{\infty} x_n$$

converges absolutely. Thus the theory of absolutely convergent infinite series is the special case of the integral for counting measure. In fact, it is worthwhile to view integration in general as some sort of "continuous" version of absolute summation.

XVIII.1.4. The Monotone Convergence Theorem

The Monotone Convergence Theorem (MCT) is one of the three main convergence or continuity theorems of integration theory, the others being Fatou's Lemma and the Dominated Convergence Theorem.

XVIII.1.4.1. THEOREM. [MONOTONE CONVERGENCE THEOREM] Let $(X, \mathcal{A}, \mu)$ be a measure space, and (f_n) a nondecreasing sequence of nonnegative extended real-valued measurable functions converging pointwise a.e. to a (nonnegative) extended real-valued measurable function f. If $E \in \mathcal{A}$, then

$$\int_E f\,d\mu = \lim_{n\to\infty} \int_E f_n\,d\mu = \sup_n \int_E f_n\,d\mu\ .$$

Note that it is the *sequence* (f_n) which is nondecreasing, i.e. $f_1 \le f_2 \le \cdots$, not the individual functions which are nondecreasing. In fact, since the f_n are real-valued functions on a general set X, it does not even make sense to ask whether such a function is nondecreasing. Note also that the hypothesis that f is measurable is almost, but not quite, automatic (if the measure space is not complete, f might have to be modified on a subset of a null set to make it measurable).

PROOF: By modifying f on a null set, we may assume that $f_n \to f$ pointwise everywhere. Since $f_n \le f$ for all n, we have $\int_E f_n\,d\mu \le \int_E f\,d\mu$ for all n. Thus if

$$L := \lim_{n\to\infty} \int_E f_n\,d\mu = \sup_n \int_E f_n\,d\mu$$

(the limit exists since the sequence of integrals is nondecreasing), we have $L \le \int_E f\,d\mu$.

So we need to show $\int_E f\,d\mu \le L$. If $L = \infty$ there is nothing to show, so we may assume $L < \infty$.

Fix r, $0 < r < 1$. Let ϕ be a simple function with $\phi \le f\chi_E$, and set

$$E_n = \{x \in E : r\phi(x) \le f_n(x)\}\ .$$

Then E_n is measurable [$E_n = E \cap \{x \in X : f_n(x) - r\phi(x) \ge 0\}$ and $f_n - r\phi$ is a measurable function], and $E_n \subseteq E_{n+1}$ for all n since $f_n \le f_{n+1}$. If $x \in E$ and $f(x) > 0$, then $f_n(x) \to f(x) > r\phi(x)$, so there is an n such that $f_k(x) > r\phi(x)$ for all $k \ge n$; thus $x \in E_n$. And if $f(x) = 0$, then $\phi(x) = f_n(x) = 0$ for all n, so $x \in E_n$ for all n. Thus $\cup_n E_n = E$. And, for each n, $r\phi\chi_{E_n} \le f_n\chi_{E_n}$, so $\int_{E_n} r\phi\,d\mu \le \int_{E_n} f_n\,d\mu \le \int_E f_n\,d\mu \le L$ by monotonicity.

By the Junior Monotone Convergence Theorem (XVIII.1.2.11.),

$$\int_E r\phi\,d\mu = \sup_n \int_{E_n} r\phi\,d\mu \le \sup_n \int_{E_n} f_n\,d\mu \le L\ .$$

Thus

$$\int_E \phi\,d\mu \le \frac{1}{r} L\ .$$

This is true for all simple $\phi \le f\chi_E$, so we have

$$\int_E f\,d\mu = \sup_{\phi \le f\chi_E} \int_E \phi\,d\mu \le \frac{1}{r} L\ .$$

Since this is true for all $r < 1$, we conclude $\int_E f\,d\mu \le L$.

XVIII.1.4.2. In some references, the MCT or its series version XVIII.1.5.5. is called the *Beppo Levi Theorem*. While there is some historical justification for this, and we do like BEPPO'S name (perhaps the main reason mathematicians use this terminology?), we prefer the more descriptive MCT term.

XVIII.1.5. Consequences of the Monotone Convergence Theorem

The Monotone Convergence Theorem is the key to several more important properties of the integral.

Linearity

XVIII.1.5.1. THEOREM. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f and g nonnegative extended real-valued measurable functions functions on $(X, \mathcal{A})$. If $E \in \mathcal{A}$, then

$$\int_E (f+g)\,d\mu = \int_E f\,d\mu + \int_E g\,d\mu\ .$$

PROOF: Let (ϕ_n) and (ψ_n) be nondecreasing sequences of simple functions converging pointwise to $f\chi_E$ and $g\chi_E$ respectively (). Then $(\phi_n + \psi_n)$ is an increasing sequence of simple functions converging pointwise to $(f+g)\chi_E$, and by XVIII.1.2.8. we have

$$\int_E (\phi_n + \psi_n)\,d\mu = \int_E \phi_n\,d\mu + \int_E \psi_n\,d\mu$$

for all n. Thus by three applications of the MCT, along with (),

$$\begin{aligned}\int_E (f+g)\,d\mu &= \lim_{n\to\infty} \int_E (\phi_n + \psi_n)\,d\mu = \lim_{n\to\infty} \left[\int_E \phi_n\,d\mu + \int_E \psi_n\,d\mu\right] \\ &= \left[\lim_{n\to\infty} \int_E \phi_n\,d\mu\right] + \left[\lim_{n\to\infty} \int_E \psi_n\,d\mu\right] = \int_E f\,d\mu + \int_E g\,d\mu\ .\end{aligned}$$

Additivity

We next establish finite additivity:

XVIII.1.5.2. COROLLARY. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a nonnegative extended real-valued measurable function on $(X, \mathcal{A})$. If $D_1, \ldots, D_n \in \mathcal{A}$ are pairwise disjoint and $E = D_1 \cup \cdots \cup D_n$, then

$$\int_E f\,d\mu = \sum_{k=1}^{n} \left[\int_{D_k} f\,d\mu\right]\ .$$

PROOF: We have $f\chi_E = f\chi_{D_1} + \cdots + f\chi_{D_n}$.

Before extending to countable additivity, we note the following special case of the MCT which extends the Junior MCT:

XVIII.1.5.3. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a nonnegative extended real-valued measurable function on $(X, \mathcal{A})$. If $E_1, E_2, \ldots$ is an increasing sequence of sets in $\mathcal{A}$, and $E = \cup_{n=1}^{\infty} E_n$, then

$$\int_E f\, d\mu = \lim_{n\to\infty} \left[\int_{E_n} f\, d\mu\right] = \sup_n \left[\int_{E_n} f\, d\mu\right] .$$

Proof: The sequence $(f\chi_{E_n})$ is nondecreasing and converges pointwise to $f\chi_E$. 👍

We then obtain countable additivity:

XVIII.1.5.4. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a nonnegative extended real-valued measurable function on $(X, \mathcal{A})$. If $D_1, \ldots, D_n, \ldots \in \mathcal{A}$ are pairwise disjoint and $E = \cup_{k=1}^{\infty} D_k$, then

$$\int_E f\, d\mu = \sum_{k=1}^{\infty} \left[\int_{D_k} f\, d\mu\right] .$$

Proof: For each n set $E_n = D_1 \cup \cdots \cup D_n$. Then the E_n are increasing and $E = \cup_n E_n$, so by XVIII.1.5.3. and XVIII.1.5.2. we have

$$\int_E f\, d\mu = \lim_{n\to\infty} \left(\int_{E_n} f\, d\mu\right) = \lim_{n\to\infty} \left(\sum_{k=1}^{n} \left[\int_{D_k} f\, d\mu\right]\right) = \sum_{k=1}^{\infty} \left[\int_{D_k} f\, d\mu\right] .$$

👍

The Monotone Convergence Theorem for Series

More generally, we have the following series version of the MCT:

XVIII.1.5.5. Theorem. [Monotone Convergence Theorem for Series] Let $(X, \mathcal{A}, \mu)$ be a measure space, and (g_k) a sequence of nonnegative extended real-valued measurable functions on $(X, \mathcal{A})$. Set

$$f = \sum_{k=1}^{\infty} g_k$$

(the series converges pointwise to an extended real-valued function since the terms are nonnegative). If $E \in \mathcal{A}$, then

$$\int_E f\, d\mu = \sum_{k=1}^{\infty} \left[\int_E g_k\, d\mu\right] .$$

Proof: For each n set

$$f_n = \sum_{k=1}^{n} g_k .$$

Then (f_n) is a nondecreasing sequence of nonnegative extended real-valued measurable functions converging pointwise to f. By the MCT and XVIII.1.5.1.,

$$\int_E f\,d\mu = \lim_{n\to\infty}\int_E f_n\,d\mu = \lim_{n\to\infty}\left[\sum_{k=1}^{n}\int_E g_k\,d\mu\right] = \sum_{k=1}^{\infty}\left[\int_E g_k\,d\mu\right]\ .$$

The Downward MCT

If (f_n) is a nonincreasing sequence of nonnegative real-valued measurable functions on a measure space $(X,\mathcal{A},\mu)$, it is not necessarily true that $\int_X f_n\,d\mu \to \int_X f\,d\mu$, even if the f_n are indicator functions of measurable sets (XVIII.1.7.1.). However, if the f_n are integrable, downward continuity holds:

XVIII.1.5.6. Theorem. [Downward Monotone Convergence Theorem] Let $(X,\mathcal{A},\mu)$ be a measure space, and (f_n) a nonincreasing sequence of nonnegative extended real-valued measurable functions converging pointwise a.e. to a (nonnegative) extended real-valued measurable function f. If $E\in\mathcal{A}$, and $\int_E f_1\,d\mu < \infty$, then

$$\int_E f\,d\mu = \lim_{n\to\infty}\int_E f_n\,d\mu = \inf_n \int_E f_n\,d\mu\ .$$

Proof: If $A=\{x\in X : f_1(x)=\infty\}$, then $\mu(A\cap E)=0$ by XVIII.1.3.9.. Thus we may replace f_n by $f_n\chi_{A^c}$ for each n without affecting the integrals over E, i.e. we may assume the f_n are real-valued.

For each n, set $g_n = f_1 - f_n$ (this is well defined since the functions are real-valued). Then (g_n) is a nondecreasing sequence of nonnegative real-valued measurable functions converging pointwise a.e. to $f_1 - f$; thus by the MCT

$$\int_E (f_1 - f)\,d\mu = \lim_{n\to\infty}\int_E g_n\,d\mu = \lim_{n\to\infty}\int_E (f_1 - f_n)\,d\mu\ .$$

For each n we have

$$\int_E f_1\,d\mu = \int_E f_n\,d\mu + \int_E (f_1 - f_n)\,d\mu$$

and, since the integrals are finite,

$$\int_E (f_1 - f_n)\,d\mu = \int_E f_1\,d\mu - \int_E f_n\,d\mu\ .$$

Similarly,

$$\int_E (f_1 - f)\,d\mu = \int_E f_1\,d\mu - \int_E f\,d\mu\ .$$

Thus we have

$$\int_E f_1\,d\mu - \int_E f\,d\mu = \lim_{n\to\infty}\left[\int_E f_1\,d\mu - \int_E f_n\,d\mu\right] = \int_E f_1\,d\mu - \lim_{n\to\infty}\int_E f_n\,d\mu$$

and the result follows.

XVIII.1.5.7. The requirement that $\int_E f_1\,d\mu < \infty$ may be relaxed to $\int_E f_n\,d\mu < \infty$ for some n by passing to a subsequence. The Downward MCT is also an immediate corollary of the Dominated Convergence Theorem.

Approximation From Above

We now discuss when the integral of a nonnegative real-valued function can be approximated from above by integrals of simple functions. Fix a measure space $(X, \mathcal{A}, \mu)$.

XVIII.1.5.8. An unbounded nonnegative real-valued function cannot be dominated by a simple function, since simple functions are bounded. And if μ is infinite, an integrable f whose support has infinite measure cannot be dominated by an integrable simple function, since the support of an integrable simple function has finite measure. Thus the only functions for which there is a hope of approximating the integral from above by integrals of simple functions are bounded (nonnegative) functions whose support has finite measure.

XVIII.1.5.9. THEOREM. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a nonnegative extended real-valued measurable function on $(X, \mathcal{A})$. Let S be the support of f. If $E \in \mathcal{A}$ and $\mu(E \cap S) < \infty$, and f is bounded on E, then

$$\int_E f\,d\mu = \inf\left\{\int_E \psi\,d\mu : \psi \text{ simple, } f\chi_E \le \psi\right\}\ .$$

PROOF: Suppose $f \le M$ on E. Then $f\chi_E \le \theta := M\chi_{E\cap S}$, θ is a simple function, and $\int_E \theta\,d\mu < \infty$. We have

$$\int_E (\theta - f)\,d\mu = \sup\left\{\int_E \phi\,d\mu : \phi \text{ simple, } \phi \le \theta - f\chi_E\right\}\ .$$

If ϕ is a simple function with $\phi \le \theta - f\chi_E$, then $\psi = \theta - \phi$ is a simple function with $f\chi_E \le \psi \le \theta$, and conversely if $f\chi_E \le \psi \le \theta$; thus

$$\int_E (\theta - f)\,d\mu = \sup\left\{\int_E (\theta - \psi)\,d\mu : \phi \text{ simple, } f\chi_E \le \psi \le \theta\right\}\ .$$

If $\psi \le \theta$, we have

$$\int_E \theta\,d\mu = \int_E \psi\,d\mu + \int_E (\theta - \psi)\,d\mu$$

and, since the integrals are finite, we have

$$\int_E (\theta - \psi)\,d\mu = \int_E \theta\,d\mu - \int_E \psi\,d\mu\ .$$

Similarly, we have

$$\int_E f\,d\mu = \int_E \theta\,d\mu - \int_E (\theta - f)\,d\mu$$

$$= \int_E \theta\,d\mu - \sup\left\{\left[\int_E \theta\,d\mu - \int_E \psi\,d\mu\right] : \phi \text{ simple, } f\chi_E \le \psi \le \theta\right\}$$

$$= \int_E \theta \, d\mu - \left[\int_E \theta \, d\mu - \inf \left\{ \int_E \psi \, d\mu : \phi \text{ simple}, \, f\chi_E \leq \psi \leq \theta \right\} \right]$$
$$= \inf \left\{ \int_E \psi \, d\mu : \phi \text{ simple}, \, f\chi_E \leq \psi \leq \theta \right\} .$$

Here is a simpler version of XVIII.1.5.9. which captures its essence:

XVIII.1.5.10. COROLLARY. Let $(X, \mathcal{A}, \mu)$ be a finite measure space, and f a bounded nonnegative real-valued measurable function on $(X, \mathcal{A})$. Then

$$\int_X f \, d\mu = \inf \left\{ \int_X \psi \, d\mu : \psi \text{ simple}, \, f \leq \psi \right\} .$$

In particular,

$$\sup \left\{ \int_X \phi \, d\mu : \phi \text{ simple}, \, \phi \leq f \right\} = \inf \left\{ \int_X \psi \, d\mu : \psi \text{ simple}, \, f \leq \psi \right\} .$$

XVIII.1.5.11. With more work, this theorem can be proved directly without use of the MCT or linearity of the integral. It then easily implies linearity of the integral for bounded functions with finite support (). From this one can obtain general additivity with some additional work (). One can then readily deduce Fatou's Lemma (), and obtain the MCT as a corollary of Fatou's Lemma (). This is the approach taken in [Roy88], for example. The approach we have taken, which is used e.g. in [MW99], seems a little better pedagogically.

The Role of Measurability

One can only reasonably define the integral directly for an indicator function or simple function if it is measurable. But the definition

$$\int_X f \, d\mu = \sup \left\{ \int_X \phi \, d\mu : \phi \text{ simple}, \, \phi \leq f \right\}$$

makes sense for any nonnegative extended real-valued function, measurable or not. Why not integrate arbitrary nonnegative functions this way? Since measurability is used in the MCT, and hence for linearity, it might be suspected that something goes wrong; in fact, the following converse of XVIII.1.5.10. shows that additivity must fail if we do not restrict to "almost measurable" functions.

XVIII.1.5.12. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a finite measure space, and f a bounded nonnegative real-valued function on $(X, \mathcal{A})$. If

$$\sup\left\{\int_X \phi\, d\mu : \phi \text{ simple, } \phi \le f\right\} = \inf\left\{\int_X \psi\, d\mu : \psi \text{ simple, } f \le \psi\right\}$$

then f is equal a.e. to an $\mathcal{A}$-measurable function.

PROOF: The supremum/infimum I is finite. Choose a sequence (ϕ_n) of (measurable) simple functions with $\phi_n \le f$ for all n and $\int_X \phi_n\, d\mu \to I$. Replacing ϕ_n by $\max_{1\le k\le n} \phi_k$, we may assume (ϕ_n) is nondecreasing. Similarly, let (ψ_n) be a nonincreasing sequence of simple functions with $f \le \psi_n$ for all n and $\int_X \psi_n\, d\mu \to I$. Then (ϕ_n) and (ψ_n) converge pointwise to measurable functions g and h respectively, and $g \le f \le h$. By monotonicity,

$$\int_X g\, d\mu = \int_X h\, d\mu = I$$

so $\int_X (h-g)\, d\mu = 0$, and hence $h - g = 0$ a.e. (XVIII.1.3.11.). Thus $f = g$ a.e. 👍

XVIII.1.5.13. This result does not quite imply that f is measurable in general if the measure space is not complete (), only that f is equal a.e. to a measurable function. But if $(X, \mathcal{A}, \mu)$ is complete, e.g. if it is Lebesgue measure on $(X, \mathcal{L})$, then f must be measurable.

Restricting and Extending Measures

In this connection, we obtain a (hardly unexpected) relation between integrals with respect to restrictions of a measure, and in particular between a measure and its completion:

XVIII.1.5.14. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, $\mathcal{B}$ a sub-σ-algebra of $\mathcal{A}$, and $\nu = \mu|_{\mathcal{B}}$. If f is a nonnegative extended real-valued $\mathcal{B}$-measurable function, and $E \in \mathcal{B}$, then

$$\int_E f\, d\nu = \int_E f\, d\mu\ .$$

PROOF: This is a good example of bootstrapping. First suppose f is χ_B for some $B \in \mathcal{B}$. Then B and $B \cap E$ are in $\mathcal{A}$, so we have

$$\int_E \chi_B\, d\nu = \nu(B \cap E) = \mu(B \cap E) = \int_E \chi_B\, d\mu\ .$$

By linearity, if ϕ is a $\mathcal{B}$-measurable simple function, then $\int_E \phi\, d\nu = \int_E \phi\, d\mu$. Now, if f is a general nonnegative extended real-valued $\mathcal{B}$-measurable function, there is an increasing sequence (ϕ_n) of $\mathcal{B}$-measurable simple functions converging pointwise to f. Then by two applications of the MCT,

$$\int_E f\, d\nu = \sup_n \int_E \phi\, d\nu = \sup_n \int_E \phi\, d\mu = \int_E f\, d\mu\ .$$

👍

XVIII.1.5.15. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, with completion $(X, \bar{\mathcal{A}}, \bar{\mu})$. If f is a nonnegative extended real-valued $\mathcal{A}$-measurable function, and $E \in A$, then

$$\int_E f \, d\mu = \int_E f \, d\bar{\mu} \ .$$

XVIII.1.5.16. Thus when a measure is extended to a larger σ-algebra, more functions become measurable and hence potentially integrable, but the integrals of functions which were already measurable do not change.

XVIII.1.6. The Lebesgue Integral and Riemann Integral

We now examine the Lebesgue integral, which is by definition the integral on the measure space $(\mathbb{R}, \mathcal{L}, \lambda)$, and its relation with the Riemann integral. We only consider nonnegative functions for now; this is not a serious restriction for bounded functions on finite intervals since a constant function can be added to make them nonnegative. The Lebesgue integral for general functions is discussed in (). In this section, "measurable" will always mean "Lebesgue measurable."

XVIII.1.6.1. If E is a measurable subset of $\mathbb{R}$ and f a nonnegative extended real-valued measurable function on $\mathbb{R}$, the *Lebesgue integral* of f over E is

$$\int_E f\, d\lambda = \sup\left\{\int_E \phi\, d\lambda : \phi \text{ simple}, \phi \le f\right\}$$

where the integral of a simple function $\phi = \sum_{k=1}^n \alpha_k \chi_{A_k}$ is

$$\int_E \phi\, d\lambda = \sum_{k=1}^n \alpha_k \lambda(A_k \cap E)$$

as in XVIII.1.2.4.. If $E = [a, b]$ and f is Riemann-integrable on E, write the Riemann integral of f over E as

$$\int_a^b f(x)\, dx$$

to distinguish it notationally from the Lebesgue integral.

XVIII.1.6.2. If an extended real-valued measurable function is defined only on a measurable subset E of $\mathbb{R}$, we will always canonically extend it to a function on $\mathbb{R}$ by setting $f(x) = 0$ for $x \notin E$. The extended function is also measurable, and (if nonnegative) has the same integral over any (measurable) subset of E. Note the following fact which is used constantly:

XVIII.1.6.3. Proposition. Let I be an interval in $\mathbb{R}$, and f a nonnegative extended real-valued real-valued measurable function on $\mathbb{R}$ (or on a measurable subset of $\mathbb{R}$, extended canonically to $\mathbb{R}$). Then

$$\int_{\bar{I}} f\, d\lambda = \int_I f\, d\lambda\ .$$

Proof: We have $f\chi_{\bar{I}} = f\chi_I$ a.e. 👍

XVIII.1.6.4. More generally, if A and B are measurable subsets of $\mathbb{R}$ differing by a null set (i.e. $\lambda(A \triangle B) = 0$), then $f\chi_A = f\chi_B$ a.e., so $\int_A f\, d\lambda = \int_B f\, d\lambda$.

The following result shows that the Lebesgue integral agrees with the Riemann integral for Riemann-integrable functions, and thus the Lebesgue integral extends and generalizes the Riemann integral:

XVIII.1.6.5. THEOREM. Let $[a,b]$ be a closed bounded interval in $\mathbb{R}$, and $f : [a,b] \to \mathbb{R}$ a function. Extend f to $\mathbb{R}$ by setting $f(x) = 0$ for $x \notin [a,b]$. If f is Riemann-integrable on $[a,b]$, then f is Lebesgue-integrable on $\mathbb{R}$ and on $[a,b]$, and

$$\int_{\mathbb{R}} f\,d\lambda = \int_{[a,b]} f\,d\lambda = \int_a^b f(x)\,dx\ .$$

PROOF: It is almost transparent that the Riemann integral equals the Lebesgue integral for nonnegative step functions (cf. ()), which are nothing but piecewise-continuous simple functions. A general (necessarily bounded) nonnegative function f is Riemann integrable on $[a,b]$ if and only if there are an increasing sequence of (nonnegative) step functions (ϕ_n) (corresponding to lower Darboux sums) and a decreasing sequence of step functions (ψ_n) such that $\phi_n \le f \le \psi_n$ for all n and

$$\sup_n \left[\int_a^b \phi_n(x)\,dx\right] = \sup_n \left[\int_{[a,b]} \phi_n\,d\lambda\right] = \inf_n \left[\int_{[a,b]} \psi_n\,d\lambda\right] = \inf_n \left[\int_a^b \phi_n(x)\,dx\right]\ .$$

Thus by (), f is equal a.e. to a Lebesgue measurable function and, since Lebesgue measure is complete, f is Lebesgue measurable. By monotonicity, we have that

$$\int_{[a,b]} \phi_n\,d\lambda \le \int_{[a,b]} f\,d\lambda \le \int_{[a,b]} \psi_n\,d\lambda$$

$$\int_a^b \phi_n(x)\,dx \le \int_a^b f(x)\,dx \le \int_a^b \psi_n(x)\,dx$$

and since the suprema of the integrals on the left and the infima of the integrals on the right are all the same, it follows that

$$\int_{[a,b]} f\,d\lambda = \int_a^b f(x)\,dx\ .$$

XVIII.1.6.6. It follows easily from the Characterization Theorem () that a Riemann-integrable function is Lebesgue measurable. However, we did not need to use this theorem to obtain the result.

XVIII.1.6.7. **Notation.** If $a, b \in \mathbb{R}$, $a < b$, and f is a nonnegative Lebesgue measurable or a Lebesgue-integrable function on $[a,b]$, then

$$\int_{[a,b]} f\,d\lambda = \int_{(a,b)} f\,d\lambda = \int_{[a,b)} f\,d\lambda = \int_{(a,b]} f\,d\lambda\ .$$

we will write

$$\int_a^b f\,d\lambda$$

for the common value of these integrals. We can extend this notation by writing

$$\int_a^a f\,d\lambda = 0$$

for any a, and

$$\int_b^a f\,d\lambda = -\int_a^b f\,d\lambda\ .$$

With these notational conventions, if f is Lebesgue-integrable or nonnegative and Lebesgue measurable on an interval containing a, b, c, in any order and not necessarily distinct, then

$$\int_a^c f\,d\lambda = \int_a^b f\,d\lambda + \int_b^c f\,d\lambda\ .$$

If f is Riemann-integrable on $[a, b]$, then

$$\int_a^b f\,d\lambda = \int_a^b f(x)\,dx\ .$$

Note the distinction, however: the first expression denotes the Lebesgue integral and the second expression the Riemann integral.

Lebesgue Integrable Functions Which Are Not Riemann Integrable

There are many additional functions on $\mathbb{R}$ which are Lebesgue-integrable, as the following examples show.

XVIII.1.6.8. Examples. (i) The indicator function $\chi_{\mathbb{Q}}$ is not Riemann Integrable over any interval () because it is "too discontinuous." But it is Lebesgue integrable over $\mathbb{R}$, or any measurable subset E of $\mathbb{R}$ (in particular, over any interval), and

$$\int_E \chi_{\mathbb{Q}}\,d\lambda = 0$$

for any $E \in \mathcal{L}$.

(ii) Set

$$f(x) = \begin{cases} \frac{1}{\sqrt{x}} & \text{if} \quad x > 0 \\ 0 & \text{if} \quad x \le 0 \end{cases}\ .$$

Then f is not Riemann integrable on $[0, 1]$ even though it is piecewise-continuous, since it is unbounded. But f is measurable, and Riemann integrable on $\left[\frac{1}{n}, 1\right]$ for any n, so

$$\int_{[0,1]} f\,d\lambda = \int_{(0,1]} f\,d\lambda = \sup_n \left[\int_{\left[\frac{1}{n},1\right]} f\,d\lambda\right]$$

$$= \sup_n \left[\int_{\frac{1}{n}}^1 \frac{1}{\sqrt{x}}\,dx\right] = \sup_n \left[2\sqrt{x}\Big|_{\frac{1}{n}}^1\right] = \sup_n \left[2 - \frac{2}{\sqrt{n}}\right] = 2$$

by XVIII.1.5.3., so f is Lebesgue integrable on $[0,1]$. In fact, f is Lebesgue integrable on any bounded interval (more generally, on any bounded measurable set) by a similar argument. Note that f is improperly Riemann integrable on $[0,1]$ (XVIII.1.6.9.).

(iii) Set

$$f(x) = \begin{cases} \frac{1}{x} & \text{if} \quad x > 0 \\ 0 & \text{if} \quad x \leq 0 \end{cases} .$$

Then f is measurable, and Riemann integrable on $\left[\frac{1}{n}, 1\right]$ for any n, so

$$\int_{[0,1]} f \, d\lambda = \int_{(0,1]} f \, d\lambda = \sup_n \left[\int_{\left[\frac{1}{n},1\right]} f \, d\lambda \right]$$

$$= \sup_n \left[\int_{\frac{1}{n}}^1 \frac{1}{x} \, dx \right] = \sup_n \left[\log x \Big|_{\frac{1}{n}}^1 \right] = \sup_n \left[-\log \frac{1}{n} \right] = \infty$$

so f is not Lebesgue integrable over $[0,1]$. In fact, if

$$f(x) = \begin{cases} x^{-r} & \text{if} \quad x > 0 \\ 0 & \text{if} \quad x \leq 0 \end{cases}$$

then f is Lebesgue integrable on $[0,1]$ if and only if $r < 1$. Note that these are exactly the power functions which are improperly Riemann integrable on $[0,1]$.

(iii) Set

$$f(x) = \begin{cases} \frac{1}{x^2} & \text{if} \quad x > 0 \\ 0 & \text{if} \quad x \leq 0 \end{cases} .$$

Then f is measurable, but not Lebesgue integrable on $[0,1]$. It is Riemann integrable on $[1,b]$ for any $b > 1$, so

$$\int_{[1,\infty)} f \, d\lambda = \sup_n \left[\int_{[1,n]} f \, d\lambda \right]$$

$$= \sup_n \left[\int_1^n \frac{1}{x^2} \, dx \right] = \sup_n \left[-\frac{1}{x} \Big|_1^n \right] = \sup_n \left[1 - \frac{1}{n} \right] = 1$$

so f is Lebesgue integrable over $[1,\infty)$. In fact, if

$$f(x) = \begin{cases} x^{-r} & \text{if} \quad x > 0 \\ 0 & \text{if} \quad x \leq 0 \end{cases}$$

then f is Lebesgue integrable on $[1,\infty)$ if and only if $r > 1$. Note that these are exactly the power functions which are improperly Riemann integrable on $[1,\infty)$.

The Lebesgue Integral and the Improper Riemann Integral

The fact that unbounded functions cannot be Riemann integrable is partially compensated by the various forms of improper Riemann integration.

XVIII.1.6.9. If f is a nonnegative function defined on $(a,b]$, and Riemann integrable on $[a+\epsilon,b]$ for every $\epsilon>0$, recall (IX.2.11.1.) that f is *improperly Riemann integrable* from a to b if

$$\lim_{\epsilon\to 0+}\left[\int_{a+\epsilon}^{b} f(x)\,dx\right]=\sup_{\epsilon>0}\left[\int_{a+\epsilon}^{b} f(x)\,dx\right]<\infty$$

and in this case, we define

$$\int_a^b f(x)\,dx=\lim_{\epsilon\to 0+}\left[\int_{a+\epsilon}^{b} f(x)\,dx\right]\ .$$

XVIII.1.6.10. Proposition. If f is a nonnegative function defined on $(a,b]$, and Riemann integrable on $[a+\epsilon,b]$ for every $\epsilon>0$, then f is improperly Riemann integrable from a to b if and only if f is Lebesgue integrable on $[a,b]$, and

$$\int_a^b f(x)\,dx=\int_{[a,b]} f\,d\lambda\ .$$

Proof: We have that $f\chi_{\left[a+\frac{1}{n},b\right]}$ is measurable for all n and $f\chi_{\left[a+\frac{1}{n},b\right]}\to f\chi_{(a,b]}$, so $f\chi_{(a,b]}$ is measurable. Thus

$$\int_{[a,b]} f\,d\lambda=\int_{(a,b]} f\,d\lambda=\sup_n\left[\int_{\left[a+\frac{1}{n},b\right]} f\,d\lambda\right]=\sup_n\left[\int_{a+\frac{1}{n}}^{b} f(x)\,dx\right]=\int_a^b f(x)\,dx$$

by XVIII.1.5.3., and in particular the suprema are either both finite or both infinite. 👍

XVIII.1.6.11. There are unbounded nonnegative functions which are continuous a.e. and Lebesgue integrable, but not improperly Riemann integrable in any reasonable sense. Let (r_k) be an enumeration of the left endpoints of the intervals removed in the construction of the Cantor set (), and

$$g(x)=\sum_{k=1}^{\infty}2^{-k}f(x-r_k)$$

where f is the function in XVIII.1.6.8.(ii). Then g is Lebesgue integrable on $[0,1]$ by XVIII.1.5.5., and continuous at all points not in the Cantor set, but not improperly Riemann integrable on $[0,1]$ in any of the usual senses.

XVIII.1.7. Continuity and Fatou's Lemma

To put the Monotone Convergence Theorem in perspective, we now note in more detail the failure of Continuity for integration (XVIII.1.1.1.) in general.

XVIII.1.7.1. EXAMPLES. (i) Let μ be counting measure on $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$. Let $E_n = \{k : k \geq n\}$. Then $\cap_n E_n = \emptyset$, so $\chi_{E_n} \to 0$ pointwise. But

$$\infty = \int_{\mathbb{N}} \chi_{E_n} \, d\mu \not\to \int_{\mathbb{N}} 0 \, d\mu = 0 \ .$$

Maybe the problem is just that the χ_{E_n} are not integrable. But:
(ii) Consider $(\mathbb{N}, \mathcal{P}(\mathbb{N}), \mu)$ again. Let $f_n = \frac{1}{n}\chi_{\{1,\ldots,n\}}$. Then $f_n \to 0$, even uniformly; however,

$$1 = \int_{\mathbb{N}} f_n \, d\mu \not\to \int_{\mathbb{N}} 0 \, d\mu = 0 \ .$$

(iii) Consider Lebesgue measure on $[0, 1]$. Let f_n be the continuous function with the following graph:

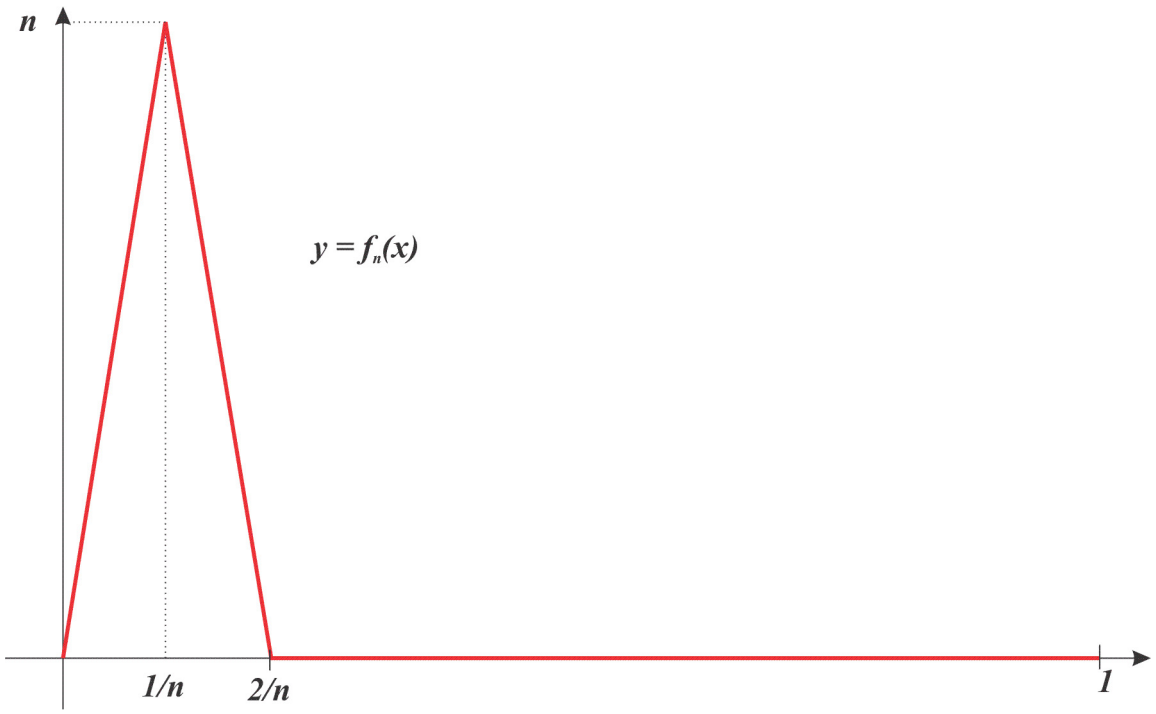

Figure XVIII.1: A continuous function

If $x \in (0,1]$, then for sufficiently large N we have $\frac{2}{N} \leq x$, so $f_n(x) = 0$ for all $n \geq N$. And $f_n(0) = 0$ for all n. So $f_n \to 0$ pointwise. However,

$$1 = \int_{[0,1]} f_n \, d\lambda \not\to \int_{[0,1]} 0 \, d\lambda = 0 \ .$$

Maybe the problem is that the functions are not uniformly bounded. But it is not quite so simple (cf. also (ii)):

(iv) Suppose we take f_n as in (iii), but the height of the triangle is n^r for fixed r. Then $f_n \to 0$ pointwise as before. If $r > 0$, the f_n are not uniformly bounded. But

$$\int_{[0,1]} f_n \, d\lambda = n^{r-1}$$

so $\int_{[0,1]} f_n \, d\lambda \to \int_{[0,1]} 0 \, d\lambda$ if and only if $r < 1$.

XVIII.1.7.2. One might note that in (iv), the difference between the case $r < 1$ and the case $r \geq 1$ is that in the case $r < 1$, there is an integrable function g such that $f_n \leq g$ for all n, namely $g(x) = x^{-r}$ (with $g(0) = 0$). (It may not be obvious that there is no such g if $r \geq 1$.) This is also the root of the difficulty in (ii). In fact, the Dominated Convergence Theorem (cf. XVIII.1.7.10.) states that existence of such a g is sufficient for convergence of the integrals.

Fatou's Lemma

XVIII.1.7.3. Another observation which might be made in these examples is that the integral of the limit is always less than or equal to the limit of the integrals. Actually this is a no-brainer in these examples since the functions are nonnegative and the integral of the limit function is zero; but experiments with less trivial similar examples suggest this is a general principle.

XVIII.1.7.4. Another motivation for why this should be so is that if (a_n) and (b_n) are (nonnegative) sequences of real numbers, then

$$\liminf_{n\to\infty} a_n + \liminf_{n\to\infty} b_n \leq \liminf_{n\to\infty} (a_n + b_n)$$

(), and equality does not hold in general, i.e. "the lim inf of a sum is greater than or equal to the sum of the lim inf's." Since integration is a continuous version of summation, we should have that "the integral of a lim inf is less than or equal to the lim inf of the integrals."

The second of the three main convergence theorems of measure theory asserts this:

XVIII.1.7.5. THEOREM. [FATOU'S LEMMA] Let $(X, \mathcal{A}, \mu)$ be a measure space, and (f_n) a sequence of nonnegative extended real-valued measurable functions on $(X, \mathcal{A})$. Set

$$f(x) = \liminf_{n\to\infty} f_n(x) = \lim_{n\to\infty} \left[\inf_{k\geq n} f_k(x) \right] = \sup_n \left[\inf_{k\geq n} f_k(x) \right]$$

(note that f is a well defined nonnegative extended real-valued measurable function). If $E \in \mathcal{A}$, then

$$\int_E f\,d\mu \leq \liminf_{n\to\infty} \int_E f_n\,d\mu\ .$$

The following special case is the one most commonly used:

XVIII.1.7.6. Corollary. Let $(X, \mathcal{A}, \mu)$ be a measure space, and (f_n) a sequence of nonnegative extended real-valued measurable functions on $(X, \mathcal{A})$, converging pointwise a.e. to a measurable function f. If $E \in \mathcal{A}$, then

$$\int_E f\,d\mu \leq \liminf_{n\to\infty} \int_E f_n\,d\mu\ .$$

XVIII.1.7.7. Fatou's Lemma has the most general hypotheses of the three major convergence theorems, but also not surprisingly the weakest conclusion.

The proof of Fatou's Lemma is easy given the Monotone Convergence Theorem:

Proof: For each n set

$$g_n = \inf_{k\geq n} f_k\ .$$

Then (g_n) is a nondecreasing sequence of nonnegative extended real-valued measurable functions, and $g_n \to f$ pointwise. We also have $g_n \leq f_k$ for all $k \geq n$, and thus

$$\int_E g_n\,d\mu \leq \int_E f_k\,d\mu$$

for $k \geq n$ by monotonicity. Thus by the MCT we have

$$\int_E f\,d\mu = \sup_n \left[\int_E g_n\,d\mu\right] \leq \sup_n \left[\inf_{k\geq n} \int_E f_k\,d\mu\right] = \liminf_{n\to\infty} \int_E f_n\,d\mu\ .$$

XVIII.1.7.8. Note that the MCT also follows almost immediately from Fatou's Lemma: if the sequence (f_n) is nondecreasing, we get $\int_E f\,d\mu \geq \sup_n \int_E f_n\,d\mu$ by monotonicity and $\int_E f\,d\mu \leq \liminf_n \int_E f_n\,d\mu$ by Fatou, so $\int_E f\,d\mu = \lim_n \int_E f_n\,d\mu$.

Of course, we used the MCT to prove Fatou's Lemma; but there are approaches where Fatou's Lemma is proved first and the MCT obtained as a consequence (cf. ()).

XVIII.1.7.9. The examples of XVIII.1.7.1. show that the inequality in Fatou's Lemma cannot be replaced by an equality in general.

The Dominated Convergence Theorem for Nonnegative Functions

We can then obtain almost immediately the nonnegative version of the Dominated Convergence Theorem:

XVIII.1.7.10. THEOREM. [DOMINATED CONVERGENCE THEOREM, NONNEGATIVE VERSION] Let $(X, \mathcal{A}, \mu)$ be a measure space, and (f_n) a sequence of nonnegative extended real-valued measurable functions on $(X, \mathcal{A})$, converging pointwise a.e. to a measurable function f. Suppose there is a nonnegative integrable function g with $f_n \leq g$ a.e. for all n. If $E \in \mathcal{A}$, then f is integrable on E and

$$\int_E f\, d\mu = \lim_{n\to\infty} \int_E f_n\, d\mu$$

(in particular, the limit exists).

PROOF: Note that f is automatically integrable since $f \leq g$ a.e. We have that $g - f_n$ is nonnegative a.e. for all n and $g - f_n \to g - f$ a.e. By two applications of Fatou's Lemma, we have

$$\int_E f\, d\mu \leq \liminf_{n\to\infty} \int_E f_n\, d\mu$$

$$\int_E g\, d\mu - \int_E f\, d\mu = \int_E (g - f)\, d\mu \leq \liminf_{n\to\infty} \int_E (g - f_n)\, d\mu$$

$$= \liminf_{n\to\infty} \left[\int_E g\, d\mu - \int_E f_n\, d\mu \right] = \int_E g\, d\mu - \limsup_{n\to\infty} \int_E f_n\, d\mu$$

(the integrals are finite so subtraction is valid). Rearranging the last inequality, we obtain

$$\int_E f\, d\mu \geq \limsup_{n\to\infty} \int_E f_n\, d\mu\ .$$

XVIII.1.7.11. The general DCT is essentially the same but applies to integrable functions which are not necessarily nonnegative. The g is called a *dominating function* for the sequence (f_n), and the reason for the name of the theorem is obvious.

XVIII.1.7.12. COROLLARY. [BOUNDED CONVERGENCE THEOREM, NONNEGATIVE VERSION] Let $(X, \mathcal{A}, \mu)$ be a measure space, and (f_n) a uniformly bounded sequence of nonnegative real-valued measurable functions on $(X, \mathcal{A})$, converging pointwise a.e. to a measurable function f. If $E \in \mathcal{A}$ with $\mu(E) < \infty$, then f is integrable on E and

$$\int_E f\, d\mu = \lim_{n\to\infty} \int_E f_n\, d\mu$$

(in particular, the limit exists).

PROOF: If $f_n(x) \leq M$ for all n and all $x \in E$, then $M\chi_E$ is a dominating function for $(f_n\chi_E)$. 

XVIII.1.7.13. The restriction that $\mu(E) < \infty$ is necessary in general, even if the f_n and f are assumed to be integrable on E and the convergence is uniform (XVIII.1.7.1.(ii)).

XVIII.1.8. The Integral For General Functions

We can extend the integral to many measurable functions which take both positive and negative values, as long as we carefully avoid the $\infty - \infty$ problem. The simplest and most satisfactory way to proceed is:

XVIII.1.8.1. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a real-valued function on X. Then f is *μ-integrable* if $f = g - h$ for nonnegative real-valued integrable functions g and h. Define the *integral* of f to be

$$\int_X f\,d\mu = \int_X g\,d\mu - \int_X h\,d\mu\ .$$

If $E \in \mathcal{A}$, then $f\chi_E = g\chi_E - h\chi_E$ is also μ-integrable; define

$$\int_E f\,d\mu = \int_X f\chi_E\,d\mu = \int_E g\,d\mu - \int_E h\,d\mu\ .$$

XVIII.1.8.2. Note that we are here only considering real-valued functions, since if g and h are nonnegative extended real-valued functions, $g - h$ might not be well defined. We consider extended real-valued functions in ().

A μ-integrable function is a difference of two measurable functions, hence automatically measurable. We often write "integrable" for "μ-integrable" if the μ is understood.

We have defined the integral of an integrable function in the only possible way to obtain a linear integral; however, it is not entirely obvious that the integral is independent of the choice of g and h. But it is:

XVIII.1.8.3. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a real-valued integrable function on X. Then the integral of f is well defined.

PROOF: Suppose $f = g_1 - h_1 = g_2 - h_2$ with g_i, h_i nonnegative real-valued integrable functions. Then $g_1 + h_2 = g_2 + h_1$, so, for any $E \in \mathcal{A}$,

$$\int_E g_1\,d\mu + \int_E h_2\,d\mu = \int_E (g_1 + h_2)\,d\mu = \int_E (g_2 + h_1)\,d\mu = \int_E g_2\,d\mu + \int_E h_1\,d\mu$$

and since the integrals are finite we may rearrange the equation by subtraction to obtain

$$\int_E g_1\,d\mu - \int_E h_1\,d\mu = \int_E g_2\,d\mu - \int_E h_2\,d\mu\ .$$

XVIII.1.8.4. Although the definition in XVIII.1.8.1. is logically satisfactory in light of XVIII.1.8.3., it is perhaps uncomfortably indefinite because the g and h are (usually) not unique. It is more satisfying to have a canonical way to write a general integrable function as a difference of two nonnegative integrable functions. This is possible:

XVIII.1.8.5. DEFINITION. Let X be a set, and $f : X \to \mathbb{R}$ a function. The *positive part* of f is $f_+ = \max(f, 0)$ and the *negative part* of f is $f_- = -\min(f, 0) = |\min(f, 0)|$.

We have

$$f_+(x) = \begin{cases} f(x) & \text{if} \quad f(x) \geq 0 \\ 0 & \text{if} \quad f(x) < 0 \end{cases}$$

$$f_-(x) = \begin{cases} |f(x)| & \text{if} \quad f(x) \leq 0 \\ 0 & \text{if} \quad f(x) > 0 \end{cases}$$

so f_+ and f_- are nonnegative functions with the properties $f_+ - f_- = f$, $f_+ + f_- = |f|$, $f_+ f_- = 0$. Conversely, if g and h are nonnegative functions with $f = g - h$ and $gh = 0$, then necessarily $g = f_+$ and $h = f_-$.

