PROOF: Let f be absolutely continuous on $[a, b]$, $A \subseteq [a, b]$ with $\lambda(A) = 0$, and $\epsilon > 0$. Choose $\delta > 0$ such that if $\{[a_k, b_k] : k \in \mathbb{N}\}$ is a sequence of nonoverlapping subintervals of $[a, b]$ with $\sum_{k=1}^{\infty}(b_k - a_k) < \delta$, then $\sum_{k=1}^{\infty} |f(b_k) - f(a_k)| < \epsilon$ (XIX.5.2.3.). Let U be an open set containing A with $\lambda(U) < \delta$ (). Then U is the disjoint union of a sequence (I_k) of open intervals. Set $\tilde{I}_k = \bar{I}_k \cap [a, b]$ (discard any $\tilde{I}_k$ that are empty). Since each $\tilde{I}_k$ is a closed bounded subinterval of $[a, b]$, f attains a maximum and a minimum on $\tilde{I}_k$ at points c_k and d_k respectively. Let $J_k = [a_k, b_k]$ be the closed interval with endpoints c_k and d_k. Then the J_k are nonoverlapping closed subintervals of $[a, b]$, and

$$\sum_{k=1}^{\infty}(b_k - a_k) \le \sum_{k=1}^{\infty} \ell(\tilde{I}_k) \le \sum_{k=1}^{\infty} \ell(I_k) = \lambda(U) < \delta \ .$$

We have $f(\tilde{I}_k) = f(J_k) = [f(d_k), f(c_k)]$, so $\lambda(f(\tilde{I}_k)) = |f(b_k) - f(a_k)|$ for each k. If $B = \cup_{k=1}^{\infty} \tilde{I}_k$, then $A \subseteq B$, so $f(A) \subseteq f(B) = \cup_{k=1}^{\infty} f(\tilde{I}_k)$ and

$$\lambda^*(f(A)) \le \lambda(f(B)) \le \sum_{k=1}^{\infty} \lambda(f(\tilde{I}_k)) = \sum_{k=1}^{\infty} |f(b_k) - f(a_k)| < \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, $\lambda^*(f(A)) = 0$.

XIX.5.2.10. LEMMA. Let f be an integrable function on $[a, b]$, and $F(x) = \int_a^x f \, d\lambda$ for $x \in [a, b]$. Then F has bounded variation on $[a, b]$ and $V_{[a,b]}(F) \le \int_a^b |f| \, d\lambda$.

PROOF: If $a \le c < d \le b$, we have $F(d) - F(c) = \int_c^d f \, d\lambda$. Let $\mathcal{P} = \{a = x_0, \ldots, x_n = b\}$ be a partition of $[a, b]$. Then

$$V(F, \mathcal{P}) = \sum_{k=1}^{n} |F(x_k) - F(x_{k-1})| = \sum_{k=1}^{n} \left| \int_{x_{k-1}}^{x_k} f \, d\lambda \right| \le \sum_{k=1}^{n} \left[\int_{x_{k-1}}^{x_k} |f| \, d\lambda \right] = \int_a^b |f| \, d\lambda \ .$$

Take the supremum over all $\mathcal{P}$.

XIX.5.2.11. LEMMA. Let f be an integrable function on $[a,b]$, and $F(x) = \int_a^x f\,d\lambda$ for $x \in [a,b]$. Then F is absolutely continuous on $[a,b]$.

PROOF: If $a \le c < d \le b$, we have $F(d) - F(c) = \int_c^d f\,d\lambda$. Let $\epsilon > 0$. Let g be a bounded measurable function (e.g. a simple function) on $[a,b]$ with

$$\int_a^b |g - f|\,d\lambda < \frac{\epsilon}{2}\ .$$

Suppose $|g| \le M$ on $[a,b]$. Set $\delta = \frac{\epsilon}{2M}$. If $\{[a_k,b_k] : 1 \le k \le n\}$ is a set of nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta$, set $B = \cup_{k=1}^n [a_k,b_k]$. Then $\lambda(B) < \delta$. We have

$$\sum_{k=1}^n |F(b_k) - F(a_k)| = \sum_{k=1}^n \left| \int_{a_k}^{b_k} f\,d\lambda \right| \le \sum_{k=1}^n \left[\int_{a_k}^{b_k} |f|\,d\lambda \right]$$

$$= \int_B |f|\,d\lambda \le \int_B |g|\,d\lambda + \int_B |f-g|\,d\lambda < M\lambda(B) + \frac{\epsilon}{2} < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon\ .$$

XIX.5.2.12. LEMMA. Let F be a continuous function on $[a,b]$ with property (N), such that F is differentiable a.e. on $[a,b]$ and F' is integrable on $[a,b]$ (satisfied if F has bounded variation on $[a,b]$). Then F is absolutely continuous on $[a,b]$, and $V_{[a,b]}(F) = \int_a^b |F'|\,d\lambda$.