If $(X, \mathcal{A})$ is a measurable space and f is measurable, then f_+ and f_- are also measurable. (And if $(X, \mathcal{T})$ is a topological space and f is continuous, then f_+ and f_- are also continuous.)

XVIII.1.8.6. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a real-valued measurable function on X. Then f is integrable if and only if f_+ and f_- are integrable. If f is integrable, then

$$\int_E f \, d\mu = \int_E f_+ \, d\mu - \int_E f_- \, d\mu$$

for any $E \in \mathcal{A}$.

PROOF: If f_+ and f_- are integrable, then f is integrable and by definition

$$\int_E f \, d\mu = \int_E f_+ \, d\mu - \int_E f_- \, d\mu$$

for any $E \in \mathcal{A}$. Conversely, if f is integrable, write $f = g - h$ for nonnegative integrable functions g and h. If $x \in X$ and $f(x) \geq 0$, then $f_+(x) = f(x) = g(x) - h(x) \leq g(x)$; if $f(x) < 0$, then $0 = f_+(x) \leq g(x)$. Thus $f_+ \leq g$. Similarly, $f_- \leq h$. Thus f_+ and f_- are integrable. 👍

XVIII.1.8.7. COROLLARY. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a real-valued function on X. If f is integrable, then $|f|$ is integrable. If f is measurable and $|f|$ is integrable, then f is integrable.

PROOF: If f is integrable, then f_+ and f_- are integrable, so $|f| = f_+ + f_-$ is integrable. Conversely, if f is measurable and $|f|$ is integrable, then $f_+, f_- \leq |f|$ so f_+ and f_- are integrable. 👍

XVIII.1.8.8. Note that it is not quite correct to say that f is integrable if and only if $|f|$ is integrable: if $|f|$ is integrable, f might not be measurable. For example, if A is a subset of $[0, 1]$ which is not Lebesgue measurable, set ✋

$$f(x) = \begin{cases} 1 & \text{if} \quad x \in A \\ -1 & \text{if} \quad x \in [0,1] \setminus A \\ 0 & \text{if} \quad x \notin [0,1] \end{cases} .$$

Then $|f| = \chi_{[0,1]}$ is Lebesgue integrable, but f is not Lebesgue measurable.

It is correct to say that *if* f is measurable, then f is integrable if and only if $|f|$ is integrable. (Note that if f is measurable, then $|f|$ is also measurable.)

XVIII.1.8.9. Thus, except for the measurability problem, a function is integrable if and only if its absolute value is integrable. So the theory of abstract Lebesgue integration is an "absolute" integration theory, analogous to the theory of absolutely convergent infinite series. In fact:

XVIII.1.8.10. COROLLARY. Let μ be counting measure on $(\mathbb{N}, \mathcal{P}(\mathbb{N}))$. If $x = (x_1, x_2, \dots)$ is a sequence in $\mathbb{R}$ (a real-valued function on $\mathbb{N}$), then x is μ-integrable if and only if the infinite series

$$\sum_{k=1}^{\infty} x_k$$

converges absolutely. We then have

$$\int_{\mathbb{N}} x \, d\mu = \sum_{k=1}^{\infty} x_k \ .$$

Integration of Complex Functions

XVIII.1.8.11. If $(X, \mathcal{A}, \mu)$ is a measure space and f is a complex-valued $\mathcal{A}$-measurable function, we say that f is μ-integrable if and only if both $Re(f)$ and $Im(f)$ are μ-integrable, and set

$$\int_A f \, d\mu = \int_A Re(f) \, d\mu + i \int_A Im(f) \, d\mu$$

for $A \in \mathcal{A}$. We then again have that if f is measurable, then f is μ-integrable if and only if $|f|$ is μ-integrable, because of the inequalities

$$|Re(f)|, |Im(f)| \leq |f| \leq (|Re(f)| + |Im(f)| \ .$$

Properties of the Integral

XVIII.1.8.12. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space.

(i) If f and g are μ-integrable, then $f + g$ is μ-integrable and

$$\int_A (f + g) \, d\mu = \int_A f \, d\mu + \int_A g \, d\mu$$

for all $A \in A$.

(ii) If f is μ-integrable and $\alpha \in \mathbb{C}$, then αf is μ-integrable and

$$\int_A \alpha f \, d\mu = \alpha \int_A f \, d\mu$$

for all $A \in A$.

(iii) If f and g are μ-integrable and real-valued, and $f \leq g$ a.e., then

$$\int_A f \, d\mu \leq \int_A g \, d\mu$$

for all $A \in \mathcal{A}$.

(iv) If f is μ-integrable, then

$$\left| \int_A f \, d\mu \right| \leq \int_A |f| \, d\mu$$

for all $A \in \mathcal{A}$.

PROOF: (i)–(iii) are straightforward and left to the reader (for (iii), consider $g - f$). For (iv), approximate f by simple functions and use the triangle inequality in $\mathbb{C}$. 👍

A Vanishing Criterion

There is a convenient and useful criterion for an integrable function to vanish almost everywhere:

XVIII.1.8.13. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f an integrable extended real-valued function on X. If $\int_A f \, d\mu = 0$ for all $A \in \mathcal{A}$, then $f = 0$ a.e.

PROOF: Let $A = \{x \in X : f(x) \geq 0\}$ and $B = \{x \in X : f(x) \leq 0\}$. Since $\int_A f \, d\mu = \int_B f \, d\mu = 0$, we have that $f|_A$ and $f|_B$ are zero a.e. by XVIII.1.3.11.. 👍

Actually we only need to assume that $\int_A f \, d\mu$ for a set of A's which generate $\mathcal{A}$ as a σ-algebra, since it then follows that $\int_X f \, d\mu = 0$, and under this assumption it is easily checked that $\{B \in \mathcal{A} : \int_B f \, d\mu = 0\}$ is a σ-algebra. The set of such A even only needs to generate $\mathcal{A}$ up to null sets. The following special case is especially useful:

XVIII.1.8.14. COROLLARY. Let $[a, b]$ be an interval in $\mathbb{R}$, and f a Lebesgue integrable function on $[a, b]$. If

$$\int_a^x f \, d\lambda = 0$$

for all $x \in [a, b]$, then $f = 0$ a.e. on $[a, b]$.

XVIII.1.9. Exercises

XVIII.1.9.1. Prove the following converse to XVIII.1.8.12.(iv). Let $(X, \mathcal{A}, \mu)$ be a measure space, f a complex-valued μ-integrable function, and g a nonnegative $\mathcal{A}$-measurable function. If

$$\left| \int_A f \, d\mu \right| \leq \int_A g \, d\mu$$

for all $A \in \mathcal{A}$, then $|f| \leq g$ a.e. [If $|f| > g$ on a set A with $\mu(A) > 0$, find a set $B \in \mathcal{A}$, $B \subseteq A$, $\mu(B) > 0$, on which $arg(f)$ is almost constant, to obtain a contradiction.]

XVIII.1.9.2. Let $(X, \mathcal{A}, \mu)$ be a measure space, and g a nonnegative measurable function on $(X, \mathcal{A})$.
(a) For $A \in \mathcal{A}$, define

$$\nu(A) = \int_A g \, d\mu \ .$$

Show that ν is a measure on $(X, \mathcal{A})$, which is finite if and only if g is μ-integrable.
(b) Show that if f is $\mathcal{A}$-measurable, then f is ν-integrable if and only if fg is μ-integrable, and that

$$\int_A f \, d\nu = \int_A fg \, d\mu$$

for every $A \in \mathcal{A}$. [Hint: bootstrap.]

XVIII.2. The Dominated Convergence Theorem

Except for the Fundamental Theorem of Calculus () which is the basis for the actual calculation of elementary integrals, the Dominated Convergence Theorem is probably the most important theorem in integration theory in the sense that it is the result used most often in applications, although the Fubini-Tonelli Theorem is a close second.

XVIII.2.1. Applications of the DCT

Here is a general result about interchanging the order of differentiation and integration. It is phrased in terms of Lebesgue measure, but can be adapted to general measure spaces with the same proof (Exercise ()).

XVIII.2.1.1. THEOREM. Let I and J be intervals in $\mathbb{R}$, and let $F : I \times J \to \mathbb{R}$. Assume that

(a) For each $y \in J$, the function $f^{[y]} : I \to \mathbb{R}$ defined by $f^{[y]}(x) = F(x, y)$ is Lebesgue measurable.

(b) There is a $y_0 \in J$ such that $f^{[y_0]}$ is Lebesgue integrable on I.

(c) For almost all $x \in I$, $\frac{\partial F}{\partial y}(x, y)$ exists for all $y \in J$.

(d) There is a nonnegative Lebesgue integrable function g on I such that, for almost all $x \in I$,

$$\left|\frac{\partial F}{\partial y}(x, y)\right| \leq g(x)$$

for all $y \in J$.

Then we have

(i) $f^{[y]}$ is Lebesgue integrable on I for all $y \in J$.

(ii) For every $y \in J$, the function ϕ^y defined by $\phi^y(x) = \frac{\partial F}{\partial y}(x, y)$ (defined a.e.) is integrable on I.

(iii) For every $y_1 \in J$,

$$\frac{d}{dy}\left[\int_I F(x, y)\, d\lambda(x)\right](y_1) = \frac{d}{dy}\left[\int_I f^{[y]}(x)\, d\lambda(x)\right](y_1) \text{ exists and equals } \int_I \frac{\partial F}{\partial y}(x, y_1)\, d\lambda(x)\ .$$

PROOF: Let A be a subset of I such that (c) and (d) hold for all $x \in A$ and $\lambda(I \setminus A) = 0$.
(i): Fix $y \in J$, and set $\psi(x) = F(x, y) - F(x, y_0)$. Thus $f^{[y]} = f^{[y_0]} + \psi$, so to show that $f^{[y]}$ is Lebesgue integrable it suffices to show that ψ is Lebesgue integrable. Note that it is Lebesgue measurable by (a). For any $x \in A$, there is a c (depending on x) such that

$$\psi(x) = \frac{\partial F}{\partial y}(x, c)(y - y_0)$$

by the Mean Value Theorem (), and hence we have

$$|\psi(x)| \leq g(x)|y - y_0|$$

for almost all $x \in I$ by (d). Since $y - y_0$ is a constant, ψ is Lebesgue integrable.
(ii): Fix $y_1 \in J$. If (h_n) is any sequence converging to 0 such that $y_1 + h_n \in J$ for all n, set

$$\phi_n(x) = \frac{F(x, y_1 + h_n) - F(x, y_1)}{h_n}$$

for each n and note that each ϕ_n is Lebesgue measurable by (a). We have $\phi_n \to \phi^{y_1}$ pointwise a.e., so ϕ^{y_1} is Lebesgue measurable. Since $|\phi^{y_1}(x)| \leq g(x)$ for almost all x by (d), ϕ^{y_1} is Lebesgue integrable.
(iii): We use the sequential criterion. Fix $y_1 \in J$, and let

$$L = \int_I \frac{\partial F}{\partial y}(x, y_1)\, d\lambda(x) = \int_I \phi^{y_1}(x)\, d\lambda(x)$$

(note that this integral is defined by (ii)). To prove (iii), it suffices to show that whenever (h_n) is a sequence of nonzero numbers such that $y_1 + h_n \in J$ for all n, we have

$$\lim_{n\to\infty} \frac{\int_I F(x, y_1 + h_n)\, d\lambda(x) - \int_I F(x, y_1)\, d\lambda(x)}{h_n} = L\ .$$

We have

$$\frac{\int_I F(x, y_1 + h_n)\, d\lambda(x) - \int_I F(x, y_1)\, d\lambda(x)}{h_n} = \int_I \frac{F(x, y_1 + h_n) - F(x, y_1)}{h_n}\, d\lambda(x) = \int_I \phi_n(x)\, d\lambda(x)$$

where ϕ_n is as in the proof of (ii). For each n and $x \in A$, by the MVT there is a c_n (depending on x as well as n) between y_1 and $y_1 + h_n$ such that

$$\phi_n(x) = \frac{F(x, y_1 + h_n) - F(x, y_1)}{h_n} = \frac{\partial F}{\partial y}(x, c_n)$$

and thus $|\phi_n(x)| \leq g(x)$ for all n and almost all x by (d). Thus by the DCT,

$$\lim_{n\to\infty} \int_I \phi_n(x)\, d\lambda(x) = \int_I \phi^{y_1}(x)\, d\lambda(x) = L$$

since $\phi_n \to \phi^{y_1}$ pointwise a.e., and the result follows. 👍

XVIII.2.1.2. Hypothesis (a) is not automatic, as the following example shows. For (a) to hold, it suffices that F be a Borel measurable function from $I \times J$ to $\mathbb{R}$. It does not quite suffice for F to be Lebesgue measurable (), but in the presence of (c) Lebesgue measurability might be sufficient. Hypotheses (a) and (b) are obviously necessary to even make sense of the left side of the equation in (iii), and hypothesis (c) is necessary to make sense of the right side (technically what we need to define the right side is that for each y, $\frac{\partial F}{\partial y}(x, y)$ is defined for almost all x).

XVIII.2.1.3. Example. Let $I = J = [-1, 1]$. Let A be a nonmeasurable subset of I, and set

$$F(x, y) = \begin{cases} y & \text{if} \quad x \in A \\ 0 & \text{if} \quad x \notin A \end{cases}\ .$$

Then F satisfies (b), (c), and (d), but not (a).

XVIII.2.2. Uniform Integrability and Vitali's Convergence Theorem

There is another convergence theorem, the Vitali Convergence Theorem, which gives a necessary and sufficient condition for convergence of integrals, although it is of limited practical use since the hypotheses are not usually easy to check. The result is most cleanly stated for finite measures, but there is a version for general measures.

Equiintegrability and Uniform Integrability

We first note the following property of integrals:

XVIII.2.2.1. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f an extended real-valued or complex-valued $\mathcal{A}$-measurable function on X. If f is μ-integrable, then for every $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $A \in \mathcal{A}$, $\mu(A) < \delta$,

$$\int_A |f|\, d\mu < \epsilon \ .$$

If μ is finite and has no atoms on which f takes an infinite value, the converse also holds: if for every $\epsilon > 0$ there is such a $\delta > 0$, then f is μ-integrable.

PROOF: There is a nonnegative simple function s with $s \le |f|$ and

$$\int_X s\, d\mu > \int_X |f|\, d\mu - \frac{\epsilon}{2} \ .$$

Then s is bounded, i.e. there is an $M > 0$ such that $|s(x)| \le M$ for all $x \in X$. Set $\delta = \frac{\epsilon}{2M}$. Then, if $A \in \mathcal{A}$, $\mu(A) < \delta$,

$$\int_A |f|\, d\mu = \int_A s\, d\mu + \int_A (|f| - s)\, d\mu \le M\mu(A) + \int_X (|f| - s)\, d\mu < M\frac{\epsilon}{2M} + \frac{\epsilon}{2} = \epsilon \ .$$

Conversely, suppose μ is finite and has no atoms on which f takes an infinite value. Fix $\delta > 0$ such that if $A \in \mathcal{A}$, $\mu(A) < \delta$, then $\int_A |f|\, d\mu < 1$. Then X can be written as a disjoint union

$$X = A_1 \cup \cdots \cup A_n \cup B_1 \cup \cdots \cup B_m$$

for some n with $\mu(A_k) < \delta$ for all k, where $B_1, \ldots, B_m$ are the atoms of μ of measure $\ge \delta$ (there are only finitely many since μ is finite). Note that f is constant and finite a.e. on each B_j, say $f = \beta_j$ a.e. on B_j. Then

$$\int_X |f|\, d\mu = \sum_{k=1}^{n} \int_{A_k} |f|\, d\mu + \sum_{j=1}^{m} \int_{B_j} |f|\, d\mu < n + \sum_{j=1}^{m} |\beta_j| \mu(B_j) < \infty$$

so f is integrable. 👍

This leads to the following definition:

XVIII.2.2.2. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $\mathcal{F}$ a set of μ-integrable functions on X. Then $\mathcal{F}$ is *equiintegrable* (μ-*equiintegrable*) on X if for every $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $A \in \mathcal{A}$ with $\mu(A) < \delta$,

$$\int_A |f|\, d\mu < \epsilon$$

for all $f \in \mathcal{F}$. If (f_n) is a sequence of μ-integrable functions, then (f_n) is equiintegrable if $\{f_n : n \in \mathbb{N}\}$ is equiintegrable.

There is a closely related notion, based on the next property:

XVIII.2.2.3. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f a μ-integrable function. Then for any $\epsilon > 0$ there is a λ such that

$$\int_{E_\lambda} |f|\, d\mu < \epsilon$$

where $E_\lambda = \{x \in X : |f(x)| > \lambda\}$.

PROOF: For $\lambda > 0$ set $D_\lambda = X \setminus E_\lambda = \{x \in X : |f(x)| \leq \lambda\}$. Then as $\lambda \to \infty$, $|f|\chi_{D_\lambda}$ increases to $|f|$ pointwise a.e. So by the MCT

$$\int_X |f|\, d\lambda = \sup_\lambda \int_X |f|\chi_{D_\lambda}\, d\mu = \int_{D_\lambda} |f|\, d\mu$$

so, as $\lambda \to \infty$,

$$\int_{E_\lambda} |f|\, d\mu = \int_X |f|\, d\mu - \int_{D_\lambda} |f|\, d\mu \to 0\ .$$

XVIII.2.2.4. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $\mathcal{F}$ a set of μ-integrable functions on X. Then $\mathcal{F}$ is *uniformly integrable* (*uniformly* μ-*integrable*) on X if for every $\epsilon > 0$ there is a λ such that

$$\int_{E_{f,\lambda}} |f|\, d\mu < \epsilon$$

for all $f \in \mathcal{F}$, where $E_{f,\lambda} = \{x \in X : |f(x)| > \lambda\}$. If (f_n) is a sequence of μ-integrable functions, then (f_n) is uniformly integrable if $\{f_n : n \in \mathbb{N}\}$ is uniformly integrable.

XVIII.2.2.5. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a finite measure space, and $\mathcal{F}$ a set of μ-integrable functions on X. Then $\mathcal{F}$ is uniformly integrable if and only if $\mathcal{F}$ is equiintegrable and there is a constant K such that

$$\int_X |f|\, d\mu \leq K$$

for all $f \in \mathcal{F}$ ($\mathcal{F}$ is L^1-*bounded*). If $(X, \mathcal{A}, \mu)$ has no atoms, then $\mathcal{F}$ is uniformly integrable if and only if it is equiintegrable.

PROOF: Suppose $\mathcal{F}$ is uniformly integrable. Let $\epsilon > 0$. Fix λ such that

$$\int_{E_{f,\lambda}} |f|\, d\mu < \frac{\epsilon}{2}$$

for all $f \in \mathcal{F}$. Set $\delta = \frac{\epsilon}{2\lambda}$. If $A \in \mathcal{A}$, $\mu(A) < \delta$, then for each $f \in \mathcal{F}$ we have

$$\begin{aligned}\int_A |f|\, d\mu &= \int_{A\cap D_{f,\lambda}} |f|\, d\mu + \int_{A\cap E_{f,\lambda}} |f|\, d\mu \\ &\leq \lambda\mu(A) + \int_{E_{f,\lambda}} |f|\, d\mu < \lambda\frac{\epsilon}{2\lambda} + \frac{\epsilon}{2} = \epsilon\ .\end{aligned}$$

Thus $\mathcal{F}$ is equiintegrable. We also have, for all $f \in \mathcal{F}$,

$$\int_X |f|\, d\mu = \int_{D_{f,\lambda}} |f|\, d\mu + \int_{E_{f,\lambda}} |f|\, d\mu \leq \lambda\mu(X) + \frac{\epsilon}{2}$$

so $\mathcal{F}$ is L^1-bounded.

Conversely, if μ has no atoms, suppose $\mathcal{F}$ is equiintegrable. Fix $\delta_0 > 0$ such that if $A \in \mathcal{A}$, $\mu(A) < \delta_0$, then $\int_A |f|\, d\mu < 1$ for all $f \in \mathcal{F}$. Since X has no atoms, X can be written as a disjoint union $X = A_1 \cup \cdots \cup A_n$ for some n, where $\mu(A_k) < \delta_0$ for all k (). Then, for all $f \in \mathcal{F}$

$$\int_X |f|\, d\mu = \sum_{k=1}^{n} \int_{A_k} |f|\, d\mu < n$$

so $\mathcal{F}$ is L^1-bounded.

Now let $\epsilon > 0$. For any $\lambda > 0$ we have, for any $f \in \mathcal{F}$,

$$\mu(E_{f,\lambda}) \leq \frac{1}{\lambda}\int_X |f|\, d\mu < \frac{n}{\lambda}\ .$$

If $\delta > 0$ is fixed so that $\int_A |f|\, d\mu < \epsilon$ for all $A \in \mathcal{A}$, $\mu(A) < \delta$, and all $f \in \mathcal{F}$, and λ is fixed so that $\frac{n}{\lambda} < \delta$, we have, for all $f \in \mathcal{F}$,

$$\int_{E_{f,\lambda}} |f|\, d\mu < \epsilon$$

so $\mathcal{F}$ is uniformly integrable. 👍

XVIII.2.2.6. Thus the only difference between equiintegrability and uniform integrability on finite measure spaces is uniform boundedness on each atom. This is not automatic: if X is a one-point space with $\mu(X) = 1$, let $\mathcal{F}$ be the set of all real-valued (constant) functions on X. Then $\mathcal{F}$ is vacuously equiintegrable (each f is integrable, and for any $\epsilon > 0$ just take $\delta = \frac{1}{2}$), but $\mathcal{F}$ is not uniformly integrable.

XVIII.2.2.7. There are various definitions of equiintegrability and uniform integrability in the literature, all of which agree for finite measure spaces without atoms. In some references, equiintegrability (by our definition) is called "uniform integrability" or "uniformly absolutely continuous integrals." ✋

Vitali's Convergence Theorem, Finite Case

XVIII.2.2.8. THEOREM. [VITALI CONVERGENCE THEOREM] Let $(X, \mathcal{A}, \mu)$ be a finite measure space, and (f_n) a sequence of μ-integrable functions converging pointwise a.e. on X to a measurable function f. If (f_n) is equiintegrable, then (f_n) is uniformly integrable, f is μ-integrable, and

$$\lim_{n\to\infty} \int_X |f_n - f|\, d\mu = 0 \ .$$

In particular,

$$\int_E f_n \, d\mu \to \int_E f \, d\mu$$

for all $E \in \mathcal{A}$.

Conversely, if $f_n \to f$ pointwise a.e., f and the f_n are integrable, and

$$\lim_{n\to\infty} \int_X |f_n - f|\, d\mu = 0$$

then (f_n) is uniformly integrable.

PROOF: Since each f_n takes infinite values only on a null set and $f_n \to f$ a.e., f is finite a.e. Thus, modifying f_n and f on null sets, we may assume that f and the f_n are finite everywhere and $f_n \to f$ everywhere.

If B is an atom of μ, then each f_n takes a constant value β_n a.e. on B, f takes a constant value β a.e. on B, and $\beta_n \to \beta$. Thus

$$\int_B f_n \, d\mu = \beta_n \mu(B) \to \beta\mu(B) = \int_B f \, d\mu \ .$$

In particular, f is integrable over B.

Suppose (f_n) is equiintegrable. Fix δ_0 such that, whenever $\mu(A) < \delta_0$, $\int_A |f_n|\, d\mu < 1$. As in the proof of XVIII.2.2.1., write

$$X = A_1 \cup \cdots \cup A_r \cup B_1 \cup \cdots \cup B_m$$

for some r with $\mu(A_k) < \delta_0$ for all k, where $B_1, \ldots, B_m$ are the atoms of μ of measure $\geq \delta_0$. If β_{nj} is the a.e. constant value of f_n on B_j, and β_j the a.e. constant value of f on B_j, then $\beta_n j \to \beta_j$ for all j. Thus the β_{nj} are uniformly bounded, i.e. there is a c with $|\beta_{nj}| \leq c$ for all n, j. For each n we have

$$\int_X |f_n|\, d\mu \leq \sum_{k=1}^{r} \int_{A_k} |f_n|\, d\mu + \sum_{j=1}^{m} \int_{B_j} |f_n|\, d\mu < r + c \sum_{j=1}^{m} \mu(B_j) =: M$$

so (f_n) is L^1-bounded, and hence (f_n) is uniformly integrable by XVIII.2.2.5.. Also, since $|f_n| \to |f|$, by Fatou's Lemma () we also have $\int_X |f|\, d\mu \leq M$. Thus f is integrable.

Let $\epsilon > 0$, and fix $\delta > 0$ such that whenever $A \in \mathcal{A}$, $\mu(A) < \delta$, $\int_A |f_n|\, d\mu < \frac{\epsilon}{3}$ for all n. We may also choose δ so that $\int_A |f|\, d\mu < \frac{\epsilon}{3}$ for any such A (actually this is automatic by Fatou's Lemma, but we could just apply XVIII.2.2.1. instead). By Egorov's Theorem (), there is a $Y \in \mathcal{A}$ with $\mu(Y) < \delta$ such that $f_n \to f$ uniformly on $X \setminus Y$. Fix N so that

$$|f_n(x) - f(x)| < \frac{\epsilon}{3\mu(X)}$$

for all $x \in X \setminus Y$ and all $n \geq N$. We then have, for $n \geq N$,

$$\int_X |f_n - f|\, d\mu = \int_Y |f_n - f|\, d\mu + \int_{X\setminus Y} |f_n - f|\, d\mu \leq \int_Y (|f_n| + |f|)\, d\mu + \int_{X\setminus Y} |f_n - f|\, d\mu$$

$$= \int_Y |f_n|\, d\mu + \int_Y |f|\, d\mu + \int_{X\setminus Y} |f_n - f|\, d\mu < \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3\mu(X)}\mu(X \setminus Y) \leq \epsilon\ .$$

For the last statement of the forward part, if $E \in \mathcal{A}$, for any n

$$\left|\int_E f_n\, d\mu - \int_E f\, d\mu\right| = \left|\int_E (f_n - f)\, d\mu\right| \leq \int_E |f_n - f|\, d\mu \leq \int_X |f_n - f|\, d\mu\ .$$

Conversely, suppose each f_n and f are integrable and

$$\lim_{n\to\infty} \int_X |f_n - f|\, d\mu = 0\ .$$

Let $\epsilon > 0$. Choose N such that $\int_X |f_n - f|\, d\mu < \frac{\epsilon}{2}$ for all $n \geq N$, and choose δ_0 so that $A \in \mathcal{A}$, $\mu(A) < \delta_0$ implies $\int_A |f|\, d\mu < \frac{\epsilon}{2}$ by XVIII.2.2.1.. If $A \in \mathcal{A}$, $\mu(A) < \delta_0$, then for all $n \geq N$,

$$\int_A |f_n|\, d\mu = \int_A |f_n - f + f|\, d\mu \leq \int_A |f_n - f|\, d\mu + \int_A |f|\, d\mu \leq \int_X |f_n - f|\, d\mu + \int_A |f|\, d\mu < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon\ .$$

If $1 \leq n < N$, there is a δ_n such that if $A \in \mathcal{A}$, $\mu(A) < \delta_n$, then $\int_A |f_n|\, d\mu < \epsilon$. Set $\delta = \min(\delta_0, \delta_1, \ldots, \delta_{N-1})$. Then if $A \in \mathcal{A}$, $\mu(A) < \delta$, then $\int_A |f_n|\, d\mu < \epsilon$ for all n, so (f_n) is equiintegrable. 👍

XVIII.2.2.9. There is a stronger form of the converse: if $f_n \to f$ pointwise a.e., f and the f_n are integrable, and

$$\int_E f_n\, d\mu \to \int_E f\, d\mu$$

for all $E \in \mathcal{A}$, then (f_n) is uniformly integrable [Bog07, 4.5.6].

Tightness

XVIII.2.2.10. Vitali's Convergence Theorem fails in general if μ is not finite. For example, note that any uniformly bounded set of integrable functions is uniformly integrable. In $(\mathbb{R}, \mathcal{L}, \lambda)$, let $f_n = \chi_{[n,n+1]}$. Then the f_n are uniformly bounded, hence uniformly integrable, and converge pointwise to 0, but $\int_{\mathbb{R}} f_n\, d\lambda = 1 \not\to 0$. And if $f_n = \chi_{[0,n]}$, then (f_n) is uniformly bounded, hence uniformly integrable, and $f_n \to \chi_{[0,+\infty)}$, which is not integrable.

The additional ingredient needed is motivated by the following:

XVIII.2.2.11. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f an integrable extended real-valued or complex-valued function. Then for any $\epsilon > 0$ there is an $A \in \mathcal{A}$ with $\mu(A) < \infty$ and

$$\int_{X \setminus A} |f| \, d\mu < \epsilon \ .$$

PROOF: Let $\epsilon > 0$. There is a simple function s with $s \leq |f|$ and

$$\int_X s \, d\mu > \int_X |f| \, d\mu - \epsilon \ .$$

There is an $A \in \mathcal{A}$ with $\mu(A) < \infty$ and s identically 0 outside A. Then

$$\int_{X \setminus A} |f| \, d\mu = \int_{X \setminus A} (|f| - s) \, d\mu \leq \int_X (|f| - s) \, d\mu < \epsilon \ .$$

XVIII.2.2.12. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space and $\mathcal{F}$ a set of μ-integrable functions on X. Then $\mathcal{F}$ is *tight* (μ-*tight*) if for every $\epsilon > 0$ there is an $A \in \mathcal{A}$ with $\mu(A) < \infty$ and

$$\int_{X \setminus A} |f| \, d\mu < \epsilon$$

for all $f \in \mathcal{F}$. A sequence (f_n) of μ-integrable functions is tight if $\{f_n : n \in \mathbb{N}\}$ is tight.

If μ is finite, then any set of integrable functions is tight.

Vitali's Convergence Theorem, General Case

XVIII.2.2.13. THEOREM. [GENERAL VITALI CONVERGENCE THEOREM] Let $(X, \mathcal{A}, \mu)$ be a measure space, and (f_n) a sequence of μ-integrable functions converging pointwise a.e. on X to a measurable function f. If (f_n) is equiintegrable and tight, then f is μ-integrable and

$$\lim_{n \to \infty} \int_X |f_n - f| \, d\mu = 0 \ .$$

In particular,

$$\int_E f_n \, d\mu \to \int_E f \, d\mu$$

for all $E \in \mathcal{A}$.

Conversely, if $f_n \to f$ pointwise a.e., f and the f_n are integrable, and

$$\lim_{n \to \infty} \int_X |f_n - f| \, d\mu = 0$$

then (f_n) is equiintegrable and tight.

PROOF: Let $\epsilon > 0$. Fix $A \in \mathcal{A}$, $\mu(A) < \infty$, such that

$$\int_{X\setminus A} |f_n|\, d\mu < \frac{\epsilon}{3}$$

for all n. Then by Fatou's Lemma we also have $\int_{X\setminus A} |f|\, d\mu \le \epsilon$ and, in particular, f is integrable over $X \setminus A$. On A, the f_n and f satisfy the hypotheses of XVIII.2.2.8., so f is integrable on A and

$$\int_A |f_n - f|\, d\mu \to 0 \ .$$

Thus f is integrable on X. Fix N such that

$$\int_A |f_n - f|\, d\mu < \frac{\epsilon}{3}$$

for all $n \ge N$. Then, if $n \ge N$,

$$\int_X |f_n - f|\, d\mu = \int_A |f_n - f|\, d\mu + \int_{X\setminus A} |f_n - f|\, d\mu \le \int_A |f_n - f|\, d\mu + \int_{X\setminus A} |f_n|\, d\mu + \int_{X\setminus A} |f|\, d\mu < \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3} = \epsilon \ .$$

Conversely, suppose f_n, f are integrable and $\int_X |f_n - f|\, d\mu \to 0$. Let $\epsilon > 0$. Fix N such that

$$\int_X |f_n - f|\, d\mu < \frac{\epsilon}{3}$$

for all $n \ge N$. By XVIII.2.2.11. there is a $D_0 \in \mathcal{A}$ with $\mu(D_0) < \infty$ and $\int_{E_0} |f|\, d\mu < \frac{\epsilon}{3}$, where $E_0 = X \setminus D_0$. If $n \ge N$, then

$$\int_{E_0} |f_n|\, d\mu = \int_{E_0} |f_n - f + f|\, d\mu \le \int_{E_0} |f_n - f|\, d\mu + \int_{E_0} |f|\, d\mu \le \int_X |f_n - f|\, d\mu + \int_{E_0} |f|\, d\mu < \frac{\epsilon}{3} + \frac{\epsilon}{3} = \frac{2\epsilon}{3} < \epsilon \ .$$

If $1 \le n < N$, then by XVIII.2.2.11. there is a set $D_n \in \mathcal{A}$, $\mu(D_n) < \infty$, such that $\int_{E_n} |f_n|\, d\mu < \frac{2\epsilon}{3}$, where $E_n = X \setminus D_n$. Set $D = D_0 \cup D_1 \cup \cdots \cup D_{N-1}$, and $E = X \setminus D = E_0 \cap \cdots \cap E_{N-1}$. Then $\mu(D) < \infty$ and

$$\int_E |f_n|\, d\mu \le \int_{E_n} |f_n|\, d\mu < \frac{2\epsilon}{3} \text{ for } 1 \le n < N$$

$$\int_E |f_n|\, d\mu \le \int_{E_0} |f_n|\, d\mu < \frac{2\epsilon}{3} \text{ for } n \ge N \ .$$

Thus (f_n) is tight. And f and the f_n satisfy the hypotheses of the converse part of XVIII.2.2.8. on D, so there is a $\delta > 0$ such that if $A \in \mathcal{A}$, $A \subseteq D$, $\mu(A) < \delta$, then $\int_A |f_n|\, d\mu < \frac{\epsilon}{3}$. So if $A \in \mathcal{A}$, $\mu(A) < \delta$, then

$$\int_A |f_n|\, d\mu = \int_{A\cap D} |f_n|\, d\mu + \int_{A\cap E} |f_n|\, d\mu \le \int_{A\cap D} |f_n|\, d\mu + \int_E |f_n|\, d\mu < \frac{\epsilon}{3} + \frac{2\epsilon}{3} = \epsilon$$

for all n. Thus (f_n) is equiintegrable. 👍

Bounded Mean-Square Convergence Theorem

A nice application of Vitali's Convergence Theorem is to sequences which are mean-square bounded.

XVIII.2.2.14. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and f an extended real-valued or complex-valued $\mathcal{A}$-measurable function. Then f is *square-integrable* (*μ-square-integrable*) if $|f|^2$ is integrable, i.e.

$$\int_X |f|^2 \, d\mu < \infty$$

(the absolute values are needed if f is complex-valued).

A set $\mathcal{F}$ of measurable functions is *mean-square bounded* if each function in $\mathcal{F}$ is square-integrable and there is a constant K such that

$$\int_X |f|^2 \, d\lambda \leq K$$

for all $f \in \mathcal{F}$. A sequence (f_n) is mean-square bounded if $\{f_n : n \in \mathbb{N}\}$ is mean-square bounded.

XVIII.2.2.15. The term "mean-square" should properly only be used if μ is finite and f is real-valued: the mean-square of f is the average value of f^2, i.e.

$$\frac{1}{\mu(X)} \int_X f^2 \, d\mu \ .$$

The square root of this average ("root-mean-square" or RMS) is often used. If μ is a probability measure, this is just the L^2-norm of f (), and is closely related to the standard deviation ().

XVIII.2.2.16. If μ is finite, a square-integrable function on X is integrable. But this is not necessarily true if μ is not finite.

XVIII.2.2.17. THEOREM. [BOUNDED MEAN-SQUARE CONVERGENCE THEOREM] Let $(X, \mathcal{A}, \mu)$ be a finite measure space, and (f_n) a sequence of extended real-valued or complex-valued $\mathcal{A}$-measurable functions on X converging pointwise a.e. to an $\mathcal{A}$-measurable function f. If (f_n) is mean-square bounded, then f is square-integrable, hence integrable, and

$$\lim_{n\to\infty} \int_X |f_n - f| \, d\mu = 0 \ .$$

In particular,

$$\int_E f_n \, d\mu \to \int_E f \, d\mu$$

for all $E \in \mathcal{A}$.

PROOF: By assumption, the f_n are square-integrable, hence integrable. Fix K so that

$$\int_X |f_n|^2 \, d\lambda \leq K$$

for all n. By Fatou's Lemma (),

$$\int_X |f|^2 \, d\lambda \leq K$$

so f is also square-integrable.

We show that (f_n) is uniformly integrable. Let $\epsilon > 0$. If $\lambda > 0$ and $n \in \mathbb{N}$, set

$$E_{n,\lambda} = \{x \in X : |f_n(x)| > \lambda\}$$

as before. For each n, we have

$$\int_{E_{n,\lambda}} |f_n| \, d\mu \leq \int_{E_{n,\lambda}} \frac{|f_n|^2}{\lambda} \, d\mu \leq \frac{1}{\lambda} \int_X |f_n|^2 \, d\mu \leq \frac{K}{\lambda} \ .$$

Choose λ large enough that $\frac{K}{\lambda} < \epsilon$. Thus (f_n) is uniformly integrable, so the conclusion follows from XVIII.2.2.5. and XVIII.2.2.8.. 👍

XVIII.2.2.18. This result is somewhat reminiscent of IV.2.12.10., at least in spirit. See [Edg98, 2.2.12] for a proof using the DCT instead of Vitali's Convergence Theorem.

XVIII.2.3. Exercises

XVIII.2.3.1. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $\delta > 0$. Show that X can be written in the form of the proof of XVIII.2.2.1..

XVIII.2.3.2. Let $(X, \mathcal{A}, \mu)$ be a measure space, and (f_n) a sequence of $\mathcal{A}$-measurable functions on X. If there is a nonnegative integrable function g on X such that $|f_n| \leq g$ a.e. for all n, show that (f_n) is equiintegrable and tight. [Use XVIII.2.2.1. and XVIII.2.2.11..] Thus the General Vitali Convergence Theorem implies the Dominated Convergence Theorem. Show that a stronger result holds: if $(f_n), f$ satisfy the hypotheses of the DCT, then

$$\lim_{n\to\infty} \int_X |f_n - f| \, d\mu = 0 \ .$$

XVIII.2.3.3. Let $(X, \mathcal{A}, \mu)$ be a measure space, (f_n) a sequence of μ-integrable functions on X, and f an integrable function with $\int_X |f_n - f| \, d\mu \to 0$. Show that (f_n) (which is equiintegrable and tight by XVIII.2.2.13.) is uniformly integrable. [Use an argument similar to the proof of XVIII.2.2.5..]

XVIII.3. Integration on Product Spaces

XVIII.3.1. The Fubini-Tonelli Theorems

XVIII.3.1.1. The Fubini-Tonelli Theorems concern calculation of integrals over a product space by iterated integrals, and/or interchange of order of integration in iterated integrals. There are two distinct but closely related results, one concerning integration of nonnegative measurable functions and the other concerning integration of integrable functions which are not necessarily nonnegative (in line with the development of Lebesgue integration itself, first done for nonnegative functions and then for general integrable functions).

It is conventional to call the nonnegative version "Tonelli's Theorem" and the integrable version "Fubini's Theorem" (the name "Fubini's Theorem" is often used generically for both). But the actual history is more complicated, and these names are not quite accurate historically: both FUBINI and TONELLI (who worked roughly simultaneously but independently) were partially responsible for both results. We will nonetheless follow convention and use the names "Tonelli's Theorem" and "Fubini's Theorem" since it is convenient to have distinct names for the two results, with just the warning that the names are not well justified historically.

Fubini's Theorem is one of the two most important theorems of integration theory, along with the Dominated Convergence Theorem, in the sense that these two theorems are by far the results used most often in applications.

XVIII.3.1.2. Some versions of Fubini's Theorem were previously "known" (if not proved); cf. IX.3.4.34.. But it is conventional to call all versions "Fubini's Theorem" and we will follow the convention.

Preliminaries

XVIII.3.1.3. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces, $C \in \mathcal{A} \otimes \mathcal{B}$. Then C is of σ-finite measure if and only if there are $A \in \mathcal{A}$, $B \in \mathcal{B}$ of σ-finite measure, and $M \in \mathcal{A}$, $N \in \mathcal{B}$ of measure 0, such that $C \subseteq (A \times B) \cup (M \times Y) \cup (X \times N)$.

PROOF: It is obvious that if there are such A, B, M, and N, then C is σ-finite (see Exercise ().) Conversely, let $C = \cup_{n=1}^{\infty} C_n$, with $(\mu \times \nu)(C_n) < \infty$. For each n there is a sequence $R_{nk} = A_{nk} \times B_{nk}$ of rectangles with $A_{nk} \in \mathcal{A}$, $B_{nk} \in \mathcal{B}$, $C_n \subseteq \cup_k R_{nk}$, and $\sum_k \mu(A_{nk})\nu(B_{nk}) < (\mu \times \nu)(C_n) + 1 < \infty$. For each k, $\mu(A_{nk}) = \infty$ implies $\nu(B_{nk}) = 0$ and $\nu(B_{nk}) = \infty$ implies $\mu(A_{nk}) = 0$. Let M_n be the union of the A_{nk} with $\mu(A_{nk}) = 0$, and N_n the union of the B_{nk} with $\nu(B_{nk}) = 0$; renumbering, we may assume $0 < \mu(A_{nk}), \nu(A_{nk}) < \infty$ for all k and $C_n \subseteq (M_n \times Y) \cup (X \times N_n) \cup \cup_k R_{nk}$. Set $A = \cup_{n,k} A_{nk}$, $B = \cup_{n,k} B_{n,k}$, $M = \cup_n M_n$, $N = \cup_n N_n$. Then $\mu(M) = \nu(N) = 0$, A and B have σ-finite measure, and $C \subseteq (A \times B) \cup (M \times Y) \cup (X \times N)$.

XVIII.3.1.4. Note: it is not true that a set of σ-finite measure in $\mathcal{A} \otimes \mathcal{B}$ is contained in a product of sets of σ-finite measure in general. For example, if ν is not σ-finite, and $x \in X$ is not an atom, then $\{x\} \times Y$ has $\mu \times \nu$-measure zero, hence is σ-finite, but is not contained in a rectangle $A \times B$ with B of σ-finite measure.

We will use the following notation, which was partially introduced in ():

XVIII.3.1.5. DEFINITION. Let X and Y be sets.
(i) If $C \subseteq X \times Y$, for each $x \in X$ the *vertical cross section* of C at x is

$$C_x = \{y \in Y : (x, y) \in C\}$$

and, for each $y \in Y$, the *horizontal cross section* of C at Y is

$$C^y = \{x \in X : (x, y) \in C\} .$$

(ii) If $f : X \times Y \to \mathbb{R}$ (or to $\mathbb{C}$) is a function, for each $x \in X$ define $f_{[x]} : Y \to \mathbb{R}$ by

$$f_{[x]}(y) = f(x, y)$$

and for each $y \in Y$, define $f^{[y]} : X \to \mathbb{R}$ by

$$f^{[y]}(x) = f(x, y) .$$

The functions $f_{[x]}$ and $f^{[y]}$ are called the *marginal functions* of f.

Cross sections and marginal functions are well-behaved under set-theoretic and algebraic operations:

XVIII.3.1.6. PROPOSITION. Let X and Y be sets.

(i) If $C \subseteq X \times Y$, then $[(X \times Y) \setminus C]_x = Y \setminus C_x$ for all $x \in X$ and $[(X \times Y) \setminus C]^y = X \setminus C^y$ for all $y \in Y$ (informally, $(C^c)_x = (C_x)^c$ and $(C^c)^y = (C^y)^c$ for all x and y).

(ii) If $\{C_i : i \in I\}$ is a collection of subsets of $X \times Y$, then $(\cup_{i \in I} C_i)_x = \cup_{i \in I} (C_i)_x$ for all $x \in X$ and $(\cup_{i \in I} C_i)^y = \cup_{i \in I} (C_i)^y$ for all $y \in Y$.

(iii) If f and g are functions from $X \times Y$ to $\mathbb{R}$, and $\alpha \in \mathbb{R}$, then $(f + g)_{[x]} = f_{[x]} + g_{[x]}$ and $(\alpha f)_{[x]} = \alpha f_{[x]}$ for all $x \in X$ and $(f + g)^{[y]} = f^{[y]} + g^{[y]}$ and $(\alpha f)^{[y]} = \alpha f^{[y]}$ for all $y \in Y$.

(iv) If $C \subseteq X \times Y$, then $(\chi_C)_x = \chi_{C_x}$ and $(\chi_C)^y = \chi_{C^y}$ for all $x \in X$, $y \in Y$.

The straightforward proof is left to the reader.

XVIII.3.1.7. Now let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces. Form the product σ-algebra $\mathcal{A} \otimes \mathcal{B}$ () and the product measure $\mu \times \nu$ on $\mathcal{A} \otimes \mathcal{B}$. We need several technical results guaranteeing that various sets and functions arising in iterated integrals are measurable. These results might be expected, but it turns out that some σ-finite hypotheses are necessary.

The first results are that cross sections of measurable sets are measurable, and margins of measurable functions are measurable. No measures are needed for these results, and in particular no σ-finite hypotheses are needed (or even make sense!)

XVIII.3.1.8. LEMMA. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measurable spaces, and $C \in \mathcal{A} \otimes \mathcal{B}$. Then $C_x \in \mathcal{B}$ for all $x \in X$ and $C^y \in \mathcal{A}$ for all $y \in Y$.

PROOF: Let $\mathcal{C}$ be the collection of all $C \in \mathcal{A} \otimes \mathcal{B}$ for which the conclusion holds. If $C = A \times B \in \mathcal{A} \times \mathcal{B}$, then

$$C_x = \begin{cases} B & \text{if} \quad x \in A \\ \emptyset & \text{if} \quad x \notin A \end{cases}$$

and thus $C_x \in \mathcal{B}$ for any x, and similarly $C^y \in \mathcal{A}$ for any y. Thus $C \in \mathcal{C}$, i.e. $\mathcal{A} \times \mathcal{B} \subseteq \mathcal{C}$. In particular, $\emptyset$ and $X \times Y$ are in $\mathcal{C}$. If $C \in \mathcal{C}$, then $(C^c)_x = (C_x)^c \in \mathcal{B}$ for any $x \in X$ since $\mathcal{B}$ is closed under complements, and similarly $(C^c)^y \in \mathcal{A}$ for all y, so $C^c \in \mathcal{C}$, i.e. $\mathcal{C}$ is closed under complements.

If (C_n) is a sequence in $\mathcal{C}$, then $(\cup_n C_n)_x = \cup_n C_x \in \mathcal{B}$ for all x since $\mathcal{B}$ is closed under countable unions, and similarly $(\cup_n C_n)^y \in \mathcal{A}$ for all y, so $\cup_n C_n \in \mathcal{C}$ and $\mathcal{C}$ is a σ-algebra containing $\mathcal{A} \times \mathcal{B}$, and thus $\mathcal{C}$ contains (and therefore equals) $\mathcal{A} \otimes \mathcal{B}$. 👍

XVIII.3.1.9. LEMMA. Let $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ be measurable spaces, and $f : X \times Y \to \mathbb{R}$. If f is $(\mathcal{A} \otimes \mathcal{B})$-measurable, then $f_{[x]}$ is $\mathcal{B}$-measurable for all $x \in X$ and $f^{[y]}$ is $\mathcal{A}$-measurable for all $y \in Y$.

PROOF: We bootstrap. If $f = \chi_C$ for $C \in \mathcal{A} \otimes \mathcal{B}$, then f is measurable by XVIII.3.1.6.(iv) and XVIII.3.1.8.. If f is a simple function, then f is measurable by XVIII.3.1.6.(iii). And if f is a general measurable function, there is a sequence (s_n) of simple functions converging pointwise to f (). For each x the sequence $((s_n)_{[x]})$ converges pointwise to $f_{[x]}$, and thus $f_{[x]}$ is measurable. Similarly, $f^{[y]}$ is measurable. 👍

We now need measures and a σ-finite hypothesis. The next result is the most delicate part of the proof of the Fubini-Tonelli Theorems.

XVIII.3.1.10. LEMMA. Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be σ-finite measure spaces, and $C \in \mathcal{A} \otimes \mathcal{B}$. For $x \in X$ set $g(x) = \nu(C_x)$ and for $y \in Y$ set $h(y) = \mu(C^y)$. Then g is $\mathcal{A}$-measurable and h is $\mathcal{B}$-measurable.

PROOF: Let $\mathcal{D}$ be the set of all C in $\mathcal{A} \otimes \mathcal{B}$ for which the functions g and h are measurable. We will show that $\mathcal{D}$ equals $\mathcal{A} \otimes \mathcal{B}$ by the Monotone Class Theorem ().

First note that if $C = A \times B \in \mathcal{A} \times \mathcal{B}$, then $g = \nu(B)\chi_A$ and $h = \mu(A)\chi_B$, so g and h are measurable and $C \in \mathcal{D}$, i.e. $\mathcal{A} \times \mathcal{B} \subseteq \mathcal{D}$. Now note that $\mathcal{E}$ is the set of finite disjoint unions of sets in $\mathcal{A} \times \mathcal{B}$. If C is the disjoint union of $A_k \times B_k$, $1 \leq k \leq n$, then

$$g = \sum_{k=1}^{n} \nu(B_k)\chi_{A_k}, \quad h = \sum_{k=1}^{n} \mu(A_k)\chi_{B_k}$$

so g and h are again measurable and $C \in \mathcal{D}$, i.e. $\mathcal{E} \subseteq \mathcal{D}$.

Now suppose (C_n) is an increasing sequence in $\mathcal{D}$ with union C. Let g_n, h_n be the functions corresponding to C_n, and g and h the functions corresponding to C. For each $x \in X$, we have that $((C_n)_x)$ is an increasing sequence in $\mathcal{B}$ with union C_x, and thus $g_n(x) = \nu((C_n)_x)$ increases to $g(x) = \nu(C_x)$ by the Baby Monotone Convergence Theorem (), i.e. $g_n \to g$ pointwise. Since $C_n \in \mathcal{D}$ for all n, the g_n are measurable, hence g is

also measurable. By an almost identical argument, h is also measurable, so $C \in \mathcal{D}$, i.e. $\mathcal{D}$ is closed under increasing sequential unions.

Next we handle decreasing intersections. This is the trickiest part, and we must use the hypothesis that μ and ν are σ-finite. Let $R_m = A_m \times B_m$ be an increasing sequence of rectangles with $A_m \in \mathcal{A}$, $\cup_{m=1}^{\infty} A_m = X$, $B_m \in \mathcal{B}$, $\cup_{m=1}^{\infty} B_m = Y$, $\mu(A_m) < \infty$, $\nu(B_m) < \infty$ for all m. Set

$$\mathcal{F} = \{C \in \mathcal{A} \otimes \mathcal{B} : C \cap (A_m \times B_m) \in \mathcal{D} \text{ for all } m\} \ .$$

By arguments identical to the ones above (or by just applying them to the product space obtained by replacing X and Y by A_m and B_m), we have that $\mathcal{E} \subseteq \mathcal{F}$ and $\mathcal{F}$ is closed under increasing sequential unions. To show that $\mathcal{F}$ is closed under decreasing intersections, let (F_n) be a decreasing sequence in $\mathcal{F}$ with intersection F. Fix m, and let g_n and h_n be the functions corresponding to $Z_n := F_n \cap (A_m \times B_m)$, and g and h the functions corresponding to $Z := F \cap (A_m \times B_m)$. Then (Z_n) is a decreasing sequence in $\mathcal{D}$ with intersection Z. If $x \in X$, then $((Z_n)_x)$ is a decreasing sequence in Y with intersection Z_x, and since each $(Z_n)_x$ is contained in B_m and thus has finite ν-measure, we have $g_n(x) = \nu((Z_n)_x) \to \nu(Z_x) = g(x)$ by downward continuity (), i.e. $g_n \to g$ pointwise. Since each Z_n is in $\mathcal{D}$, g_n is measurable, so g is measurable. Similarly, h is measurable. So $Z \in \mathcal{D}$. This is true for every m, so $F \in \mathcal{F}$. Thus $\mathcal{F}$ is a monotone class containing $\mathcal{E}$, so it contains (and equals) $\sigma(\mathcal{E}) = \mathcal{A} \otimes \mathcal{B}$ by the Monotone Class Theorem.

Finally, let $C \in \mathcal{A} \otimes \mathcal{B}$. Set $C_m = C \cap (A_m \times B_m)$. Then (C_m) is an increasing sequence with union C. We have that $C_m \in \mathcal{D}$ for all m since $C \in \mathcal{F}$. Since $\mathcal{D}$ is closed under increasing sequential unions, $C \in \mathcal{D}$. Thus $\mathcal{D} = \mathcal{A} \otimes \mathcal{B}$. 👍

XVIII.3.1.11. LEMMA. Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be σ-finite measure spaces, and $f : X \times Y \to \mathbb{R}$ a nonnegative extended real-valued $(\mathcal{A} \otimes \mathcal{B})$-measurable function. Set

$$g(x) = \int_Y f_{[x]} \, d\nu = \int_Y f(x, y) \, d\nu(y)$$

$$h(y) = \int_X f^{[y]} \, d\mu = \int_X f(x, y) \, d\mu(x) \ .$$

Then g is $\mathcal{A}$-measurable and h is $\mathcal{B}$-measurable.

PROOF: Bootstrap. If $f = \chi_C$ for $C \in \mathcal{A} \otimes \mathcal{B}$, then $f_{[x]} = \chi_{C_x}$ and $f^{[y]} = \chi_{C^y}$ for $x \in X$, $y \in Y$, so

$$g(x) = \int_Y f_{[x]} \, d\nu = \int_Y \chi_{C_x} \, d\nu = \nu(C_x)$$

$$h(y) = \int_X f^{[y]} \, d\mu = \int_X \chi_{C^y} \, d\mu = \mu(C^y)$$

so g and h are measurable by Lemma XVIII.3.1.10.. Note also that if $f_1, \ldots, f_n$ are nonnegative extended real-valued measurable functions with corresponding $g_1, \ldots, g_n$ and $h_1, \ldots, h_n$, then $f = f_1 + \cdots + f_n$ has corresponding functions $g = g_1 + \cdots + g_n$ and $h = h_1 + \cdots h_n$, so if all g_k and h_k are measurable, so are g and h. Similarly, if f has measurable g and h, and $\alpha > 0$, then αf has measurable αg and αh. In particular, if f is a simple function, then the corresponding g and h are measurable.

For a general f with corresponding functions g and h, let (s_n) be an increasing sequence of simple functions converging pointwise to f, with corresponding functions g_n and h_n. Then, for each $x \in X$, $((s_n)_{[x]})$ is an increasing sequence of $\mathcal{B}$-measurable functions converging pointwise to $f_{[x]}$, so

$$g_n(x) = \int_Y (s_n)_{[x]}\, d\nu \to \int_Y f_{[x]}\, d\nu = g(x)$$

by the Monotone Convergence Theorem, i.e. $g_n \to g$ pointwise. Each g_n is measurable, so g is measurable. Similarly, h is measurable. 👍

The Junior Tonelli Theorem

The next result is called the *Junior Tonelli Theorem* since it is Tonelli's theorem for characteristic or indicator functions. It is a measure-theoretic version of *Cavalieri's Principle*: to find the volume of a solid, integrate the cross-sectional area over the length of the solid (cf. [].)

XVIII.3.1.12. Theorem. [Junior Tonelli Theorem] Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be σ-finite measure spaces, and $C \in \mathcal{A} \otimes \mathcal{B}$. Then $C_x \in \mathcal{B}$ for each $x \in X$, $C^y \in \mathcal{A}$ for all $y \in A$, $g(x) = \nu(C_x)$ is μ-measurable, $h(y) = \mu(C^y)$ is ν-measurable, and

$$(\mu \times \nu)(C) = \int_X \nu(C_x)\, d\mu(x) = \int_Y \mu(C^y)\, d\nu(y)\,.$$

Proof: If $C \in \mathcal{A} \otimes \mathcal{B}$, the first four assertions hold by Lemmas XVIII.3.1.8. and XVIII.3.1.10., so the integrals make sense. For $C \in \mathcal{A} \otimes \mathcal{B}$, define

$$\theta(C) = \int_X \nu(C_x)\, d\mu = \int_X g\, d\mu\ .$$

We show θ is a measure. Obviously $\theta(\emptyset) = 0$. If (C_n) is a sequence of pairwise disjoint sets in $\mathcal{A} \otimes \mathcal{B}$ with union C, then for each $x \in X$, $((C_n)_x)$ is a sequence of pairwise disjoint sets in $\mathcal{B}$, so we have

$$\theta(C) = \theta\left(\bigcup_{n=1}^{\infty} C_n\right) = \int_X \nu\left(\left[\bigcup_{n=1}^{\infty} C_n\right]_x\right) d\mu = \int_X \nu\left(\bigcup_{n=1}^{\infty} (C_n)_x\right) d\mu = \int_X \left[\sum_{n=1}^{\infty} \nu((C_n)_x)\right] d\mu$$

$$= \sum_{n=1}^{\infty} \left[\int_X \nu((C_n)_x)\, d\mu\right] = \sum_{n=1}^{\infty} \theta(C_n)$$

where the interchange of integral and sum is justified by the Monotone Convergence Theorem. So θ is a measure. If $A \times B \in \mathcal{A} \times \mathcal{B}$, then

$$\theta(A \times B) = \int_X \nu((A \times B)_x)\, d\mu = \int_X \nu(B)\chi_A\, d\mu = \mu(A)\nu(B) = (\mu \times \nu)(A \times B)\ .$$

Thus by the uniqueness part of the Extension Theorem in the σ-finite case, $\theta = \mu \times \nu$ on $\mathcal{A} \otimes \mathcal{B}$, and the first equality is proved. The proof that $(\mu \times \nu)(C) = \int_Y \mu(C^y)\, d\nu(y)$ for $C \in \mathcal{A} \otimes \mathcal{B}$ is analogous. 👍

Tonelli's Theorem

Tonelli's Theorem concerns calculating the integral of a nonnegative measurable function over a product space by iterated integrals, and/or interchanging the order of integration in iterated integrals of nonnegative measurable functions.

XVIII.3.1.13. THEOREM. [TONELLI'S THEOREM] Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be σ-finite measure spaces, and f a nonnegative extended real-valued $(\mathcal{A} \otimes \mathcal{B})$-measurable function on $X \times Y$, with marginal functions $f_{[x]}$ and $f^{[y]}$. Then

(i) $f_{[x]}$ is $\mathcal{B}$-measurable for all $x \in X$.

(i′) $f^{[y]}$ is $\mathcal{A}$-measurable for all $y \in Y$.

(ii) g defined by $g(x) = \int_Y f_{[x]}\, d\nu$ is $\mathcal{A}$-measurable.

(ii′) h defined by $h(y) = \int_X f^{[y]}\, d\mu$ is $\mathcal{B}$-measurable.

(iii) We have

$$\int_{X\times Y} f\, d(\mu\times\nu) = \int_X g\, d\mu = \int_X \left[\int_Y f_{[x]}\, d\nu\right] d\mu = \int_X \left[\int_Y f(x,y)\, d\nu(y)\right] d\mu(x)$$
$$= \int_Y h\, d\nu = \int_Y \left[\int_X f^{[y]}\, d\mu\right] d\nu = \int_Y \left[\int_X f(x,y)\, d\mu(x)\right] d\nu(y)\ .$$

In particular, the iterated integrals

$$\int_X \left[\int_Y f(x,y)\, d\nu(y)\right] d\mu(x) = \int_Y \left[\int_X f(x,y)\, d\mu(x)\right] d\nu(y)$$

exist and are equal.

PROOF: We have (i) and (i′) by Lemma XVIII.3.1.9., and (ii) and (ii′) by Lemma XVIII.3.1.11.. For (iii), we bootstrap. If $f = \chi_C$, $C \in \mathcal{A} \otimes \mathcal{B}$, the equalities hold by the Junior Tonelli Theorem XVIII.3.1.12.. It is also clear from the (nonnegative) linearity of integrals that if the equalities hold for $f_1, \ldots, f_n$, and if $\alpha_1, \ldots, \alpha_n \geq 0$, then the equalities hold for $\alpha_1 f_1 + \cdots + \alpha_n f_n$. In particular, they hold if f is a simple function.

Now let f be a general nonnegative $(\mathcal{A}\otimes\mathcal{B})$-measurable function. Let (s_n) be a sequence of simple functions increasing pointwise to f. Then $(s_n)_{[x]}$ increases pointwise to $f_{[x]}$ for all $x \in X$, so by the Monotone Convergence Theorem we have

$$g_n(x) := \int_Y (s_n)_{[x]}\, d\nu \to \int_Y f_{[x]}\, d\nu = g(x)$$

for all $x \in X$, i.e. g_n increases pointwise to g. Thus, by two more applications of the MCT,

$$\int_{X\times Y} f\, d(\mu\times\nu) = \lim_{n\to\infty}\left[\int_{X\times Y} s_n\, d(\mu\times\nu)\right] = \lim_{n\to\infty}\left[\int_Y g_n\, d\mu\right] = \int_Y g\, d\mu$$

and the first equality is proved for f. The proof of the second equality is analogous. 👍

Fubini's Theorem

Fubini's Theorem is analogous to Tonelli's Theorem, but instead of nonnegative measurable functions it deals with integrable functions which are not necessarily nonnegative.

XVIII.3.1.14. THEOREM. [FUBINI'S THEOREM] Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be σ-finite measure spaces, and f a complex-valued $(\mathcal{A} \otimes \mathcal{B})$-measurable function with marginal functions $f_{[x]}$ and $f^{[y]}$ for $x \in X$, $y \in Y$. Assume at least one of the following integrals exists and is finite:

$$\int_{X \times Y} |f| \, d(\mu \times \nu), \quad \int_Y \left[\int_X |f(x,y)| \, d\mu(x) \right] d\nu(y), \quad \int_X \left[\int_Y |f(x,y)| \, d\nu(y) \right] d\mu(x) \ .$$

Then all three integrals exist and are finite and equal, hence f is $(\mu \times \nu)$-integrable, and

(i) $f_{[x]}$ is ν-integrable for μ-almost all $x \in X$.

(i′) $f^{[y]}$ is μ-integrable for ν-almost all $y \in Y$.

(ii) g defined by $g(x) = \int_Y f_{[x]} \, d\nu$ (which is defined μ-a.e.) is equal μ-a.e. to a μ-integrable function.

(ii′) h defined by $h(y) = \int_X f^{[y]} \, d\mu$ (which is defined ν-a.e.) is equal ν-a.e. to a ν-integrable function.

(iii) We have

$$\int_{X \times Y} f \, d(\mu \times \nu) = \int_X g \, d\mu = \int_X \left[\int_Y f_{[x]} \, d\nu \right] d\mu = \int_X \left[\int_Y f(x,y) \, d\nu(y) \right] d\mu(x)$$

$$= \int_Y h \, d\nu = \int_Y \left[\int_X f^{[y]} \, d\mu \right] d\nu = \int_Y \left[\int_X f(x,y) \, d\mu(x) \right] d\nu(y) \ .$$

In particular, the iterated integrals

$$\int_X \left[\int_Y f(x,y) \, d\nu(y) \right] d\mu(x) = \int_Y \left[\int_X f(x,y) \, d\mu(x) \right] d\nu(y)$$

exist and are equal.

PROOF: We prove the theorem for f real-valued; the complex-valued case follows by taking real and imaginary parts.

The first integral in the hypotheses automatically exists, and by Tonelli's Theorem the other two also exist and equal the first one; thus if one is finite, they all are, and are equal. For each $x \in X$, we have that $f_{[x]}$ is $\mathcal{B}$-measurable by Lemma XVIII.3.1.9., and $|f_{[x]}| = |f|_{[x]}$; and since

$$\int_{X \times Y} |f| \, d(\mu \times \nu) = \int_Y \left[\int_X |f|_{[x]} \, d\nu \right] d\mu = \int_Y \left[\int_X |f_{[x]}| \, d\nu \right] d\mu < \infty$$

it follows that

$$\int_X |f_{[x]}| \, d\nu < \infty$$

for almost all x (), i.e. $f_{[x]}$ is ν-integrable for almost all $x \in X$. Similarly, $f^{[y]}$ is μ-integrable for almost all $y \in Y$.

Let f_+ and f_- be the positive and negative parts of f; then $f_+, f_- \leq |f|$, so are $(\mu \times \nu)$-integrable. We have $(f_+)_{[x]} = (f_{[x]})_+$ and $(f_-)_{[x]} = (f_{[x]})_-$ for all $x \in X$, and if

$$g_+(x) = \int_Y (f_+)_{[x]}\, d\nu = \int_Y (f_{[x]})_+\, d\nu$$

$$g_-(x) = \int_Y (f_-)_{[x]}\, d\nu = \int_Y (f_{[x]})_-\, d\nu$$

we have that

$$g_+(x) \leq \bar{g}(x) := \int_Y |f_{[x]}|\, d\nu = \int_Y |f|_{[x]}\, d\nu$$

and since

$$\int_X \bar{g}\, d\mu = \int_{X\times Y} |f|\, d(\mu \times \nu) < \infty$$

by Tonelli's Theorem, g_+ is μ-integrable. Similarly, g_- is μ-integrable. In particular, g_+ and g_- are finite μ-a.e., and if they are both finite at x, then $f_{[x]} = (f_{[x]})_+ - (f_{[x]})_-$ and

$$g(x) = \int_Y f_{[x]}\, d\mu = \int_Y [(f_{[x]})_+ - (f_{[x]})_-]\, d\mu = \int_Y (f_{[x]})_+\, d\mu - \int_Y (f_{[x]})_-\, d\mu = g_+(x) - g_-(x)\ .$$

Thus g is defined μ-a.e. and is equal μ-a.e. to a μ-integrable function (note though that g_+ and g_- are not necessarily the positive and negative parts of g). We also have

$$\int_X g\, d\mu = \int_X g_+\, d\mu - \int_X g_-\, d\mu = \int_X \left[\int_Y (f_+)_{[x]}\, d\nu\right]\, d\mu - \int_X \left[\int_Y (f_-)_{[x]}\, d\nu\right]\, d\mu$$

$$= \int_{X\times Y} f_+\, d(\mu \times \nu) - \int_{X\times Y} f_-\, d(\mu \times \nu) = \int_{X\times Y} f\, d(\mu \times \nu)$$

by Tonelli's Theorem applied to f_+ and f_-. The proof of the second equality is analogous. 👍

Examples where σ-finite hypothesis is necessary

The Complete Case

Extension to Sets of σ-Finite Measure

Fubini-Tonelli

We have the following corollary of the Fubini-Tonelli Theorem, which can be used to justify the usual iterated integrals encountered in vector calculus problems:

XVIII.3.1.15. COROLLARY. Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces, $C \in \mathcal{A} \otimes \mathcal{B}$ of σ-finite measure, and $f : C \to \mathbb{R}$ a function which is either nonnegative and $(\mu \times \nu)$-measurable, or integrable over C (i.e. $f\chi_C$ is integrable over $X \times Y$.) Then

(i) The function $g(x) = \int_{C_x} f(x,y)\, d\nu(y)$ is $\mathcal{A}$-measurable, and is μ-integrable for almost all x if f is $(\mu \times \nu)$-integrable over C. *****FIX

(ii) The function $h(y) = \int_{C^y} f(x,y)\, d\mu(x)$ is $\mathcal{B}$-measurable, and is ν-integrable for almost all x if f is $(\mu \times \nu)$-integrable over C. *****FIX

(iii) We have that

$$\int_C f\, d(\mu \times \nu) = \int_X \left[\int_{C_x} f(x,y)\, d\nu(y) \right] d\mu(x) = \int_Y \left[\int_{C^y} f(x,y)\, d\mu(x) \right] d\nu(y)\,.$$

PROOF: Let $A, M \in \mathcal{A}$, $B, N \in \mathcal{B}$ be as in the proposition. Then

$$\int_C f\, d(\mu \times \nu) = \int_{X \times Y} f\chi_C\, d(\mu \times \nu) = \int_{A \times B} f\chi_C\, d(\mu \times \nu)$$

(since $f\chi_C = f\chi_C\chi_{A\times B}$ a.e.) Then, by the Fubini-Tonelli Theorem applied to $f\chi_C$ on $A \times B$, $g_0(x) = \int_B f(x,y)\chi_C(x,y)\, d\nu(y) = \int_{B\cap C_x} f(x,y)\, d\nu(y)$ is $\mathcal{A}$-measurable, and integrable for almost all x if f is integrable. Since $C_x \setminus B \subseteq N$, we have $g_0(x) = \int_{C_x} f(x,y)\, d\nu(y)$, i.e. $g(x) = g_0(x)$ for $x \in A$. Also, $g(x) = 0$ for $x \notin A \cup M$ since $C_x \subseteq N$, so $g(x) = 0$ a.e. on $X \setminus A$. Then, by Fubini-Tonelli on $A \times B$,

$$\int_{A\times B} f\chi_C\, d(\mu \times \nu) = \int_A \left[\int_B f(x,y)\chi_C(x,y)\, d\nu(y) \right] d\mu(x)$$

$$= \int_A \left[\int_B f(x,y)\chi_{C_x}(x,y)\, d\nu(y) \right] d\mu(x) = \int_A \left[\int_{C_x} f(x,y)\, d\nu(y) \right] d\mu(x)$$

$$= \int_A \left[\int_{C_x} f(x,y)\, d\nu(y) \right] d\mu(x) + \int_M \left[\int_{C_x} f(x,y)\, d\nu(y) \right] d\mu(x) +$$

$$+ \int_{X\setminus(A\cup M)} \left[\int_{C_x} f(x,y)\, d\nu(y) \right] d\mu(x) = \int_X \left[\int_{C_x} f(x,y)\, d\nu(y) \right] d\mu(x)$$

since $\mu(M) = 0$ and $\nu(C_x) = 0$ for $x \notin A \cup M$. The proof for the iterated integral in the opposite order is nearly identical. 👍

XVIII.3.1.16. As a sample application, suppose C is a region in $\mathbb{R}^2$ of the form

$$\{(x,y) : g(x) \le y \le h(x), a \le x \le b\}$$

where g, h are continuous functions with $g(x) \le h(x)$ for $a \le x \le b$, and suppose f is a Lebesgue measurable function from C to $\mathbb{R}$ which is either nonnegative or integrable over C (e.g. a continuous function.) Then $C_x = [g(x), h(x)]$ for each $x \in [a,b]$, and so

$$\int_C f\, d\lambda^{(2)} = \int_{[a,b]} \left[\int_{[g(x),h(x)]} f(x,y)\, d\lambda(y) \right] d\lambda(x) = \int_a^b \left[\int_{g(x)}^{h(x)} f(x,y)\, dy \right] dx\,.$$

XVIII.3.2. Lebesgue Integration on $\mathbb{R}^n$

XVIII.3.3. Exercises

XVIII.3.3.1. Another Nonmeasurable Set. [?] Assume the Continuum Hypothesis, and let $\precsim$ be a well-ordering on $[0,1]$ according to the first uncountable ordinal, i.e. such that the set of predecessors of any element is countable. Set

$$E = \{(x,y) \in [0,1]^2 : x \precsim y\} \ .$$

(a) For fixed $y \in [0,1]$, the set $E^y = \{x \in [0,1] : x \precsim y\}$ is countable, hence Lebesgue measurable, and $\lambda(E^y) = 0$. Thus, if E is Lebesgue measurable, by the Junior Tonelli Theorem (XVIII.3.1.12.)

$$\lambda^{(2)}(E) = \int_0^1 \lambda(E^y)\, d\lambda(y) = 0 \ .$$

(b) For fixed $x \in [0,1]$, the set $E_x = \{y \in [0,1] : x \precsim y\}$ is cocountable, hence Lebesgue measurable, and $\lambda(E_x) = 1$. Thus, if E is Lebesgue measurable, by the Junior Tonelli Theorem

$$\lambda^{(2)}(E) = \int_0^1 \lambda(E_x)\, d\lambda(x) = 1 \ .$$

(c) Conclude that E is not a Lebesgue measurable subset of $[0,1]^2$.

This suggests why the CH cannot be proved in ZF: there can be no "measurable" bijection from $\mathbb{R}$ to ω_1.

XVIII.3.3.2. [?] Let X be the set of ordinals less than the first uncountable ordinal, $\mathcal{A}$ the σ-algebra of countable-cocountable subsets of X, and μ the measure on $(X,\mathcal{A})$ with $\mu(A) = 0$ if A is countable and $\mu(A) = 1$ if A is cocountable. Let $E = \{(\alpha,\beta) : \alpha \leq \beta\} \subseteq X \times X$.

(a) Show that the iterated integrals

$$\int_X \int_X \chi_E(\alpha,\beta)\, d\mu(\alpha)\, d\mu(\beta) \text{ and } \int_X \int_X \chi_E(\alpha,\beta)\, d\mu(\beta)\, d\mu(\alpha)$$

both exist but are not equal.

(b) Conclude that E is not $(\mathcal{A}\bar{\otimes}\mathcal{A})$-measurable, i.e. χ_E is not $\overline{(\mu \times \mu)}$-integrable. (It is not hard to see directly that $E \notin \mathcal{A} \otimes \mathcal{A}$.)

This is a variation of XVIII.3.3.1. which does not use the Continuum Hypothesis or the AC.

XVIII.3.3.3. (a) Let $f : \mathbb{R} \to \mathbb{R}$ be a function such that the graph $\Gamma(f)$ is a Lebesgue measurable subset of $\mathbb{R}^2$. Show that $\lambda^{(2)}(\Gamma(f)) = 0$. [Use the Junior Tonelli Theorem ().]

(b) Characterize the functions whose graphs are Lebesgue measurable.

(c) Generalize to functions from $\mathbb{R}^n$ to $\mathbb{R}^m$, and between more general measure spaces.

Note that if f is continuous, there is an elementary proof (IX.3.2.17.). Compare also with **??**.

XVIII.3.3.4. Fubini's Theorem for Signed and Complex Measures. (a) Let μ and ν be finite signed measures on measurable spaces $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ respectively. If $\mu \times \nu$ is defined as in XVII.9.5.7., show that the statement of Fubini's Theorem (XVIII.3.1.14.) remains valid if "σ-finite" is replaced by "finite signed."

(b) Let μ and ν be complex measures on measurable spaces $(X, \mathcal{A})$ and $(Y, \mathcal{B})$ respectively. If $\mu \times \nu$ is defined as in XVII.9.5.8., show that the statement of Fubini's Theorem remains valid if "σ-finite" is replaced by "complex."

XVIII.4. The Henstock-Kurzweil Integral

The Henstock-Kurzweil (HK) integral on $\mathbb{R}$ is a beautiful and rather simple extension of the Riemann integral. The only modification which needs to be made is to consider a more general and flexible notion of "fineness" of a partition than its mesh. Once some preliminary technicalities are handled, the theory proceeds essentially identically to the Riemann integral case. One ends up with an integral which not only extends the Riemann integral, but even (slightly) the Lebesgue integral, with nice properties such as an unrestricted Fundamental Theorem of Calculus.

XVIII.4.1. Definition and Basic Properties

Recall the definition of gauges and fine partitions ().

XVIII.4.1.1. DEFINITION. Let $[a,b]$ be a closed bounded interval and $f : [a,b] \to \mathbb{R}$ a function. Then f is *HK-integrable* on $[a,b]$, with integral I, if for every $\epsilon > 0$ there is a gauge δ on I such that $|\mathcal{R}(f,\dot{\mathcal{P}}) - I| < \epsilon$ for every δ-fine partition $\dot{\mathcal{P}}$ of $[a,b]$.

It is obvious that the integral I is unique if it exists.

We first observe that the HK-integral extends the Riemann integral:

XVIII.4.1.2. PROPOSITION. Let $f : [a,b] \to \mathbb{R}$ be Riemann integrable on $[a,b]$. Then f is HK-integrable on $[a,b]$, with integral $I = \displaystyle\int_a^b f(t)\,dt$.

PROOF: Let $\epsilon > 0$, and choose $\delta > 0$ such that whenever $\dot{\mathcal{P}}$ is a tagged partition with $\|\mathcal{P}\| < \delta$, we have $|\mathcal{R}(f,\dot{\mathcal{P}}) - I| < \delta$. Then the constant gauge δ works in the definition of HK-integration. 👍

XVIII.4.1.3. Thus we may justifiably use the notation $\displaystyle\int_a^b f(t)\,dt$ for the HK-integral of an HK-integrable function.

Conversely, if we can always choose a constant gauge for any ϵ, then f is Riemann integrable. Since there are many nonconstant gauges with varying properties which can be used in the definition of HK-integration, it is much easier to satisfy the HK definition for a given f and one might expect that many more functions are HK-integrable. The next result illustrates this dramatically:

XVIII.4.1.4. THEOREM. Let $[a,b]$ be a closed bounded interval, and A a Lebesgue measurable subset of $[a,b]$. Then χ_A is HK-integrable over $[a,b]$ with integral $\lambda(A)$.

PROOF: Set $B = [a,b] \setminus A$. Let $\epsilon > 0$. There is a sequence (I_n) of open intervals such that $A \subseteq \cup_n I_n$ and $\sum_n \ell(I_n) < \lambda(A) + \epsilon$, and a sequence (J_n) of open intervals such that $B \subseteq \cup_n J_n$ and $\sum_n \ell(J_n) < \lambda(B) + \epsilon$. If $t \in A$, choose an n (say, the smallest n) for which $t \in I_n$, and set $\delta(t)$ equal to the distance from t to I_n^c, and similarly if $t \in B$ choose an n for which $t \in J_n$ and set $\delta(t)$ equal to the distance from t to J_n^c. Then δ is a gauge on $[a,b]$.

Let $\dot{\mathcal{P}} = \{a = x_0, \ldots, x_m = b; t_1, \ldots, t_m\}$ be a δ-fine partition of $[a, b]$. Then each t_k is either in A or B. Let N_1 be the set of k for which $t_k \in A$, and N_2 the set of k for which $t_k \in B$. For each $k \in N_1$, the interval (x_{k-1}, x_k) is contained in I_n for some n; thus we have

$$\sum_{k \in N_1} \ell([x_{k-1}, x_k]) \leq \sum_n \ell(I_n) < \lambda(A) + \epsilon \ .$$

Similarly, we have

$$\sum_{k \in N_2} \ell([x_{k-1}, x_k]) \leq \sum_n \ell(J_n) < \lambda(B) + \epsilon = (b - a) - [\lambda(A) - \epsilon] \ .$$

Since

$$\sum_{k \in N_1} \ell([x_{k-1}, x_k]) + \sum_{k \in N_2} \ell([x_{k-1}, x_k]) = \sum_{k=1}^{m} \ell([x_{k-1}, x_k]) = b - a$$

we have

$$\lambda(A) - \epsilon < \mathcal{R}(\chi_A, \dot{\mathcal{P}}) = \sum_{k \in N_1} \ell([x_{k-1}, x_k]) < \lambda(A) + \epsilon \ .$$

XVIII.4.1.5. Unbounded functions cannot be Riemann integrable, but they can be HK-integrable because gauges can be made to force certain points to be tags. See XVIII.4.2.4. for examples.

XVIII.4.2. The Fundamental Theorem of Calculus

The following version of the Fundamental Theorem of Calculus is one of the most attractive features of HK-integration. It fails for Riemann integration () and even for Lebesgue integration (). The proof is quite simple but uses a clever choice of gauge.

XVIII.4.2.1. Theorem. [Fundamental Theorem of Calculus, HK Version] Let $[a, b]$ be a closed bounded interval, and f a differentiable function on $[a, b]$. Then f' is HK-integrable on $[a, b]$ and

$$\int_a^b f'(t)\, dt = f(b) - f(a) \ .$$

Proof: Let $\epsilon > 0$. For each $t \in [a, b]$ there is a $\delta(t) > 0$ such that

$$\left| \frac{f(x) - f(t)}{x - t} - f'(t) \right| < \frac{\epsilon}{b - a}$$

whenever $x \in [a, b]$, $0 < |x - t| < \delta(t)$. Then δ is a gauge on $[a, b]$.
Let $\dot{\mathcal{P}} = \{a = x_0, \ldots, x_n = b; t_1, \ldots, t_n\}$ be a δ-fine partition of $[a, b]$. For each k, since $x_{k-1} \leq t_k \leq x_k$ we have

$$|f(x_k) - f(x_{k-1}) - f'(t_k)(x_k - x_{k-1})| = |f(x_k) - f(t_k) - f'(t_k)(x_k - t_k) + f(t_k) - f(x_{k-1}) - f'(t_k)(t_k - x_{k-1})|$$

$$\leq |f(x_k) - f(t_k) - f'(t_k)(x_k - t_k)| + |f(t_k) - f(x_{k-1}) - f'(t_k)(t_k - x_{k-1})|$$
$$< \frac{\epsilon}{b-a}(x_k - t_k) + \frac{\epsilon}{b-a}(t_k - x_{k-1}) = \frac{\epsilon}{b-a}(x_k - x_{k-1})$$

since $x_k - t_k, t_k - x_{k-1} < \delta(t_k)$, and thus

$$|f(b) - f(a) - \mathcal{R}(f', \dot{\mathcal{P}})| = \left|\sum_{k=1}^{n}[f(x_k) - f(x_{k-1}) - f'(t_k)(x_k - x_{k-1})]\right|$$

$$\leq \sum_{k=1}^{n} |f(x_k) - f(x_{k-1}) - f'(t_k)(x_k - x_{k-1})| \leq \sum_{k=1}^{n} \frac{\epsilon}{b-a}(x_k - x_{k-1}) = \frac{\epsilon}{b-a}(b-a) = \epsilon \ .$$

We can extend this result to the case where f is not quite differentiable everywhere:

XVIII.4.2.2. THEOREM. [FUNDAMENTAL THEOREM OF CALCULUS, GENERAL HK VERSION] Let $[a, b]$ be a closed bounded interval, and f a continuous function on $[a, b]$ which is differentiable except at countably many points. If g is a function on $[a, b]$ which equals f' a.e. on $[a, b]$, then g is HK-integrable on $[a, b]$ and

$$\int_a^b g(t)\, dt = f(b) - f(a) \ .$$

XVIII.4.2.3. In XVIII.4.2.2., we cannot relax the hypothesis that f be differentiable except at countably many points to simply require that f be differentiable almost everywhere. If g is a nonnegative measurable function on $[a, b]$ which is not Lebesgue integrable on $[a, b]$, hence not HK-integrable on $[a, b]$ (), there is a continuous and a.e. differentiable function f on $[a, b]$ with $f' = g$ a.e. (XIX.5.2.26.).

XVIII.4.2.4. EXAMPLES. (i) Let $f(x) = x^2 \sin \frac{1}{x^2}$ (with $f(0) = 0$). Then f is differentiable everywhere, and

$$f'(x) = 2x \sin \frac{1}{x^2} - \frac{2}{x} \cos \frac{1}{x^2}$$

($f'(0) = 0$). But f' is not Lebesgue integrable on any interval containing 0; however, it is HK-integrable on any (closed bounded) interval. This is an example of an unbounded function which is HK-integrable.

(ii) For a simpler example, $f(x) = 2\sqrt{x}$ is continuous on $[0, 1]$ and differentiable except at 0. Then $f'(x) = x^{-1/2}$ is HK-integrable on $[0, 1]$ even though it is unbounded. We have

$$\int_0^1 t^{-1/2}\, dt = 2\sqrt{1} - 2\sqrt{0} = 2$$

i.e. the HK-integral equals the improper Riemann integral. This holds generally ().

XVIII.5. Convolution

The operation of convolution of functions is valuable in a great many contexts. It is a "multiplication" of functions quite different from ordinary pointwise product, which bears some resemblance to matrix multiplication.

An informal motivation for the operation of convolution comes from multiplying series. We give a completely heuristic version which ignores all questions of convergence. Suppose

$$\sum_{k=-\infty}^{\infty} a_k x^k \quad \text{and} \quad \sum_{k=-\infty}^{\infty} b_k x^k$$

are two-way infinite summations. We want to "multiply" these to get a new two-way infinite summation

$$\left[\sum_{k=-\infty}^{\infty} a_k x^k\right]\left[\sum_{k=-\infty}^{\infty} b_k x^k\right] = \sum_{k=-\infty}^{\infty} c_k x^k$$

and the "formula" for c_k is obtained by formally multiplying the two expressions and collecting together like powers of x to obtain

$$c_k = \sum_{i+j=k} a_j b_i = \sum_{j=-\infty}^{\infty} a_j b_{k-j} \ .$$

Such a computation is meaningless as done informally here, but with suitable tweaking and interpretation becomes meaningful and useful.

We will not trace the full convoluted history of the development of this subject here.

XVIII.5.1. Convolution of Functions on $\mathbb{R}$, Continuous Case

In this subsection, we will discuss properties of convolution which do not require a knowledge of Lebesgue integration; all integrals in this subsection will be Riemann integrals or improper Riemann integrals. We will consider only continuous functions, and mostly only functions with *compact support*, i.e. functions which vanish (are identically zero) outside a bounded interval.

XVIII.5.1.1. Definition. Let f and g be continuous functions from $\mathbb{R}$ to $\mathbb{R}$. Suppose for every $x \in \mathbb{R}$ the integral

$$\int_{-\infty}^{+\infty} f(y)g(x-y)\,dy = \int_{\mathbb{R}} f(y)g(x-y)\,dy$$

exists as an improper Riemann integral and is finite. The function $f * g : \mathbb{R} \to \mathbb{R}$ defined by

$$(f*g)(x) = \int_{-\infty}^{+\infty} f(y)g(x-y)\,dy$$

is called the *convolution* of f and g.

XVIII.5.1.2. PROPOSITION. Let f and g be continuous functions on $\mathbb{R}$. If $f * g$ is defined, then $g * f$ is also defined and $g * f = f * g$.

PROOF: Fix $x \in \mathbb{R}$. Then

$$(f * g)(x) = \int_{-\infty}^{+\infty} f(y)g(x-y)\,dy = \lim_{a\to-\infty, b\to+\infty} \int_a^b f(y)g(x-y)\,dy\ .$$

Make the change of variable $z = x - y$. Then, for $a, b \in \mathbb{R}$,

$$\int_a^b f(y)g(x-y)\,dy = \int_{x-a}^{x-b} f(x-z)g(z)\,(-1)dz = \int_{x-b}^{x-a} f(x-z)g(z)\,dz$$

and since $c = x - b \to -\infty$ and $d = x - a \to +\infty$ as $a \to -\infty$ and $b \to +\infty$, we have that

$$\int_{-\infty}^{+\infty} g(z)f(x-z)\,dz = \lim_{c\to-\infty, d\to+\infty} \int_c^d g(z)f(x-z)\,dz = \lim_{a\to-\infty, b\to+\infty} \int_a^b f(y)g(x-y)\,dy$$

exists as an improper Riemann integral and equals $(f * g)(x)$. 👍

XVIII.5.1.3. One can be fooled into thinking that $g * f = -f * g$ since the substitution $z = x - y$ introduces a minus sign into the integrand. But the direction of integration is also reversed, canceling the negation. It is more straightforward to use the change-of-variables formula (); cf. (). To see that $g * f$ must be $+f * g$ and not $-f * g$, consider the case where f and g are nonnegative; then $f * g$ and $g * f$ are also nonnegative.

The Compact Support Case

XVIII.5.1.4. Suppose f and g are continuous functions, and f has compact support. Then $f * g$ is defined. For if f vanishes outside $[a, b]$, then for each x we have

$$(f * g)(x) = \int_{-\infty}^{+\infty} f(y)g(x-y)\,dy = \int_a^b f(y)g(x-y)\,dy$$

as an ordinary Riemann integral. The convolution $g * f$ is also defined by XVIII.5.1.2.. So for existence of the convolution it suffices that one of the functions have compact support.

Continuity of the Convolution

To discuss continuity of $f * g$, we need the following fact:

XVIII.5.1.5. PROPOSITION. Let f be a continuous function on $\mathbb{R}$. For $x \in \mathbb{R}$, define $f_x(y) = f(x + y)$. If $x_n \to x$ in $\mathbb{R}$, then $f_{x_n} \to f_x$ u.c.

PROOF: Let $\epsilon > 0$, and $[a, b]$ a bounded interval in $\mathbb{R}$. Since f is uniformly continuous on bounded intervals (), there is a $\delta > 0$ such that if $y, z \in [a + x - 1, b + x + 1]$ and $|y - z| < \delta$, then $|f(y) - f(z)| < \epsilon$. Fix N such that $|x_n - x| < \min(\delta, 1)$ for all $n \geq N$. Then, if $y \in [a, b]$ and $n \geq N$, we have

$$|f_{x_n}(y) - f_x(y)| = |f(x_n + y) - f(x + y)| < \epsilon\ .$$

👍

XVIII.5.1.6. PROPOSITION. Let f and g be continuous functions, with f of compact support. Then $f * g$ is continuous.

PROOF: Let $x_n \to x$ in $\mathbb{R}$. Set $h_n(y) = f(y)g(x_n - y) = f(y)g_{x_n}(-y)$ and $h(y) = f(y)g(x-y) = f(y)g_x(-y)$. Since $g_{x_n} \to g_x$ u.c. by XVIII.5.1.5. and f has compact support, $h_n \to h$ uniformly on $\mathbb{R}$; and the h_n and h all vanish outside a finite interval $[a, b]$ (the support of f). Thus

$$(f * g)(x_n) = \int_{-\infty}^{+\infty} f(y)g(x_n - y)\,dy = \int_a^b h_n(y)\,dy \to \int_a^b h(y)\,dy = \int_{-\infty}^{+\infty} f(y)g(x-y)\,dy = (f * g)(x)$$

so $f * g$ is continuous by the Sequential Criterion. 👍

XVIII.5.1.7. PROPOSITION. Let f and g be continuous functions of compact support contained in $[a, b]$ and $[c, d]$ respectively. Then $f * g$ has compact support contained in $[a + c, b + d]$.

PROOF: If $x < a + c$, then for every y either $y < a$ or $x - y < c$, so $f(y)g(x - y) = 0$ for all y, and similarly for $x > b + d$. 👍

Differentiability of the Convolution

The convolution of two functions f and g has the pleasant property of being least as smooth as the smoother of f and g. We next show the continuous version of this principle.

XVIII.5.1.8. THEOREM. Let f be a continuous function and g a $\mathcal{C}^r$ function on $\mathbb{R}$ $(0 \le r \le \infty)$. Suppose either f or g has compact support. Then $f * g$ is $\mathcal{C}^r$, and $(f * g)^{(k)} = f * (g^{(k)})$ for $1 \le k \le r$.

PROOF: The case $r = 0$ is XVIII.5.1.6.. Suppose g is $\mathcal{C}^1$. Then the support of g' is contained in the support of g, so $f * (g')$ is defined.

Set $H(x, y) = f(y)g(x - y)$. Then $\frac{\partial H}{\partial x}(x, y) = f(y)g'(x - y)$, which is continuous by assumption.

If f has compact support contained in $[a, b]$, then by () we have

$$(f * g)'(x) = \frac{d}{dx}\left(\int_{-\infty}^{+\infty} f(y)g(x-y)\,dy\right)(x) = \frac{d}{dx}\left(\int_a^b H(x, y)\,dy\right)(x)$$

$$= \int_a^b \frac{\partial H}{\partial x}(x, y)\,dy = \int_{-\infty}^{+\infty} f(y)g'(x-y)\,dy = (f * (g'))(x)\ .$$

The argument if g has compact support is similar, but slightly more complicated. Suppose the support of g is contained in $[a, b]$. Fix x_0, and fix an interval $[c, d]$ with $x_0 \in (c, d)$. Then, restricting x to $[c, d]$,

$$(f * g)'(x_0) = \frac{d}{dx}\left(\int_{-\infty}^{+\infty} f(y)g(x-y)\,dy\right)(x_0) = \frac{d}{dx}\left(\int_{c-b}^{d-a} H(x, y)\,dy\right)(x_0)$$

$$= \int_{c-b}^{d-a} \frac{\partial H}{\partial x}(x_0, y)\,dy = \int_{-\infty}^{+\infty} f(y)g'(x_0 - y)\,dy = (f * (g'))(x_0)\ .$$

This proves the result for $r = 1$. For larger r apply the $r = 1$ case inductively to f and $g^{(k)}$. 👍

XVIII.5.1.9. Of course, by XVIII.5.1.2., the result also holds if f is $\mathcal{C}^r$, g is continuous, and at least one has compact support; in this case $(f * g)^{(k)} = (f^{(k)}) * g$. If f and g are both $\mathcal{C}^1$, and at least one has compact support, then $(f') * g = f * (g')$. If f and g are $\mathcal{C}^2$, then $(f'') * g = (f') * (g') = f * (g'')$, etc.