PROOF: Set

$$G(x) = \int_a^x |F'|\,d\lambda$$

for $x \in [a,b]$. Then G is absolutely continuous on $[a,b]$ by XIX.5.2.11.. Let $N \subseteq [a,b]$ be a null set such that F is differentiable everywhere on $[a,b] \setminus N$. Then, since F is continuous and has property (N), for $a \le c < d \le b$,

$$|F(d) - F(c)| \le \lambda(F([c,d])) \le \lambda^*(F([c,d] \setminus N)) + \lambda(F(N)) = \lambda^*(F([c,d] \setminus N)) \le \int_{[c,d]\setminus N} |F'|\,d\lambda = \int_c^d |F'|\,d\lambda$$

by XIX.5.1.15..

Let $\epsilon > 0$, and choose $\delta > 0$ so that whenever $\{[a_k,b_k] : 1 \le k \le n\}$ is a set of nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta$, we have

$$\sum_{k=1}^n |G(b_k) - G(a_k)| = \sum_{k=1}^n \left[\int_{a_k}^{b_k} |F'|\,d\lambda \right] < \epsilon\ .$$

Then

$$\sum_{k=1}^n |F(b_k) - F(a_k)| \le \sum_{k=1}^n \left[\int_{a_k}^{b_k} |F'|\,d\lambda \right] < \epsilon\ .$$

Thus F is absolutely continuous.
If $\mathcal{P} = \{a = x_0, \ldots, x_n = b\}$ is a partition of $[a, b]$, we have

$$V(F, \mathcal{P}) = \sum_{k=1}^{n} |F(x_k) - F(x_{k-1})| \leq \sum_{k=1}^{n} \left[\int_{x_{k-1}}^{x_k} |F'| \, d\lambda \right] = \int_a^b |F'| \, d\lambda \ .$$

Taking the supremum over all $\mathcal{P}$, we obtain $V_{[a,b]}(F) \leq \int_a^b |F'| \, d\lambda$. The opposite inequality follows from XIX.4.2.5.. 👍

XIX.5.2.13. PROPOSITION. Let f be an integrable function on $[a, b]$. Suppose $\int_a^x f \, d\lambda = 0$ for all $x \in [a, b]$. Then $f = 0$ a.e. on $[a, b]$.

PROOF: If $[c, d] \subseteq [a, b]$, then

$$\int_c^d f \, d\lambda = \int_a^d f \, d\lambda - \int_a^c f \, d\lambda = 0 - 0 = 0 \ .$$

Thus if I is any subinterval of $[a, b]$, $\int_I f \, d\lambda = 0$. If U is a relatively open set in $[a, b]$, then U is a disjoint union of relatively open intervals I_k, so $\int_U f \, d\lambda = \sum_k \int_{I_k} f \, d\lambda = 0$. If $B = \cap_n U_n$ is a G_δ in $[a, b]$, then

$$0 = \int_{U_n} f \, d\lambda \to \int_B f \, d\lambda$$

by the DCT, so $\int_B f \, d\lambda = 0$. If A is any Lebesgue measurable subset of $[a, b]$, there is a G_δ $B \subseteq [a, b]$ with $A \subseteq B$ and $\lambda(B \setminus A) = 0$, so

$$\int_A f \, d\lambda = \int_B f \, d\lambda = 0 \ .$$

The result now follows from (). 👍

XIX.5.2.14. COROLLARY. Let f and g be integrable functions on $[a, b]$. If

$$\int_a^x f \, d\lambda = \int_a^x g \, d\lambda$$

for all $x \in [a, b]$, then $f = g$ a.e. on $[a, b]$.

PROOF: Apply XIX.5.2.13. to $f - g$. 👍

The Fundamental Theorem of Calculus 1

We can now prove the following version of the Fundamental Theorem of Calculus, which is a strong version of XIX.5.2.5.[(iv) ⇒ (v)]:

XIX.5.2.15. THEOREM. [FUNDAMENTAL THEOREM OF CALCULUS, LEBESGUE VERSION 1A] Let $[a,b]$ be a closed bounded interval, and $f:[a,b]\to\mathbb{R}$ a Lebesgue integrable function. Let

$$F(x)=\int_a^x f\,d\lambda$$

for all $x\in[a,b]$. Then F is differentiable a.e. and $F'=f$ a.e. on $[a,b]$.