In fact, we have:

XVIII.5.1.10. Corollary. Let f be a $\mathcal{C}^r$ function and g a $\mathcal{C}^s$ function on $\mathbb{R}$ $(0 \leq r, s < \infty)$. Suppose either f or g has compact support. Then $f * g$ is $\mathcal{C}^{r+s}$, and $(f * g)^{(r+s)} = (f^{(r)}) * (g^{(s)})$.

Proof: The convolution $f * g$ is $\mathcal{C}^r$ and $(f * g)^{(r)} = (f^{(r)}) * g$; and $(f^{(r)}) * g$ is $\mathcal{C}^s$ with $[(f^{(r)}) * g]^{(s)} = (f^{(r)}) * (g^{(s)})$. 👍

Convolutions on Intervals

XVIII.5.1.11. If f has compact support contained in $[a, b]$, and g is any continuous function on $\mathbb{R}$, then for any interval $[c, d]$ the values of $f * g$ on $[c, d]$ depend only on the values of g on the interval $[c - b, d - a]$. This leads to two important observations:

(1) The function g can be modified arbitrarily outside the interval $[c - b, d - a]$ without affecting the values of $f * g$ on $[c, d]$. In particular, there is a continuous function h of compact support agreeing with g on an arbitrarily large interval such that $f * h$ agrees with $f * g$ on $[c, d]$. This observation is useful in studying local properties of $f * g$; in particular, it can be used to give an alternate proof of the "harder" half of XVIII.5.1.8..

(2) If g is any continuous function on $[c - b, d - a]$, then we can define the convolution of f and g as a function on the interval $[c, d]$.

Algebraic Properties of Convolution

Convolution satisfies all the algebraic properties of a reasonable "multiplication". We have already established the commutative property $f * g = g * f$ (XVIII.5.1.2.). Another simple property whose proof is left to the reader (Exercise ()) is the distributive or bilinear property:

XVIII.5.1.12. Proposition. Let f_1, f_2, g be continuous functions on $\mathbb{R}$, and $\alpha \in \mathbb{R}$.

(i) If $f_1 * g$ and $f_2 * g$ are defined, then $(f_1 + f_2) * g$ is defined and $(f_1 + f_2) * g = f_1 * g + f_2 * g$.

(ii) If $f_1 * g$ is defined, then $(\alpha f_1) * g$ is defined and $(\alpha f_1) * g = \alpha(f_1 * g)$.

In other words, for fixed g, convolution $f * g$ is linear in f. Of course, by commutativity, $f * g$ is also linear in g for fixed f. Thus convolution is *bilinear*.

The other important algebraic property, associativity, also holds; the proof requires Fubini's Theorem for vector calculus ().

XVIII.5.1.13. PROPOSITION. Let f, g, h be continuous functions on $\mathbb{R}$. Suppose at least two of the functions have compact support. Then $(f * g) * h = f * (g * h)$.

PROOF: If $x_0 \in \mathbb{R}$, then the function which does not have compact support can be replaced by a function of compact support without changing either $(f*g)*h$ or $f*(g*h)$ in an interval around x_0, by two applications of XVIII.5.1.11.(1). Thus to prove the result we may assume all three functions have compact support. We have

$$[(f * g) * h](x_0) = \int_{-\infty}^{+\infty} \left[\int_{-\infty}^{+\infty} f(z)g(y - z)\, dz \right] h(x_0 - y)\, dy$$

$$[f * (g * h)](x_0) = \int_{-\infty}^{+\infty} f(z) \left[\int_{-\infty}^{+\infty} g(y)h(x_0 - z - y)\, dy \right] dz$$

where the integrals are actually over a sufficiently large bounded region (rectangle) in $\mathbb{R}^2$. By Fubini's Theorem () the integrals are equal to the double integrals

$$\iint_{\mathbb{R}^2} f(z)g(y - z)h(x_0 - y)\, dy\, dz$$

$$\iint_{\mathbb{R}^2} f(z)g(y)h(x_0 - z - y)\, dy\, dz$$

respectively, where the integrals are again really over a sufficiently large bounded region.

Make the change of variables $\phi(u, v) = (u + v, v)$. Writing $y = u + v$, $z = v$, we have $x_0 - y = x_0 - u - v$ and $y - z = u$. We have $\Delta_\phi(u, v) \equiv 1$, so by the change-of-variables formula for double integrals () we have

$$\iint_{\mathbb{R}^2} f(z)g(y-z)h(x_0-y)\, dy\, dz = \iint_{\mathbb{R}^2} f(v)g(u)h(x_0-u-v)|\Delta_\phi(u, v)|\, du\, dv = \iint_{\mathbb{R}^2} f(v)g(u)h(x_0-u-v)\, du\, dv$$

(where the integrals are over large bounded regions), so the double integrals are equal. 👍

Integrable Functions

We can give various other conditions insuring the existence of the convolution. If neither function has compact support, then in general restrictions on both functions are necessary.

XVIII.5.1.14. DEFINITION. Let $f : \mathbb{R} \to \mathbb{R}$ be a continuous function. Then f is *integrable* (over $\mathbb{R}$) if

$$\|f\|_1 := \int_{-\infty}^{+\infty} |f(x)|\, dx < \infty$$

(i.e. the improper integral converges).

XVIII.5.1.15. The set $CL^1(\mathbb{R})$ of integrable continuous functions on $\mathbb{R}$ is a real vector space, and $\|\cdot\|_1$ is a norm () on $CL^1(\mathbb{R})$. Every continuous function of compact support is in $CL^1(\mathbb{R})$, but $CL^1(\mathbb{R})$ is much larger than the set $C_c(\mathbb{R})$ of continuous functions of compact support: for example, an integrable continuous function need not even be bounded (Example XVIII.5.1.19.). The set $BCL^1(\mathbb{R})$ of bounded continuous integrable functions on $\mathbb{R}$ is a vector space properly between $C_c(\mathbb{R})$ and $CL^1(\mathbb{R})$.

XVIII.5.1.16. PROPOSITION. Let f and g be continuous functions on $\mathbb{R}$, with f integrable and g bounded. Then $f * g$ is defined and bounded, and $\|f * g\|_\infty \leq \|f\|_1 \|g\|_\infty$.

PROOF: We have that, for each x,

$$\int_{-\infty}^{+\infty} |f(x-y)g(y)|\,dy \leq \int_{-\infty}^{+\infty} |f(x-y)|\|g\|_\infty\,dy = \|g\|_\infty \int_{-\infty}^{+\infty} |f(x-y)|\,dy = \|f\|_1\|g\|_\infty$$

so by () the improper integral

$$\int_{-\infty}^{+\infty} f(x-y)g(y)\,dy$$

converges and

$$|(f*g)(x)| = \left|\int_{-\infty}^{+\infty} f(x-y)g(y)\,dy\right| \leq \int_{-\infty}^{+\infty} |f(x-y)g(y)|\,dy \leq \|f\|_1\|g\|_\infty \ .$$

👍

XVIII.5.1.17. PROPOSITION. Let f and g be continuous functions on $\mathbb{R}$, with f integrable and g bounded (or vice versa). Then $f * g$ is continuous.

PROOF: Let (f_n) be a sequence of continuous functions of compact support with $\|f_n - f\|_1 \to 0$ (). Then

$$\|f_n * g - f * g\|_\infty = \|(f_n - f) * g\|_\infty \leq \|f_n - f\|_1\|g\|_\infty \to 0$$

so $f_n * g \to f * g$ uniformly. By XVIII.5.1.6., each $f_n * g$ is continuous; hence $f * g$ is continuous by (). 👍

XVIII.5.1.18. PROPOSITION. Let f and g be integrable continuous functions on $\mathbb{R}$, with at least one of f and g bounded. Then $f * g$ is defined and in $BCL^1(\mathbb{R})$, and

$$\|f * g\|_1 \leq \|f\|_1\|g\|_1 \ .$$

PROOF: By XVIII.5.1.16. and XVIII.5.1.17., $f * g$ is defined, and is bounded and continuous. To show it is integrable, consider the integral

$$\iint_{\mathbb{R}^2} |f(y)||g(x-y)|\,dx\,dy \ .$$

We can change variables in this integral using $\phi : \mathbb{R}^2 \to \mathbb{R}^2$ defined by $\phi(z,y) = (z+y, y)$. Then $x = z + y$, $z = x - y$, and we have $\Delta_\phi(z,y) \equiv 1$, so

$$\iint_{\mathbb{R}^2} |f(y)||g(x-y)|\,dx\,dy = \iint_{\mathbb{R}^2} |f(y)||g(z)||\Delta_\phi(z,y)|\,dz\,dy = \iint_{\mathbb{R}^2} |f(y)||g(z)|\,dz\,dy \ .$$

By the Fubini-Tonelli Theorem () this integral can be computed as an iterated integral

$$\int_{\mathbb{R}}\int_{\mathbb{R}} |f(y)||g(z)|\,dz\,dy = \int_{\mathbb{R}} |f(y)| \left[\int_{\mathbb{R}} |g(z)|\,dz\right] dy = \left[\int_{\mathbb{R}} |f(y)|\,dy\right]\left[\int_{\mathbb{R}} |g(z)|\,dz\right] = \|f\|_1\|g\|_1 \ .$$

👍

XVIII.5.1.19. EXAMPLE. Here is an example showing that the boundedness hypothesis in XVIII.5.1.18. cannot be deleted. Define a nonnegative continuous function f on $\mathbb{R}$ as follows:

$$f(x) = \begin{cases} 0 & \text{if} \quad x \in \left[0, \frac{15}{8}\right] \\ n & \text{if} \quad x \in \left[n - \frac{1}{2n^3}, n + \frac{1}{2n^3}\right], n \geq 2 \\ \text{linear} & \text{if} \quad x \in \left[n - \frac{1}{n^3}, n - \frac{1}{2n^3}\right], n \geq 2 \\ \text{linear} & \text{if} \quad x \in \left[n + \frac{1}{2n^3}, n + \frac{1}{n^3}\right], n \geq 2 \\ 0 & \text{if} \quad x \in \left[n + \frac{1}{n^3}, n + 1 - \frac{1}{(n+1)^3}\right], n \geq 2 \\ f(-x) & \text{if} \quad x < 0 \end{cases} .$$

The graph of f is identically 0 except for small "blunt spikes" around integers; see Figure (). We have

$$\int_{-\infty}^{+\infty} f(x)\, dx < \infty$$

$$\int_{-\infty}^{+\infty} [f(x)]^2\, dx = \infty$$

i.e. f is integrable but not square-integrable.

Consider $f * f$. We have

$$\int_{-\infty}^{+\infty} f(y) f(-y)\, dy = \int_{-\infty}^{+\infty} [f(y)]^2\, dy = \infty$$

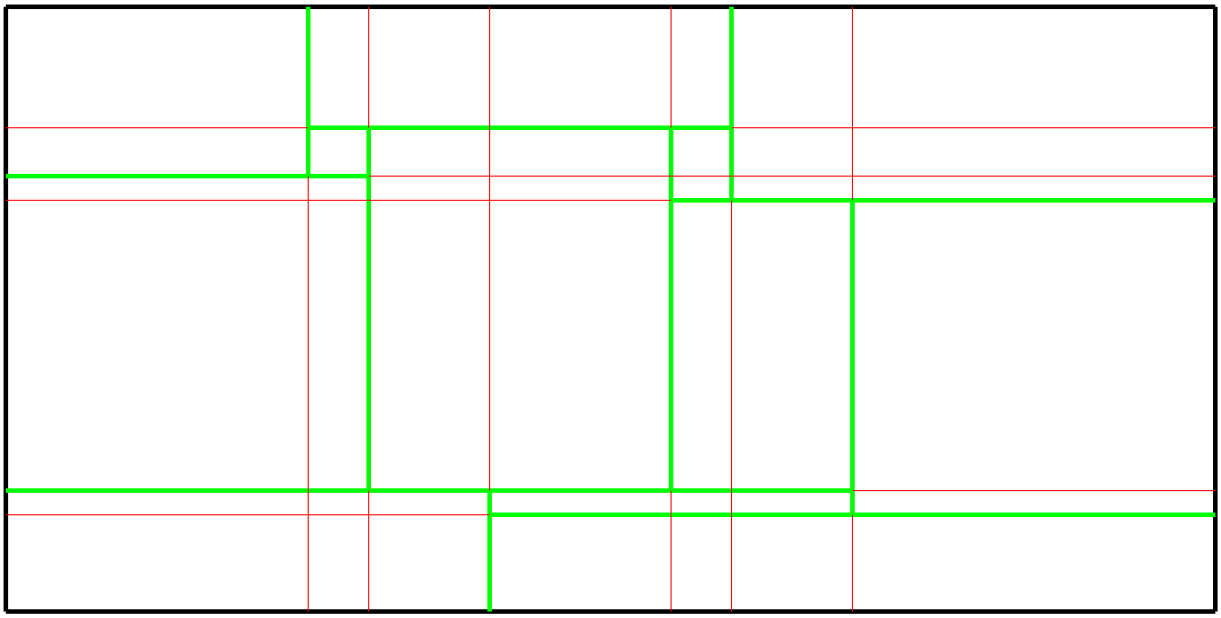
so $f * f(0)$ is not defined. In fact, $f * f(x)$ is defined if and only if x is not an integer.

XVIII.5.1.20. It turns out that using Lebesgue measure and integration we can still make a reasonable definition of the convolution $f * f$ of XVIII.5.1.19. (or of any two integrable functions), but the convolution is not continuous and only defined "almost everywhere." This is in fact one of the historical motivations for developing a more general theory of measure and integration. See section ().

XVIII.5.1.21. Thus convolution gives a binary operation of $BCL^1(\mathbb{R})$. Convolution on $BCL^1(\mathbb{R})$ retains nice algebraic properties: associativity (), commutativity (XVIII.5.1.2.), and bilinearity ().

XVIII.5.1.22. Using Hölder's inequality (), XVIII.5.1.16. can be extended. If $1 \leq p < \infty$, a continuous function f on $\mathbb{R}$ is *p-integrable* if

$$\|f\|_p^p := \int_{-\infty}^{+\infty} |f(x)|^p\, dx < \infty .$$



XVIII.5.1.23. THEOREM. Let $1 < p < \infty$, and $q = \frac{p}{p-1}$ the conjugate exponent () of p. Let f and g be continuous functions which are p-integrable and q-integrable respectively. Then $f * g$ is defined, continuous, and bounded, and $\|f * g\|_\infty \leq \|f\|_p \|g\|_q$.

See () for the proof, which actually gives a more general statement not requiring f and g to be continuous. Using this, another version of XVIII.5.1.18. can be obtained with an identical proof:

XVIII.5.1.24. COROLLARY. Let f and g be integrable continuous functions on $\mathbb{R}$. Suppose there is a p, $1 < p < \infty$, such that f is p-integrable and g is q-integrable, where $q = \frac{p}{p-1}$ is the conjugate exponent to p. Then $f * g$ is defined and in $BCL^1(\mathbb{R})$, and

$$\|f * g\|_1 \leq \|f\|_1 \|g\|_1 \ .$$

In particular, if f and g are continuous, integrable, and 2-integrable (square-integrable), then $f * g$ is defined, continuous, and bounded.

XVIII.6. The Radon-Nikodým Theorem

The Radon-Nikodým Theorem is one of the important results of the theory of measure and integration, with many varied applications. It describes a precise way that two measures on the same measurable space can be compared.

XVIII.6.1. Density Functions

XVIII.6.1.1. Let μ be a measure on a measurable space $(X, \mathcal{A})$, and ϕ a nonnegative extended real-valued $\mathcal{A}$-measurable function. For $A \in \mathcal{A}$, define

$$\nu(A) = \int_A \phi \, d\mu \ .$$

Then ν is a measure on $(X, \mathcal{A})$ (XVIII.1.9.2.). The function ϕ is a *density function* for ν with respect to μ (μ-*density function for* ν).

XVIII.6.1.2. If μ is a fixed measure on $(X, \mathcal{A})$, which measures ν on $(X, \mathcal{A})$ have μ-density functions? There is a simple necessary condition: ν must be absolutely continuous () with respect to μ, i.e. $\nu(A) = 0$ whenever $A \in \mathcal{A}$ and $\mu(A) = 0$.

XVIII.6.1.3. Proposition. Let μ and ν be measures on $(X, \mathcal{A})$. If ν has a μ-density function, then $\nu \ll \mu$.

Proof: Let ϕ be a μ-density function for ν. If $A \in \mathcal{A}$ and $\mu(A) = 0$, then

$$\nu(A) = \int_A \phi \, d\mu = 0$$

by XVIII.1.3.2.(iv). 👍

XVIII.6.1.4. The Radon-Nikodým Theorem asserts the converse if μ is σ-finite: if $\nu \ll \mu$, then there is a μ-density function for ν.

XVIII.6.1.5. Example. Let λ be Lebesgue measure on $([0,1], \mathcal{L})$, and μ counting measure on $([0,1], \mathcal{L})$. Then $\lambda \ll \mu$ (in fact, any measure on $([0,1], \mathcal{L})$ is absolutely continuous with respect to μ since only $\emptyset$ has μ-measure 0). But there cannot be a Lebesgue-measurable function ϕ such that $\lambda(A) = \int_A \phi \, d\mu$ for all $A \in \mathcal{L}$: for any such ϕ, we would have

$$0 = \lambda(\{x\}) = \int_{\{x\}} \phi \, d\mu = \phi(x)$$

for every $x \in [0,1]$. Note that λ is a finite measure on $([0,1], \mathcal{L})$, but that μ is not σ-finite, although it is decomposable.

Borel Measures on the Line

XVIII.6.1.6. The case where μ is Lebesgue measure on $(\mathbb{R}, \mathcal{B})$ is especially important (we write μ instead of λ since we are working with $\mathcal{B}$ instead of $\mathcal{L}$, i.e. $\mu = \lambda|_{\mathcal{B}}$). Suppose ν is a finite Borel measure on $\mathbb{R}$, with cdf F_ν (). Then, as shown in ():

XVIII.6.1.7. THEOREM. Let ν be a finite Borel measure on $\mathbb{R}$ with cdf F_ν. The following are equivalent:

(i) $\nu \ll \mu$.

(ii) F_ν is absolutely continuous.

(iii) $\nu(B) = \int_B F'_\nu \, d\mu$ for every Borel set B.

(iv) ν has a μ-density function.

The equivalence of (i) and (iv) is the Radon-Nikodým Theorem in this special case. The equivalence of (i) and (ii) is motivation for the term "absolutely continuous" for measures.

XVIII.6.1.8. In fact, in the case of finite Borel measures on $\mathbb{R}$, if $\nu \ll \mu$, then F'_ν is a μ-density function for ν. Thus the μ-density function for ν is a "derivative." In the general setting, there is no direct analog of a cdf, but the μ-density function for ν, if it exists, is often called the *Radon-Nikodým derivative* of ν with respect to μ and written $\frac{d\nu}{d\mu}$ (essential uniqueness of the density function will be discussed in XVIII.6.1.10.). The idea that $\frac{d\nu}{d\mu}$ is a "derivative" is reflected in the formula

$$\nu(A) = \int_A \frac{d\nu}{d\mu} \, d\mu$$

for $A \in \mathcal{A}$, which is reminiscent of the Fundamental Theorem of Calculus.

Essential Uniqueness of Density Functions

The following observation, a special case of (), implies that if μ is σ-finite, a μ-density function for a measure ν, if it exists, is essentially unique, and is also the key idea in using the theory of signed measures to prove the Radon-Nikodým Theorem.

XVIII.6.1.9. PROPOSITION. Let μ be a finite measure on $(X, \mathcal{A})$, and ν a measure on $(X, \mathcal{A})$ with a density function ϕ. For each $r \in \mathbb{R}$, set

$$P_r = \{x \in X : \phi(x) \geq r\} \, .$$

Then $(P_r, X \setminus P_r)$ is a Hahn decomposition of X for the signed measure $\nu - r\mu$, and in particular P_r is a positive set and $X \setminus P_r$ a negative set for $\nu - r\mu$.

XVIII.6.1.10. PROPOSITION. Let μ be a σ-finite measure on a measurable space $(X, \mathcal{A})$, and ν a measure on $(X, \mathcal{A})$. If ϕ and ψ are μ-density functions for ν, then $\phi = \psi$ μ-a.e.

PROOF: First suppose μ is finite. Set $A = \{x \in X : \phi(x) < \psi(x)\}$, and for each $r, s \in \mathbb{Q}$, $r < s$,

$$A_{r,s} = \{x \in X : \phi(x) < r \text{ and } \psi(x) > s\} .$$

We then have

$$A = \cup\{A_{r,s} : r, s \in \mathbb{Q}, r < s\}$$

and since this is a countable union, to show that A is μ-null it suffices to show that $A_{r,s}$ is μ-null for each $r, s \in \mathbb{Q}$, $r < s$. Fix r and s. Using the notation of XVIII.6.1.9. (where P_s uses ψ and P_r uses ϕ), we have that $A_{r,s} \subseteq P_s \cap (X \setminus P_r)$. In particular, $A_{r,s}$ is a positive set for $\nu - s\mu$ and a negative set for $\nu - r\mu$. We thus have

$$(\nu - r\mu)(A_{r,s}) \leq 0, \quad \nu(A_{r,s}) \leq r\mu(A_{r,s})$$

and in particular $\nu(A_{r,s}) < \infty$ since $\mu(A_{r,s}) < \infty$. We also have

$$(\nu - s\mu)(A_{r,s}) \geq 0, \quad \nu(A_{r,s}) \geq s\mu(A_{r,s})$$

and combining the two, we get

$$s\mu(A_{r,s}) \leq r\mu(A_{r,s})$$

and since $r < s$ and $\mu(A_{r,s}) \geq 0$, we conclude that $\mu(A_{r,s}) = 0$. Thus $\mu(A) = 0$. Similarly,

$$\mu(\{x \in X : \psi(x) < \phi(x)\}) = 0 .$$

Thus $\phi = \psi$ μ-a.e.

If μ is only σ-finite, partition X into a countable collection (X_n) of measurable sets with $\mu(X_n) < \infty$ for all n, and set $\mu_n = \mu|_{X_n}$, $\nu_n = \nu|_{X_n}$, $\phi_n = \phi|_{X_n}$, $\psi_n = \psi|_{X_n}$. Then, for each n, ϕ_n and ψ_n are μ_n-density functions for ν_n, so $\phi_n = \psi_n$ μ_n-a.e. and therefore $\phi = \psi$ μ-a.e.

XVIII.6.1.11. Thus, in the σ-finite case, density functions, if they exist, are essentially unique, so by slight abuse of terminology we may refer to *the* μ-density function of ν (if there is one). But it should be kept in mind that the density function is only determined μ-a.e. and is technically not unique; any nonnegative measurable function agreeing a.e. with a μ-density function for ν is also a μ-density function for ν. In particular, the Radon-Nikodým derivative $\frac{d\nu}{d\mu}$ (XVIII.6.1.8.) is technically not defined as a specific function, but only as an equivalence class of functions, and thus some authors write $\left[\frac{d\nu}{d\mu}\right]$ for the Radon-Nikodým derivative to emphasize the nonuniqueness of definition, although this notation seems to be passing out of favor. (The distinction rarely causes any difficulties.)

Actually, it is even a slight abuse of language to say that $\frac{d\nu}{d\mu}$ is uniquely determined a.e.; it is technically not uniquely determined anywhere in most cases, in the sense that $\frac{d\nu}{d\mu}(x)$ is not uniquely determined for any specific x. We will nonetheless sometimes use this language for brevity.

XVIII.6.2. Statement and Proof of the Theorem

There are several proofs known of the Radon-Nikodým Theorem. The one we give is not the shortest, but it gives the most general result, and we think it gives the best insight into why the theorem is true. There are some slicker proofs of the case where ν, as well as μ, is σ-finite (admittedly by far the most important case), cf. (), (). Our proof is adapted from [Roy88] and [MW99] (note that in [**?**] this proof has been replaced by the proof in ()).

XVIII.6.2.1. THEOREM. [RADON-NIKODÝM THEOREM] Let $(X, \mathcal{A})$ be a measurable space, and μ and ν measures on $(X, \mathcal{A})$, with μ σ-finite. If $\nu \ll \mu$, then there is a μ-density function for ν, i.e. there is a nonnegative extended real-valued $\mathcal{A}$-measurable function ϕ such that

$$\nu(A) = \int_A \phi \, d\mu$$

for all $A \in \mathcal{A}$. The function ϕ is uniquely determined a.e. and is called the *Radon-Nikodým derivative* of ν with respect to μ, denoted $\frac{d\nu}{d\mu}$.

PROOF: First assume μ is finite. Using XVIII.6.1.9. as motivation, for each nonnegative *rational* number r we take a Hahn decomposition (P_r, N_r) for the signed measure $\nu - r\mu$. The set

$$Q_r = [\cup_{s \geq r} P_s] \cup [\cap_{s < r} P_s]$$

(since r and s only range over the countable set $\mathbb{Q}_+$, this set is $\mathcal{A}$-measurable) is a positive set for $\nu - r\mu$ containing P_r, so $(Q_r, X \setminus Q_r)$ is also a Hahn decomposition for $\nu - r\mu$. We have $Q_s \subseteq Q_r$ if $r < s$. Also take $Q_0 = X$. (It simplifies the argument to use the Q_r.)

Now set

$$\phi(x) = \sup\{r : x \in Q_r\}$$

for $x \in X$. We claim ϕ is a μ-density function for ν. Note that $Q_r = \{x : \phi(x) \geq r\}$.

First note that $\phi = \sup_{r \in \mathbb{Q}_+} \phi_r$, where $\phi_r = r\chi_{Q_r}$. Since each ϕ_r is $\mathcal{A}$-measurable, ϕ is $\mathcal{A}$-measurable, and obviously nonnegative.

We now fix $A \in \mathcal{A}$. Let $A_\infty = \{x \in A : \phi(x) = \infty\}$. Then $A_\infty \subseteq Q_r$ for all r, so is a positive set for $\nu - r\mu$, i.e. $\nu(A_\infty) \geq r\mu(A_\infty)$ for all $r \geq 0$. If $\mu(A_\infty) > 0$, we have $\nu(A_\infty) = \infty$; if $\mu(A_\infty) = 0$, then $\nu(A_\infty) = 0$ since $\nu \ll \mu$. In either case, we have

$$\nu(A_\infty) = \int_{A_\infty} \phi \, d\mu \ .$$

In particular, if $\mu(A_\infty) > 0$, the density formula holds for ϕ and A: both $\nu(A)$ and $\int_A \phi \, d\mu$ are ∞.

Now assume $\mu(A_\infty) = 0$. Fix $n \in \mathbb{N}$, and for each $k \in \mathbb{N}$ set

$$A_{n,k} = \left\{ x \in A : \frac{k-1}{n} \leq \phi(x) < \frac{k}{n} \right\} \ .$$

Then A is the disjoint union of A_∞ and the $A_{n,k}$ (and these sets are all $\mathcal{A}$-measurable). Then

$$\frac{k-1}{n}\mu(A_{n,k}) \leq \int_{A_{n,k}} \phi \, d\mu \leq \frac{k}{n}\mu(A_{n,k}) \ .$$

We have

$$A_{n,k} \subseteq Q_{(k-1)/n} \setminus Q_{k/n}$$

so we have

$$\frac{k-1}{n}\mu(A_{n,k}) \leq \nu(A_{n,k}) \leq \frac{k}{n}\mu(A_{n,k}) \ .$$

Thus

$$\int_{A_{n,k}} \phi \, d\mu - \frac{1}{n}\mu(A_{n,k}) \leq \nu(A_{n,k}) \leq \int_{A_{n,k}} \phi \, d\mu + \frac{1}{n}\mu(A_{n,k}) \ .$$

Since A is the disjoint union of A_∞ and the $A_{n,k}$, and $\mu(A_\infty) = 0$ (so $\nu(A_\infty) = 0$), summing over k we have

$$\int_A \phi \, d\mu - \frac{1}{n}\mu(A) \leq \nu(A) \leq \int_A \phi \, d\mu + \frac{1}{n}\mu(A)$$

(if one of $\int_A \phi \, d\mu$ and $\nu(A)$ is ∞, so is the other). If $\int_A \phi \, d\mu$ and $\nu(A)$ are finite, this is true for all $n \in \mathbb{N}$, so

$$\int_A \phi \, d\mu = \nu(A) \ .$$

This proves the theorem if μ is finite.

Now suppose μ is just σ-finite. Partition X into a countable collection (X_n) of measurable sets with $\mu(X_n) < \infty$ for all n, and set $\mu_n = \mu|_{X_n}$ and $\nu_n = \nu|_{X_n}$ for each n. Then there is a μ_n-density function ϕ_n for each n. Let ϕ be the function on X whose restriction to X_n is ϕ_n for each n. Then ϕ is a nonnegative $\mathcal{A}$-measurable function on X. If $A \in \mathcal{A}$, we have

$$\int_A \phi \, d\mu = \sum_{n=1}^{\infty} \int_{A \cap X_n} \phi \, d\mu = \sum_{n=1}^{\infty} \int_{A \cap X_n} \phi_n \, d\mu_n = \sum_{n=1}^{\infty} \nu_n(A \cap X_n) = \sum_{n=1}^{\infty} \nu(A \cap X_n) = \nu(A)$$

so ϕ is a μ-density function for ν.

The last assertion is XVIII.6.1.10.. 👍

Note that the proof uses the Countable AC (where?)

XVIII.6.2.2. Without the σ-finite hypothesis on μ, the result can fail. A nice standard example is XVIII.6.1.5.. There is even an extremely simple and rather stupid counterexample: let $X = \{x\}$ be a singleton set, and define μ and ν on $(X, \mathcal{P}(X))$ by $\mu(X) = \infty$ and $\nu(X) = 1$. Then $\nu \ll \mu$, but there is no density function. There is an extension of the theorem to the case where μ is decomposable, but it must be carefully stated; cf. [HS75, 19.27].

Using (), the Radon-Nikodým Theorem can be extended:

XVIII.6.2.3. Corollary. Let μ and ν be measures on a measurable space $(X, \mathcal{A})$, with μ σ-finite and $\nu \ll \mu$. Then there is a nonnegative extended real-valued $\mathcal{A}$-measurable function $\frac{d\nu}{d\mu}$, uniquely determined a.e., with the following properties:

(i) If f is a nonnegative extended real-valued $\mathcal{A}$-measurable function, then

$$\int_A f\,d\nu = \int_A f\frac{d\nu}{d\mu}\,d\mu$$

for all $A \in \mathcal{A}$.
(ii) If f is a ν-integrable function, then $f\frac{d\nu}{d\mu}$ is μ-integrable and

$$\int_A f\,d\nu = \int_A f\frac{d\nu}{d\mu}\,d\mu$$

for all $A \in \mathcal{A}$.

Finiteness of the Radon-Nikodým Derivative

XVIII.6.2.4. Let μ and ν be measures on $(X, \mathcal{A})$, with μ σ-finite and $\nu \ll \mu$. Set

$$X_\infty = \left\{x \in X : \frac{d\nu}{d\mu}(x) = \infty\right\}$$

(where $\frac{d\nu}{d\mu}$ is some fixed Radon-Nikodým derivative). If $A \in \mathcal{A}$, $A \subseteq X_\infty$, then $\nu(A)$ is either 0 (if $\mu(A) = 0$) or ∞ (if $\mu(A) > 0$). Thus if ν is σ-finite (or, more generally, semifinite), then $\mu(X_\infty) = 0$, i.e. $\frac{d\nu}{d\mu}$ is finite a.e. It can thus be modified on a set of measure 0 to be finite everywhere. Conversely, if $\frac{d\nu}{d\mu}$ is finite a.e. then ν must be σ-finite. (This has the interesting consequence that if μ is σ-finite and $\nu \ll \mu$ is semifinite, then ν is actually σ-finite.)

History

XVIII.6.2.5. Theorem XVIII.6.1.7. was proved by Lebesgue. Beppo Levi criticized the rigor of Lebesgue's proof and suggested fixes, and Lebesgue wrote two additional papers about the result. According to [Bog07], "Large portions of [these two papers] are occupied by Lebesgue's polemics with B. Levi with respect to the critical remarks of the latter and the rigor of his arguments." The result for Borel measures on $\mathbb{R}^n$ was proved by Radon, and the general theorem by Nikodým. Some authors call the theorem the "Lebesgue-Radon-Nikodým Theorem," sometimes incorporating the Lebesgue Decomposition Theorem () into the result. Although the attributions may not be clearcut, we have used the most common names for these results.

XVIII.6.3. The Lebesgue Decomposition Theorem

XVIII.6.4. Signed and Complex Measures

XVIII.6.5. Conditional Expectations

One of the most striking applications of the Radon-Nikodým Theorem is to the existence of conditional expectations. Although these can be defined somewhat more generally, we will restrict attention to probability measures, both for simplicity and for the fact that conditional expectations are particularly important in probability.

XVIII.6.5.1. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a probability measure space, and f a μ-integrable function (real- or complex-valued). If $\mathcal{B}$ is a sub-σ-algebra of $\mathcal{A}$, a *conditional expectation of f given $\mathcal{B}$* is a $\mathcal{B}$-measurable function ϕ satisfying

$$\int_B \phi \, d\mu = \int_B f \, d\mu$$

for all $B \in \mathcal{B}$.

XVIII.6.5.2. A conditional expectation, if it exists, is essentially unique in the sense that any two conditional expectations for f given $\mathcal{B}$ are equal a.e. Conversely, any $\mathcal{B}$-measurable function equal a.e. to a conditional expectation is also a conditional expectation. By slight abuse of terminology, we will denote a conditional expectation for f given $\mathcal{B}$ by $\mathbf{E}(f|\mathcal{B})$.

> "[I]n almost every discussion involving conditional expectations, *almost everywhere* or *almost surely*, or their abbreviations *a.e.*, *a.s.*, will be sure to appear almost everywhere."
>
> *J. Doob*[1]

XVIII.6.5.3. What is the content of this concept, i.e. how does $\mathbf{E}(f|\mathcal{B})$ differ from f? The key is that $\mathbf{E}(f|\mathcal{B})$ must be $\mathcal{B}$-measurable, whereas f is merely $\mathcal{A}$-measurable (and integrable). Recall that the smaller the σ-algebra, the harder it is for a function to be measurable. (Of course, if f happens to be $\mathcal{B}$-measurable, we can indeed take $\mathbf{E}(f|\mathcal{B}) = f$, but this situation is generally exceptional.)

XVIII.6.5.4. EXAMPLES. (i) Suppose $\mathcal{B} = \{\emptyset, X\}$. Then the only $\mathcal{B}$-measurable functions are constant functions. If f is $\mathcal{A}$-measurable and μ-integrable, $\mathbf{E}(f|\mathcal{B})$ must be a constant function α with the property that

$$\int_X \alpha \, d\mu = \int_X f \, d\mu \ .$$

Since μ is a probability measure, the left side is just α, so

$$\mathbf{E}(f|\mathcal{B}) = \int_X f \, d\mu$$

where the right side is regarded as a constant function. Recall that in probability the right side is called the *expectation* of f. Thus the conditional expectation of f given the trivial σ-algebra is just the expectation of f (regarded as a constant function).

(ii) For a slightly less trivial example, fix a set $A \in \mathcal{A}$ with $0 < \mu(A) < 1$ (so $\mu(A^c) > 0$). Let $\mathcal{B} = \{\emptyset, A, A^c, X\}$ be the σ-algebra generated by A. The $\mathcal{B}$-measurable functions are precisely the functions which are constant on A and on A^c. If f is $\mathcal{A}$-measurable and μ-integrable, and $\mathbf{E}(f|\mathcal{B})$ is a conditional expectation, then the constant value α that $\mathbf{E}(f|\mathcal{B})$ takes on A must satisfy

$$\int_A \alpha \, d\mu = \int_A f \, d\mu$$

[1] [Doo94, p. 180].

and since the left side is $\alpha\mu(A)$, we obtain

$$\alpha = \frac{1}{\mu(A)} \int_A f \, d\mu$$

which can be interpreted as the average value of f on A. Probabilists call this number the *conditional expectation of f given A*. Similarly, the constant value $\mathbf{E}(f|\mathcal{B})$ must take on A^c is

$$\beta = \frac{1}{\mu(A^c)} \int_{A^c} f \, d\mu$$

which is the conditional expectation of f given A^c. If $f = \chi_B$, then we have

$$\alpha = \frac{1}{\mu(A)} \int_A \chi_B \, d\mu = \frac{\mu(A \cap B)}{\mu(A)}$$

which probabilists call the *conditional probability of B given A*, and

$$\beta = \frac{\mu(A^c \cap B)}{\mu(A^c)}$$

which is the conditional probability of B given A^c.

If $\mathbf{E}(f|\mathcal{B})$ is defined this way, we automatically have

$$\int_X \mathbf{E}(f|\mathcal{B}) \, d\mu = \int_A \mathbf{E}(f|\mathcal{B}) \, d\mu + \int_{A^c} \mathbf{E}(f|\mathcal{B}) \, d\mu = \int_A f \, d\mu + \int_{A^c} f \, d\mu = \int_X f \, d\mu$$

so $\mathbf{E}(f|\mathcal{B})$ is indeed a conditional expectation for f given $\mathcal{B}$. This example is the origin of the name "conditional expectation" for the concept in XVIII.6.5.1..

(iii) Let $(X, \mathcal{A}_1, \mu)$ and $(Y, \mathcal{A}_2, \nu)$ be probability measure spaces, and form $(X \times Y, \mathcal{A}_1 \otimes \mathcal{A}_2, \mu \times \nu)$, which is again a probability measure space. Let

$$\mathcal{B} = \{A \times Y : A \in \mathcal{A}_1\} \, .$$

Then $\mathcal{B}$ is a sub-σ-algebra of $\mathcal{A}_1 \otimes \mathcal{A}_2$. A function f on $X \times Y$ is $\mathcal{B}$-measurable if and only it is of the form $f(x, y) = g(x)$ for an $\mathcal{A}_1$-measurable function g, i.e. if it is constant on vertical cross sections. If f is an $(\mathcal{A}_1 \times \mathcal{A}_2)$-measurable function which is $(\mu \times \nu)$-integrable, a conditional expectation $\mathbf{E}(f|\mathcal{B})$ must be constant on vertical sections and satisfy

$$\int_{A \times Y} \mathbf{E}(f|\mathcal{B}) \, d(\mu \times \nu) = \int_{A \times Y} f \, d(\mu \times \nu)$$

for all $A \in \mathcal{A}_1$. By Fubini's Theorem, we may (and must) take the constant value on the vertical cross section $\{x\} \times Y$ to be

$$E(f|\mathcal{B})(x, z) = \int_Y f(x, y) d\nu(y)$$

for all $z \in Y$.

XVIII.6.5.5. If $\mathcal{B}$ is a complicated σ-algebra, it is highly unclear how a conditional expectation for an f can be defined or even whether one exists. But the Radon-Nikodým Theorem comes to the rescue in a quite simple way:

XVIII.6.5.6. THEOREM. Let $(X, \mathcal{A}, \mu)$ be a probability measure space, and f an $\mathcal{A}$-measurable, μ-integrable complex-valued function on X. If $\mathcal{B}$ is any sub-σ-algebra of $\mathcal{A}$, then there exists a conditional expectation for f given $\mathcal{B}$.

PROOF: On the measurable space $(X, \mathcal{B})$, for $B \in \mathcal{B}$, define

$$\nu(B) = \int_B f \, d\mu \ .$$

Then ν is a complex measure on $(X, \mathcal{B})$, and $\nu \ll \mu|_{\mathcal{B}}$. Thus there is a $\mathcal{B}$-measurable function $\phi = \frac{d\nu}{d(\mu|_{\mathcal{B}})}$ such that

$$\nu(B) = \int_B \phi \, d(\mu|_{\mathcal{B}}) = \int_B \phi \, d\mu$$

for all $B \in \mathcal{B}$ (). Thus we can set $\mathbf{E}(f|\mathcal{B}) = \phi$. 👍

Properties of Conditional Expectations

Conditional expectations have most of the nice properties one would expect or hope for, although the lack of exactness in their definition makes precise statements annoyingly complicated.

XVIII.6.5.7. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a probability measure space, and $\mathcal{B}$ a sub-σ-algebra of $\mathcal{A}$.
(i) If f and g are $\mathcal{A}$-measurable and μ-integrable functions, then

$$\mathbf{E}(f + g|\mathcal{B}) = \mathbf{E}(f|\mathcal{B}) + \mathbf{E}(g|\mathcal{B})$$

in the sense that $\mathbf{E}(f|\mathcal{B}) + \mathbf{E}(g|\mathcal{B})$ is a conditional expectation for $f + g$ given $\mathcal{B}$.
(ii) If f is an $\mathcal{A}$-measurable and μ-integrable function and $\alpha \in \mathbb{C}$, then

$$\mathbf{E}(\alpha f|\mathcal{B}) = \alpha \mathbf{E}(f|\mathcal{B})$$

in the sense that $\alpha\mathbf{E}(f|\mathcal{B})$ is a conditional expectation for αf given $\mathcal{B}$.
(iii) If f and g are $\mathcal{A}$-measurable and μ-integrable functions, and $f = g$ a.e., then $\mathbf{E}(f|\mathcal{B}) = \mathbf{E}(g|\mathcal{B})$ a.e.
(iv) If f is an $\mathcal{A}$-measurable and μ-integrable function which is nonnegative a.e., then $\mathbf{E}(f|\mathcal{B})$ is nonnegative a.e.
(v) If f and g are $\mathcal{A}$-measurable and μ-integrable functions, and $f \leq g$ a.e., then $\mathbf{E}(f|\mathcal{B}) \leq \mathbf{E}(g|\mathcal{B})$ a.e.
(vi) If f is an $\mathcal{A}$-measurable and μ-integrable function, then $\mathbf{E}(f|\mathcal{B}) = f$ a.e. if and only if f is equal a.e. to a $\mathcal{B}$-measurable function.
(vii) If f is an $\mathcal{A}$-measurable and μ-integrable function, then $|\mathbf{E}(f|\mathcal{B})| \leq \mathbf{E}(|f||\mathcal{B})$ a.e.
(viii) If (f_n) is a nondecreasing sequence of nonnegative $\mathcal{A}$-measurable functions converging pointwise a.e. to f and f is μ-integrable, then $\mathbf{E}(f_n|\mathcal{B}) \to \mathbf{E}(f, \mathcal{B})$ a.e.

PROOF: (i)–(iii) and (vi) are straightforward and left to the reader. For (iv), if $\mathbf{E}(f|\mathcal{B})$ is negative on a set B of positive measure, then $\int_B \mathbf{E}(f|\mathcal{B})\,d\mu = \int_B f\,d\mu < 0$ (), contradicting that $f \geq 0$ a.e. (v) then follows from (iv), (i), and (ii). For (vii), we apply XVIII.1.9.1., since for any $B \in \mathcal{B}$,

$$\left|\int_B \mathbf{E}(f|\mathcal{B})\,d\mu\right| = \left|\int_B f\,d\mu\right| \leq \int_B |f|\,d\mu = \int_B \mathbf{E}(|f||\mathcal{B})\,d\mu\ .$$

For (viii), we have $\mathbf{E}(f_n|\mathcal{B}) \leq \mathbf{E}(f_{n+1}|\mathcal{B}) \leq \mathbf{E}(f,\mathcal{B})$ a.e. for each n by (v). Set $g = \sup_n \mathbf{E}(f_n|\mathcal{B})$. Then $g \leq \mathbf{E}(f|\mathcal{B})$ a.e. By the MCT, for each $B \in \mathcal{B}$ we have

$$\int_B \mathbf{E}(f_n|\mathcal{B})\,d\mu = \int_B f_n\,d\mu \to \int_B f\,d\mu = \int_B \mathbf{E}(f|\mathcal{B})\,d\mu$$

and since

$$\int_B E(f_n|\mathcal{B})\,d\mu \leq \int_B g\,d\mu \leq \int_B \mathbf{E}(f|\mathcal{B})\,d\mu$$

for each n and B, we conclude that

$$\int_B g\,d\mu = \int_B \mathbf{E}(f|\mathcal{B})\,d\mu\ , \quad \int_B [\mathbf{E}(f|\mathcal{B}) - g]\,d\mu = 0$$

for each B, and thus $\mathbf{E}(f|\mathcal{B}) = g$ a.e. 👍

XVIII.6.5.8. It is not true that $\mathbf{E}(fg|\mathcal{B}) = \mathbf{E}(f|\mathcal{B})\mathbf{E}(g|\mathcal{B})$ for general f and g, even if fg is integrable (which is not automatic). But we have an important partial version:

XVIII.6.5.9. PROPOSITION. Let $(X,\mathcal{A},\mu)$ be a probability measure space, and $\mathcal{B}$ a sub-σ-algebra of $\mathcal{A}$. Let f be an $\mathcal{A}$-measurable and μ-integrable complex-valued function and g a $\mathcal{B}$-measurable complex-valued function such that fg is μ-integrable (this will be automatic if g is bounded). Then $\mathbf{E}(fg|\mathcal{B}) = g\mathbf{E}(f|\mathcal{B})$ a.e.

PROOF: If for $B \in \mathcal{B}$ we define

$$\nu(B) = \int_B f\,d\mu = \int_B \mathbf{E}(f|\mathcal{B})\,d\mu$$

then g is ν-integrable by XVII.9.5.4., and we have

$$\int_B g\,d\nu = \int_B fg\,d\mu$$

for every $B \in \mathcal{B}$. By another application of XVII.9.5.4., $g\mathbf{E}(f|\mathcal{B})$ is μ-integrable and

$$\int_B g\,d\nu = \int_B g\mathbf{E}(f|\mathcal{B})\,d\mu$$

for all $B \in \mathcal{B}$. Putting these together, we get

$$\int_B fg\,d\mu = \int_B g\mathbf{E}(f|\mathcal{B})\,d\mu$$

for all $B \in \mathcal{B}$. This means $g\mathbf{E}(f|\mathcal{B})$ is a conditional expectation for fg given $\mathcal{B}$. 👍

Successive Conditional Expectations

XVIII.6.5.10. Suppose $(X, \mathcal{A}, \mu)$ is a probability measure space, $\mathcal{B}$ is a sub-σ-algebra of $\mathcal{A}$, and $\mathcal{D}$ a sub-σ-algebra of $\mathcal{B}$. Then we have conditional expectations of $\mathcal{A}$-measurable and μ-integrable functions given both $\mathcal{B}$ and $\mathcal{D}$, and for $\mathcal{B}$-measurable and $\mu|_{\mathcal{B}}$-integrable functions given $\mathcal{D}$. How are these related? The relation turns out to be as nice as could be hoped:

XVIII.6.5.11. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a probability measure space, $\mathcal{B}$ a sub-σ-algebra of $\mathcal{A}$, and $\mathcal{D}$ a sub-σ-algebra of $\mathcal{B}$. Then, for any $\mathcal{A}$-measurable and μ-integrable function f, we have

$$\mathbf{E}(f, \mathcal{D}) = \mathbf{E}(\mathbf{E}(f|\mathcal{B})|\mathcal{D})) \text{ a.e.}$$

PROOF: If $D \in \mathcal{D}$, we have

$$\int_D \mathbf{E}(\mathbf{E}(f|\mathcal{B})|\mathcal{D}))\, d\mu = \int_D \mathbf{E}(f|\mathcal{B})\, d\mu = \int_D f\, d\mu$$

since $\mathcal{D} \subseteq \mathcal{B}$, so $\mathbf{E}(\mathbf{E}(f|\mathcal{B})|\mathcal{D}))$ is a conditional expectation for f given $\mathcal{D}$. 👍

Reduction to Equivalence Classes

XVIII.6.5.12. The lack of uniqueness in conditional expectations can be nicely remedied. Recall that $\mathcal{L}^1_{\mathbb{R}}(X, \mathcal{A}, \mu)$ and $\mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \mu)$ are the spaces of $\mathcal{A}$-measurable and μ-integrable real- and complex-valued functions respectively. On each of these, define an equivalence relation by setting $f \sim g$ if $f = g$ a.e. (It is easy to check this is an equivalence relation.) Let $L^1_{\mathbb{R}}(X, \mathcal{A}, \mu)$ and $L^1_{\mathbb{C}}(X, \mathcal{A}, \mu)$ be the sets of equivalence classes. There are well-defined operations of addition and scalar multiplication on these sets, defined in the obvious way: $[f] + [g] = [f + g]$ and $\alpha[f] = [\alpha f]$, where $[f]$ denotes the equivalence class of f. These operations make $L^1_{\mathbb{R}}(X, \mathcal{A}, \mu)$ and $L^1_{\mathbb{C}}(X, \mathcal{A}, \mu)$ into real and complex vector spaces respectively. Although strictly speaking $L^1_{\mathbb{R}}(X, \mathcal{A}, \mu)$ is not a subset of $L^1_{\mathbb{C}}(X, \mathcal{A}, \mu)$, there is an obvious natural identification making $L^1_{\mathbb{R}}(X, \mathcal{A}, \mu)$ a real vector subspace of $L^1_{\mathbb{C}}(X, \mathcal{A}, \mu)$.

XVIII.6.5.13. If $\mathcal{B}$ is a sub-σ-algebra of $\mathcal{A}$, then $L^1_{\mathbb{F}}(X, \mathcal{B}, \mu|_{\mathcal{B}})$ ($\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$) is technically not a subset of $L^1_{\mathbb{F}}(X, \mathcal{A}, \mu)$, but it can be naturally identified with the set of equivalence classes of $\mathcal{B}$-measurable and μ-integrable functions, a vector subspace.

XVIII.6.5.14. Now suppose μ is a probability measure. The (not well-defined) map $f \mapsto \mathbf{E}(f|\mathcal{B})$ gives a well-defined function $\mathbf{E}$ from $L^1_{\mathbb{F}}(X, \mathcal{A}, \mu)$ to the subspace $L^1_{\mathbb{F}}(X, \mathcal{B}, \mu|_{\mathcal{B}})$ by XVIII.6.5.7.(iii). This function is linear by XVIII.6.5.7.(i)–(ii), and has other properties from the other parts of XVIII.6.5.7.. From (vi), $\mathbf{E}$ is *idempotent*, i.e. $\mathbf{E}([\mathbf{E}([f])]) = \mathbf{E}([f])$.

XVIII.6.5.15. We can also define $L^\infty_{\mathbb{F}}(X, \mathcal{A}, \mu)$ to be the set of equivalence classes of bounded $\mathcal{A}$-measurable functions. Since μ is finite, a bounded measurable function is integrable, so we may identify $L^\infty_{\mathbb{F}}(X, \mathcal{A}, \mu)$ with a subset of $L^1_{\mathbb{F}}(X, \mathcal{A}, \mu)$, which is clearly a vector subspace. $L^\infty_{\mathbb{F}}(X, \mathcal{A}, \mu)$ also has a multiplication (pointwise product) making it into an $\mathbb{F}$-algebra, and $L^1_{\mathbb{F}}(X, \mathcal{A}, \mu)$ is a module over $L^\infty_{\mathbb{F}}(X, \mathcal{A}, \mu)$ ().

If $\mathcal{B}$ is a sub-σ-algebra of $\mathcal{A}$, then $L^\infty_{\mathbb{F}}(X, \mathcal{B}, \mu|_{\mathcal{B}})$ can be identified with a subset (subalgebra) of $L^\infty_{\mathbb{F}}(X, \mathcal{A}, \mu)$, so $L^1_{\mathbb{F}}(X, \mathcal{A}, \mu)$ can be regarded as a module over $L^\infty_{\mathbb{F}}(X, \mathcal{B}, \mu|_{\mathcal{B}})$.

XVIII.6.5.16. If $f \in L^\infty_{\mathbb{F}}(X, \mathcal{A}, \mu)$, then $|f| \leq M$ for some M which can be regarded as a constant function: thus

$$|\mathbf{E}(f|\mathcal{B})| \leq \mathbf{E}(|f||\mathcal{B}) \leq \mathbf{E}(M|\mathcal{B}) = M$$

by various parts of XVIII.6.5.7.. Thus $\mathbf{E}$ sends $L^\infty_{\mathbb{F}}(X, \mathcal{A}, \mu)$ into $L^\infty_{\mathbb{F}}(X, \mathcal{B}, \mu|_{\mathcal{B}})$. Also, by XVIII.6.5.9., the map $\mathbf{E}$ from $L^1_{\mathbb{F}}(X, \mathcal{A}, \mu)$ to $L^1_{\mathbb{F}}(X, \mathcal{B}, \mu|_{\mathcal{B}})$ is a module-homomorphism when they are regarded as $L^\infty_{\mathbb{F}}(X, \mathcal{B}, \mu|_{\mathcal{B}})$-modules.

See XX.15.8. for more on conditional expectations. There is an important generalization to operator algebras; see e.g. [Bla06, II.6.10].

XVIII.6.6. Change of Variable

The Radon-Nikodým Theorem gives an extremely general change-of-variable theorem for integrals. There are two versions which are easily stated and proved; however, relating them to classical change-of-variable theorems and applying them can be somewhat complicated.

Integration for Push-Forwards

XVIII.6.6.1. We first make a simple observation. Let $(X, \mathcal{A}, \mu)$ be a measure space, $(Y, \mathcal{B})$ a measurable space, and $\phi : X \to Y$ an $(\mathcal{A}, \mathcal{B})$-measurable function. Then () we may push μ forward to a measure $\phi_*\mu$ on $(Y, \mathcal{B})$ defined by $\phi_*\mu(B) = \mu(\phi^{-1}(B))$.

XVIII.6.6.2. Proposition. Let f be either a $\phi_*\mu$-integrable function or a nonnegative $\mathcal{B}$-measurable function on Y. Then $f \circ \phi$ is μ-integrable (if f is $\phi_*\mu$-integrable) or nonnegative and $\mathcal{A}$-measurable (if f is nonnegative), and, for any $E \in \mathcal{B}$,

$$\int_E f \, d(\phi_*\mu) = \int_{\phi^{-1}(E)} (f \circ \phi) \, d\mu \ .$$

Proof: This is a standard bootstrap argument. We may assume $E = Y$ without loss of generality. We have that $f \circ \phi$ is $\mathcal{A}$-measurable. First let $f = \chi_B$ for some $B \in \mathcal{B}$. Then

$$\int_Y \chi_B \, d(\phi_*\mu) = \phi_*\mu(B) = \mu(\phi^{-1}(B)) = \int_X \chi_{\phi^{-1}(B)} \, d\mu = \int_X (\chi_B \circ \phi) \, d\mu \ .$$

The formula thus holds for indicator functions; hence for simple functions by linearity, for nonnegative measurable functions by the Monotone Convergence Theorem, and then for $(\phi_*\mu)$-integrable functions again by linearity. 👍

Converting Integrals

If in the above setting ν is a measure on $(Y, \mathcal{B})$, what we want to do is convert an integral over X with respect to μ into one over Y with respect to ν or (more importantly for applications) vice versa. There are two easy ways to do this using the Radon-Nikodým Theorem. We need modest additional hypotheses, slightly different in the two cases, concerning preservation of null sets under ϕ.

XVIII.6.6.3. Definition. Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces, and $\phi : X \to Y$ an $(\mathcal{A}, \mathcal{B})$-measurable function.

(i) The function ϕ *preserves null sets backward* if, whenever $B \in \mathcal{B}$ with $\nu(B) = 0$, then $\mu(\phi^{-1}(B)) = 0$.

(ii) The function ϕ *preserves null sets forward* if, whenever $B \in \mathcal{B}$ and $\mu(\phi^{-1}(B)) = 0$, then $\nu(B) = 0$.

XVIII.6.6.4. The function ϕ preserves null sets backward if and only if $\phi_*\mu \ll \nu$, and preserves null sets forward if and only if $\nu \ll \phi_*\mu$. A function ϕ which preserves null sets forward and whose range is in $\mathcal{B}$ must be "almost surjective" in the sense that $\nu(Y \setminus \phi(X)) = 0$. Similarly, if ν is purely nonatomic and singletons are in $\mathcal{B}$, if ϕ preserves null sets backward it is "almost injective" in the sense that the preimage of every point is a null set. (These conditions are far from sufficient.)

There is a closely related property (cf. XIX.5.1.2.):

XVIII.6.6.5. Definition. Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces, and $\phi : X \to Y$ an $(\mathcal{A}, \mathcal{B})$-measurable function. The function ϕ *has property (N)* if

(i) For every $A \in \mathcal{A}$, $\phi(A) \in \mathcal{B}$.

(ii) Whenever $A \in \mathcal{A}$ with $\mu(A) = 0$, then $\nu(\phi(A)) = 0$.

XVIII.6.6.6. If X and Y are open sets in Euclidean space with Lebesgue measure (this can be relaxed), and ϕ is continuous, then property (i) is automatic from property (ii): any Lebesgue measurable set E is the union of a Borel set and a null set; the null set is a subset of a null Borel set, so its image $\phi(E)$ is the union of an analytic set () and a subset of an analytic null set, and is thus Lebesgue measurable (). (But see ().)

XVIII.6.6.7. Proposition. Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces, and $\phi : X \to Y$ an $(\mathcal{A}, \mathcal{B})$-measurable function. If ϕ has property (N) and is almost surjective in the sense of XVIII.6.6.4., then ϕ preserves null sets forward.

Proof: Let $C = Y \setminus \phi(X)$. By hypothesis $C \in \mathcal{B}$ and $\nu(C) = 0$. If $B \in \mathcal{B}$, and $\mu(\phi^{-1}(B)) = 0$, we have $\nu(\phi(\phi^{-1}(B))) = 0$, and $B \subseteq \phi(\phi^{-1}(B)) \cup C$, a ν-null set. 👍

XVIII.6.6.8. THEOREM. [FORWARD CHANGE OF VARIABLE IN INTEGRALS] Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces, with ν σ-finite, and $\phi : X \to Y$ an $(\mathcal{A}, \mathcal{B})$-measurable function which preserves null sets backward. Then, if f is a measurable function on Y such that either f is nonnegative or $f \circ \phi$ is μ-integrable, then for every $E \in \mathcal{B}$,

$$\int_{\phi^{-1}(E)} (f \circ \phi)\, d\mu = \int_E \left(f \cdot \frac{d(\phi_* \mu)}{d\nu} \right) d\nu$$

where $\frac{d(\phi_* \mu)}{d\nu}$ is the Radon-Nikodým derivative (in particular, the integrand on the right is ν-integrable if $f \circ \phi$ is μ-integrable).

PROOF: Since $\phi_* \mu \ll \nu$, by XVIII.6.6.2. and the Radon-Nikodým Theorem we have

$$\int_{\phi^{-1}(E)} (f \circ \phi)\, d\mu = \int_E f\, d(\phi_* \mu) = \int_E \left(f \cdot \frac{d(\phi_* \mu)}{d\nu} \right) d\nu \ .$$

XVIII.6.6.9. THEOREM. [BACKWARD CHANGE OF VARIABLE IN INTEGRALS] Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be measure spaces, with μ σ-finite, and $\phi : X \to Y$ an $(\mathcal{A}, \mathcal{B})$-measurable function which preserves null sets forward. Then, if f is a measurable function on Y such that f is either nonnegative or ν-integrable, then for every $E \in \mathcal{B}$,

$$\int_E f\, d\nu = \int_{\phi^{-1}(E)} \left[(f \circ \phi) \cdot \left(\frac{d\nu}{d(\phi_* \mu)} \circ \phi \right) \right] d\mu$$

where $\frac{d\nu}{d(\phi_* \mu)}$ is the Radon-Nikodým derivative (in particular, the integrand on the right is μ-integrable if f is ν-integrable).

PROOF: Since $\nu \ll \phi_* \mu$, by XVIII.6.6.2. and the Radon-Nikodým Theorem we have

$$\int_E f\, d\mu = \int_E \left(f \cdot \frac{d\nu}{d(\phi_* \mu)} \right) d(\phi_* \mu) = \int_{\phi^{-1}(E)} \left[(f \circ \phi) \cdot \left(\frac{d\nu}{d(\phi_* \mu)} \circ \phi \right) \right] d\mu$$

(to apply the Radon-Nikodým Theorem, note that $\phi_* \mu$ is σ-finite).

XVIII.6.6.10. The names "Forward/Backward Change of Variable" are nonstandard and rather arbitrary, but nicely describe the direction the integral is converted (but note that in each the ϕ must preserve null sets in the *opposite* direction). The Backward Change of Variable is generally more useful than the forward, since the integral on the left can be typically taken to be a given one to compute in a problem, and the Backward Theorem is used to convert it to a new integral over a subset of X. The integral on the right appears more complicated, but in practice it sometimes has a nice form which can be evaluated. However, it can be difficult to explicitly compute the Radon-Nikodým derivative, and it will take some work to write it in a more useful form in nice cases.

XVIII.6.7. Exercises

XVIII.6.7.1. What is the difficulty in extending the Radon-Nikodým Theorem to the case where μ is merely decomposable, using the argument in the last part of the proof of XVIII.6.2.1.? (See XVIII.6.1.5..) Give a valid statement in this case; cf. [HS75, 19.27].

XVIII.6.7.2. Let ν be a complex measure on $(X, \mathcal{A})$.

(a) Use the complex Radon-Nikodým Theorem to show that there is a $u \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$ such that

$$\nu(A) = \int_A u \, d|\nu|$$

for all $A \in \mathcal{A}$.

(b) Use Exercise XVII.9.5.1.(b) to show that $|u| = 1$ a.e.

(c) Let $f \in \mathcal{L}^1_{\mathbb{C}}(X, \mathcal{A}, \nu)$, and define a complex measure σ on $(X, \mathcal{A})$ by $\sigma(A) = \int_A f \, d\nu$ (). Show that

$$|\sigma|(A) = \int_A |f| \, d|\nu|$$

for $A \in \mathcal{A}$.

XVIII.6.7.3. Use Theorem XVIII.6.5.6. to give a proof that if $(X, \mathcal{A}, \mu)$ is a σ-finite measure space with completion $(X, \bar{\mathcal{A}}, \bar{\mu})$, and f is a real-valued $\bar{\mathcal{A}}$-measurable function, then there is an $\mathcal{A}$-measurable function g with $g = f$ $\bar{\mu}$-a.e. [The case where μ is finite and f is integrable is immediate. In the general case, decompose X into sets of finite measure and write f as a pointwise limit of integrable functions.]

Chapter XIX

Advanced Analysis on Euclidean Spaces

In this chapter, we collect together results connecting continuity, differentiation, and integration of functions on $\mathbb{R}$ and $\mathbb{R}^n$. The integration used is Lebesgue integration and sometimes integration with respect to more general measures on the Borel sets. In particular, we examine several natural classes of functions and their properties.

A common theme in this chapter is the principle that "what happens on null sets can frequently be ignored" (i.e. that null sets are frequently "negligible"). We will thus often think of two functions as being essentially the same if they agree almost everywhere, and many phenomena only hold almost everywhere. We can even relax the basic notions of limits, continuity, and differentiability to "approximate" ones where "small" sets are ignored. (However, considerable work is sometimes needed to justify ignoring null sets, and it is not always possible.)

XIX.1. Borel Measures on $\mathbb{R}$ and Cumulative Distribution Functions

A *finite Borel measure* on $\mathbb{R}$ is a finite measure defined on $(\mathbb{R}, \mathcal{B})$. We will also study finite Borel measures on intervals in $\mathbb{R}$, and defined in the same way, and σ-finite Borel measures on $\mathbb{R}$ which are finite on bounded sets (*positive Radon measures*). Such measures are important in many contexts, and especially in probability theory.

XIX.1.1. Cumulative Distribution Functions

XIX.1.1.1. We would like to have a way of describing the finite Borel measures on $\mathbb{R}$ (or an interval in $\mathbb{R}$). If μ is a finite Borel measure on $\mathbb{R}$, for each $x \in \mathbb{R}$ we can compute $\mu((-\infty, x])$. It turns out that these numbers are sufficient to recover μ by the Carathéodory extension process (XIX.1.1.4.).

This data is conveniently described by a function F_μ from $\mathbb{R}$ to $\mathbb{R}$, setting $F_\mu(x) = \mu((-\infty, x])$. Then if $a, b \in \mathbb{R}$, $a < b$, we have $\mu((a, b]) = F_\mu(b) - F_\mu(a)$.

XIX.1.1.2. Definition. F_μ is called the *cumulative distribution function* (or *cdf*) of μ.

XIX.1.1.3. Proposition. The function F_μ has the following properties:

(i) F_μ is increasing (nondecreasing).

(ii) F_μ is continuous from the right.

(iii) $\lim_{x \to -\infty} F_\mu(x) = 0$.

(iv) F_μ is bounded, and $\sup_{x \in \mathbb{R}} F_\mu(x) = \lim_{x \to +\infty} F_\mu(x) = \mu(\mathbb{R})$.

Proof: (i) is obvious, and (iii) and (iv) follow immediately from () since $\cup_{n \in \mathbb{N}}(-\infty, n] = \mathbb{R}$ and $\cap_{n \in \mathbb{N}}(-\infty, -n] = \emptyset$. (ii) also follows from () since for any $x \in \mathbb{R}$, $(-\infty, x] = \cap_{n \in \mathbb{N}} \left(-\infty, x + \frac{1}{n}\right]$. 👍

The choice to make cdf's continuous from the right is simply an arbitrary convention. We could have equally well made them continuous from the left by defining $F_\mu(x) = \mu((-\infty, x))$.

Conversely, a function satisfying (i)–(iv) is the cdf of a unique finite Borel measure:

XIX.1.1.4. Theorem. Let $F : \mathbb{R} \to \mathbb{R}$ be a function with the following properties:

(i) F is increasing (nondecreasing).

(ii) F is continuous from the right.

(iii) $\lim_{x \to -\infty} F(x) = 0$.

(iv) F is bounded.

Then there is a unique finite Borel measure μ on $\mathbb{R}$ with $F = F_\mu$, and $\mu(\mathbb{R}) = \sup_{x\in\mathbb{R}} F(x) = \lim_{x\to+\infty} F(x)$.

PROOF: Let $\mathcal{S}$ be the collection of all intervals of the form $(a, b]$, for $a, b \in \mathbb{R}$, $(-\infty, b]$ for $b \in \mathbb{R}$, and $(a, +\infty)$ for $a \in \mathbb{R}$, along with $\mathbb{R}$ and $\emptyset$. Set $M = \sup_{x\in\mathbb{R}} F(x) = \lim_{x\to+\infty} F(x)$. Define

$$\iota((-\infty, b]) = F(b)$$

$$\iota((a, b]) = F(b) - F(a)$$

$$\iota((a, +\infty)) = M - F(a)$$

$$\iota(\mathbb{R}) = M$$

$$\iota(\emptyset) = 0.$$

It is easily verified that $\mathcal{S}$ is a semialgebra () and that ι is a premeasure (XVII.4.5.2.) on $\mathcal{S}$. Thus there is a unique measure μ on the σ-algebra $\sigma(\mathcal{S}) = \mathcal{B}$ extending ι by the Extension Theorem (XVII.4.5.8.), and obviously $F = F_\mu$. 👍

XIX.1.1.5. The finite Borel measure μ for which $F = F_\mu$ is called the *Lebesgue-Stieltjes measure* of (or corresponding to) F. If g is a μ-integrable function, $\int g\, d\mu$ is sometimes written $\int g\, dF$ and called the *Lebesgue-Stieltjes integral* of g with respect to F.

XIX.1.1.6. DEFINITION. Let F be a nondecreasing function from $\mathbb{R}$ to $\mathbb{R}$. Then F is continuous except possibly at a countable number of jump discontinuities at $\{x_n : n \in \mathbb{N}\}$. If $E \subseteq \mathbb{R}$, set

$$F^{\rightarrow}(E) = F(E) \cup \{[F(x_n-), F(x_n+)] : x_n \in E\} .$$

$F^{\rightarrow}(E)$ is the "image" of E, saturated by adding intervals for jump discontinuities of F as in ().

XIX.1.1.7. THEOREM. Let μ be a finite Borel measure on $\mathbb{R}$, with cdf F_μ. If E is any Borel subset of $\mathbb{R}$, then $F_\mu^{\rightarrow}(E)$ is a Borel set, and $\mu(E) = \lambda(F_\mu^{\rightarrow}(E))$.

Note that this result is false, even meaningless, if E is merely a Lebesgue measurable subset of $\mathbb{R}$; $F_\mu^{\rightarrow}(E)$ need not be Lebesgue measurable (), and $\mu(E)$ may not be defined.

XIX.1.2. Density Functions and Absolute Continuity

XIX.1.2.1. For some, but not all, finite Borel measures, there is a corresponding density function. If μ is a finite Borel measure on $\mathbb{R}$, and there is a Borel measurable function ϕ from $\mathbb{R}$ to $\mathbb{R}$ (necessarily nonnegative and integrable) such that $\mu(E) = \int_E \phi\, d\lambda$ for all Borel sets $E \subseteq \mathbb{R}$, then ϕ is called a *density function* for μ. Two density functions for μ must agree almost everywhere (with respect to λ), so by slight abuse of terminology we may refer to *the* density function of μ. Any nonnegative integrable function ϕ on $\mathbb{R}$ is the density function of a unique measure μ_ϕ, defined by $\mu_\phi(E) = \int_E \phi\, d\lambda$ for $E \subseteq \mathbb{R}$ Borel.

The function ϕ is actually the "derivative" of the function F_{μ_ϕ}. This is a precise relationship in nice cases:

XIX.1.2.2. EXAMPLE. Let ϕ be a nonnegative continuous function on $\mathbb{R}$ with $\int_{-\infty}^{\infty} \phi(t)\,dt$ finite. For a Borel set $E \subseteq \mathbb{R}$, set $\mu_\phi(E) = \int_E \phi\,d\lambda$ as above. Then, for $a, b \in \mathbb{R}$, $a < b$, we have

$$F_{\mu_\phi}(b) - F_{\mu_\phi}(a) = \mu_\phi((a,b]) = \int_a^b \phi(t)\,dt$$

and thus by the Fundamental Theorem of Calculus 1, F_{μ_ϕ} is an antiderivative for ϕ, i.e. F_{μ_ϕ} is differentiable and $F'_{\mu_\phi} = \phi$.

This example generalizes to arbitrary density functions ϕ:

XIX.1.2.3. THEOREM. Let $\phi \in \mathcal{L}^1_+(\mathbb{R})$, and F_{μ_ϕ} the cdf of the corresponding measure μ_ϕ with density function ϕ. Then F_{μ_ϕ} is continuous, differentiable λ-a.e., and $F'_{\mu_\phi} = \phi$ λ-a.e.

This theorem will be proved in XIX.5.2.6..

A finite Borel measure need not have a density function. Its cdf need not even be continuous:

XIX.1.2.4. EXAMPLE. Let δ_0 be the Dirac measure (unit point mass) at 0. Then

$$F_{\delta_0}(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ \\ 0 & \text{if } x < 0 \end{cases}.$$

XIX.1.2.5. In fact, the cdf of a finite Borel measure μ is a continuous function if and only if μ is a continuous measure: in general, for $x \in \mathbb{R}$,

$$F_\mu(x+) - F_\mu(x-) = F_\mu(x) - F_\mu(x-) = \mu(\{x\})$$

where, as usual, $F_\mu(x+) = \lim_{y \to x+} F_\mu(y)$ and $F_\mu(x-) = \lim_{y \to x-} F_\mu(y)$. (This fact was crucial motivation for the choice of the term "continuous" for a measure with no atoms.)

But even a continuous μ need not have a density function:

XIX.1.2.6. EXAMPLE. Let F be the Cantor function on $[0,1]$ (), extended to be 0 on $(-\infty, 0]$ and 1 on $[1, \infty)$. F satisfies the conditions of XIX.1.1.4., and thus it is F_μ for a unique continuous finite Borel measure μ on $\mathbb{R}$ with $\mu(\mathbb{R}) = \mu([0,1]) = 1$. If μ had a density function ϕ, then ϕ would have to be equal to F' λ-a.e. But $F' = 0$ λ-a.e., so ϕ would have to be 0 λ-a.e. and μ would be 0. Thus μ has no density function.

This μ is not absolutely continuous with respect to λ. For example, if K is the Cantor set, $\lambda(K) = 0$, but $\mu(K) = 1$; this follows from XIX.1.1.7., but can also easily be seen directly by noting that $\mu(I) = 0$ for any interval I in the complement of K, since F is constant on I. This μ is actually the push-forward of the measure of () under the natural map from $\{0,1\}^{\mathbb{N}}$ to $K \subseteq \mathbb{R}$.

XIX.1.2.7. So which finite Borel measures have density functions? It follows immediately from () that for μ to have a density function, it is necessary for μ to be absolutely continuous with respect to λ. This condition also turns out to be sufficient:

XIX.1.2.8. THEOREM. A finite Borel measure has a density function if and only if it is absolutely continuous with respect to λ.

The "if" part of this theorem is a special case of the Radon-Nikodým Theorem (). See XIX.5.2.6. for a proof.

XIX.1.2.9. COROLLARY. A finite Borel measure μ is absolutely continuous with respect to λ if and only if its cdf F_μ is absolutely continuous in the sense of XIX.5.2.1..

In fact, this result is the reason behind the choice of the term "absolutely continuous" for the functions of XIX.5.2.1..

XIX.1.2.10. Even if μ does not have a density function, it has a density in a generalized sense (), which is the "derivative" of F_μ. Thus, for example, we informally think of the "Dirac δ-function" as the "derivative" of the function $\chi_{[0,\infty)}$. We can think of the actual measure μ as being identified with F_μ, in which case the "density" of μ is regarded as the "derivative" of μ, or we can regard μ as being identified with its "density", with F_μ regarded as the "antiderivative" of μ. The second point of view is more common.

XIX.1.3. Finite Borel Measures on Intervals

XIX.1.3.1. If I is an interval in $\mathbb{R}$, then finite Borel measures on I can be thought of as finite Borel measures on $\mathbb{R}$ giving measure 0 to $\mathbb{R} \setminus I$. The cdf of such a measure is constant on $\mathbb{R} \setminus I$.

If I is bounded above, and $b = \sup(I)$, then the cdf F_μ of a finite Borel measure μ on I must satisfy $F_\mu(b) = \mu(I)$ $(= \mu(\mathbb{R}))$. If $b \notin I$, then F_μ is continuous at b; but if $b \in I$, then F_μ can have a discontinuity at b if $\mu(\{b\}) > 0$. In any event, $\mu(I) = \sup_{x \in I} F_\mu(x)$.

If I is bounded below with $a = \inf(I)$, then F_μ is identically 0 on $(-\infty, a)$, but if $a \in I$, then $F_\mu(a) = \mu(\{a\})$, so $\inf_{x \in I} F_\mu(x)$ is not necessarily 0. But if $a \notin I$, then we must have $\inf_{x \in I} F_\mu(x) = 0$.

The Mean Value Theorem for Integrals Revisited

Here is perhaps the most general version of the Mean Value Theorem for Integrals IX.2.7.14.:

XIX.1.3.2. THEOREM. [MEAN VALUE THEOREM FOR INTEGRALS, VERSION 4] Let f be a continuous function on $[a, b]$, and μ a finite Borel measure on $[a, b]$. Then there is a $c \in [a, b]$ for which

$$f(c)\mu([a, b]) = \int_{[a,b]} f \, d\mu \ .$$

PROOF: If $\mu = 0$ there is nothing to prove. If $\mu([a,b]) > 0$, then, if M and m are the maximum and minimum values of f on $[a,b]$, we have

$$m\mu([a,b]) \leq \int_{[a,b]} f\, d\mu \leq M\mu([a,b])$$

and thus by the Intermediate Value Theorem there is a $c \in [a,b]$ with

$$f(c) = \frac{\int_{[a,b]} f\, d\mu}{\mu([a,b])} \ .$$

👍

An apparently more general version is:

XIX.1.3.3. COROLLARY. [MEAN VALUE THEOREM FOR INTEGRALS, VERSION 5] Let f be a continuous function on $[a,b]$, μ a finite Borel measure on $[a,b]$, and g a nonnegative μ-integrable function on $[a,b]$. Then fg is μ-integrable on $[a,b]$, and there is a $c \in [a,b]$ for which

$$f(c) \int_{[a,b]} g\, d\mu = \int_{[a,b]} fg\, d\mu \ .$$

PROOF: If E is a Borel subset of $[a,b]$, set $\nu(E) = \int_E g\, d\mu$. Then ν is again a finite Borel measure on $[a,b]$. We have that fg is μ-integrable on $[a,b]$ and that $\int_{[a,b]} fg\, d\mu = \int_{[a,b]} f\, d\nu$ by XVIII.1.9.2.. Apply XIX.1.3.2. with ν in place of μ. 👍

XIX.1.4. Stieltjes Integrals

XIX.1.5. Unbounded Distribution Functions and Positive Radon Measures

XIX.1.5.1. The requirement that $\lim_{x \to -\infty} F(x) = 0$ for a cdf F is a convenient normalization, but is not really necessary. If μ is a finite Borel measure on $\mathbb{R}$, c is any constant, and $G(x) = F_\mu(x) + c$, then G can be used just as well as F_μ to recover μ, since for any finite interval $(a,b]$, we have

$$\mu((a,b]) = F_\mu(b) - F_\mu(a) = G(b) - G(a) \ .$$

If F_μ is regarded as an "antiderivative" of μ, then the general "antiderivative" of μ is a constant translate of F_μ, and one antiderivative is as good as another for most purposes.

XIX.1.5.2. Taking this observation one step farther, if F is any nondecreasing, right-continuous function from $\mathbb{R}$ to $\mathbb{R}$, not necessarily bounded above or below, then F has a Lebesgue-Stieltjes measure μ defined by the Carathéodory extension process using $\mu((a,b]) = F(b) - F(a)$ for $a, b \in \mathbb{R}$, $a < b$, and F can be regarded as a cdf for μ. This μ is a positive Radon measure (finite on bounded sets) which is always σ-finite, but not finite if F is unbounded. Two nondecreasing right-continuous functions define the same Lebesgue-Stieltjes measure if and only if they differ by a constant. The function $F(x) = x$ is the cdf of Lebesgue measure itself.

XIX.1.5.3. If F is such a cdf, and $a, b \in \mathbb{R}$, then F can be truncated at a and b to a function G by setting

$$G(x) = \begin{cases} F(a-) & \text{if } x < a \\ F(x) & \text{if } a \leq x \leq b \\ F(b) & \text{if } x > b \end{cases} .$$

Then G is a cdf for the measure $\mu|_{[a,b]}$, which is a finite Borel measure. Thus the study of positive Radon measures on $\mathbb{R}$ and their cdf's can be effectively reduced to the theory of finite Borel measures.

XIX.1.5.4. The theory can be further extended by allowing F to take extended real values. Then $\{x : F(x) \in \mathbb{R}\}$ is an interval I, and F may be thought of as a positive Radon measure on I, i.e. finite on closed subintervals in the interior of I.

XIX.1.5.5. Example. Let $F(x) = \tan x$ for $-\pi/2 < x < \pi/2$. Set $F = -\infty$ on $(-\infty, -\pi/2]$ and $+\infty$ on $[\pi/2, \infty)$. Then F is the cdf of a σ-finite Borel measure μ on $(-\pi/2, \pi/2)$ which is finite on any closed subinterval. This μ is absolutely continuous with respect to $\lambda|_{(-\pi/2,\pi/2)}$, and has density function $g(x) = \sec^2 x$.

XIX.1.6. Signed Measures and Nonincreasing Distribution Functions

Using the theory of signed measures, many of the results of this section generalize to cdf's which are not increasing. There are considerable complications in this case, but also important applications. Details are found in ().

XIX.1.7. Borel Measures and Distribution Functions on $\mathbb{R}^n$

XIX.1.8. Integration By Parts

We may combine the above notions with the Fubini-Tonelli Theorem to obtain a very general version of Integration by Parts.

XIX.1.8.1. Let $[a, b]$ be a closed bounded interval. Let μ and ν be finite Borel measures on $[a, b]$ with cdf's F and G respectively. Set $I = (a, b]$. We have

$$(\mu \times \nu)(I^2) = \mu(I)\nu(I) = [F(b) - F(a)][G(b) - G(a) = F(b)G(b) + F(a)G(a) - F(a)G(b) - F(b)G(a) .$$

Set $A = \{(x, y) \in I^2 : x \leq y\}$ and $B = \{(x, y) \in I^2 : y \leq x\}$. Then $A \cup B = I^2$ and $A \cap B = \Delta = \{(x, x) : a < x \leq b\}$, the diagonal. By Tonelli's Theorem we have

$$(\mu \times \nu)(A) = \int_I \mu((a, y])\, d\nu(y) = \int_I (F(y)) - F(a))\, d\nu(y) = \int_I F(y)\, d\nu(y) - F(a)[G(b) - G(a)]$$

$$(\mu \times \nu)(B) = \int_I \nu((a, x])\, d\mu(x) = \int_I (G(x) - G(a))\, d\mu(x) = \int_I G(x)\, d\mu(x) - G(a)[F(b) - F(a)]$$

so we have

$$(\mu \times \nu)(A) + (\mu \times \nu)(B) = (\mu \times \nu)(I^2) - (\mu \times \nu)(\Delta)$$

$$\int_I F\,d\nu - F(a)G(b) + F(a)G(a) + \int_I G\,d\mu - G(a)F(b) + G(a)F(a)$$
$$= F(b)G(b) + F(a)G(a) - F(a)G(b) - F(b)G(a) - (\mu\times\nu)(\Delta)$$
$$\int_I F\,d\nu + \int_I G\,d\mu = F(b)G(b) - F(a)G(a) - (\mu\times\nu)(\Delta)\ .$$

By Tonelli's Theorem we have

$$(\mu\times\nu)(\Delta) = \int_I \nu(\{x\})\,d\mu(x) = \sum_x \mu(x)\nu(x)$$

(sum over the countably many x with $\mu(x)\nu(x) > 0$). So $(\mu\times\nu)(\Delta) = 0$ if and only if μ and ν do not both give a positive measure to the same singleton, i.e. F and G have no common discontinuities. In this case we obtain the Integration by Parts formula, i.e. we have proved:

XIX.1.8.2. Theorem. [Integration by Parts, General Version] Let $[a,b]$ be a closed bounded interval. Let μ and ν be finite Borel measures on $[a,b]$ with cdf's F and G respectively. If F and G have no common discontinuities, then

$$\int_{(a,b]} G\,d\mu = F(b)G(b) - F(a)G(a) - \int_{(a,b]} F\,d\nu\ .$$

XIX.1.8.3. Using the Stieltjes integral notation, the last formula can be put into more familiar form: if we write dF for $d\mu$ and dG for $d\nu$, we have

$$\int_{(a,b]} G\,dF = F(b)G(b) - F(a)G(a) - \int_{(a,b]} F\,dG\ .$$

XIX.1.8.4. If μ and ν are absolutely continuous with respect to Lebesgue measure, with density functions f and g respectively, then F and G are absolutely continuous on $[a,b]$ and $F' = f$ a.e., $G' = g$ a.e., and the formula becomes

$$\int_a^b fG\,d\lambda = F(b)G(b) - F(a)G(a) - \int_a^b gF\,d\lambda\ .$$

See XIX.5.5.2. for another derivation of this case not requiring Tonelli's Theorem.

XIX.1.8.5. Various further generalizations are possible:

The result extends to unbounded intervals and Radon measures.

The result extends to signed measures.

The result works on regions in $\mathbb{R}^n$.

The straightforward details are left to the interested reader. See () for another general version.

XIX.2. Monotone Functions

In this section, we describe the properties of monotone functions.

XIX.2.1. Definitions and Basics

XIX.2.1.1. DEFINITION. Let I be an interval. A function $f : I \to \mathbb{R}$ is *nondecreasing* on I if $f(x) \leq f(y)$ whenever $x, y \in I$ and $x < y$, and *nonincreasing* on I if $f(x) \geq f(y)$ whenever $x, y \in I$ and $x < y$. A function is *monotone* on I if it is either nondecreasing or nonincreasing on I.

XIX.2.1.2. A nondecreasing function is sometimes called *increasing*, but this term is somewhat ambiguous. If $f(x) < f(y)$ whenever $x, y \in I$, $x < y$, we will say that f is *strictly increasing* on I. A strictly increasing function is, of course, nondecreasing. Strictly decreasing functions are defined analogously. A function is *strictly monotone* on I if it is strictly increasing or strictly decreasing on I. "Increasing" could potentially mean either "nondecreasing" or "strictly increasing," and different authors use both meanings. We will avoid using the terms "increasing" and "decreasing" with regard to functions on intervals.

XIX.2.1.3. We will work with monotone functions on a closed bounded interval $[a, b]$ for simplicity. Analogous results hold for monotone functions on intervals which are not closed and/or not bounded, but there are some technical complications (e.g. such functions need not be bounded). We will also concentrate on the case of nondecreasing functions; the nonincreasing case is essentially identical with only a few notational changes needed.

The first result is almost obvious.

XIX.2.1.4. PROPOSITION. Let f be a monotone function on $[a, b]$. Then f is bounded on $[a, b]$.

PROOF: If f is nondecreasing on $[a, b]$, then $f(a) \leq f(x) \leq f(b)$ for all $x \in [a, b]$. The argument for nonincreasing functions is almost identical. 👍

One of the most important facts about monotone functions is that they are "almost continuous", and that the only possible discontinuities are of a very simple form.

XIX.2.1.5. DEFINITION. Let f be a function defined in a neighborhood of $c \in \mathbb{R}$, and $h > 0$. Then f has a *jump discontinuity of height* h at c if $\lim_{x \to c+} f(x)$ and $\lim_{x \to c-} f(x)$ both exist and

$$\left| \left[\lim_{x \to c+} f(x) \right] - \left[\lim_{x \to c-} f(x) \right] \right| = h$$

(One could also keep track of the sign of the jump by removing the absolute values and allowing $h < 0$.)

XIX.2.1.6. If $[\lim_{x \to c+} f(x)]$ exists, we will denote it by $f(c+)$. Similarly, if $[\lim_{x \to c-} f(x)]$ exists, we will denote it by $f(c-)$. We will extend this notation and the notion of a jump discontinuity at an endpoint of the domain of a function f: if a is the left endpoint of the domain, set $f(a-) = f(a)$, and at the right endpoint b set $f(b+) = f(b)$.

XIX.2.1.7. PROPOSITION. Let f be a monotone function on an interval I, and $c \in I$. Then $f(c+)$ and $f(c-)$ both exist, and $f(c)$ satisfies

$f(c-) \le f(c) \le f(c+)$ if f is nondecreasing on I.

$f(c-) \ge f(c) \ge f(c+)$ if f is nonincreasing on I.

If $d \in I$ and $c < d$, and f is nondecreasing [*resp.* nonincreasing], then $f(c+) \le f(d-)$ [*resp.* $f(c+) \ge f(d-)$].

PROOF: We will suppose c is an interior point of I; the case of an endpoint is similar but easier. Suppose f is nondecreasing on I. Set $u = \inf_{x>c} f(x)$. Since $f(c) \le f(x)$ for all $x > c$, $f(c)$ is a lower bound for $\{f(x) : x > c\}$, so u exists and $f(c) \le u$. We claim $u = f(c+)$. Let $\epsilon > 0$. There is a $y > c$ with $f(y) < u + \epsilon$, by definition of u. Set $\delta = y - c$; then $\delta > 0$ and, if $c < x < c + \delta$, then $c < x < y$ and $u \le f(x) \le f(y) < u + \epsilon$, so $|f(x) - u| < \epsilon$. Similarly, if $v = \sup_{x<c} f(x)$, then $v = f(c-)$ and $v \le f(c)$. If $d > c$, choose x with $c < x < d$; then $f(c+) \le f(x) \le f(d-)$. The proof for nonincreasing f is almost identical. 👍

It follows that if f is monotone on I and $c \in I$, then either f is continuous at c (if $f(c-) = f(c+)$), or f has a jump discontinuity at c (if $f(c-) \ne f(c+)$).

XIX.2.1.8. PROPOSITION. Let f be monotone on a closed interval $[a, b]$, with jump discontinuities at $x_1, \ldots, x_n \in [a, b]$. Let h_j be the height of the jump discontinuity of f at x_j. If $M = |f(b) - f(a)|$, then $\sum_{j=1}^{n} h_j \le M$.

PROOF: Suppose f is nondecreasing. We may assume

$$a \le x_1 < x_2 < \cdots < x_n \le b$$

so we have

$$f(a) \le f(x_1-) < f(x_1+) \le f(x_2-) < f(x_2+) \le \cdots \le f(x_n-) < f(x_n+) \le f(b) \ .$$

Thus,

$$h_1 + \cdots + h_n = [f(x_1+) - f(x_1-)] + \cdots + [f(x_n+) - f(x_n-)]$$
$$\le [f(x_1+) - f(a)] + [f(x_2+) - f(x_1+)] + \cdots + [f(b) - f(x_{n-1}+)] = M \ .$$

The case of nonincreasing f is the same with some inequalities reversed. 👍

XIX.2.1.9. COROLLARY. Let f be monotone on $[a, b]$, and $\epsilon > 0$. If $M = |f(b) - f(a)|$, then f has no more than M/ϵ jump discontinuities on $[a, b]$ of height $\ge \epsilon$.

We summarize these results in a theorem.

XIX.2.1.10. THEOREM. Let f be monotone on an interval I. Then f has only countably many discontinuities on I, each of which is a jump discontinuity.

PROOF: We have proved everything except the countability of the set of discontinuities. But if $[a,b] \subseteq I$, and $M = |f(b) - f(a)|$, then for each $n \in \mathbb{N}$, f has only finitely many jump discontinuities of height $\geq \frac{1}{n}$ (no more than Mn) on $[a,b]$, and hence only countably many jump discontinuities in all. Since I is a countable union of closed bounded subintervals, f can only have countably many jump discontinuities on all of I. 👍

XIX.2.1.11. COROLLARY. Let f be a monotone function on an interval I. Then there is a monotone function g on I which is right continuous on I, and which agrees with f except at countably many points.

PROOF: For $x \in I$, set $g(x) = f(x+)$. Wherever f is continuous, $f(x) = f(x+) = g(x)$. 👍

The same result holds if g is to be left continuous: set $g(x) = f(x-)$ for all x.

XIX.2.2. Differentiability of Monotone Functions

A much deeper and more remarkable result is true about monotone functions: they are not only continuous almost everywhere, but even differentiable almost everywhere. This result is due to Lebesgue.

XIX.2.2.12. THEOREM. Let f be monotone on an interval I. Then f is differentiable almost everywhere (with respect to Lebesgue measure).

However, the set where a monotone function is nondifferentiable is not necessarily countable. For example, the Cantor function () is not differentiable at the points of K, which is uncountable (but has measure 0).

XIX.2.2.13. THEOREM. Let f be a nondecreasing function on $[a,b]$. Then f' is integrable on $[a,b]$ and

$$\int_a^b f' \, d\lambda \leq f(b) - f(a) \ .$$

PROOF: By XIX.2.2.12., f' is defined almost everywhere on $[a,b]$. Extend f to $[a,b+1]$ by setting $f(x) = f(b)$ for $b \leq x \leq b+1$. Define

$$g_n(x) = n\left[f\left(x + \frac{1}{n}\right) - f\left(x\right)\right]$$

for $n \in \mathbb{N}$. Then $g_n \to f'$ pointwise a.e., so f' is measurable. The g_n and f' are nonnegative, so by Fatou's Lemma we have

$$\int_a^b f' \, d\lambda \leq \liminf_n \int_a^b g_n \, d\lambda = \liminf_n \ n\int_a^b \left[f\left(x + \frac{1}{n}\right) - f\left(x\right)\right] \, d\lambda(x)$$

$$= \liminf_n \left[n\int_{a+\frac{1}{n}}^{b+\frac{1}{n}} f \, d\lambda - n\int_a^b f \, d\lambda\right] = \liminf_n \left[n\int_b^{b+\frac{1}{n}} f \, d\lambda - n\int_a^{a+\frac{1}{n}} f \, d\lambda\right] \ .$$

Since f is constant on $\left[b, b+\frac{1}{n}\right]$, the first integral in the last expression is $\frac{f(b)}{n}$; and $f(x) \geq f(a)$ for $a \leq x \leq a+\frac{1}{n}$, so the second integral is at least $\frac{f(a)}{n}$. Thus we have

$$\int_a^b f' \, d\lambda \leq f(b) - \limsup_n \; n \int_a^{a+\frac{1}{n}} f \, d\lambda \leq f(b) - f(a) \; .$$

XIX.2.2.14. We do not have equality in XIX.2.2.13. in general. If f is the Cantor function (), then f is nondecreasing on $[0,1]$, but $f' = 0$ a.e., so we have

$$0 = \int_0^1 f' \, d\lambda < f(1) - f(0) = 1 \; .$$

We do have equality for absolutely continuous functions (and only for absolutely continuous functions) ().

XIX.2.3. Fubini's Series Theorem

We have the following interesting and useful result of Fubini. We call this "Fubini's Series Theorem" (not a standard name) since the name "Fubini's Theorem" is usually reserved for his better-known result on iterated integrals ().