See XIX.5.2.24. for a variation.

PROOF: Suppose first that f is nonnegative. Then F is nondecreasing. By XIX.5.2.11., F is absolutely continuous, and thus has bounded variation and Property (N) by XIX.5.2.8. and XIX.5.2.9.. By XIX.5.2.12. we have that

$$F(d)-F(c)=V_{[c,d]}(F)=\int_c^d |F'|\,d\lambda=\int_c^d F'\,d\lambda$$

for any $[c,d]\subseteq[a,b]$ since $F'\geq 0$ whenever it exists, and in particular

$$F(x)=\int_a^x F'\,d\lambda=\int_a^x f\,d\lambda$$

for any $x\in[a,b]$. Thus $F'=f$ a.e. by XIX.5.2.14..

For a general real f, write $f=f_+-f_-$, and set $F_+(x)=\int_a^x f_+\,d\lambda$ and $F_-(x)=\int_a^x f_-\,d\lambda$; then $F=F_+-F_-$, so $F'=F'_+-F'_-$ (defined a.e.) We have $F'_+=f_+$ a.e. and $F'_-=f_-$ a.e., so $F'=f$ a.e. For complex f, consider real and imaginary parts. 👍

The Proof of the Main Theorem

XIX.5.2.16. We can now give the proof of Theorem XIX.5.2.5.. (i) ⇒ (ii) by XIX.5.2.8. and XIX.5.2.9., and (ii) ⇒ (i) and (ii) ⇒ (iii) by XIX.5.2.12.. (iv) ⇒ (i) by XIX.5.2.11.. (iv) ⇒ (v) by XIX.5.2.15. (strictly speaking we do not need this implication, although we need XIX.5.2.15. for (i) ⇒ (v) below), and (v) ⇒ (iv) is trivial.

It remains to show (iii) ⇒ (i) ⇒ (v). For (i) ⇒ (v), suppose F is absolutely continuous on $[a,b]$. Then F has bounded variation on $[a,b]$ and F' is integrable on $[a,b]$. Set

$$G(x)=\int_a^x F'\,d\lambda$$

for $x\in[a,b]$. Then G is absolutely continuous on $[a,b]$, and $G'=F'$ a.e. by XIX.5.2.15.. So $F-G$ is absolutely continuous on $[a,b]$ by XIX.5.2.7., so has property (N) by XIX.5.2.9.. We have $(F-G)'=0$ a.e. on $[a,b]$, so $F-G$ is constant on $[a,b]$ by XIX.5.1.18.. Since $G(a)=0$, we have $F-G=F(a)$, so

$$F(x)=F(a)+G(x)=F(a)+\int_a^x F'\,d\lambda$$

for all $x\in[a,b]$.

For (iii) $\Rightarrow$ (i), suppose F is continuous, bounded variation, and $V_{[a,b]}(F) = \int_a^b |F'|\,d\lambda$. For any $x \in [a,b]$, we have $\int_a^x |F'|\,d\lambda \le V_{[a,x]}(F)$ and $\int_x^b |F'|\,d\lambda \le V_{[x,b]}(F)$, and

$$V_{[a,b]}(F) = \int_a^b |F'|\,d\lambda = \int_a^x |F'|\,d\lambda + \int_x^b |F'|\,d\lambda \le V_{[a,x]}(F) + V_{[x,b]}(F) = V_{[a,b]}(F)$$

and it follows that $V_{[a,x]}(F) = \int_a^x |F'|\,d\lambda$ (and $V_{[x,b]}(F) = \int_x^b |F'|\,d\lambda$), i.e.

$$(TF)(x) = \int_a^x |F'|\,d\lambda$$

for all $x \in [a,b]$, where TF is the total variation function of F. Thus TF is absolutely continuous by XIX.5.2.11.. Let $\epsilon > 0$, and choose $\delta > 0$ so that if $\{[a_k, b_k] : 1 \le k \le n\}$ is a set of nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta$, then $\sum_{k=1}^n |TF(b_k) - TF(a_k)| < \epsilon$. Then, since

$$|F(b_k) - F(a_k)| \le V_{[a_k,b_k]}(F) = TF(b_k) - TF(a_k)$$

for all k, we have $\sum_{k=1}^n |F(b_k) - F(a_k)| < \epsilon$. Thus F is absolutely continuous.

This completes the proof of Theorem XIX.5.2.5.. 

An interesting corollary of the proof, combined with previous results, is:

XIX.5.2.17. Corollary. Let F be a continuous function on $[a,b]$. Then F is absolutely continuous if and only if it has bounded variation and its total variation function TF is absolutely continuous. If TF is absolutely continuous, then $(TF)' = |F'|$ a.e. on $[a,b]$.