XIX.2.3.1. Theorem. [Fubini's Series Theorem] Let (f_k) be a sequence of nondecreasing functions on a closed bounded interval $[a,b]$. Suppose $\sum_{k=1}^{\infty} f_k$ converges pointwise on $[a,b]$ to a real-valued function f. Then

(i) The series $\sum_{k=1}^{\infty} f_k$ converges to f uniformly on $[a,b]$.

(ii) The series $\sum_{k=1}^{\infty} f_k'$ converges to f' pointwise a.e. on $[a,b]$. In particular, $f_k' \to 0$ pointwise a.e. on $[a,b]$. (Note that by XIX.2.2.12., f and each f_k are differentiable a.e. on $[a,b]$.)

Of course, there is an analogous result for nonincreasing functions.

The statement of the theorem can be rephrased in terms of convergence of sequences of functions (i.e. the partial sums of the series), but it is a little awkward to do so since the hypothesis is that the successive differences of the functions in the sequence, not the functions themselves, must be nondecreasing.

For the proof of XIX.2.3.1., we need two lemmas:

XIX.2.3.2. Lemma. To prove the theorem, it suffices to assume that each f_k is nonnegative and $f_k(a) = 0$.

Proof: Let (f_k) be as in the statement of the theorem. For each k, set $g_k(x) = f_k(x) - f_k(a)$. Then $g_k(a) = 0$, and g_k is nonnegative and nondecreasing since f_k is nondecreasing. We have

$$\sum_{k=1}^{n} g_k(x) = \sum_{k=1}^{n} f_k(x) - \sum_{k=1}^{n} f_k(a)$$

for each n. Since the first sum converges to $f(x)$ and the second sum to $f(a)$ as $n \to \infty$, $\sum_{k=1}^{\infty} g_k(x)$ converges to $g(x) := f(x) - f(a)$ for every $x \in [a,b]$. If the conclusion of the theorem holds for the g_k, then $\sum_{k=1}^{\infty} g_k$ converges uniformly to g, so for any $\epsilon > 0$ there is an N such that

$$\left| g(x) - \sum_{k=1}^{n} g_k(x) \right| < \frac{\epsilon}{2}$$

for all $n \geq N$ and all $x \in [a,b]$, and

$$\left| f(a) - \sum_{k=1}^{n} f_k(a) \right| < \frac{\epsilon}{2}$$

for all $n \geq N$. Then, for all $n \geq N$ and $x \in [a,b]$,

$$\left| f(x) - \sum_{k=1}^{n} f_k(x) \right| = \left| (g(x) + f(a)) - \sum_{k=1}^{n} (g_k(x) + f_k(a)) \right| \leq \left| f(x) - \sum_{k=1}^{n} f_k(x) \right| + \left| f(a) - \sum_{k=1}^{n} f_k(a) \right| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon$$

so $\sum_{k=1}^{\infty} f_k$ converges uniformly to f on $[a,b]$. Part (ii) for f obviously follows from part (ii) for g since $f_k' = g_k'$ for each k and $f' = g'$. 👍

XIX.2.3.3. LEMMA. Under the hypotheses of XIX.2.3.1., we have that $\sum_{k=1}^{\infty} f_k$ converges uniformly to f and that $f_k' \to 0$ pointwise a.e. on $[a,b]$.

PROOF: By XIX.2.3.2., we may assume each f_k is nonnegative and $f_k(a) = 0$. For each n, set

$$s_n(x) = \sum_{k=1}^{n} f_k(x) \ .$$

If $\epsilon > 0$, choose N such that

$$0 \leq f(b) - s_n(b) = f(b) - \sum_{k=1}^{n} f_k(b) < \epsilon$$

for all $n \geq N$. Then, for any $n \geq N$ and $x \in [a,b]$, we have

$$0 \leq f(x) - s_n(x) \leq f(b) - s_n(b) < \epsilon$$

since $f - s_n$ is nonnegative and nondecreasing. Thus $s_n \to f$ uniformly on $[a,b]$.

Set

$$E = \{x \in [a,b] : f \text{ and each } f_k \text{ are differentiable at } x\} \ .$$

By XIX.2.2.12., $[a,b] \setminus E$ is a countable union of null sets, so is a null set. Each s_n is differentiable on E, and since $s_{n+1} - s_n = f_{n+1}$ and $f - s_n$ are nondecreasing, we have $(s_{n+1} - s_n)'(x) \geq 0$ and $(f - s_n)'(x) \geq 0$ for all $x \in E$. So, for every $x \in E$, we have

$$s_1'(x) \leq s_2'(x) \leq \cdots \leq f'(x)$$

and hence $(s_n'(x))$ converges for $x \in E$, which implies that $f_n'(x) \to 0$ for all $x \in E$. 👍

XIX.2.3.4. To complete the proof of XIX.2.3.1., we need to show that $s_n' \to f'$ pointwise a.e. on $[a,b]$. Let E be the set in the proof of XIX.2.3.3.. Since the sequence $(s_n'(x))$ is nondecreasing for each $x \in E$, it suffices to find a subsequence that converges pointwise to f' a.e. on E. For each j, choose an n_j such that $f(b) - s_{n_j}(b) < 2^{-j}$, and set $t_j = f - s_{n_j}$. Then

$$0 \le t_j(x) = f(x) - s_{n_j}(x) \le f(b) - s_{n_j}(b) < 2^{-j}$$

for all $x \in [a,b]$, and thus the series $\sum_{j=1}^{\infty} t_j$ satisfies the hypotheses of XIX.2.3.1.. So by XIX.2.3.3. we have $t_j' \to 0$ pointwise on

$$E' = \{x \in [a,b] : t \text{ and each } t_j \text{ are differentiable at } x\}$$

(where $t = \sum_{j=1}^{\infty} t_j$), i.e. $s_{n_j}' \to f'$ pointwise on $E \cap E'$. Thus $s_n' \to f'$ pointwise on $E \cap E'$, whose complement is a null set.

XIX.2.3.5. Note that we do not necessarily have $E \subset E'$ since there is no assurance that t is differentiable on E, and thus $\sum_{k=1}^{\infty} f_k'$ does not necessarily converge to f' on all of E. See Exercise XIX.2.4.2..

Examples

EXAMPLES. (i) A nonconstant increasing function f can have $f' = 0$ a.e. The Cantor function () is an example. One can even have a strictly increasing function g with $g' = 0$ a.e.: take $g = \sum_{n=1}^{\infty} 2^{-n} f_n$, where the f_n are copies of the Cantor function scaled to each of the subintervals where f and all the previous rescalings of f are constant. (Expand)***

(ii) There is a strictly increasing function f on $[0,1]$ (or any other interval), which is continuously differentiable on all of $[0,1]$, and whose derivative vanishes on a set of positive measure. Let K be a Cantor set of positive measure (), and $g : [0,1] \to [0,1]$ a continuous function with $g^{-1}(\{0\}) = K$ (e.g. $g(x) = \rho(x,K)$; cf. ()). Define

$$f(x) = \int_0^x g(t)\,dt\ .$$

Then $f' = g$ exists and is continuous on all of $[0,1]$ (), and, for any $a, b \in [0,1]$, $a < b$,

$$f(b) - f(a) = \int_a^b g(t)\,dt > 0$$

since g is continuous, nonnegative, and not identically 0 on $[a,b]$ (); recall that K contains no nontrivial intervals). Thus f is strictly increasing. But $f' = g = 0$ on K. K can be taken to have measure $1 - \epsilon$, for any $\epsilon > 0$.

Note that if f is differentiable everywhere on an interval I and $f' = 0$ a.e. on I, then f is constant on I ().

(iii) [POMPEIU] [?] There is a strictly increasing everywhere differentiable function f on a closed bounded interval (actually any interval), with bounded derivative, for which $f' = 0$ on a dense set. Let (r_k) be an enumeration of the rationals in $[0,1]$, and set $g_k(x) = 2^{-k}\sqrt[3]{x - r_k}$,

$$g(x) = \sum_{k=1}^{\infty} g_k(x) = \sum_{k=1}^{\infty} 2^{-k}\sqrt[3]{x - r_k}$$

for $x \in [0,1]$. The series converges uniformly on $[0,1]$, and thus g is a strictly increasing continuous function on $[0,1]$. Let $[a,b]$ be the range of g, and $f : [a,b] \to [0,1]$ the inverse function.

We claim that f is differentiable everywhere on $[a,b]$. Each g_k is differentiable everywhere except at r_k, where its extended derivative is $+\infty$. Thus, by the Mean Value Theorem, we have, for all $x, y \in [0,1]$, $x \neq y$, we have

$$\frac{g(y) - g(x)}{y - x} \geq \frac{g_1(y) - g_1(x)}{y - x} \geq \frac{1}{6}$$

and so all Dini derivatives of g are $\geq \frac{1}{6}$ at every point. Thus to show that f is differentiable everywhere on $[a,b]$, by the Inverse Function Theorem () it suffices to show that g has an extended derivative everywhere on $[0,1]$. It will then also follow that $0 \leq f'(x) \leq 6$ for all $x \in [a,b]$.

In fact, we will show that at every $x \in [0,1]$, the extended derivative of g at x equals $\sum_{k=1}^{\infty} g_k'(x)$. This is clear if $x = r_k \in \mathbb{Q}$ [g is the sum of g_k and another nondecreasing continuous function, so $g'(x) = g_k'(x) = +\infty$]. Suppose $x \notin \mathbb{Q}$ but $\sum_{k=1}^{\infty} g_k'(x) = +\infty$. Set $h_n = \sum_{k=1}^{n} g_k$. Then for each M there is an n such that

$$h_n'(x) = \lim_{y \to x} \frac{h_n(y) - h_n(x)}{y - x} > M$$

so there is a $\delta > 0$ such that for all $y \in [x - \delta, x + \delta]$ we have

$$\frac{g(y) - g(x)}{y - x} \geq \frac{h_n(y) - h_n(x)}{y - x} > M$$

and thus $g'(x) = +\infty = \sum_{k=1}^{\infty} g_k'(x)$.

Now suppose $x \in [0,1]$ and $\sum_{k=1}^{\infty} g_k'(x) < \infty$. Then $x \notin \mathbb{Q}$. We have

$$|s^{1/3} - t^{1/3}| \leq \frac{4}{3} s^{-2/3} |s - t|$$

for all $s, t \in \mathbb{R}$, $s \neq 0$ (Exercise XIX.2.4.1.). Setting $s = x - r_k$ (recall that $x \notin \mathbb{Q}$) and $t = y - r_k$ we obtain

$$\left| \frac{g_k(y) - g_k(x)}{y - x} \right| \leq 4 g_k'(x)$$

for all k and all $y \neq x$. Thus we have, for $y \neq x$ and any n,

$$\left| \frac{g(y) - g(x)}{y - x} - \sum_{k=1}^{\infty} g_k'(x) \right| = \left| \sum_{k=1}^{\infty} \left(\frac{g_k(y) - g_k(x)}{y - x} - g_k'(x) \right) \right|$$

$$\leq \sum_{k=1}^{\infty} \left| \frac{g_k(y) - g_k(x)}{y - x} - g_k'(x) \right| = \sum_{k=1}^{n} \left| \frac{g_k(y) - g_k(x)}{y - x} - g_k'(x) \right| + \sum_{k=n+1}^{\infty} \left| \frac{g_k(y) - g_k(x)}{y - x} - g_k'(x) \right|$$

for every $y \neq x$ and every n. Fix $\epsilon > 0$ and choose n such that $\sum_{k=n+1}^{\infty} 5 g_k'(x) < \frac{\epsilon}{2}$. There is a $\delta > 0$ such that if $0 < |y - x| < \delta$, we have

$$\left| \frac{g_k(y) - g_k(x)}{y - x} - g_k'(x) \right| < \frac{\epsilon}{2n}$$

for $1 \leq k \leq n$. For $0 < |y - x| < \delta$, we have

$$\left| \frac{g(y) - g(x)}{y - x} - \sum_{k=1}^{\infty} g_k'(x) \right| \leq \sum_{k=1}^{n} \left| \frac{g_k(y) - g_k(x)}{y - x} - g_k'(x) \right| + \sum_{k=n+1}^{\infty} \left| \frac{g_k(y) - g_k(x)}{y - x} - g_k'(x) \right|$$

$$\leq \sum_{k=1}^{n} \left| \frac{g_k(y) - g_k(x)}{y - x} - g_k'(x) \right| + \sum_{k=n+1}^{\infty} 5g_k'(x) < n\frac{\epsilon}{2n} + \frac{\epsilon}{2} = \epsilon \ .$$

Thus $g'(x)$ exists and equals $\sum_{k=1}^{\infty} g_k'(x)$.

Since the extended derivative of g is $+\infty$ at every point of $\mathbb{Q} \cap [0,1]$, we have $f' = 0$ at all points of $g(\mathbb{Q} \cap [0,1])$ (), which is dense in $[a,b]$. We also have $f'(x) = 0$ for many x not in this countable set: the set

$$A = \{x \in [a,b] : f'(x) = 0\}$$

is dense in $[a,b]$, hence A must contain the set

$$B = \{x \in [a,b] : f' \text{ is continuous at } x\}$$

which is a residual set by (). (However, the meager set $[a,b] \setminus A$ must be dense in $[a,b]$ and have positive measure in every subinterval by ().)

XIX.2.4. Exercises

XIX.2.4.1. Show that if $s, t \in \mathbb{R}$, $s \neq 0$, then

$$|s^{1/3} - t^{1/3}| \leq \frac{4}{3} s^{-2/3} |s - t| \ .$$

[Convert the problem into showing that

$$|y - z| \leq \frac{4}{3y^2} |y^3 - z^3|$$

for $y \neq 0$ and use the factorization

$$y^3 - z^3 = (y - z)(y^2 + yz + z^2) \ .]$$

XIX.2.4.2. [vRS82, 4.H] For each k, let

$$f_k(x) = \frac{1}{k} \tan^{-1} kx - \frac{1}{k+1} \tan^{-1}(k+1)x \ .$$

(a) Show that f_k is strictly increasing and differentiable on $\mathbb{R}$.
(b) Show that $\sum_{k=1}^{\infty} f_k(x)$ converges pointwise (in fact, uniformly) to $f(x) = \tan^{-1} x$.
(c) Show that $\sum_{k=1}^{\infty} f_k'(0)$ does not converge to $f'(0)$.

XIX.2.4.3. Let f be a monotone function on $[a,b]$.
(a) Show that f is Borel measurable. [Show that $f^{-1}((c, +\infty))$ is an interval for any $c \in \mathbb{R}$.]
(b) Show that f is Baire class 1 (cf. XVI.2.10.5..)

XIX.3. Convex Functions

In this section, we define and derive the most important properties of convex functions.

XIX.3.1. Definitions

XIX.3.1.1. Definition. Let f be a function from an interval I to $\mathbb{R}$. Then f is *convex* on I if for all $x, y \in I$ and $0 < t < 1$, we have

$$f(tx + (1-t)y) \leq tf(x) + (1-t)f(y) \ .$$

Geometrically, this means that the graph of f between x and y lies below the chord between $(x, f(x))$ and $(y, f(y))$, for any $x, y \in I$ (Figure 1).

The terms *concave upward* and *convex downward* are sometimes used as synonyms for *convex* (although for us *concave upward* will mean "strictly convex," cf. V.8.3.1.). The term *convex* is most common, and is motivated by the following observation:

XIX.3.1.2. Proposition. Let f be a real-valued function on an interval I. Then f is a convex function if and only if its *supergraph*

$$S_f = \{(x, y) : x \in I, y \geq f(x)\}$$

is a convex subset () of $\mathbb{R}^2$.

XIX.3.1.3. Proposition. [Chordal Slope Criterion] Let I be an interval and $f : I \to \mathbb{R}$. The following are equivalent:

(i) f is convex on I.

(ii) For all $x, y, z \in I$, $x < y < z$, we have

$$\frac{f(y) - f(x)}{y - x} \leq \frac{f(z) - f(x)}{z - x} \ .$$

(iii) For all $x, y, z \in I$, $x < y < z$, we have

$$\frac{f(z) - f(x)}{z - x} \leq \frac{f(z) - f(y)}{z - y} \ .$$

(iv) For all $x, y, z \in I$, $x < y < z$, we have

$$\frac{f(y) - f(x)}{y - x} \leq \frac{f(z) - f(y)}{z - y} \ .$$

(See Figure 2.)

PROOF: (i) $\Rightarrow$ (ii): Suppose f is convex on I and $x, y, z \in I$, $x < y < z$. Set $t = \frac{z-y}{z-x}$. Then

$$tx + (1-t)z = \frac{z-y}{z-x}x + \frac{y-x}{z-x}z = \frac{xz - xy + yz - xz}{z-x} = \frac{yz-xy}{z-x} = y$$

so

$$f(y) \le tf(x) + (1-t)f(z) = \frac{z-y}{z-x}f(x) + \frac{y-x}{z-x}f(z)$$

and therefore

$$f(y) - f(x) \le \left[\frac{z-y}{z-x} - 1\right] f(x) + \frac{y-x}{z-x}f(z)$$

$$= -\frac{y-x}{z-x}f(x) + \frac{y-x}{z-x}f(z) = \frac{y-x}{z-x}[f(z) - f(x)]$$

So we have

$$\frac{f(y)-f(x)}{y-x} \le \frac{f(z)-f(x)}{z-x} \ .$$

(ii) $\Rightarrow$ (i): Let $x, z \in I$, $x < z$, and $0 < t < 1$, and set $y = tx + (1-t)z$. Then $x < y < z$, and $t = \frac{z-y}{z-x}$. The steps in (i) $\Rightarrow$ (ii) can be reversed to show that

$$f(y) \le \frac{z-y}{z-x}f(x) + \frac{y-x}{z-x}f(z) = tf(x) + (1-t)f(z) \ .$$

(ii) $\Rightarrow$ (iii): Let $x, y, z \in I$, $x < y < z$. Suppose

$$\frac{f(y)-f(x)}{y-x} \le \frac{f(z)-f(x)}{z-x} \ .$$

Since

$$\frac{f(z)-f(x)}{z-x}(z-x) = f(z) - f(x) = \frac{f(y)-f(x)}{y-x}(y-x) + \frac{f(z)-f(y)}{z-y}(z-y)$$

$$\le \frac{f(z)-f(x)}{z-x}(y-x) + \frac{f(z)-f(y)}{z-y}(z-y)$$

we have

$$\frac{f(z)-f(x)}{z-x}(z-x) - \frac{f(z)-f(x)}{z-x}(y-x) \le \frac{f(z)-f(y)}{z-y}(z-y)$$

$$\frac{f(z)-f(x)}{z-x}[(z-x)-(y-x)] = \frac{f(z)-f(x)}{z-x}(z-y) \le \frac{f(z)-f(y)}{z-y}(z-y)$$

and the result follows from dividing by $z-y$.

(iii) $\Rightarrow$ (ii) is almost identical to (ii) $\Rightarrow$ (iii), and is left to the reader.

(iii) $\Rightarrow$ (iv): (iv) is an immediate combination of (ii) and (iii).

(iv) $\Rightarrow$ (ii) and (iii): Let $x, y, z \in I$, $x < y < z$. Then

$$\frac{f(z)-f(x)}{z-x} = \frac{y-x}{z-x}\frac{f(y)-f(x)}{y-x} + \frac{z-y}{z-x}\frac{f(z)-f(y)}{z-y}$$

so $\frac{f(z)-f(x)}{z-x}$ is a weighted average of $\frac{f(y)-f(x)}{y-x}$ and $\frac{f(z)-f(y)}{z-y}$ and thus lies in between. 👍

XIX.3.1.4. This result can be rephrased (cf. [vRS82, §2]). For a function f defined on an interval I, define, for $x, y \in I$,

$$\Phi_1 f(x,y) = \frac{f(y) - f(x)}{x - y} \ .$$

For $x, y, z \in I$, all distinct, define

$$\Phi_2 f(x,y,z) = \frac{\frac{f(z)-f(y)}{z-y} - \frac{f(y)-f(x)}{y-x}}{z - x} \ .$$

Note that the values of $\Phi_1 f$ and $\Phi_2 f$ are unchanged if the variables are permuted, i.e. $\Phi_1 f(x,y) = \Phi_1 f(y,x)$, $\Phi_2(x,y,z) = \Phi_2(x,z,y)$, etc.

XIX.3.1.5. Corollary. Let f be a real-valued function on an interval I. The following are equivalent:

(i) f is convex on I.

(ii) For each $x \in I$, the function $\Phi_1 f(x, \cdot)$ is increasing on $I \setminus \{x\}$.

(iii) $\Phi_2 f(x,y,z) \geq 0$ for all distinct $x, y, z \in I$.

Here are some other consequences of XIX.3.1.3.:

XIX.3.1.6. Corollary. Let f be convex on I, and $w, x, y, z \in I$, $w < x < y < z$. Then

$$\frac{f(x) - f(w)}{x - w} \leq \frac{f(z) - f(y)}{z - y} \ .$$

Proof: Compare both to $\frac{f(y)-f(x)}{y-x}$. 👍

XIX.3.1.7. Corollary. If f is differentiable on I, and f' is nondecreasing on I, then f is convex on I. In particular, if f'' exists and is nonnegative on I, then f is convex on I.

The converse is also true, and the assumption that f is differentiable is almost automatic (XIX.3.1.16.).

Proof: Suppose f' is nondecreasing on I. Let $x, y, z \in I$, $x < y < z$. By the Mean Value Theorem (), there are $c, d \in I$ with $x < c < y < d < z$ such that

$$f'(c) = \frac{f(y) - f(x)}{y - x} \quad \text{and} \quad f'(d) = \frac{f(z) - f(y)}{z - y} \ .$$

Since f' is nondecreasing, $f'(c) \leq f'(d)$. Apply XIX.3.1.3.(iv). 👍

XIX.3.1.8. EXAMPLES. (i) Any linear (affine) function is convex on $(-\infty, \infty)$.
(ii) $f(x) = x^r$ is convex on $[0, \infty)$ if $r = 0$ or $r \geq 1$, convex on $(0, \infty)$ if $r < 0$, and not convex on any interval if $0 < r < 1$. If $n \in \mathbb{N}$ is even, $f(x) = x^n$ is convex on $(-\infty, \infty)$ and $g(x) = x^{-n}$ is convex on $(-\infty, 0)$.
(iii) $f(x) = e^x$ is convex on $(-\infty, \infty)$.
(iv) A convex function need not be differentiable everywhere: $f(x) = |x|$ is convex on $(-\infty, \infty)$.
(v) A convex function need not even be continuous. The following function is convex on $[0, 1]$:

$$f(x) = \begin{cases} 0 & \text{if } 0 \leq x < 1 \\ 1 & \text{if } x = 1 \end{cases}$$

XIX.3.1.9. PROPOSITION. (i) If f and g are convex on I, then $f + g$ is convex on I.
(ii) If f is convex on I and $c \geq 0$, then cf is convex on I.
(iii) If I and J are intervals, f is convex on I, $f(I) \subseteq J$, and g is nondecreasing and convex on J, then $g \circ f$ is convex on I.

PROOF: (i) and (ii) are straightforward, and are left to the reader. For (iii), if $x, y \in I$ and $0 < t < 1$, then

$$g(f(tx + (1-t)y)) \leq g(tf(x) + (1-t)f(y)) \leq tg(f(x)) + (1-t)g(f(y)) \ .$$

XIX.3.1.10. Note, however, that a product of convex functions is not convex in general, even if both are nonnegative and one is linear. For example $f(x) = x^2$ and $g(x) = 1 - x$ are convex and nonnegative on $[0, 1]$, but fg is not convex on $[0, 1]$. (A product of two nonnegative, nondecreasing, convex functions is convex (XIX.3.1.24.).) Also note that (iii) fails in general if g is not nondecreasing, e.g. if $g(x) = -x$.

Limits and Suprema of Convex Functions

XIX.3.1.11. PROPOSITION. Let I be an interval, and (f_n) a sequence of convex functions on I converging pointwise on I to a function f. Then f is convex on I.

PROOF: If $x, y \in I$ and $0 < t < 1$, then $f_n(tx + (1-t)y) \to f(tx + (1-t)y)$ and $tf_n(x) + (1-t)f_n(y) \to tf(x) + (1-t)f(y)$. It follows immediately that f is convex. 

In fact, such a convergent sequence of convex functions almost converges uniformly (XIX.3.3.1.).

XIX.3.1.12. PROPOSITION. Let $\{f_i\}$ be a set of convex functions on an interval I. If $f = \sup_i f_i$ is finite on I, then f is convex on I. In particular, if $f_1, \ldots, f_n$ are convex on I, then $f_1 \vee \cdots \vee f_n = \max(f_1, \ldots, f_n)$ is convex on I.

PROOF: This follows immediately from XIX.3.1.2. and (), since $S_f = \cap_i S_{f_i}$.

Continuity of Convex Functions

The discontinuity in XIX.3.1.8.(v) can only happen at an endpoint. In fact, we have:

XIX.3.1.13. PROPOSITION. Let f be convex on I, and $[a,b]$ a closed bounded interval contained in the interior of I. Then f is Lipschitz on $[a,b]$.

PROOF: Let $c,d \in I$, $c < a < b < d$. If $x,y \in [a,b]$, then by XIX.3.1.6. we have

$$\frac{f(a)-f(c)}{a-c} \leq \frac{f(y)-f(x)}{y-x} \leq \frac{f(d)-f(b)}{d-b}$$

and so $|f(y)-f(x)| \leq M|y-x|$, where

$$M = \max\left(\left|\frac{f(a)-f(c)}{a-c}\right|, \left|\frac{f(d)-f(b)}{d-b}\right|\right) .$$

XIX.3.1.14. PROPOSITION. Let f be convex on I. Then f is continuous on the interior of I. If I has a left endpoint a [*resp.* right endpoint b], then $\lim_{x\to a+} f(x)$ exists [*resp.* $\lim_{x\to b-} f(x)$] exists, and $\lim_{x\to a+} f(x) \leq f(a)$ [*resp.* $\lim_{x\to b-} f(x) \leq f(b)$]. In particular, f is lower semicontinuous at endpoints of I.

PROOF: Continuity of f on the interior of I follows immediately from XIX.3.1.13., since a Lipschitz function is (uniformly) continuous.

Suppose I has a left endpoint a. Let $c \in I$, $c > a$. Then, if $a < x < c$, we have by XIX.3.1.3.(iii),

$$g(x) := \frac{f(c)-f(x)}{c-x} \geq \frac{f(c)-f(a)}{c-a}$$

and $g(x)$ decreases as x decreases; thus

$$L := \lim_{x\to a+} \frac{f(c)-f(x)}{c-x} = \inf_{a<x<c} \frac{f(c)-f(x)}{c-x}$$

exists, and satisfies

$$L \geq \frac{f(c)-f(a)}{c-a} .$$

Since $\lim_{x\to a+}(c-x) = c-a$ exists and is nonzero, $m := \lim_{x\to a+} f(x)$ also exists and satisfies

$$L = \frac{f(c)-m}{c-a} \geq \frac{f(c)-f(a)}{c-a}$$

and so $m = \lim_{x\to a+} f(x) \leq f(a)$. The argument for a right endpoint b of I is virtually identical.

Differentiability of Convex Functions

An almost identical argument shows that the left and right derivatives of a convex function exist at every point:

XIX.3.1.15. THEOREM. Let f be a convex function on an interval I. Then the left and right derivatives $D_L f$ and $D_R f$ of f exist at every point of I (except a left or right endpoint respectively), and are finite except possibly at endpoints of I. If $x, y \in I$, $x < y$, then

$$D_L f(x) \le D_R f(x) \le D_L f(y) \le D_R f(y) \ .$$

$D_L f$ is continuous from the left wherever it is finite (i.e. except possibly at a right endpoint of I), and $D_R f$ is continuous from the right wherever it is finite (i.e. except possibly at a left endpoint of I).

In fact, if I has a right endpoint b, and f is continuous at b, and $D_L f(b) = +\infty$, then $\lim_{x \to b-} D_L f(x) = +\infty$ (cf. **??**), i.e. $D_L f$ is "continuous" at b. A similar statement holds for $D_R f$ at a left endpoint of I.

PROOF: Let $x \in I$, not a right endpoint. Then there is an $\epsilon > 0$ such that $x + \epsilon \in I$. Then

$$g(h) := \frac{f(x+h) - f(x)}{h}$$

exists for $0 < h < \epsilon$. By XIX.3.1.3.(ii), $g(h)$ decreases as h decreases, so

$$D_R f(x) = \lim_{h \to 0+} \frac{f(x+h) - f(x)}{h} = \inf_{0<h<\epsilon} \frac{f(x+h) - f(x)}{h}$$

exists as an extended real number and is not $+\infty$. If x is not a left endpoint, let $a \in I$, $a < x$; then by XIX.3.1.3.(iv) we have

$$\frac{f(x+h) - f(x)}{h} \ge \frac{f(x) - f(a)}{x - a}$$

for $0 < h < \epsilon$, so $D_R f(x)$ is finite (i.e. not $-\infty$). A similar argument shows that if x is not a left endpoint, then $D_L f(x)$ exists and is not $-\infty$; and if x is not a right endpoint, $D_L f(x)$ is finite (not $+\infty$). If $x, y \in I$, $x < y$, then

$$\frac{f(x+h) - f(x)}{h} \le \frac{f(y) - f(y-h)}{h}$$

for $0 < h < (y - x)/2$ by XIX.3.1.6., and hence $D_R f(x) \le D_L f(y)$.

To prove left-continuity of $D_L f$, suppose x is not a left endpoint of I and $D_L f(x)$ is finite. It follows that f is continuous at x. Let $\epsilon > 0$. Then there is a $y \in I$, $y < x$, such that

$$D_L f(x) - \epsilon < \frac{f(y) - f(x)}{y - x} \le D_L f(x) \ .$$

If (x_n) is a sequence in (y, x) converging to x, we have $f(x_n) \to f(x)$, so for sufficiently large n we have

$$D_L f(x) - \epsilon < \frac{f(y) - f(x_n)}{y - x_n} \le D_L f(x_n) \le D_L f(x) \ .$$

Right-continuity of $D_R f$ is almost identical. 👍

XIX.3.1.16. COROLLARY. Let f be convex on I. Then f is differentiable on I except on a countable set (which may be finite or empty), f' is continuous on the set on which it is defined, and f' is nondecreasing on I.

PROOF: It is immediate from XIX.3.1.15. that $D_L f$ is nondecreasing on I, and hence is continuous except at countably many points (). If $x \in I$, then $D_L f(x) \le D_R f(x) \le D_L f(y)$ for all $y > x$, and hence $D_R f(x) = D_L f(x)$ if $D_L f$ is continuous from the right at x (and only at such points). Thus f is differentiable at any point where $D_L f$ is continuous, hence at all but countably many points. 👍

We then get the following "geometrically obvious" consequence:

XIX.3.1.17. COROLLARY. Let f be convex and continuous on an interval I. Then one of the following holds:

(i) $D_L f(x) \ge 0$ for all $x \in I$.

(ii) $D_L f(x) \le 0$ for all $x \in I$.

(iii) There are unique $c, d \in I$, $c \le d$, with $D_L f(x) < 0$ for all $x \in I$, $x < c$, $D_L f(x) > 0$ for all $x \in I$, $x > d$, and, if $c < d$, $D_L f(x) = 0$ for $c < x \le d$.

Thus either f is nondecreasing on I, f is nonincreasing on I, or there are unique $c, d \in I$, $c \le d$, such that f is strictly decreasing on $I \cap (-\infty, c]$, strictly increasing on $I \cap [d, +\infty)$, and, if $c < d$, constant on $[c, d]$.

In fact, if $D_L f$ takes both positive and negative values on I, then $c = \sup\{x \in I : D_L f(x) < 0\}$ and $d = \inf\{x \in I : D_L f(x) > 0\}$. Note that we often have $c = d$; this will happen unless f is constant on a subinterval.

XIX.3.1.18. COROLLARY. Let f be convex on an interval I. Then for each c in the interior of I there is a linear function L on I with $L(c) = f(c)$ and $L(x) \le f(x)$ for all $x \in I$.

PROOF: We can take for L the linear function with $L(c) = f(c)$ and with slope m, for any m satisfying

$$D_L f(c) \le m \le D_R f(c) \ .$$

👍

XIX.3.1.19. Conversely, if f is a continuous function on an interval I with the property that for each c in the interior of I, there is a linear function L_c on I with $L_c(c) = f(c)$ and $L_c(x) \le f(x)$ for all $x \in I$, then $f = \sup_c(L_c)$, and each L_c is convex on I, so f is convex on I by XIX.3.1.12..

Let I be an interval, and $g : I \to \mathbb{R}$ a nondecreasing function. Then g is Riemann integrable over every closed bounded subset of I (). Fix $c \in I$, and for $x \in I$ define

$$f(x) = \int_c^x g(t)\, dt \ .$$

XIX.3.1.20. PROPOSITION. f is convex on I.

PROOF: Let $x, y, z \in I$, $x < y < z$. Then

$$\frac{f(y) - f(x)}{y - x} = \frac{1}{y - x} \int_x^y g(t)\, dt$$

is the average value of g on $[x, y]$, and similarly $\frac{f(z)-f(y)}{z-y}$ is the average value of g on $[y, z]$. Since g is nondecreasing,

$$\frac{f(y) - f(x)}{y - x} \leq g(y) \leq \frac{f(z) - f(y)}{z - y} \ .$$

Apply XIX.3.1.3.. 👍

XIX.3.1.21. We will show that the converse is true, i.e. that every convex function on an open interval is the primitive of a nondecreasing function. This follows immediately from XIX.3.1.13. along with () and (), using the theory of Lebesgue integration and absolute continuity. However, it is not necessary to use Lebesgue integration since bounded nondecreasing functions are Riemann integrable on closed bounded intervals:

XIX.3.1.22. THEOREM. Let f be convex on an open interval I. Then f' is Riemann integrable over every closed bounded subinterval of I. If $a \in I$ is fixed, then, for every $x \in I$,

$$f(x) = f(a) + \int_a^x f'(t)\, dt \ .$$

PROOF: This is a special case of (). We have that $D_L f$ is increasing on I, hence Riemann integrable over every closed bounded subinterval of I, and equal to f' except at countably many points of I. 👍

XIX.3.1.23. COROLLARY. Let f be a function on an open interval I. Then f is convex on I if and only if f is absolutely continuous on every closed bounded subinterval of I and f' is increasing on a subset A of I with $\lambda(I \setminus A) = 0$.

XIX.3.1.24. COROLLARY. Let f and g be nonnegative, nondecreasing, and convex on an open interval I. Then fg is convex on I.

PROOF: Let $[a, b] \subseteq I$. Then f and g are bounded and Lipschitz on $[a, b]$ (XIX.3.1.13.), and hence fg is also Lipschitz and thus absolutely continuous on $[a, b]$. Let A be the set of points where f and g are both differentiable; then $I \setminus A$ is countable. By the product rule, if $x \in A$, then fg is differentiable at x and

$$(fg)'(x) = f(x)g'(x) + f'(x)g(x) \ .$$

Since f, g, f', and g' are all nonnegative and nondecreasing on A, $(fg)'$ is nondecreasing on A. 👍

*** Is there an elementary proof of this? ***

Here is a generalization of the last sentence of XIX.3.1.7. (cf. [**?**, p. 39]; [HS75, 17.37(c)]). Recall () that

$$\overline{D}_S^{(2)}(f)(x) = \limsup_{h\to 0} \frac{f(x+h)+f(x-h)-2f(x)}{h^2}$$

$$\underline{D}_S^{(2)}(f)(x) = \liminf_{h\to 0} \frac{f(x+h)+f(x-h)-2f(x)}{h^2}$$

XIX.3.1.25. PROPOSITION. Let f be a function on an open interval I. Then the following are equivalent:

(i) f is convex on I.

(ii) f is continuous on I and $\overline{D}_S^{(2)}(f)(x) \geq 0$ for all $x \in I$.

(iii) f is continuous on I and $\underline{D}_S^{(2)}(f)(x) \geq 0$ for all $x \in I$.

PROOF: (i) $\Rightarrow$ (iii): If f is convex on I and $x \in I$, then there is an $\epsilon > 0$ such that $(x-\epsilon, x+\epsilon) \subseteq I$. Then, if $|h| < \epsilon$,

$$f(x) \leq \frac{1}{2}f(x-h) + \frac{1}{2}f(x+h)$$

and hence $f(x+h)+f(x-h)-2f(x) \geq 0$. Thus $\underline{D}_S^{(2)}(f)(x) \geq 0$. And f is continuous on I by XIX.3.1.14..
(iii) $\Rightarrow$ (ii) is trivial.
(ii) $\Rightarrow$ (i): Suppose f is continuous and $\overline{D}_S^{(2)}(f) \geq 0$ on I, and let $[a,b] \subseteq I$, and $\epsilon > 0$. Set

$$\phi(x) = f(x) - \left[f(a) + \frac{f(b)-f(a)}{b-a}(x-a)\right] + \epsilon(x-a)(x-b)$$

for $a \leq x \leq b$. Then ϕ is continuous on $[a,b]$, $\phi(a) = \phi(b) = 0$, and $\overline{D}_S^{(2)}(\phi) \geq 2\epsilon$ on $[a,b]$. If $\max_{[a,b]} \phi > 0$, then ϕ has a local maximum at some $x_0 \in (a,b)$, and we would have $\overline{D}_S^{(2)}(\phi)(x_0) \leq 0$, a contradiction. Thus $\phi(x) \leq 0$ on $[a,b]$,

$$f(x) \leq f(a) + \frac{f(b)-f(a)}{b-a}(x-a) - \epsilon(x-a)(x-b)$$

for all $x \in [a,b]$. Since $\epsilon > 0$ is arbitrary, we have

$$f(x) \leq f(a) + \frac{f(b)-f(a)}{b-a}(x-a)$$

for all $x \in [a,b]$. Since $[a,b]$ is arbitrary, f is convex on I. 👍

XIX.3.2. Midpoint-Convex Functions

There is a weaker condition which almost implies convexity:

XIX.3.2.1. Definition. A real-valued function f on an interval I is *midpoint-convex* if, for every $x, y \in I$, we have

$$f\left(\frac{x+y}{2}\right) \leq \frac{f(x)+f(y)}{2} \ .$$

A convex function is midpoint-convex. The converse is false (assuming the Axiom of Choice – Exercise XIX.3.7.2.), but is "almost true" (i.e. true under very mild additional hypotheses), as the results of this subsection show. These results are quite useful since midpoint-convexity is often much easier to check than convexity.

This exposition is adapted from [**?**].

XIX.3.2.2. Proposition. Let f be a midpoint-convex function on an interval I. Then, for every $x, y \in I$ and dyadic rational $t \in [0,1]$,

$$f(tx + (1-t)y) \leq tf(x) + (1-t)f(y) \ .$$

Proof: We prove this for t of the form $\frac{p}{2^n}$ by induction on n. The case $n = 1$ holds by definition. Suppose it is true for n, and let $t = \frac{p}{2^{n+1}}$. Since the condition is symmetric in t and $1-t$, we may assume $p < 2^n$, so $q := 2^{n+1} - p > 2^n$. Set $r = q - 2^n$, so $p + r = 2^n$. Then

$$z := \frac{p}{2^{n+1}}x + \frac{q}{2^{n+1}}y = \frac{1}{2}\left[\frac{p}{2^n}x + \frac{r}{2^n}y + y\right]$$

so we have

$$f(z) \leq \frac{1}{2}\left[f\left(\frac{p}{2^n}x + \frac{r}{2^n}y\right) + f(y)\right] \leq \frac{1}{2}\left[\frac{p}{2^n}f(x) + \frac{r}{2^n}f(y) + f(y)\right] = \frac{p}{2^{n+1}}f(x) + \frac{q}{2^{n+1}}f(y) \ .$$

XIX.3.2.3. Corollary. If f is continuous and midpoint-convex on an interval I, then f is convex on I.

Proof: For fixed $x, y \in I$, the inequality

$$f(tx + (1-t)y) \leq tf(x) + (1-t)f(y)$$

for arbitrary $t \in [0,1]$ follows from the inequality for dyadic rational t by continuity and density of the dyadic rationals.

We can say much more. A midpoint-convex function which is not convex must be not only discontinuous, but rather bizarre:

XIX.3.2.4. THEOREM. Let f be a midpoint-convex function on an open interval I. If f is not convex on I, then f is not bounded above in any subinterval. If $c \in I$, then there is a sequence (x_n) in I with $x_n \to c$ and $\lim_{n\to\infty} f(x_n) = +\infty$. In particular, f is discontinuous everywhere on I.

PROOF: By XIX.3.2.3., f is discontinuous at some $x_0 \in I$. By translation and adding a constant, we may assume $x_0 = 0$ and that $f(0) = 0$ for ease of notation. There is a sequence (y_n) in I with $y_n \to 0$ and $f(y_n) \to m \neq 0$. If $f(y_n) < 0$, we have that $f(-y_n) \geq -f(y_n) > 0$ since $0 = f(0) \leq \frac{1}{2}(f(y_n) + f(-y_n))$. Thus, by replacing (y_n) by a subsequence of $(-y_n)$ if necessary, we may assume $m > 0$. If $m = +\infty$, we are done. Otherwise, we have

$$2f(y_n) \leq f(0) + f(2y_n) = f(2y_n)$$

and so $\liminf_{n\to\infty} f(2y_n) \geq 2m$. Continuing inductively, for each k we have

$$f(2^k y_n) \geq 2^k f(y_n)$$

for all n large enough that $2^k y_n \in I$, and hence $\liminf_{n\to\infty} f(2^k y_n) \geq 2^k m$. Since for fixed k we have $2^k y_n \to 0$, we have that f is unbounded above in every neighborhood of 0, and there is a sequence $(z_n) \in I$ with $z_n \to 0$ and $f(z_n) \to +\infty$.

Now let a be the largest number (or $+\infty$) for which $(-a, a) \subseteq I$, and let $c \in (-a, a)$. We have that $x_n := c + 2z_n \to c$, so $x_n \in I$ for sufficiently large n. Also,

$$f(z_n) = f\left(\frac{c + 2z_n - c}{2}\right) \leq \frac{f(c + 2z_n) + f(-c)}{2} = \frac{f(x_n) + f(-c)}{2}$$

and, since $f(z_n) \to +\infty$, it follows that $f(x_n) \to +\infty$. Thus f is unbounded above in every subinterval of $(-a, a)$ and discontinuous everywhere on $(-a, a)$.

We end up with an open subinterval J of I, extending to at least one end of I, such that f is unbounded above on every subinterval of J and hence discontinuous everywhere on J. If $J \neq I$, repeat the argument with an $x_0 \in J$ near the endpoint of J not exhausting I to get another such interval J_2 centered at x_0. If $J \cup J_2 \neq I$, then $J \subseteq J_2$, and J_2 is approximately twice the length of J, with the same properties. Repeating the process, in finitely many steps we cover any bounded subinterval of I, which suffices to prove the result. 👍

XIX.3.2.5. A midpoint-convex function which is not convex can be bounded below: in fact, if f is midpoint-convex, so is $\max(f, 0)$.

XIX.3.2.6. COROLLARY. A midpoint-convex function on an interval I which is bounded on at least one subinterval of I is convex.

This result considerably extends XIX.3.2.3..

We can extend XIX.3.2.4. even further. A midpoint-convex function which is not convex cannot even be bounded on a set of positive Lebesgue measure. The next result is due to Ostrowski [**?**,]

XIX.3.2.7. THEOREM. Let f be midpoint-convex on an interval I. If there is a Lebesgue-measurable subset E of I with $\lambda(E) > 0$ on which f is bounded, then f is convex on I.

PROOF: Assume f is not convex on I. By replacing I by $I \cap (-n, n)$ and E by $E \cap (-n, n)$ for some sufficiently large n, we may assume $I = (a, b)$ is bounded. There is an open set $U \subseteq (a, b)$ with $E \subseteq U$ and $\lambda(U) < \frac{4}{3}\lambda(E)$ (). U is a disjoint union of finitely or countably many open intervals J_n, and we have

$$\lambda(E) = \sum_n \lambda(E \cap J_n) \leq \sum_n \lambda(J_n) < \frac{4}{3} \sum_n \lambda(E \cap J_n)$$

so there is an n such that

$$0 < \lambda(E \cap J_n) \leq \lambda(J_n) < \frac{4}{3}\lambda(E \cap J_n)$$

and replacing I by J_n and E by $E \cap J_n$ we may assume $\lambda(I) < \frac{4}{3}\lambda(E)$.

Suppose $f(x) \leq M$ for all $x \in E$. The set

$$S = \{x \in I : f(x) > M\}$$

is dense in I by XIX.3.2.4., so by contracting I slightly we may assume the midpoint of I is in S. By translating, we may assume $I = (-c, c)$ and that $0 \in S$, to simplify notation. Set

$$\bar{S} = \{-x : x \in S\} .$$

For any $x \in I$, we have

$$M < f(0) \leq \frac{f(x) + f(-x)}{2}$$

so either x or $-x$ is in S, i.e. $S \cup \bar{S} = I$. The set S is not obviously Lebesgue measurable, but in any case we have $\lambda^*(\bar{S}) = \lambda^*(S)$, where λ^* denotes Lebesgue outer measure (). We have $E \cap S = \emptyset$, so $E \subseteq \bar{S}$ and $S \subseteq (I \setminus E)$. Then

$$\lambda(E) \leq \lambda^*(\bar{S}) = \lambda^*(S) \leq \lambda(I \setminus E) = \lambda(I) - \lambda(E)$$

$$2\lambda(E) \leq \lambda(I) < \frac{4}{3}\lambda(E)$$

which is a contradiction (to the assumption that f is not convex on I). 👍

We then obtain the following corollary, due to Sierpiński:

XIX.3.2.8. COROLLARY. Let f be a midpoint-convex function on an interval I. If f is a Lebesgue measurable function, then f is convex on I.

PROOF: We have that $E_n = f^{-1}([-n, n])$ is a Lebesgue measurable subset of I for all n, and $\cup_n E_n = I$, so $\sup_n \lambda(E_n) = \lambda(I) > 0$, and f is bounded on each E_n. 👍

Summarizing, and combining with XIX.3.1.13., we have:

XIX.3.2.9. THEOREM. Let f be a midpoint-convex function on an interval I, and $[a,b]$ a closed bounded interval in the interior of I. The following are equivalent:

(i) f is convex on $[a,b]$.

(ii) f is Lipschitz on $[a,b]$.

(iii) f is continuous on $[a,b]$.

(iv) f is bounded on $[a,b]$.

(v) f is Lebesgue measurable on $[a,b]$.

XIX.3.3. Convergence of Sequences of Convex Functions

Pointwise convergence of a sequence of convex functions implies several much stronger types of convergence. We describe some of the rather remarkable consequences of pointwise convergence in this subsection.

XIX.3.3.1. THEOREM. Let I be an interval, and (f_n) a sequence of convex functions on I converging pointwise on I to a function f. Then f is convex on I, and the convergence is uniform on any closed bounded interval contained in I on which f is continuous (e.g. any closed bounded interval contained in the interior of I).

PROOF: It has been noted in XIX.3.1.11. that f is convex.

If $[a,b]$ is a closed bounded interval in I, suppose the convergence is not uniform on $[a,b]$. Then there is an $\eta > 0$ such that, for infinitely many n, there is a $c_n \in [a,b]$ with $|f_n(c_n) - f(c_n)| \geq \eta$. Passing to a subsequence, we may assume we have such a c_n for all n.

The sequence (c_n) cannot have any eventually constant subsequences, which would contradict the pointwise convergence $f_n \to f$. Thus (c_n) has a strictly monotone subsequence. Passing to this subsequence, we may assume (c_n) is strictly monotone. In the rest of the argument, we will assume (c_n) is strictly increasing; the strictly decreasing case is essentially identical, interchanging the roles of a and b.

We have $c_n \to c$ for some c, $a < c \leq b$. There are two cases to consider:

Case 1. $f_n(c_n) \geq f(c_n) + \eta$ for infinitely many n. Again passing to a subsequence, in this case we may assume $f_n(c_n) \geq f(c_n) + \eta$ for all n. Fix $\epsilon > 0$. Choose n_0 so that, for all $n \geq n_0$, we have $c_n > c - \epsilon$, $|f_n(c) - f(c)| < \frac{\eta}{2}$, and $|f_n(a) - f(a)| < \frac{\eta}{2}$. Then, for $n \geq n_0$, we have

$$\frac{f(c) - f(a) - \eta}{c - a} < \frac{f_n(c) - f_n(a)}{c - a} \leq \frac{f_n(c) - f_n(c_n)}{c - c_n} < -\frac{\eta/2}{\epsilon} \ .$$

This is a contradiction if $f(c) - f(a) - \eta \geq 0$, or if $f(c) - f(a) - \eta < 0$ and ϵ is sufficiently small, specifically if

$$\epsilon < \frac{\eta(c-a)}{2[\eta + f(a) - f(c)]} \ .$$

Case 2. $f_n(c_n) \le f(c_n) - \eta$ for infinitely many n; we may again assume this holds for all n. Fix z with $a < z < c$ and let $\lambda > 0$ with

$$-\lambda < \frac{f(z) - f(a) - \eta}{z - a} .$$

Fix d with $a < d < c$ such that $d > c - \frac{\eta}{4\lambda}$ and $|f(x) - f(c)| < \frac{\eta}{4}$ for all $x \in [d, c]$ (this is possible since f is continuous at c). Choose n_0 such that, for all $n \ge n_0$, $c_n > d$, $|f_n(a) - f(a)| < \frac{\eta}{2}$, $|f_n(z) - f(z)| < \frac{\eta}{2}$, and $|f_n(d) - f(d)| < \frac{\eta}{4}$. Then, for $n \ge n_0$, we have $f_n(d) > f(c) - \frac{\eta}{2}$ and $f_n(c_n) < f(c_n) - \eta < f(c) - \frac{3\eta}{4}$. Thus $f_n(c_n) - f_n(d) < -\frac{\eta}{4}$. We also have

$$\frac{f_n(c_n) - f_n(d)}{c_n - d} \ge \frac{f_n(z) - f_n(a)}{z - a} \ge \frac{f(z) - f(a) - \eta}{z - a} > -\lambda .$$

Then, since $0 < c_n - d < \frac{\eta}{4\lambda}$, we get

$$\frac{4\lambda}{\eta}(f_n(c_n) - f_n(d)) > -\lambda$$

$$f_n(c_n) - f_n(d) > -\frac{\eta}{4}$$

which is a contradiction.

(If $c < b$ in Case 2, a contradiction can be obtained somewhat more simply using an argument similar to the one in Case 1.) 👍

The first statement of this result which I have found is in [Con74]; however, the proof there is incorrect. A stronger assertion, which is incorrect (see the following example), is made in [**?**, IX, Book IV, Chapter I, §4, p. 52]; the proof outlined there only gives a slightly weaker conclusion than XIX.3.3.1. (cf. XIX.3.7.6.(a)-(b)), but can be adapted to give the full result (XIX.3.7.6.(c)-(d)).

XIX.3.3.2. Example. If f is not continuous on I, we do not have uniform convergence on all of I in general, even if I is closed and bounded. If $f_n(x) = x^n$, then f_n is convex on $[0, 1]$ and converges pointwise on $[0, 1]$ to the function of XIX.3.1.8.(v). But the convergence is not uniform on $[0, 1]$.

If I is not closed and bounded, simple examples show that we do not have uniform convergence on all of I in general, even if f is continuous on I: if I is unbounded, consider $f_n(x) = \frac{x}{n}$, and if $I = (0, 1]$, consider $f_n(x) = \frac{1}{x + \frac{1}{n}}$.

Here is a closely related result:

XIX.3.3.3. Theorem. Let (f_n) be a sequence of convex functions on an interval I, converging pointwise on I to a (convex) function f. Then

(i) If x is not a left endpoint of I, then

$$\liminf_{n\to\infty} D_L f_n(x) \ge D_L f(x) .$$

(ii) If x is not a right endpoint of I, then

$$\limsup_{n\to\infty} D_R f_n(x) \le D_R f(x) .$$

In particular, if x is an interior point of I and f is differentiable at x, then

$$\lim_{n\to\infty} D_L f_n(x) = \lim_{n\to\infty} D_R f_n(x) = f'(x)$$

(i.e. the limits both exist and equal $f'(x)$).

PROOF: We prove only (i); the proof of (ii) is entirely symmetric and is left to the reader. So suppose x is not a left endpoint of I, and fix $m < D_L f(x)$ (note that $D_L f(x) \neq -\infty$). Then there is a $y \in I$, $y < x$, such that

$$\frac{f(y) - f(x)}{y - x} > m$$

and thus there is an $\epsilon > 0$ such that

$$m' := \frac{f(y) - f(x) + 2\epsilon}{y - x} > m$$

(note that $y - x < 0$). There is an N such that $|f_n(x) - f(x)| < \epsilon$ and $|f_n(y) - f(y)| < \epsilon$ for all $n \geq N$. Then, for $n \geq N$, we have $f_n(y) < f(y) + \epsilon$ and $f_n(x) > f(x) - \epsilon$, and thus, for any z, $y \leq z < x$, we have, using convexity of f_n,

$$\frac{f_n(z) - f_n(x)}{z - x} \geq \frac{f_n(y) - f_n(x)}{y - x} > \frac{[f(y) + \epsilon] - [f(x) - \epsilon]}{y - x} = m'$$

so $D_L f_n(x) \geq m' > m$ for $n \geq N$, and hence $\liminf_{n\to\infty} D_L f_n(x) \geq m' > m$.

For the final statement, since $D_L f_n(x) \leq D_R f_n(x)$ for all n, we have

$$f'(x) \leq \liminf_{n\to\infty} D_L f_n(x) \leq \limsup_{n\to\infty} D_L f_n(x) \leq \limsup_{n\to\infty} D_R f_n(x) \leq f'(x)$$

$$f'(x) \leq \liminf_{n\to\infty} D_L f_n(x) \leq \liminf_{n\to\infty} D_R f_n(x) \leq \limsup_{n\to\infty} D_R f_n(x) \leq f'(x)$$

so all the inequalities are equalities. 👍

XIX.3.3.4. COROLLARY. Let (f_n) be a sequence of convex functions on an interval I converging pointwise on I to a (convex) function f. Then $f_n' \to f'$ pointwise almost everywhere.

This corollary can also be proved by combining the next theorem with ().

XIX.3.3.5. THEOREM. [Con74] Let (f_n) be a sequence of convex functions on a closed bounded interval $[a, b]$, converging pointwise on $[a, b]$ to a continuous (convex) function f. Then $f_n' \to f'$ in the L^1-norm (), i.e.

$$\lim_{n\to\infty} \|f_n' - f'\|_1 = \lim_{n\to\infty} \int_a^b |f_n'(x) - f'(x)|\, dx = 0 \ .$$

XIX.3.3.6. COROLLARY. Let (f_n) be a sequence of convex functions on a closed bounded interval $[a,b]$, converging pointwise on $[a,b]$ to a continuous (convex) function f. Then $f_n \to f$ in the total variation norm ().

To see this, we may assume that each f_n is continuous on $[a,b]$ by redefining it at the endpoints. Then f and each f_n is absolutely continuous on I, and by () the total variation norm of an absolutely continuous function g on $[a,b]$ is

$$\|g\|_{TV} = |g(a)| + \int_a^b |g'(x)|\, d\lambda(x) \ .$$

To prove XIX.3.3.5., we need a lemma:

XIX.3.3.7. LEMMA. Let f and g be convex functions on an interval I, and $P(x) = f(a) + \frac{f(b)-f(a)}{b-a}(x-a)$. Then

$$\|f' - P'\|_1 = 2\|f - P\|_\infty$$

$$\|g' - P'\|_1 \le \|f' - P'\|_1 + 4\|f - g\|_\infty$$

where $\|\phi\|_\infty = \sup\{|\phi(x)| : a \le x \le b\}$ is the uniform norm.

PROOF: For the equality, note that $f - P$ is convex and is 0 at a and b, and there is a $c \in (a,b)$ such that f is nonincreasing on $[a,c]$ and nondecreasing on $[c,b]$, so the total variation $\|f' - P'\|_1$ is $2|m|$, where $m = f(c)$ is the minimum of $f - P$ on $[a,b]$; and we also have $|m| = \|f - P\|_\infty$.

For the inequality, $g - P$ is convex on $[a,b]$, so either $g - P$ is monotone on $[a,b]$, in which case

$$\|g' - P'\|_1 = |[g(b) - P(b)] - [g(a) - P(a)]| = |[g(b) - f(b)] - [g(a) - f(a)]| \le 2\|f - g\|_\infty$$

or there is a $d \in (a,b)$ with $g - P$ nonincreasing on $[a,d]$ and nondecreasing on $[d,b]$, in which case

$$\|g' - P'\|_1 = ([g(a) - P(a)] - [g(d) - P(d)]) + ([g(b) - P(b)] - [g(d) - P(d)])$$

$$= ([g(a) - f(a)] - [g(d) - P(d)]) + ([g(b) - f(b)] - [g(d) - P(d)]) = 2[P(d) - g(d)] + [g(a) - f(a)] + [g(b) - f(b)]$$

$$\le 2|g(d) - P(d)| + 2\|g - f\|_\infty \le 2(|g(d) - f(d)| + |f(d) - P(d)|) + \|g - f\|_\infty$$

$$\le 2\|f - P\|_\infty + 4\|g - f\|_\infty = \|f' - P'\|_1 + 4\|f - g\|_\infty \ .$$

We now give the proof of XIX.3.3.5..

PROOF: Let $\epsilon > 0$. Using (), fix a partition $\mathcal{P} = \{a = t_0 < t_1 < \cdots < t_m = b\}$ of $[a,b]$ for which

$$\|f' - (\mathcal{P}f)'\|_1 < \frac{\epsilon}{4}$$

where $\mathcal{P}f$ is the polygonal function whose graph has vertices $(t_k, f(t_k))$ for $0 \le k \le m$. Since $f_n \to f$ uniformly, choose N such that

$$\|f_n - f\|_\infty < \frac{\epsilon}{8m}$$

for all $n \geq N$. For such an n, by Lemma XIX.3.3.7. we have, for each k,

$$\int_{t_{k-1}}^{t_k} |f_n' - (\mathcal{P}f)'| \leq \left[\int_{t_{k-1}}^{t_k} |f' - (\mathcal{P}f)'|\right] + 4\|f_n - f\|_\infty < \left[\int_{t_{k-1}}^{t_k} |f' - (\mathcal{P}f)'|\right] + \frac{\epsilon}{2m} .$$

Thus we have

$$\begin{aligned}
\int_a^b |f_n' - f'| &\leq \int_a^b |f_n' - (\mathcal{P}f)'| + \int_a^b |(\mathcal{P}f)' - f'| \\
&\leq \left[\sum_{k=1}^m \int_{t_{k-1}}^{t_k} |f_n' - (\mathcal{P}f)'|\right] + \frac{\epsilon}{4} \\
&< \sum_{k=1}^m \left[\left(\int_{t_{k-1}}^{t_k} |f' - (\mathcal{P}f)'|\right) + \frac{\epsilon}{2m}\right] + \frac{\epsilon}{4} \\
&= \int_a^b |f' - (\mathcal{P}f)'| + \frac{\epsilon}{2} + \frac{\epsilon}{4} < \frac{\epsilon}{4} + \frac{\epsilon}{2} + \frac{\epsilon}{4} = \epsilon .
\end{aligned}$$

If the limit function is differentiable on I, we can say something stronger:

XIX.3.3.8. PROPOSITION. Let (f_n) be a sequence of convex functions on a closed bounded interval $[a, b]$, converging pointwise on $[a, b]$ to a (convex) function f. If f is differentiable on $[a, b]$, then $(D_L f_n)$ and $(D_R f_n)$ converge uniformly to f' on $[a, b]$ (i.e. (f_n') "converges uniformly" to f' on $[a, b]$).

Indeed, under the hypotheses, f' is continuous on $[a, b]$, so the proposition follows from the next more general result, which is strongly reminiscent of Dini's Theorem ():

XIX.3.3.9. PROPOSITION. Let (g_n) be a sequence of nondecreasing functions on a closed bounded interval $[a, b]$ converging pointwise on $[a, b]$ to a (necessarily nondecreasing) continuous function g. Then $g_n \to g$ uniformly on $[a, b]$.

PROOF: Let $\epsilon > 0$. By continuity of g, choose a partition $\{a = t_0 < t_1 < \cdots < t_m = b\}$ of $[a, b]$ such that $g(t_k) - g(t_{k-1}) < \frac{\epsilon}{2}$ for $1 \leq k \leq m$. Choose N such that $|g_n(t_k) - g(t_k)| < \frac{\epsilon}{2}$ for all $n \geq N$ and $0 \leq k \leq m$. Then, if $t_{k-1} \leq x \leq t_k$, we have, for $n \geq N$,

$$g(t_k) - \epsilon < g(t_{k-1}) - \frac{\epsilon}{2} \leq g_n(t_{k-1}) \leq g_n(x) \leq g_n(t_k) \leq g(t_k) + \frac{\epsilon}{2}$$

and we also have

$$g(t_k) - \frac{\epsilon}{2} < g(t_{k-1}) \leq g(x) \leq g(t_k)$$

and thus it follows that $|g_n(x) - g(x)| < \epsilon$. This is true for every k, i.e. for every $x \in [a, b]$.

If f is not differentiable everywhere, we do not have $f_n' \to f'$ uniformly in general, even on closed bounded intervals contained in the interior of I:

XIX.3.3.10. EXAMPLE. Let $f(x) = |x|$, and for each n let $f_n(x) = |x|^{1+1/n}$. Then f and each f_n are convex, f_n is differentiable everywhere, with f_n' continuous, and $f_n \to f$ pointwise on $\mathbb{R}$ (and uniformly on any bounded subinterval). But f_n' does not converge uniformly to f' on any (deleted) interval around 0.

XIX.3.4. Jensen's Inequality

A simple induction on n, beginning with $n = 2$, shows:

XIX.3.4.1. PROPOSITION. If f is convex on an interval I, $x_1, \ldots, x_n \in I$, and $t_1, \ldots, t_n \geq 0$, $t_1 + \cdots + t_n = 1$, then $t_1x_1 + \cdots + t_nx_n \in I$ and

$$f(t_1x_1 + \cdots + t_nx_n) \leq t_1f(x_1) + \cdots + t_nf(x_n) \ .$$

The inequality is strict if the x_k are distinct and the t_k nonzero, unless f is linear on an interval containing the x_k.

This can be rephrased:

XIX.3.4.2. COROLLARY. Let f be convex on an interval I, $x_1, \ldots, x_n \in I$, and $s_1, \ldots, s_n \geq 0$. Then

$$\frac{s_1x_1 + \cdots + s_nx_n}{s_1 + \cdots + s_n} \in I$$

and

$$f\left(\frac{s_1x_1 + \cdots + s_nx_n}{s_1 + \cdots + s_n}\right) \leq \frac{s_1f(x_1) + \cdots + s_nf(x_n)}{s_1 + \cdots + s_n} \ .$$

The inequality is strict if the x_k are distinct and the s_k nonzero, unless f is linear on an interval containing the x_k.

For the proof, just set $t_k = \frac{s_k}{s_1+\cdots+s_n}$.

A particularly important sample application is:

XIX.3.4.3. COROLLARY. Let $x_1, \ldots, x_n$ be positive numbers, and $\lambda_1, \ldots, \lambda_n$ positive numbers with $\lambda_1 + \cdots + \lambda_n = 1$. Then

$$x_1^{\lambda_1}x_2^{\lambda_2}\cdots x_n^{\lambda_n} \leq \lambda_1x_1 + \cdots + \lambda_nx_n$$

with strict inequality unless all the x_k are equal.

PROOF: Note that $f(x) = e^x$ is convex on $\mathbb{R}$. Set $y_k = \log x_k$, so $x_k = e^{y_k}$. We then have

$$(e^{y_1})^{\lambda_1}\cdots(e^{y_n})^{\lambda_n} = e^{\lambda_1y_1+\cdots+\lambda_ny_n} \leq \lambda_1e^{y_1} + \cdots + \lambda_ne^{y_n}$$

which is the desired inequality. 👍

The special case where all $\lambda_k = \frac{1}{n}$ is

XIX.3.4.4. COROLLARY. Let $x_1, \ldots, x_n$ be positive numbers. Then the geometric mean of $\{x_1, \ldots, x_n\}$ is less than or equal to the arithmetic mean, i.e.

$$[x_1 x_2 \cdots x_n]^{1/n} \leq \frac{1}{n}[x_1 + \cdots + x_n]$$

with strict inequality unless all the x_k are equal.

Jensen's Inequality is a generalization of XIX.3.4.2.. If $(X, \mathcal{A}, \mu)$ is a finite measure space and f is a μ-integrable function, recall () that the *average value* of f is

$$av(f) = \frac{1}{\mu(X)} \int_X f \, d\mu \ .$$

XIX.3.4.5. THEOREM. [JENSEN'S INEQUALITY] Let $(X, \mathcal{A}, \mu)$ be a finite measure space, f a μ-integrable function taking values in an interval I, and ϕ a convex function on I. Let $c = av(f)$. Then $c \in I$, and if either ϕ is nonnegative on I or $\phi \circ f$ is μ-integrable, then

$$\phi(c) \leq \frac{1}{\mu(X)} \int_X \phi \circ f \, d\mu \ .$$

The inequality is strict unless f is constant a.e. or ϕ is linear on a subinterval containing the essential range of f.

The condition that ϕ is nonnegative or that $\phi \circ f$ is integrable is simply needed to define the right side of the inequality. (Integrability of $\phi \circ f$ is not automatic; cf. Exercise XIX.3.7.3..) Actually, in general it turns out that $(\phi \circ f)_-$ is always integrable (Exercise XIX.3.7.4.), so $\phi \circ f$ is integrable in the extended sense of () and the right side is well defined as $+\infty$ if $\phi \circ f$ is not integrable, even if ϕ is not nonnegative.

PROOF: If ϕ is nonnegative but $\phi \circ f$ is not integrable, the inequality is trivial, so it only needs proof in the case where $\phi \circ f$ is integrable. Let us assume this.

To see that $c \in I$, it suffices to show that if $a < f(x) < b$ for all $x \in X$, then $a < c < b$. But in this case the function $g(x) = f(x) - a$ is strictly positive on X, so $\int_X g \, d\mu > 0$ (), and similarly $h(x) = b - f(x)$ has $\int_X h \, d\mu > 0$. In fact c is in the interior of I unless $f(x)$ is equal almost everywhere to one of the endpoints of I, in which case the inequality is a trivial equality.

Let m be any number between $D_L\phi(c)$ and $D_R\phi(c)$ (), and let $L(t) = \phi(c) + m(t - c)$ for $x \in I$. Then L is a linear function, and $L(t) \leq \phi(t)$ for all $t \in I$. Thus we have

$$\phi(c)\mu(X) = \int_X [\phi(c) + m(f(x) - c)] \, d\mu(x) = \int_X L(f(x)) \, d\mu(x) \leq \int_X \phi(f(x)) \, d\mu(x) \ .$$

We have equality if and only if $L \circ f = \phi \circ f$ μ-a.e., which is equivalent to the condition in the last line of the statement.

XIX.3.4.6. The inequality XIX.3.4.2. can be regarded as a special case of Jensen's Inequality, where X is an n-point space and $\{s_1, \ldots, s_n\}$ are the masses of the points.

Here are some of the other most commonly stated special cases of Jensen's Inequality:

XIX.3.4.7. Corollary. Let f be integrable on $[a,b]$ with values in an interval I, and let ϕ be convex on I. Let

$$c = \frac{1}{b-a}\int_a^b f\,d\lambda\ .$$

Then $c \in I$, and if ϕ is nonnegative or $\phi \circ f$ is integrable on $[a,b]$, then

$$\phi(c) \le \frac{1}{b-a}\int_a^b \phi\circ f\,d\lambda\ .$$

A slightly more general version allows a weight function:

XIX.3.4.8. Corollary. Let f be Lebesgue measurable on $[a,b]$ with values in an interval I, and let ϕ be convex on I. Let ω be a nonnegative Lebesgue integrable function on $[a,b]$, with $f\omega$ integrable on $[a,b]$. Set

$$c = \frac{1}{\int_a^b \omega\,d\lambda}\int_a^b f\omega\,d\lambda\ .$$

Then $c \in I$, and if ϕ is nonnegative or $(\phi\circ f)\omega$ is integrable on $[a,b]$, then

$$\phi(c) \le \frac{1}{\int_a^b \omega\,d\lambda}\int_a^b (\phi\circ f)\omega\,d\lambda\ .$$

If f is continuous, then everything can be stated and proved in terms of Riemann integration:

XIX.3.4.9. Corollary. Let f be continuous on $[a,b]$ with values in an interval I, and let ϕ be convex and continuous on I. Let

$$c = \frac{1}{b-a}\int_a^b f(x)\,dx.$$

Then $c \in I$, and

$$\phi(c) \le \frac{1}{b-a}\int_a^b \phi(f(x))\,dx\ .$$

An examination of the proof of XIX.3.4.5. shows that only Riemann integrals need be considered in this case. Without the continuity assumption on ϕ, $\phi\circ f$ can fail to be Riemann-integrable on $[a,b]$ (Exercise XIX.3.7.5.).

XIX.3.5. Log-Convex Functions

XIX.3.5.1. Definition. If I is an interval, a function $g : I \to (0,\infty)$ is *log-convex* on I if $\log g$ is convex on I.

XIX.3.5.2. Alternatively, a positive function g on an interval I is log-convex on I if, for all $a, b \in I$, $0 \leq \lambda \leq 1$,

$$g(\lambda a + (1-\lambda)b) \leq g(a)^{\lambda} g(b)^{1-\lambda} \ .$$

The right-hand side is a sort of weighted geometric mean of $g(a)$ and $g(b)$. If g is continuous, then by XIX.3.2.3. g is log-convex if and only if, for every $a, b \in I$,

$$g\left(\frac{a+b}{2}\right) \leq \sqrt{g(a)g(b)} \ .$$

XIX.3.5.3. Proposition. A log-convex function is convex.

Proof: This follows immediately from XIX.3.5.2. and XIX.3.4.3.. 👍

XIX.3.5.4. The converse is false. $g(x) = x^2$ is convex on $(0, \infty)$, but not log-convex on any subinterval. In fact, an increasing log-convex function on an interval (a, ∞) must grow at least exponentially as $x \to +\infty$.

XIX.3.5.5. Since a sum of convex functions is convex, it is obvious that a product of log-convex functions is log-convex. It is also clear that a positive scalar multiple of a log-convex function is log-convex. It is less obvious, but true, that a sum of log-convex functions is log-convex (XIX.3.5.7.).

XIX.3.5.6. Lemma. Let $a_1, a_2, b_1, b_2, c_1, c_2$ be positive real numbers. If $a_1c_1 - b_1^2 \geq 0$ and $a_2c_2 - b_2^2 \geq 0$, then

$$(a_1 + a_2)(c_1 + c_2) - (b_1 + b_2)^2 \geq 0 \ .$$

Proof: If a, b, c are positive real numbers, then the polynomial $f(x) = ax^2 + 2bx + c$ takes only nonnegative real values (for x real) if and only if $ac - b^2 \geq 0$. By assumption, the polynomials $f_1(x) = a_1x^2 + 2b_1x + c_1$ and $f_2(x) = a_2x^2 + 2b_2x + c_2$ take only nonnegative real values, and hence

$$f_1(x) + f_2(x) = (a_1 + a_2)x^2 + 2(b_1 + b_2)x + (c_1 + c_2)$$

also takes only nonnegative real values. 👍

XIX.3.5.7. Proposition. A sum of log-convex functions on an interval I is log-convex on I.

Proof: Since log-convex functions are continuous, by XIX.3.5.2. it suffices to show that if f and g are log-convex on I and $x, y \in I$, then

$$\left[f\left(\frac{x+y}{2}\right) + g\left(\frac{x+y}{2}\right)\right]^2 \leq (f(x) + g(x))(f(y) + g(y)) \ .$$

Apply XIX.3.5.6. with $a_1 = f(x)$, $a_2 = g(x)$, $b_1 = f\left(\frac{x+y}{2}\right)$, $b_2 = g\left(\frac{x+y}{2}\right)$, $c_1 = f(y)$, $c_2 = g(y)$. 👍

XIX.3.5.8. The conclusion of XIX.3.5.7. extends to arbitrary finite sums. Since a positive pointwise limit of log-convex functions is obviously log-convex, it also extends to a positive pointwise limit of finite sums of log-convex functions, e.g. a pointwise-convergent infinite series. By approximating the integrals by Riemann sums, we also obtain:

XIX.3.5.9. PROPOSITION. Let f be a function on $I \times [a,b]$ for some interval I and $a,b \in \mathbb{R}$, $a < b$. If $f(x,t)$ is log-convex on I for each fixed t, and $f(x,t)$ is continuous on $[a,b]$ for each fixed x, then

$$g(x) = \int_a^b f(x,t)\,dt$$

is log-convex on I.

PROOF: Let $n \in \mathbb{N}$ and $h = \frac{b-a}{n}$. Then $g_n(x) = h(f(x,a)+f(x,a+h)+\cdots+f(x,a+(n-1)h)$ is log-convex, and $g_n \to g$ pointwise. Since f is strictly positive, it is obvious that g is also strictly positive. 👍

This result extends to improper integrals:

XIX.3.5.10. COROLLARY. Let f be a function on $I \times (a,b)$ for some interval I and $a,b \in [-\infty,\infty]$, $a < b$. If $f(x,t)$ is log-convex on I for each fixed t, $f(x,t)$ is continuous on (a,b) for each fixed x, and the improper Riemann integral $\int_a^b f(x,t)\,dt$ converges for all $x \in I$, then

$$g(x) = \int_a^b f(x,t)\,dt$$

is log-convex on I.

PROOF: Let (a_n) be a decreasing sequence with $a_n \to a$, (b_n) an increasing sequence with $b_n \to b$, $a_n < b_n$ for all n. Set

$$g_n(x) = \int_{a_n}^{b_n} f(x,t)\,dt\ .$$

Then g_n is log-convex on I for all n by XIX.3.5.9., and $g_n \to g$ pointwise on I. It is also clear that g is strictly positive. 👍

XIX.3.6. Higher-Dimensional Versions of Convexity

XIX.3.7. Exercises

XIX.3.7.1. Let $f : \mathbb{R} \to \mathbb{R}$ be an additive function, i.e. $f(x+y) = f(x) + f(y)$ for all $x,y \in \mathbb{R}$. Show that if there is any nontrivial closed bounded interval $[a,b]$ on which f is bounded or Lebesgue measurable, then f is linear on $\mathbb{R}$, i.e. there is an $m \in \mathbb{R}$ with $f(x) = mx$ for all $x \in \mathbb{R}$. [Show that f and $-f$ are midpoint-convex, and use XIX.3.2.7..]

XIX.3.7.2. [?] Let $\{x_i : i \in I\}$ be a Hamel basis () for $\mathbb{R}$ over $\mathbb{Q}$, i.e. for each $x \in \mathbb{R}$ there is a unique representation

$$x = \sum_{i \in I} c_i(x) x_i$$

where $c_i(x) \in \mathbb{Q}$ for each i and only finitely many $c_i(x)$ are nonzero. (The Axiom of Choice is needed here.)

(a) Show that each function c_i is $\mathbb{Q}$-linear, i.e. $c_i(x+y) = c_i(x) + c_i(y)$ and $c_i(ax) = ac_i(x)$ for all $x, y \in \mathbb{R}$, $a \in \mathbb{Q}$.

(b) Show that each c_i is a midpoint-convex function on $\mathbb{R}$ (and that $-c_i$ is also midpoint-convex).

(c) Show that c_i is discontinuous everywhere. [If $j \neq i$, then $\mathbb{Q}x_j$ and $x_i + \mathbb{Q}x_j$ are both dense in $\mathbb{R}$.]

(d) Conclude that c_i is not convex on any interval. It then follows from XIX.3.2.4. that c_i is unbounded on every interval (this can be seen directly by noting that if $j \neq i$, then $nx_i + \mathbb{Q}x_j$ is dense in $\mathbb{R}$ for each $n \in \mathbb{Z}$). Conclude also that the restriction of c_i to any interval is not Lebesgue measurable.

XIX.3.7.3. Let $X = (0,1)$ with Lebesgue measure. Let $f(x) = x$, $I = (0,1)$, and $\phi(x) = e^{1/x}$. Show that X, f, I, ϕ satisfy the hypotheses of Jensen's Inequality, but that $\phi \circ f$ is not integrable on X.

XIX.3.7.4. Let $(X, \mathcal{A}, \mu)$ be a finite measure space, f a μ-integrable function on X taking values in an integral I, and ϕ a convex function on I. Show that $(\phi \circ f)_-$ is μ-integrable. [There is a linear function L such that $\phi \geq L$ on I.]

XIX.3.7.5. Let K be a Cantor set of positive measure (), and f a continuous function from $[0,1]$ to $[0,1]$ which takes the value 1 precisely on K, e.g. $f(x) = 1 - dist(x, K)$. Let ϕ be the convex function on $[0,1]$ defined in XIX.3.1.8.(v). Then $\phi \circ f$ is not Riemann-integrable on $[0,1]$.

XIX.3.7.6. Let $\mathcal{F}$ be a collection of convex functions on an interval $[a,b]$, and $[c,d]$ a closed bounded subinterval of (a,b).

(a) If the functions in $\mathcal{F}$ are uniformly bounded above at a and b, and there is an $x_0 \in (a,b)$ such that the functions in $\mathcal{F}$ are uniformly bounded below at x_0, show that $\mathcal{F}$ is uniformly bounded on $[a,b]$.

(b) Under the hypotheses of (a), show that there are real numbers m and M such that

$$m \leq D_L f(x) \leq D_R f(x) \leq M$$

for all $f \in \mathcal{F}$ and all $x \in [c,d]$. Conclude that $\mathcal{F}$ is uniformly equicontinuous () on $[c,d]$. In particular, $\mathcal{F}$ is equicontinuous on (a,b).

(c) If (f_n) is a sequence of convex functions on $[a,b]$ converging pointwise on $[a,b]$ to a (convex) function f, use (a), (b), and the Arzela-Ascoli Theorem () to conclude that $f_n \to f$ uniformly on $[c,d]$ (cf. XIX.3.3.1.).

(d) If (f_n) is a sequence of continuous convex functions on $[a,b]$ converging pointwise on $[a,b]$ to a continuous (convex) function f, show that the set

$$\mathcal{F} = \{f_n : n \in \mathbb{N}\}$$

is uniformly bounded and equicontinuous on $[a,b]$.

(e) If (f_n) is a sequence of convex functions on $[a,b]$ converging pointwise on $[a,b]$ to a function f, use (d) and the Arzela-Ascoli Theorem () to give an alternate proof of XIX.3.3.1..

XIX.3.7.7. Let f be convex on an interval I with right endpoint b, and suppose f is continuous at b. Show that if $\sup_{x<b} D_L f(x) = m < \infty$, then $D_L f(b) = m$.

XIX.3.7.8. Let f be convex on $[a, +\infty)$ for some a. Show that

$$\lim_{x\to+\infty} \frac{f(x)}{x}$$

exists (possibly as $+\infty$, but not $-\infty$) and equals

$$\lim_{x\to+\infty} D_L f(x) = \lim_{x\to+\infty} D_R f(x) = \sup_{x>a} D_L f(x) = \sup_{x\geq a} D_R f(x) \ .$$

Prove a similar statement for $-\infty$.

XIX.3.7.9. Let f be a function on an interval I taking only positive values, with f'' defined everywhere on I.

(a) Show that f is log-convex on I if and only if

$$f(x)f''(x) \geq [f'(x)]^2$$

for all $x \in I$. [Set $g(x) = \log f(x)$, and compute g''.]

(b) What if f'' is only defined on the complement of a countable set? What if f'' is only defined almost everywhere?

XIX.3.7.10. Let f and g be convex functions on an interval of the form $(a, +\infty)$ for some a. Show that if

$$\lim_{n\to\infty} [f(n) - g(n)] = 0$$

(limit for $n \in \mathbb{N}$), then

$$\lim_{x\to+\infty} [f(x) - g(x)] = 0$$

(limit for $x \in \mathbb{R}$).

XIX.4. Functions of Bounded Variation

Functions of bounded variation are ones which vary in a controlled way. Geometrically, a function has bounded variation on an interval if its graph has finite arc length. Functions of bounded variation are well-behaved, with perhaps unexpectedly nice properties which are technically useful.

XIX.4.1. The Total Variation of a Function

XIX.4.1.1. In the definition, we will use the positive and negative part notation: if x is a real number, write $x_+ = \max(x, 0) = \frac{|x|+x}{2}$ and $x_- = \max(-x, 0) = \frac{|x|-x}{2}$, so that $x = x_+ - x_-$ and $|x| = x_+ + x_-$. Thus if y and z are real numbers, we will write $(y-z)_+$ for $\max(y-z, 0)$ and $(y-z)_- = \max(z-y, 0)$. Thus $(y-z)_+ = y - z$ if $y \geq z$ and 0 otherwise, and $(y-z)_- = |y-z|$ if $y \leq z$ and 0 otherwise. We always have $(y-z)_+ - (y-z)_- = y - z$ and $(y-z)_+ + (y-z)_- = |y-z|$.

XIX.4.1.2. Proposition. If $x, y \in \mathbb{R}$, then $(x+y)_+ \leq x_+ + y_+$ and $(x+y)_- \leq x_- + y_-$.

This can be proved brute-force on a case-by-case basis, or using the triangle inequality (Exercise ()).

XIX.4.1.3. Definition. Let f be a real-valued function on an interval $[a, b]$. If

$$\mathcal{P} = \{a = x_0, x_1, \ldots, x_n = b\}$$

is a partition of $[a, b]$, set

$$V^+(f, \mathcal{P}) = \sum_{k=1}^{n} [f(x_k) - f(x_{k-1})]_+$$

$$V^-(f, \mathcal{P}) = \sum_{k=1}^{n} [f(x_k) - f(x_{k-1})]_-$$

$$V(f, \mathcal{P}) = V^+(f, \mathcal{P}) + V^-(f, \mathcal{P}) = \sum_{k=1}^{n} |f(x_k) - f(x_{k-1})| \ .$$

$V^+(f, \mathcal{P})$, $V^-(f, \mathcal{P})$, and $V(f, \mathcal{P})$ are respectively the *positive variation*, *negative variation*, and *total variation* of f over the partition $\mathcal{P}$.

These numbers of course depend on the interval $[a, b]$, which is implicitly coded in the partition $\mathcal{P}$.

XIX.4.1.4. Proposition. If $\mathcal{P}$ is any partition of $[a, b]$, then $V^+(f, \mathcal{P})$ and $V^-(f, \mathcal{P})$ are nonnegative real numbers, and

$$V^+(f, \mathcal{P}) - V^-(f, \mathcal{P}) = f(b) - f(a) \ .$$

Proof: The sums are obviously nonnegative and finite. We have

$$V^+(f, \mathcal{P}) - V^-(f, \mathcal{P}) = \sum_{k-1}^{n} ([f(x_k) - f(x_{k-1})]_+ - [f(x_k) - f(x_{k-1})]_-)$$

$$= \sum_{k=1}^{n} [f(x_k) - f(x_{k-1})] = f(b) - f(a)$$

by telescoping. 👍

XIX.4.1.5. PROPOSITION. If $\mathcal{P}$ is a partition of $[a,b]$ and $\mathcal{Q}$ is a refinement of $\mathcal{P}$, then $V^+(f,\mathcal{P}) \le V^+(f,\mathcal{Q})$, $V^-(f,\mathcal{P}) \le V^-(f,\mathcal{Q})$, and $V(f,\mathcal{P}) \le V(f,\mathcal{Q})$.

PROOF: It suffices to prove the result when $\mathcal{Q}$ has just one additional point y. Fix k with $x_{k-1} < y < x_k$ (where $\mathcal{P} = \{x_0, \dots, x_n\}$). For V^+, we need only show that

$$[f(x_k) - f(x_{k-1})]_+ \le [f(x_k) - f(y)]_+ + [f(y) - f(x_{k-1})]_+$$

which follows immediately from XIX.4.1.2.. The proof for V^- is almost identical (or can be immediately obtained by noting that $V^-(f,\mathcal{P}) = V^+(-f,\mathcal{P})$ for any f and $\mathcal{P}$), and the inequalities add for V. 👍

XIX.4.1.6. DEFINITION. Let f be a real-valued function on an interval $[a,b]$. Define

$$V^+_{[a,b]}(f) = \sup_{\mathcal{P}} V^+(f,\mathcal{P})$$

$$V^-_{[a,b]}(f) = \sup_{\mathcal{P}} V^-(f,\mathcal{P})$$

$$V_{[a,b]}(f) = \sup_{\mathcal{P}} V(f,\mathcal{P})$$

where in each case the supremum is over all partitions $\mathcal{P}$ of $[a,b]$. $V^+_{[a,b]}(f)$, $V^-_{[a,b]}(f)$, $V_{[a,b]}(f)$ are called the *total positive variation*, *total negative variation*, and *total variation* of f over $[a,b]$. These are nonnegative extended real numbers.

The function f has *bounded variation* on $[a,b]$ if $V_{[a,b]}(f) < +\infty$.

XIX.4.1.7. EXAMPLES. (i) Any monotone function on an interval $[a,b]$ has bounded variation. If f is nondecreasing on $[a,b]$, then $V^+_{[a,b]}(f) = V_{[a,b]}(f) = f(b) - f(a)$ and $V^-_{[a,b]}(f) = 0$; if f is nonincreasing on $[a,b]$, then $V^-_{[a,b]}(f) = V_{[a,b]}(f) = f(a) - f(b)$ and $V^+_{[a,b]}(f) = 0$.

(ii) A Lipschitz function on $[a,b]$ has bounded variation. If f is Lipschitz with Lipschitz constant M, i.e. $|f(x) - f(y)| \le M|x - y|$ for all $x, y \in [a,b]$, then if $\mathcal{P} = \{a = x_0, x_1, \dots, x_n = b\}$ is any partition of $[a,b]$, we have

$$V(f,\mathcal{P}) = \sum_{k=1}^{n} |f(x_k) - f(x_{k-1})| \le \sum_{k=1}^{n} M|x_k - x_{k-1}| = M(b-a)$$

so $V_{[a,b]}(f) \le M(b-a)$. In particular, if f is differentiable on $[a,b]$ and f' is bounded, then f has bounded variation on $[a,b]$.

(iii) A continuous function need not have bounded variation. Continuous but everywhere nondifferentiable functions cannot have bounded variation (XIX.4.2.4.(iv)). Even a function which is differentiable everywhere need not have bounded variation. Let

$$f(x) = x^2 \sin\left(\frac{1}{x^2}\right)$$

for $x \neq 0$, $f(0) = 0$ (Figure V.4). Then f is differentiable everywhere, but not of bounded variation on $[0,1]$. For each n, let

$$x_n = \frac{1}{\sqrt{\frac{\pi}{2} + \pi(n-1)}} \ .$$

Then

$$f(x_n) = \pm \frac{1}{\frac{\pi}{2} + \pi(n-1)}$$

where the signs alternate, so

$$|f(x_{n+1}) - f(x_n)| = \frac{1}{\frac{\pi}{2} + \pi n} + \frac{1}{\frac{\pi}{2} + \pi(n-1)} \geq \frac{1}{\pi n}$$

so if $\mathcal{P}$ runs over partitions containing large initial finite segments of $\{x_n : n \in \mathbb{N}\}$, $V(f, \mathcal{P})$ is arbitrarily large since the harmonic series diverges (IV.2.2.11.). Thus $V_{[0,1]}(f) = +\infty$. The problem is, roughly speaking (even precisely speaking; cf. XIX.4.2.5.), that f' is not Lebesgue integrable on $[0,1]$.

It turns out that if f is differentiable everywhere on $[a,b]$ and f' is Lebesgue integrable on $[a,b]$, then f has bounded variation on $[a,b]$, but this requires considerable work to prove (). This cannot, however, be relaxed to just requiring that f be continuous, differentiable almost everywhere, and with integrable derivative ().

Example (i) shows that a function of bounded variation need not be continuous. But it must be "almost continuous": it can have only countably many discontinuities, each of which is a jump discontinuity (XIX.4.2.4.).

XIX.4.1.8. PROPOSITION. Let f be a real-valued function on an interval $[a,b]$, and let Γ_f be its graph

$$\Gamma_f = \{(x, f(x)) : a \leq x \leq b\} \ .$$

Then f has bounded variation on $[a,b]$ if and only if the arc length () $\ell(\Gamma_f)$ of Γ_f is finite. In fact,

$$V_{[a,b]}(f) \leq \ell(\Gamma_f) \leq (b-a) + V_{[a,b]}(f) \ .$$

PROOF: We have that

$$\ell(\Gamma_f) = \sup_{\mathcal{P}} \left\{ \sum_{k=1}^{n} \|(x_k, f(x_k)) - (x_{k-1}, f(x_{k-1}))\| \right\}$$

$$= \sup_{\mathcal{P}} \left\{ \sum_{k=1}^{n} \sqrt{[x_k - x_{k-1}]^2 + [f(x_k) - f(x_{k-1})]^2} \right\}$$

$$\leq \sup_{\mathcal{P}} \left\{ \sum_{k=1}^{n} \left([x_k - x_{k-1}] + |f(x_k) - f(x_{k-1})| \right) \right\}$$
$$= \sup_{\mathcal{P}} \left\{ (b-a) + \sum_{k=1}^{n} |f(x_k) - f(x_{k-1})| \right\}$$
$$= \sup_{\mathcal{P}} \{(b-a) + V(f, \mathcal{P})\} = (b-a) + V_{[a,b]}(f)$$

where the suprema are over all partitions $\mathcal{P} = \{a = x_0, \ldots, x_n = b\}$ of $[a, b]$. The first inequality is evident. 👍

The first inequality is always strict if f has bounded variation, but the second inequality can be an equality ().

XIX.4.1.9. Since a function f of bounded variation need not be continuous, the graph of f need not be an arc (a homeomorphic image of $[0, 1]$). We normally only consider arc length for arcs. But since a function of bounded variation has only jump discontinuities, and only finitely many jumps of length more than ϵ for any $\epsilon > 0$, the graph of f can be expanded to an arc by adding vertical line segments across the jumps. The arc length of this arc is still no more than $(b-a) + V_{[a,b]}(f)$.

We now explore properties of the variations of a function.

XIX.4.1.10. Proposition. Let f be a real-valued function on an interval $[a, b]$. Then

$$V^+_{[a,b]}(f) + V^-_{[a,b]}(f) = V_{[a,b]}(f)$$

and, if f has bounded variation on $[a, b]$, then

$$V^+_{[a,b]}(f) - V^-_{[a,b]}(f) = f(b) - f(a) \ .$$

If f does not have bounded variation, then $V^+_{[a,b]}(f) = V^-_{[a,b]}(f) = +\infty$.

Proof: If $\mathcal{P}$ is any partition of $[a, b]$, we have

$$V(f, \mathcal{P}) = V^+(f, \mathcal{P}) + V^-(f, \mathcal{P}) \leq V^+_{[a,b]}(f) + V^-_{[a,b]}(f)$$

and thus $V_{[a,b]}(f) \leq V^+_{[a,b]}(f) + V^-_{[a,b]}(f)$. For the opposite inequality, there is nothing to prove if $V_{[a,b]}(f) = +\infty$, so assume $V_{[a,b]}(f)$ is finite. Since $V^+_{[a,b]}(f) \leq V_{[a,b]}(f)$ and $V^-_{[a,b]}(f) \leq V_{[a,b]}(f)$, they are both also finite. Let $\epsilon > 0$. Choose a partition $\mathcal{P}$ fine enough that $V^+(f, \mathcal{P}) \geq V^+_{[a,b]}(f) - \epsilon$ and $V^-(f, \mathcal{P}) \geq V^-_{[a,b]}(f) - \epsilon$. Then

$$V^+_{[a,b]}(f) + V^-_{[a,b]}(f) - 2\epsilon \leq V^+(f, \mathcal{P}) + V^-(f, \mathcal{P}) = V(f, \mathcal{P}) \leq V_{[a,b]}(f)$$

and since $\epsilon > 0$ is arbitrary, $V^+_{[a,b]}(f) + V^-_{[a,b]}(f) \leq V_{[a,b]}(f)$.