Proof: The last part of the proof of (iii) $\Rightarrow$ (i) above shows that if TF is absolutely continuous, so is F. Conversely, if F is absolutely continuous, then F has bounded variation and Property (N), so $V_{[a,b]}(F) = \int_a^b |F'|\,d\lambda$ by XIX.5.2.12., and by the first half of the proof of (iii) $\Rightarrow$ (i) the function TF is absolutely continuous, and

$$(TF)(x) = \int_a^x |F'|\,d\lambda$$

for all $x \in [a,b]$. Thus $(TF)' = |F'|$ a.e. by XIX.5.2.15..

Lipschitz Functions

XIX.5.2.18. Theorem. Let $[a,b]$ be a closed bounded interval, and $F : [a,b] \to \mathbb{R}$ a function. Then F is Lipschitz on $[a,b]$ if and only if F is absolutely continuous, hence differentiable a.e. on $[a,b]$, and F' is bounded on $[a,b]$. Set

$$M = \sup\left\{\left|\frac{F(y) - F(x)}{y - x}\right| : x, y \in [a,b], x \ne y\right\}$$

$$M' = \sup\{|D^+F(x)|, |D_+F(x)|, |D^-F(x)|, |D_-F(x)| : x \in [a,b]\}$$

$$M'' = \sup\{|F'(x)| : x \in [a,b], F'(x) \text{ exists}\}\ .$$

If F is Lipschitz, then $M = M' = M''$ is finite and is the smallest Lipschitz constant for F on $[a, b]$.

PROOF: We have already seen (XIX.5.2.4.) that a Lipschitz function is absolutely continuous. Conversely, if F is absolutely continuous on $[a, b]$ and M'' is finite, then for $x, y \in [a, b]$, $x < y$, we have

$$|F(y) - F(x)| = \left| \int_x^y F' \, d\lambda \right| \leq \int_x^y |F'| \, d\lambda \leq M''(y - x)$$

so F is Lipschitz on $[a, b]$ and M'' is a Lipschitz constant for F. If F is Lipschitz, i.e. M is finite, then M is the smallest Lipschitz constant for F on $[a, b]$, so we have $M \leq M''$. But $M'' \leq M' \leq M$ since every Dini derivative (in particular, any derivative) of F is a limit of difference quotients, so $M = M' = M''$ (and in particular M'' is finite). 👍

Everywhere Differentiable Functions

If a function F is differentiable everywhere on $[a, b]$, we have a more precise result, which applies more generally if F fails to be differentiable at only countably many points:

XIX.5.2.19. THEOREM. Let F be continuous on $[a, b]$ and differentiable except possibly on a countable subset of $[a, b]$. Then the following are equivalent:

(i) F is absolutely continuous on $[a, b]$.

(ii) F has bounded variation on $[a, b]$.

(iii) F' is Lebesgue integrable on $[a, b]$.

PROOF: (i) $\Rightarrow$ (ii) by XIX.5.2.8., and (ii) $\Rightarrow$ (iii) by (). If F satisfies the hypotheses, then F has property (N) by XIX.5.1.17., so if F' is Lebesgue integrable on $[a, b]$, then F is absolutely continuous by XIX.5.2.12., giving (iii) $\Rightarrow$ (i). 👍

XIX.5.2.20. In XIX.5.2.19., "differentiable except possibly on a countable subset" cannot be weakened to "differentiable a.e." The Cantor function is a counterexample. The conditions can fail, even if F is differentiable everywhere on $[a, b]$ (IX.2.9.10.(i)). ✋

The Fundamental Theorem of Calculus Again

The equivalence of (i) and (v) of XIX.5.2.5. can be rephrased as the other version of the Fundamental Theorem of Calculus:

XIX.5.2.21. THEOREM. [FUNDAMENTAL THEOREM OF CALCULUS, LEBESGUE VERSION 2A] Let F be a function which is absolutely continuous on $[a, b]$, with derivative f (defined a.e.). Then f is Lebesgue integrable on $[a, b]$, and for all $x \in [a, b]$ we have

$$F(x) = F(a) + \int_a^x f \, d\lambda$$

and so, in particular,

$$\int_a^b f \, d\lambda = F(b) - F(a) \ .$$

Conversely, if F can be so represented, it is absolutely continuous.