For the last equation, suppose f has bounded variation. Let $\epsilon > 0$, and fix a partition $\mathcal{P}$ fine enough that $|V^+_{[a,b]}(f) - V^+(f, \mathcal{P})| < \frac{\epsilon}{2}$ and $|V^-_{[a,b]}(f) - V^-(f, \mathcal{P})| < \frac{\epsilon}{2}$. Since by XIX.4.1.4. we have $V^+(f, \mathcal{P}) - V^-(f, \mathcal{P}) = f(b) - f(a)$, we have

$$|[V^+_{[a,b]}(f) - V^-_{[a,b]}(f)] - [f(b) - f(a)]|$$

$$= |[V^+(f,\mathcal{P}) - V^-(f,\mathcal{P})] - [f(b) - f(a)] + [V^+_{[a,b]}(f) - V^+(f,\mathcal{P})] + [V^-(f,\mathcal{P}) - V^-_{[a,b]}(f)]|$$

$$\leq |[V^+(f,\mathcal{P}) - V^-(f,\mathcal{P})] - [f(b) - f(a)]| + |V^+_{[a,b]}(f) - V^+(f,\mathcal{P})| + |V^-(f,\mathcal{P}) - V^-_{[a,b]}(f)| < 0 + \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon$$

and, since $\epsilon > 0$ is arbitrary, $V^+_{[a,b]}(f) - V^-_{[a,b]}(f) = f(b) - f(a)$.

Finally, if $V_{[a,b]}(f) = +\infty$, then at least one of $V^+_{[a,b]}(f)$ and $V^-_{[a,b]}(f)$ is infinite. Suppose $V^+_{[a,b]}(f) = +\infty$ and $V^-_{[a,b]}(f) < +\infty$. If $M \in \mathbb{R}$, fix a partition $\mathcal{P}$ such that $V^+(f,\mathcal{P}) \geq M + V^-_{[a,b]}(f)$. Then

$$f(b) - f(a) = V^+(f,\mathcal{P}) - V^-(f,\mathcal{P}) \geq V^+(f,\mathcal{P}) - V^-_{[a,b]}(f) \geq M \ .$$

This is a contradiction since M is arbitrary. The other case is similar. 👍

The next simple result is used repeatedly.

XIX.4.1.11. PROPOSITION. Let f be a real-valued function on $[a,b]$, and $c \in (a,b)$. Then $V^+_{[a,b]}(f) = V^+_{[a,c]}(f) + V^+_{[c,b]}(f)$, $V^-_{[a,b]}(f) = V^-_{[a,c]}(f) + V^-_{[c,b]}(f)$, and $V_{[a,b]}(f) = V_{[a,c]}(f) + V_{[c,b]}(f)$.

PROOF: Since $V^+(f,\mathcal{P})$ increases as $\mathcal{P}$ becomes finer, in computing $V^+_{[a,b]}(f)$ we may restrict to partitions of $[a,b]$ containing c. Any such $\mathcal{P}$ splits into a partition $\mathcal{P}_1$ of $[a,c]$ and a partition $\mathcal{P}_2$ of $[c,b]$. Conversely, any partitions $\mathcal{P}_1$ of $[a,c]$ and $\mathcal{P}_2$ of $[c,b]$ combine into a partition $\mathcal{P}$ of $[a,b]$ containing c. For any such $\mathcal{P}$, we have $V^+(f,\mathcal{P}) = V^+(f,\mathcal{P}_1) + V^+(f,\mathcal{P}_2)$. Taking suprema over $\mathcal{P}_1$ and $\mathcal{P}_2$ corresponds to taking supremum over $\mathcal{P}$. The argument for V^- and V is identical. 👍

XIX.4.1.12. COROLLARY. If f has bounded variation on $[a,b]$, and $[c,d]$ is any (closed) subinterval of $[a,b]$, then f has bounded variation on $[c,d]$, and $V^+_{[c,d]}(f) \leq V^+_{[a,b]}(f)$, $V^-_{[c,d]}(f) \leq V^-_{[a,b]}(f)$, $V_{[c,d]}(f) \leq V_{[a,b]}(f)$.

XIX.4.1.13. PROPOSITION. Let f and g be real-valued functions on $[a,b]$, and $\alpha \in \mathbb{R}$. Then

(i) $V^+_{[a,b]}(f+g) \leq V^+_{[a,b]}(f) + V^+_{[a,b]}(g)$, $V^-_{[a,b]}(f+g) \leq V^-_{[a,b]}(f) + V^-_{[a,b]}(g)$, $V_{[a,b]}(f+g) \leq V_{[a,b]}(f) + V_{[a,b]}(g)$.

(ii) $V_{[a,b]}(\alpha f) = |\alpha| V_{[a,b]}(f)$. If $\alpha \geq 0$, then $V^+_{[a,b]}(\alpha f) = \alpha V^+_{[a,b]}(f)$ and $V^-_{[a,b]}(\alpha f) = \alpha V^-_{[a,b]}(f)$; if $\alpha < 0$, then $V^+_{[a,b]}(\alpha f) = |\alpha| V^-_{[a,b]}(f)$ and $V^-_{[a,b]}(\alpha f) = |\alpha| V^+_{[a,b]}(f)$.

Part (i) follows immediately from XIX.4.1.2., and the simple proof of (ii) is left as an exercise.

XIX.4.1.14. This result shows that if $BV[a,b]$ is the set of functions of bounded variation on $[a,b]$, then $BV[a,b]$ is a vector space of functions and $\|f\|_{BV} = |f(a)| + V_{[a,b]}(f)$ is a norm on $BV[a,b]$. In fact, $BV[a,b]$ is a Banach space under this norm ().

XIX.4.2. The Total Variation Functions

We can use the results of the previous section to define positive, negative, and total variation functions for any function of bounded variation, which yield strong structure results about such functions.

XIX.4.2.1. DEFINITION. Let f be a function of bounded variation on $[a,b]$. For $x \in [a,b]$, define

$$T^+f(x) = V^+_{[a,x]}(f)$$

$$T^-f(x) = V^-_{[a,x]}(f)$$

$$Tf(x) = V_{[a,x]}(f) = T^+f(x) + T^-f(x)\ .$$

T^+f, T^-f, and Tf are called the *positive variation function*, the *negative variation function*, and the *total variation function* of f on $[a,b]$.

These functions depend (up to constants) on the choice of left endpoint of the interval $[a,b]$; when it is necessary to specify the starting point a, we will write $T^+_a f$, $T^-_a f$, $T_a f$.

XIX.4.2.2. The functions T^+f, T^-f, Tf are nonnegative and nondecreasing by XIX.4.1.12.. We define all to be 0 at a. By XIX.4.1.4., $T^+f(x) - T^-f(x) = f(x) - f(a)$ for all $x \in [a,b]$. Thus we obtain the following important consequence:

XIX.4.2.3. THEOREM. Every function of bounded variation on an interval $[a,b]$ can be written as a difference of two nondecreasing functions on $[a,b]$.

In fact, if f has bounded variation, then $f = (f(a) + T^+f) - T^-f$.

Because of the known properties of nondecreasing functions, we obtain:

XIX.4.2.4. COROLLARY. Let f be a function of bounded variation on an interval $[a,b]$. Then

(i) f is Borel measurable ().

(ii) f has left and right limits at every point of $[a,b]$ (XIX.2.1.7.).

(iii) f has only countably many discontinuities on $[a,b]$, each of which is a jump discontinuity (XIX.2.1.10.).

(iv) f is differentiable a.e. on $[a,b]$ (XIX.2.2.12.).

XIX.4.2.5. PROPOSITION. Let f be a function of bounded variation on $[a,b]$. Then f' (which is defined a.e. on $[a,b]$) is integrable on $[a,b]$, and

$$\int_a^b |f'|\,d\lambda \le V_{[a,b]}(f)\ .$$

PROOF: Extend f to $[a,b+1]$ by setting $f(x)=f(b)$ for $x\in[b,b+1]$. For each n define

$$f_n(x)=n\left[f\left(x+\frac{1}{n}\right)-f\left(x\right)\right]\ .$$

Then each f_n is (Borel) measurable, and $f_n(x)\to f'(x)$ for any $x\in(a,b)$ for which f is differentiable at x. Thus $f_n\to f'$ pointwise a.e., so f' is measurable. Also, since T^+f, T^-f, Tf are nondecreasing, they are differentiable a.e., with nonnegative derivatives, and since $f=(f(a)+T^+f)-T^-f$, we have $f'=(T^+f)'-(T^-f)'$ a.e., and thus

$$|f'|\le (T^+f)'+(T^-f)'=(Tf)' \text{ a.e.}$$

By XIX.2.2.13.,

$$\int_a^b |f'|\,d\lambda \le \int_a^b (Tf)'\,d\lambda \le Tf(b)-Tf(a)=V_{[a,b]}(f)\ .$$

XIX.4.2.6. PROPOSITION. Let f be a function of bounded variation on $[a,b]$. Then the variation functions T^+f, T^-f, Tf are continuous wherever f is continuous.

PROOF: Let $f\in BV([a,b])$, and $x\in(a,b]$. We show that if f is left continuous at x, then T^+f is also left continuous at x. The other parts of the proof are essentially identical.

Let $\epsilon>0$, and choose $\delta>0$ so that if $x-\delta<y<x$, $|f(y)-f(x)|<\frac{\epsilon}{2}$. Choose a partition

$$\mathcal{P}=\{a=x_0,x_1,\dots,x_n,x_{n+1}=x\}$$

of $[a,x]$ with $n+1$ subintervals such that

$$T^+f(x)=V^+_{[a,x]}(f)<V^+(f,\mathcal{P})+\frac{\epsilon}{2}$$

$$V^+(f,\mathcal{P})>T^+f(x)-\frac{\epsilon}{2}\ .$$

By adding an additional point to $\mathcal{P}$ if necessary (which can only increase $V^+(f,\mathcal{P})$), we may assume the next-to-last point x_n satisfies $x_n>x-\delta$. Let $\mathcal{Q}$ be the partition $\{a=x_0,x_1,\dots,x_n\}$ of $[a,x_n]$. Then we have

$$V^+(f,\mathcal{P})=\left(\sum_{k=1}^{n}[f(x_k)-f(x_{k-1})]_+\right)+[f(x)-f(x_n)]_+=V^+(f,\mathcal{Q})+[f(x)-f(x_n)]_+<V^+(f,\mathcal{Q})+\frac{\epsilon}{2}\ .$$

If $x_n \le y \le x$, then

$$T^+f(x) - \epsilon = V^+_{[a,x]}(f) - \epsilon < V^+(f,\mathcal{P}) - \frac{\epsilon}{2} < V^+(f,\mathcal{Q}) \le V^+_{[a,x_n]}(f) = T^+f(x_n) \le T^+f(y) \le T^+f(x)$$

so $|T^+f(y) - T^+f(x)| < \epsilon$. Since $\epsilon > 0$ is arbitrary, T^+f is left continuous at x. 👍

XIX.4.2.7. Corollary. If f is a continuous function of bounded variation on $[a,b]$, then T^+f, T^-f, Tf are also continuous on $[a,b]$. Thus f can be written as a difference of two continuous nondecreasing functions on $[a,b]$.

XIX.4.3. Banach's Multiplicity Theorem

For continuous real-valued functions on a closed bounded interval, there is a close relationship between the notion of bounded variation and the Multiplicity Function (XVI.2.8.1.): a function is informally of bounded variation if its graph does not "wiggle up and down" too much, hence the function does not take "too many values too many times." This theorem is due to Banach ().

XIX.4.3.1. Theorem. Let f be a continuous function from a closed bounded interval $[a,b]$ to $\mathbb{R}$. Then N_f is finite a.e. and (Lebesgue) integrable on $[c,d] = f([a,b])$ if and only if f has bounded variation on $[a,b]$, and in any case

$$\int_c^d N_f \, d\lambda = V_{[a,b]}(f) \ .$$

Proof: Recall (XVI.2.8.4.) that N_f is nonnegative and (Borel) measurable, so $\int_c^d N_f \, d\lambda$ makes sense. For each n let ϕ_n be the function defined in the proof of XVI.2.8.4.. Then we have

$$\int_c^d \phi_n \, d\lambda = \sum_{k=1}^{2^n} \lambda(f(J_k)) = \sum_{k=1}^{2^n} \lambda(f(\bar{J}_k)) \le \sum_{k=1}^{2^n} V_{[x_{k-1},x_k]}(f) = V_{[a,b]}(f)$$

(where the x_k are the numbers from the proof of XVI.2.8.4., i.e. the endpoints of the intervals J_k). We have $\int_c^d \phi_n \, d\lambda \to \int_c^d N_f \, d\lambda$ by the Monotone Convergence Theorem. So if f has bounded variation on $[a,b]$, we have that N_f is integrable on $[c,d]$ and in particular finite a.e. on $[c,d]$, and

$$\int_c^d N_f \, d\lambda \le V_{[a,b]}(f) \ .$$

Conversely, suppose N_f is finite a.e. and integrable on $[c,d]$. For $a \le x \le b$, let f_x be the restriction of f to $[a,x]$, and set $S(x) = \int_c^d N_{f_x} \, d\lambda$. We have $N_{f_x} \le N_f$, and for $a \le x_1 \le x_2 \le b$ we have

$$0 = S(a) \le S(x_1) \le S(x_2) \le S(b) = \int_c^d N_f \, d\lambda$$

and, furthermore, since f takes every value between $f(x_1)$ and $f(x_2)$ on $[x_1, x_2]$ by the Intermediate Value Theorem (), we have $N_{f_{x_2}}(y) \geq N_{f_{x_1}}(y) + 1$ for all y between $f(x_1)$ and $f(x_2)$ and thus we have

$$S(x_2) - S(x_1) = \int_c^d (N_{f_{x_2}} - N_{f_{x_1}})\, d\lambda \geq \left| \int_{f(x_1)}^{f(x_2)} 1\, d\lambda \right| = |f(x_2) - f(x_1)| \ .$$

So if $a \leq x_0 < x_1 < \cdots < x_n \leq b$, we have

$$\int_c^d N_f\, d\lambda = S(b) - S(a) \geq \sum_{k=1}^{n} [S(x_k) - S(x_{k-1})] \geq \sum_{k=1}^{n} |f(x_k) - f(x_{k-1})|$$

and taking the supremum over all such finite subsets of $[a, b]$ we obtain

$$\int_c^d N_f\, d\lambda \geq V_{[a,b]}(f)$$

and thus f has bounded variation, and the opposite inequality holds by the first part of the proof, giving equality.

If f does not have bounded variation, equality still holds since both sides are $+\infty$. 👍

XIX.4.4. Extensions of Bounded Variation

Noncompact Intervals

We can extend the notion of bounded variation to noncompact intervals:

XIX.4.4.1. DEFINITION. Let I be an interval, and f a real-valued function on I. Define

$$V_I^+(f) = \sup V_{[a,b]}^+(f)$$

$$V_I^-(f) = \sup V_{[a,b]}^-(f)$$

$$V_I(f) = \sup V_{[a,b]}(f)$$

where the suprema are taken over all closed bounded subintervals $[a, b]$ of I.
The function f has *bounded variation on* I if $V_I(f) < +\infty$.

Most properties of bounded variation for closed bounded intervals carry over directly. We list some without proof; proofs are similar to the earlier ones and are left to the reader.

XIX.4.4.2. PROPOSITION. (i) $V_I(f) = V_I^+(f) + V_I^-(f)$.
(ii) If f has bounded variation on I, then f is bounded on I and

$$\sup_{x \in I} f(x) - \inf_{x \in I} f(x) \leq V_I(f) \ .$$

(iii) If J is a subinterval of I, then $V_J^+(f) \le V_I^+(f)$, $V_J^-(f) \le V_I^-(f)$, $V_J(f) \le V_I(f)$. If f has bounded variation on I, then f has bounded variation on J.

(iv) If f is bounded variation on I, and a and b are the left and right endpoints of I (we do not necessarily have $a, b \in I$; we can have $a = -\infty$ and/or $b = +\infty$), then $\lim_{x \to a+} f(x)$ and $\lim_{x \to b-} f(x)$ exist.

(v) If f has bounded variation on I, then f is Borel measurable, has left and right limits at every point, has only countably many discontinuities each of which is a jump discontinuity, and is differentiable a.e. on I.

(vi) If f has bounded variation on I, then f' is Lebesgue integrable on I and

$$\int_I |f'| \, d\lambda \le V_I(f) \ .$$

We can also define variation functions for a function of bounded variation:

XIX.4.4.3. DEFINITION. Let I be an interval, and a the left endpoint of I (we do not necessarily have $a \in I$; a can be $-\infty$). Define

$$T^+ f(x) = \begin{cases} V^+_{[a,x]}(f) & \text{if} \quad a \in I \\ V^+_{(a,x]}(f) & \text{if} \quad a \notin I \end{cases}$$

$$T^- f(x) = \begin{cases} V^-_{[a,x]}(f) & \text{if} \quad a \in I \\ V^-_{(a,x]}(f) & \text{if} \quad a \notin I \end{cases}$$

$$Tf(x) = \begin{cases} V_{[a,x]}(f) & \text{if} \quad a \in I \\ V_{(a,x]}(f) & \text{if} \quad a \notin I \end{cases}$$

for $x \in I$.

$T^+ f$, $T^- f$, Tf are nonnegative and nondecreasing; $Tf = T^+ f + T^- f$, $T^+ f - T^- f = f - C$, where $C = f(a)$ if $a \in I$ and $C = \lim_{x \to a+} f(x)$ if $a \notin I$.

Complex-Valued Functions

XIX.4.4.4. We can also define bounded variation for complex-valued functions. If f is a complex-valued function on $[a, b]$ and $\mathcal{P} = \{a = x_0, \ldots, x_n = b\}$, then $V^+(f, \mathcal{P})$ and $V^-(f, \mathcal{P})$ do not make sense, but we can still define

$$V(f, \mathcal{P}) = \sum_{k=1}^{n} |f(x_k) - f(x_{k-1})|$$

$$V_{[a,b]}(f) = \sup_{\mathcal{P}} V(f, \mathcal{P})$$

as before. Then f has bounded variation on $[a, b]$ if $V_{[a,b]}(f) < +\infty$.

XIX.4.4.5. If g and h are the real and imaginary parts of f, i.e. $f = g + ih$ with g, h real-valued, then we have

$$V_{[a,b]}(g), V_{[a,b]}(h) \le V_{[a,b]}(f) \le V_{[a,b]}(g) + V_{[a,b]}(h)$$

so f has bounded variation if and only if both g and h have bounded variation. (There is, however, no simple formula for $V_{[a,b]}(f)$ in terms of $V_{[a,b]}(g)$ and $V_{[a,b]}(h)$.) We still have:

XIX.4.4.6. PROPOSITION. Let f be a complex-valued function on $[a,b]$, and $c \in (a,b)$. Then

$$V_{[a,b]}(f) = V_{[a,c]}(f) + V_{[c,b]}(f) \ .$$

XIX.4.4.7. PROPOSITION. If f is a complex-valued function of bounded variation on $[a,b]$, then f is differentiable a.e. on $[a,b]$, f' is integrable on $[a,b]$, and

$$\int_a^b |f'| \, d\lambda \le V_{[a,b]}(f) \ .$$

XIX.4.4.8. We can also define the total variation function Tf as in the real case, which is nonnegative and nondecreasing, and continuous wherever f is continuous. If g and h are the real and imaginary parts of f, then

$$Tg, Th \le Tf \le Tg + Th$$

but there is no simple formula for Tf in terms of Tg and Th.

XIX.4.5. Exercises

XIX.4.5.1. Let f be a function of bounded variation on $[a,b]$. Show directly that f has one-sided limits at every point of $[a,b]$, as follows:

(a) Let $c \in (a,b]$. Suppose

$$\liminf_{x \to c-} f(x) < \limsup_{x \to c-} f(x) \ .$$

Choose $\alpha, \beta \in \mathbb{R}$ such that

$$\liminf_{x \to c-} f(x) < \alpha < \beta < \limsup_{x \to c-} f(x) \ .$$

Choose an increasing sequence (x_n) in (a,c) converging to c such that $f(x_n) < \alpha$ for n odd and $f(x_n) > \beta$ for n even.

(b) If $\mathcal{P} = \{a = x_0, x_1, \ldots, x_{n+1}, b\}$, show that $V(f, \mathcal{P}) > n(\beta - \alpha)$. Conclude that $V_{[a,b]}(f)$ must be $+\infty$.

(c) Give a similar argument for limits from the right.

(d) Conclude from V.8.6.7.(a) that f has only countably many discontinuities, each of which is a jump discontinuity.

XIX.4.5.2. Let f be the function of IX.2.9.10.(i). Show that f does not have bounded variation on $[0,1]$ (or on $[0,b]$ for any $b>0$). Note that f is differentiable everywhere, and f' is continuous except at 0.

XIX.4.5.3. Slightly modify the proof of XIX.4.2.6. to show that if $f \in BV([a,b])$, $x \in (a,b]$, and f is left lower semicontinuous at x, then T^+f is left continuous at x. State and prove similar statements for T^-f and for right semicontinuity.

XIX.4.5.4. Let I be an interval in $\mathbb{R}$, and f a one-to-one continuous function from I to $\mathbb{R}$. Then

(a) f is a homeomorphism onto its range J, which is also an interval (XIII.19.1.28., or give a more direct argument).

(b) f has bounded variation on any closed bounded subinterval of I (V.3.10.15.).

(c) f is differentiable a.e. on I (XIX.2.2.12.).

(d) If $\mathbb{R}$ is replaced by $\mathbb{R}^n$ for $n>1$, then (a) remains true (XIII.19.1.28.), but (b) does not make sense and (c) is false in general: let g be a continuous function from $\mathbb{R}$ to $\mathbb{R}$ which is not differentiable anywhere, and define $\boldsymbol{f}:\mathbb{R}^2\to\mathbb{R}^2$ by $\boldsymbol{f}(x,y)=(x,y+g(x))$. Then $\boldsymbol{f}$ is a homeomorphism from $\mathbb{R}^2$ onto $\mathbb{R}^2$ which is not differentiable anywhere.

XIX.5. Absolute Continuity and Lebesgue Density

A function which is differentiable everywhere on an interval $[a, b]$ need not have a (Lebesgue) integrable derivative, hence may not be the integral of its derivative (IX.2.9.10.(i)); the problem is that such a function need not have bounded variation. But even bounded variation is not sufficient to insure that a continuous function can be recovered from its derivative by integration if it is only differentiable almost everywhere. The Cantor function is the prototype example of a continuous monotone function (hence of bounded variation) which is differentiable almost everywhere, yet is not the integral of its derivative. In this section we discuss conditions which do suffice to recover a function by integration.

Applications of the results to indicator functions demonstrate a remarkable density property of Lebesgue measurable sets: such sets cannot be too uniformly distributed in the real line and must be either thick or sparse almost everywhere.

XIX.5.1. Luzin's Property (N)

XIX.5.1.1. The principal property of the Cantor function f which causes difficulties in the context of this section is that there are null sets N for which $f(N)$ is not a null set. In fact, the Cantor set K is a null set and $f(K)$ is the entire interval $[0, 1]$.

From the point of view of Borel measures, the measure on $[0, 1]$ whose cdf is the Cantor function is a probability measure which is continuous, but concentrated on K, and hence is not absolutely continuous with respect to Lebesgue measure.

We thus make the following definition. This condition was first defined and studied by N. Luzin, who appreciated its importance and relevance to the problem of reconstructing a function by integration.

XIX.5.1.2. Definition. Let I be an interval, and $f : I \to \mathbb{R}$. Then f has *Property (N)* (or *Luzin's Property (N)*) on I if, whenever N is a subset of I with $\lambda(N) = 0$, we have $\lambda(f(N)) = 0$ (i.e. f sends λ-null sets to λ-null sets).

The next result is an immediate rephrasing of the definition.

XIX.5.1.3. Proposition. Let μ be a continuous finite Borel measure on $[a, b]$, with cdf F. Then $\mu \ll \lambda$ if and only if F has property (N).

The corresponding statement for signed measures is false ($\mu \ll \lambda$ implies Property (N) is true, but the converse fails in general), and it is quite tricky to get the right condition. See ().

XIX.5.1.4. Proposition. [**?**] Let I be an interval, and $f : I \to \mathbb{R}$ a continuous function. Then f has property (N) if and only if, whenever A is a Lebesgue measurable subset of I, $f(A)$ is Lebesgue measurable.

Proof: Suppose f has property (N). If $A \subseteq I$ is Lebesgue measurable, then $A = E \cup N$, where E is an F_σ and N a null set (XVII.4.4.5.(iv)). Then $f(E)$ is an F_σ since f is continuous (XIII.11.7.11.), and $f(N)$ is a null set since f has Property (N); hence $f(A) = f(E) \cup f(N)$ is Lebesgue measurable. Conversely, if N is a null set and $f(N)$ is not a null set (i.e. $f(N)$ has positive Lebesgue outer measure), then $f(N)$ contains a

nonmeasurable set B (XVII.4.10.7.). If $A = f^{-1}(B) \cap N$, then $A \subseteq N$ and hence A is Lebesgue measurable, and $f(A) = B$ is nonmeasurable. 👍

XIX.5.1.5. Property (N) is complementary to bounded variation, even for continuous functions: the Cantor function is continuous and monotone, hence has bounded variation, but not Property (N), and there are continuous functions with Property (N) which do not have bounded variation, and are even not differentiable a.e. (XIX.5.8.2.).

There is an interesting variation on Property (N), due to Banach:

XIX.5.1.6. Definition. Let I be an interval, and $f : I \to \mathbb{R}$. Then f has *Property (S)* (or *Banach's Property (S)*) on I if for every $\epsilon > 0$ there is a $\delta > 0$ such that, whenever A is a Lebesgue measurable subset of I with $\lambda(A) < \delta$, we have $\lambda^*(f(A)) < \epsilon$.

XIX.5.1.7. A function with Property (S) obviously has Property (N); hence, if f is continuous with Property (S), it sends measurable sets to measurable sets, and λ^* can be replaced by λ in the definition. There are continuous functions with Property (N) which do not have Property (S) (XIX.5.8.3.).

In fact, we have:

XIX.5.1.8. Theorem. [**?**] Let I be an interval, and $f : I \to \mathbb{R}$ a continuous function. Then f has property (S) if and only if it has Property (N) and N_f () is finite a.e.

Combining this with XIX.4.3.1., we obtain:

XIX.5.1.9. Corollary. Let I be an interval, and $f : I \to \mathbb{R}$ a continuous function of bounded variation. Then f has property (S) if and only if it has Property (N).

XIX.5.1.10. There are continuous functions with Property (S) which do not have bounded variation, and are even not differentiable a.e. (XIX.5.8.2.).

XIX.5.1.11. Banach said a function f satisfies Property (T_1) if N_f is finite a.e., and Property (T_2) if N_f is countable a.e. (i.e. f takes almost all values only countably many times). We will avoid this terminology since it could be confused with separation axioms of topology.

The next goal is to show that differentiable functions have Property (N). The next lemma is crucial.

XIX.5.1.12. LEMMA. Let A be a Lebesgue measurable subset of $\mathbb{R}$, and $f : A \to \mathbb{R}$ a function. Suppose there is a constant M such that, for every $x \in A$, there is a $\delta > 0$ such that $|f(y) - f(x)| \leq M(y - x)$ for all $y \in A \cap (x, x + \delta)$. Then $\lambda^*(f(A)) \leq M\lambda(A)$.

PROOF: We first make a reduction. For each n, let

$$B_n = \{x \in A : |f(y) - f(x)| \leq M(y - x) \text{ for all } y \in A \cap (x, x + 1/n)\} .$$

If $x \in A \cap \bar{B}_n$, there is a monotone sequence (x_k) in B_n with $x_k \to x$, so for sufficiently large k we have $|f(x) - f(x_k)| \leq M|x - x_k|$. Thus $f(x) = \lim_{k\to\infty} f(x_k)$ and, if $y \in A \cap (x, x + 1/n)$, then for sufficiently large k we have $y \in (x_k, x_k + 1/n)$, so $|f(y) - f(x_k)| \leq M(y - x_k)$. Taking $k \to \infty$, we conclude $x \in B_n$. Thus $B_n = A \cap \bar{B}_n$, and in particular B_n is measurable. We have that $A = \cup_n B_n$, so $\lambda(A) = \sup_n \lambda(B_n)$ and $\lambda^*(f(A)) = \sup_n \lambda^*(f(B_n))$. Thus it suffices to show $\lambda^*(f(B_n)) \leq M\lambda(B_n)$ for each n. Fix n; write B_n as a disjoint union of measurable sets A_{nm} of diameter $< 1/n$. Then $\lambda(B_n) = \sum_m \lambda(A_{nm})$ and $\lambda^*(f(B_n)) \leq \sum_m \lambda^*(f(A_{nm}))$. Thus it suffices to show that $\lambda^*(f(A_{nm})) \leq M\lambda(A_{nm})$ for all n, m. But A_{nm} has the property that if $x, y \in A_{nm}$, $x < y$, then $|f(y) - f(x)| \leq M(y - x)$. Replacing A by A_{nm}, we may assume A has the property that $|f(y) - f(x)| \leq M|y - x|$ for all $x, y \in A$. We may also assume $\lambda(A) < \infty$.

Let $\epsilon > 0$. Fix a sequence (I_n) of open intervals covering A with $\sum_n \ell(I_n) < \lambda(A) + \epsilon$. If $x, y \in A \cap I_n$, then $|f(y) - f(x)| \leq M|y - x|$, so $f(A \cap I_n)$ is contained in an interval J_n of length $\leq M\ell(I_n)$. We then have

$$\lambda^*(f(A)) \leq \sum_{n=1}^{\infty} \lambda^*(f(A \cap I_n)) \leq \sum_{n=1}^{\infty} \ell(J_n) \leq M \sum_{n=1}^{\infty} \ell(I_n) \leq M(\lambda(A) + \epsilon) .$$

This is true for all $\epsilon > 0$, and the result follows. 👍

XIX.5.1.13. COROLLARY. Let A be a Lebesgue measurable subset of $\mathbb{R}$, and $f : A \to \mathbb{R}$ a function. Suppose there is a constant M such that, for every $x \in A$, f is differentiable at x and $|f'(x)| \leq M$. Then $\lambda^*(f(A)) \leq M\lambda(A)$.

PROOF: Let $\epsilon > 0$. For each $x \in A$, since

$$\left| \lim_{y\to x} \frac{f(y) - f(x)}{y - x} \right| \leq M$$

there is a $\delta > 0$ such that

$$\left| \frac{f(y) - f(x)}{y - x} \right| \leq M + \epsilon$$

whenever $0 < |y - x| < \delta$. Thus $\lambda^*(f(A)) \leq (M + \epsilon)\lambda(A)$. Since $\epsilon > 0$ is arbitrary, the result follows. 👍

As a special case, we obtain the general one-dimensional version of Sard's Theorem (), due to LUZIN:

XIX.5.1.14. COROLLARY. Let I be an interval, and $f : I \to \mathbb{R}$ a function. Set

$$A = \{x \in I : f'(x) \text{ exists and equals } 0\} .$$

Then $f(A)$ is a null set.

PROOF: A is Lebesgue measurable by (). We may write $A = \cup_n A_n$, where $\lambda(A_n) < \infty$. Then $\lambda^*(f(A_n)) = 0$ for all n, and hence $\lambda^*(f(A)) \leq \sum_n \lambda^*(f(A_n)) = 0$. 👍

We can now obtain a sharpening of XIX.5.1.13.:

XIX.5.1.15. THEOREM. Let f be a function on $[a, b]$, and $A \subseteq [a, b]$ a Lebesgue measurable set. If f is differentiable at every point of A, then $f(A)$ is Lebesgue measurable and

$$\lambda(f(A)) \leq \int_A |f'| \, d\lambda .$$

PROOF: A is a union of a null set N and a countable collection (K_n) of compact sets (). Then $f(N)$ is a null set by XIX.5.1.14., and $f(K_n)$ is compact for each n since f is continuous on A. Thus $f(A) = f(N) \cup (\cup_n f(K_n))$ is Lebesgue measurable.
Let $\epsilon > 0$. For each $n \in \mathbb{N}$ let

$$A_n = \{x \in A : (n-1)\epsilon \leq |f'(x)| < n\epsilon\} .$$

Then A is the disjoint union of the A_n. For each n, A_n is measurable since $|f'|$ is measurable, and

$$\lambda^*(f(A_n)) \leq n\epsilon\lambda(A_n) \leq \int_{A_n} [|f'| + \epsilon] \, d\lambda = \int_{A_n} |f'| \, d\lambda + \epsilon\lambda(A_n)$$

by XIX.5.1.13.. Thus

$$\lambda(f(A)) \leq \sum_{n=1}^{\infty} \lambda^*(f(A_n)) \leq \sum_{n=1}^{\infty} \left[\int_{A_n} |f'| \, d\lambda \right] + \epsilon \sum_{n=1}^{\infty} \lambda(A_n) = \int_A |f'| \, d\lambda + \epsilon\lambda(A) .$$

Since $\epsilon > 0$ is arbitrary, the result follows. 👍

We then obtain:

XIX.5.1.16. THEOREM. Let B be a Lebesgue measurable set, and $f : B \to \mathbb{R}$ a function which is differentiable on B except possibly at countably many points of B. If A is a subset of B with $\lambda(A) = 0$, then $\lambda(f(A)) = 0$.

PROOF: Let C be a countable subset of B such that f is differentiable on $B \setminus C$. For each n let

$$D_n = \{x \in B \setminus C : |f'(x)| \leq n\} .$$

Each D_n is measurable. If A is a measurable subset of B with $\lambda(A) = 0$, then $f(A)$ is the union of $f(A \cap C)$ and $f(A \cap D_n)$ for all n. $f(A \cap C)$ is countable, hence has measure 0; and by XIX.5.1.13. we have $\lambda^*(f(A \cap D_n)) \leq n\lambda(A \cap D_n) = 0$. Thus

$$\lambda^*(f(A)) \leq \lambda^*(A \cap C) + \sum_{n=1}^{\infty} \lambda(A \cap D_n) = 0 .$$

XIX.5.1.17. COROLLARY. Let I be an interval, and $f : I \to \mathbb{R}$ a function. If f is differentiable on I except possibly at countably many points of I, then f has Property (N) on I.

Property (N) is relevant in extending consequences of the Mean Value Theorem:

XIX.5.1.18. THEOREM. Let I be an interval, and $f : I \to \mathbb{R}$ a continuous function with Property (N) on I. If f is differentiable a.e. and $f' \geq 0$ a.e. on I, then f is nondecreasing on I (and hence $f' \geq 0$ everywhere it is defined). Similarly, if $f' \leq 0$ a.e. on I, then f is nonincreasing on I. If $f' = 0$ a.e. on I, then f is constant on I.

PROOF: If $f' > 0$ a.e., the proof is identical to the proof of V.8.4.1.(i), since if f is differentiable except on a null set A, then $f(A)$ is also a null set since f has Property (N) and thus contains no interval (cf. V.8.4.4.). In the general case, we proceed as follows. Set

$$A = \{x \in I : f \text{ is not differentiable at } x\}$$

$$B = \{x \in I : f'(x) < 0\}$$

$$C = \{x \in I : f'(x) = 0\}$$

Then A and B are null sets by assumption, so $f(A)$ and $f(B)$ are null sets since f has Property (N). And $f(C)$ is a null set by XIX.5.1.14.. Thus $f(A \cup B \cup C)$ is a null set, and contains no interval.

Suppose there are $a, b \in I$ with $a < b$ and $f(a) > f(b)$. Then there is an $r \notin f(A \cup B \cup C)$ with $f(a) > r > f(b)$. There is an $x \in [a, b]$ with $f(x) = r$ by the Intermediate Value Theorem. Set

$$c = \sup\{x \in [a, b] : f(x) = r\} .$$

Then $f(c) = r$ by continuity, and $c < b$. Then $c \notin A \cup B \cup C$ since $r = f(c) \notin f(A \cup B \cup C)$, so f is differentiable at c and $f'(c) > 0$. We have $c < b$ since $f(b) < r$, and if $c < x \leq b$ we have $f(x) < f(c) = r$, so $\frac{f(x)-f(c)}{x-c} < 0$. Thus

$$f'(c) = \lim_{x \to c+} \frac{f(x) - f(c)}{x - c} \leq 0$$

contradicting that $f'(c) > 0$. 👍

Combining this result with XIX.5.1.17., we obtain:

XIX.5.1.19. Corollary. Let I be an interval, and $f : I \to \mathbb{R}$ a continuous function, which is differentiable on I except possibly at countably many points. If $f' \geq 0$ a.e. on I, then f is nondecreasing on I (and hence $f' \geq 0$ everywhere it is defined). Similarly, if $f' \leq 0$ a.e. on I, then f is nonincreasing on I. If $f' = 0$ a.e. on I, then f is constant on I.

Here is an interesting consequence of XIX.5.1.14.:

XIX.5.1.20. Corollary. Let $[a, b]$ be a closed bounded interval, and $f : [a, b] \to \mathbb{R}$ a continuous function. If f is differentiable on $[a, b]$ except possibly at countably many points, then N_f is finite a.e. on $[a, b]$, so f has Property (S) on $[a, b]$.

Proof: Let C be a countable set such that f is differentiable on $[a, b] \setminus C$. Let

$$A = \{x \in [a, b] : f'(x) = 0\} .$$

By XIX.5.1.14., $f(A)$ has measure 0. Since C is countable, $f(A \cup C)$ has measure 0.

Suppose $N_f(y) = \infty$. Then $f^{-1}(\{y\})$ is an infinite subset of $[a, b]$, hence has an accumulation point x. If $f'(x)$ exists, it must be zero; so $x \in A \cup C$, and hence $y \in f(A \cup C)$. So if $B = \{y : N_f(y) = \infty\}$, then $B \subseteq f(A \cup C)$, $\lambda(B) = 0$. The last statement follows from XIX.5.1.8.. 👍

XIX.5.2. Absolutely Continuous Functions

Our basic definition is a refinement of uniform continuity:

XIX.5.2.1. Definition. Let $[a, b]$ be a closed bounded interval, and $f : [a, b] \to \mathbb{R}$ (or $\mathbb{C}$) a function. Then f is *absolutely continuous* on $[a, b]$ if for every $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $[a_1, b_1], \ldots, [a_n, b_n]$ are finitely many nonoverlapping intervals in $[a, b]$ (nonoverlapping means distinct intervals may have endpoints but not interior points in common) with total length $< \delta$, i.e.

$$\sum_{k=1}^{n} (b_k - a_k) < \delta$$

we have

$$\sum_{k=1}^{n} |f(b_k) - f(a_k)| < \epsilon \ .$$

Note that the definition of uniform continuity is the same, but with only one subinterval allowed.

XIX.5.2.2. Although it will not be necessary, we may assume the intervals $[a_1, b_1], \ldots, [a_n, b_n]$ are in increasing order. The nonoverlapping condition then means

$$a \leq a_1 < b_1 \leq a_2 < b_2 \leq \cdots < b_n \leq b \ .$$

There is also no harm, and some technical advantage, in allowing some intervals to be degenerate, i.e. $a_k = b_k$, since such degenerate intervals make no contribution to the sums $\sum_{k=1}^{n}(b_k - a_k)$ and $\sum_{k=1}^{n} |f(b_k) - f(a_k)|$. We may also allow infinite collections of subintervals:

XIX.5.2.3. Proposition. Let $[a, b]$ be a closed bounded interval, and $f : [a, b] \to \mathbb{R}$ a function. Then f is absolutely continuous on $[a, b]$ if and only if for every $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $\{[a_k, b_k] : k \in \mathbb{N}\}$ is a sequence of pairwise nonoverlapping subintervals (not necessarily nondegenerate) of $[a, b]$ with

$$\sum_{k=1}^{\infty}(b_k - a_k) < \delta$$

we have

$$\sum_{k=1}^{\infty} |f(b_k) - f(a_k)| < \epsilon \ .$$

Proof: If f satisfies this condition, it is clearly absolutely continuous (take all but finitely many of the intervals to be degenerate). Conversely, suppose f is absolutely continuous. Let $\epsilon > 0$, and choose $\delta > 0$ corresponding to $\frac{\epsilon}{2}$ in the definition of absolute continuity. If $\{[a_k, b_k] : k \in \mathbb{N}\}$ is a sequence of pairwise nonoverlapping subintervals (not necessarily nondegenerate) of $[a, b]$ with

$$\sum_{k=1}^{\infty}(b_k - a_k) < \delta$$

we have, for each n,

$$\sum_{k=1}^{n}(b_k - a_k) < \delta$$

and therefore

$$\sum_{k=1}^{n} |f(b_k) - f(a_k)| < \frac{\epsilon}{2} \ .$$

Thus

$$\sum_{k=1}^{\infty} |f(b_k) - f(a_k)| \leq \frac{\epsilon}{2} < \epsilon \ .$$

XIX.5.2.4. EXAMPLES. (i) If f is Lipschitz on $[a,b]$, i.e. there is a constant $M>0$ such that

$$|f(y)-f(x)| \le M(y-x)$$

whenever $x,y \in [a,b]$, $x<y$, let $\epsilon>0$, and set $\delta = \frac{\epsilon}{M}$. If $[a_1,b_1],\dots,[a_n,b_n]$ are finitely many nonoverlapping intervals in $[a,b]$ with $\sum_{k=1}^n (b_k-a_k)<\delta$, then

$$\sum_{k=1}^n |f(b_k)-f(a_k)| \le \sum_{k=1}^n M(b_k-a_k) = M\sum_{k=1}^n (b_k-a_k) < M\delta = \epsilon$$

so f is absolutely continuous on $[a,b]$. (Conversely, we will see that every absolutely continuous function is "almost Lipschitz.")

(ii) Let f be the Cantor function (). The standard construction of the Cantor set K is as $K=\cap_n K_n$, where K_n is a disjoint union of 2^n closed intervals of length 3^{-n}. If $[a_1,b_1],\dots,[a_m,b_m]$ $(m=2^n)$ are the intervals in K_n, we have that

$$\sum_{k=1}^m (b_k-a_k) = \left(\frac{2}{3}\right)^n$$

but

$$\sum_{k=1}^m |f(b_k)-f(a_k)| = 1$$

since f is constant on the subintervals not included in K_n. Since $\left(\frac{2}{3}\right)^n \to 0$, f is not absolutely continuous on $[0,1]$. Thus a continuous function, even one of bounded variation and in particular differentiable a.e., is not necessarily absolutely continuous. There are even functions which are differentiable everywhere on an interval $[a,b]$ which are not absolutely continuous; cf. ().

Our main result, which will be proved in stages, is the following theorem giving various characterizations of absolute continuity, which shows that absolutely continuous functions are precisely the functions which can be recovered from their derivatives by integration.

XIX.5.2.5. THEOREM. Let $[a,b]$ be a closed bounded interval, and $F:[a,b]\to\mathbb{R}$ (or $\mathbb{C}$) a function. The following are equivalent:

(i) F is absolutely continuous on $[a,b]$.

(ii) F is continuous, has bounded variation, and property (N) on $[a,b]$.

(iii) F is continuous, has bounded variation, and $V_{[a,b]}(F) = \int_a^b |F'|\,d\lambda$.

(iv) There is a Lebesgue integrable function $f:[a,b]\to\mathbb{R}$ such that F is the indefinite integral of f on $[a,b]$, i.e.

$$F(x) = F(a) + \int_a^x f\,d\lambda$$

for all $x\in[a,b]$.

(v) F is differentiable a.e. on $[a,b]$, F' is integrable on $[a,b]$, and F is the indefinite integral of F' on $[a,b]$, i.e.

$$F(x) = F(a) + \int_a^x F'\, d\lambda$$

for all $x \in [a,b]$.

XIX.5.2.6. Corollary. Let μ be a finite continuous Borel measure on $[a,b]$, with CDF F. Then $\mu \ll \lambda$ if and only if F is absolutely continuous on $[a,b]$. If $\mu \ll \lambda$, then μ has a density function F', i.e. $\mu(B) = \int_B F'\, d\lambda$ for any Borel set $B \subseteq [a,b]$.

Proof: Since μ is continuous, F is a continuous function. Since it is nondecreasing, it has bounded variation. So F satisfies (ii) if and only if it has Property (N). Apply XIX.5.1.3.. If $\mu \ll \lambda$, then F is absolutely continuous, hence the last statement follows from (v). 👍

This corollary motivates the term *absolutely continuous*. The last statement is the Radon-Nikodým Theorem for Lebesgue measure on $(\mathbb{R}, \mathcal{B})$. An extension to signed and complex measures will be given in XIX.5.3.7..

We obtain a series of results leading to the proof of Theorem XIX.5.2.5.. Our exposition roughly follows [vRS82].

XIX.5.2.7. Proposition. A (finite) linear combination of absolutely continuous functions is absolutely continuous.

Proof: Since a scalar multiple of an absolutely continuous function is obviously absolutely continuous, it suffices to show that if f and g are absolutely continuous on $[a,b]$, then so is $f+g$. Let $\epsilon > 0$. Choose δ_1 so that whenever $\{[a_k,b_k] : 1 \le k \le n\}$ is a set of nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta_1$, then $\sum_{k=1}^n |f(b_k) - f(a_k)| < \frac{\epsilon}{2}$, and δ_2 so that if $\{[a_k,b_k] : 1 \le k \le n\}$ is a set of nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta_2$, then $\sum_{k=1}^n |g(b_k) - g(a_k)| < \frac{\epsilon}{2}$. Set $\delta = \min(\delta_1, \delta_2)$. If $\{[a_k,b_k] : 1 \le k \le n\}$ is a set of nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta$, then

$$\sum_{k=1}^n |f(b_k) + g(b_k) - f(a_k) - g(a_k)| \le \sum_{k=1}^n [|f(b_k) - f(a_k)| + |g(b_k) - g(a_k)|] < \epsilon\ .$$

👍

XIX.5.2.8. Lemma. An absolutely continuous function on $[a,b]$ has bounded variation on $[a,b]$.

Proof: Let f be absolutely continuous on $[a,b]$. Choose $\delta > 0$ such that if $\{[a_k,b_k] : 1 \le k \le n\}$ is a set of nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta$, then $\sum_{k=1}^n |f(b_k) - f(a_k)| < 1$. Let $N > \frac{b-a}{\delta}$, and partition $[a,b]$ into N subintervals $[x_{k-1}, x_k]$ $(1 \le k \le N)$ of equal length $\frac{b-a}{N} < \delta$. Fix k. If $\mathcal{P}$ is any

partition of $[x_{k-1}, x_k]$, then by choice of δ we have $V(f, \mathcal{P}) < 1$. Thus $V_{[x_{k-1},x_k]}(f) \le 1$. This is true for all k, so

$$V_{[a,b]}(f) = \sum_{k=1}^{N} V_{[x_{k-1},x_k]}(f) \le N \ .$$

XIX.5.2.9. LEMMA. An absolutely continuous function on $[a, b]$ has property (N).