Combining XIX.5.2.15. with XIX.5.2.19., we get another version of Version 2 for everywhere differentiable functions:

XIX.5.2.22. THEOREM. [FUNDAMENTAL THEOREM OF CALCULUS, LEBESGUE VERSION 2B] Let F be a function which is continuous on $[a, b]$ and differentiable except possibly on a countable subset of $[a, b]$, with derivative f (defined a.e.). If f is Lebesgue integrable on $[a, b]$, then for all $x \in [a, b]$ we have

$$F(x) = F(a) + \int_a^x f \, d\lambda$$

and so, in particular,

$$\int_a^b f \, d\lambda = F(b) - F(a) \ .$$

The same caution as in XIX.5.2.20. applies here.

XIX.5.2.23. Thus care must be taken in the statement that Lebesgue integration and differentiation are inverse processes: the derivative of an integral is the function started with, but only almost everywhere in general by XIX.5.2.15. (a better result cannot be expected in general since functions which agree almost everywhere have the same Lebesgue integral), but a function is the integral of its derivative if and only if it is absolutely continuous (XIX.5.2.21.).

Theorems XIX.5.2.21. and XIX.5.2.22. are true generalizations of the Fundamental Theorem of Calculus 2. But Theorem XIX.5.2.15. is not a true generalization of the Fundamental Theorem of Calculus 1. In fact, XIX.5.2.15. does not assert that $F'(x) = f(x)$ for any *specific* $x \in [a, b]$, only for "almost all" x's. But there is a true generalization of the FTC1, obtained by just replacing Riemann integrals with Lebesgue integrals in the statement and proof:

XIX.5.2.24. THEOREM. [FUNDAMENTAL THEOREM OF CALCULUS, LEBESGUE VERSION 1B] Let f be Lebesgue integrable on $[a,b]$, and

$$F(x) = \int_a^x f\,d\lambda$$

for $x \in [a,b]$. If f is continuous at $x_0 \in [a,b]$, then F is differentiable at x_0 and $F'(x_0) = f(x_0)$.

PROOF: We have, for $x \in [a,b]$, $x \neq x_0$,

$$F(x) - F(x_0) = \int_a^x f\,d\lambda - \int_a^{x_0} f\,d\lambda = \int_{x_0}^x f\,d\lambda$$

(interpreted as $-\int_x^{x_0} f\,d\lambda$ if $x < x_0$), so

$$\frac{F(x) - F(x_0)}{x - x_0} = \frac{1}{x - x_0}\int_{x_0}^x f\,d\lambda\ .$$

We also have

$$f(x_0) = \frac{1}{x - x_0}\int_{x_0}^x f(x_0)\,d\lambda$$

(since $f(x_0)$ is just a constant), and so

$$\frac{F(x) - F(x_0)}{x - x_0} - f(x_0) = \frac{1}{x - x_0}\int_{x_0}^x [f - f(x_0)]\,d\lambda\ .$$

Let $\epsilon > 0$. Since f is continuous at x_0, there is a $\delta > 0$ such that, whenever $x \in [a,b]$ and $|x - x_0| < \delta$, $|f(x) - f(x_0)| < \epsilon$. If $x \in [a,b]$ and $|x - x_0| < \delta$, then $|t - x_0| < \delta$ for all t between x_0 and x, and hence

$$\left|\int_{x_0}^x [f - f(x_0)]\,d\lambda\right| < \epsilon|x - x_0|$$

by (); so we have

$$\left|\frac{F(x) - F(x_0)}{x - x_0} - f(x_0)\right| = \frac{1}{|x - x_0|}\left|\int_{x_0}^x [f - f(x_0)]\,d\lambda\right| < \epsilon$$

and therefore

$$F'(x_0) = \lim_{x \to x_0}\frac{F(x) - F(x_0)}{x - x_0} = f(x_0)\ .$$

Characterizing Functions as Derivatives

Theorem XIX.5.2.5. has another interesting consequence: integrable functions can be characterized without any explicit reference to integration. The next result generalizes part of IX.2.9.4. (see XIX.5.2.31. for the other part)

XIX.5.2.25. Corollary. Let f be a Lebesgue measurable real-valued function on an interval $[a,b]$. Then f is Lebesgue integrable on $[a,b]$ if and only if there is an absolutely continuous function F on $[a,b]$ with $F' = f$ a.e. on $[a,b]$.

If the word "absolutely" is removed from the statement, the result is false (). In fact, it is remarkable that *every* Lebesgue measurable function is a.e. the derivative of a continuous function. This result is due to Luzin; our proof is adapted from [Sak64].

XIX.5.2.26. Theorem. Let f be a Lebesgue measurable real-valued function on an interval $[a,b]$. Then there is a continuous function F on $[a,b]$ which is differentiable a.e. and $F' = f$ a.e. In fact, if G is any continuous function on $[a,b]$, for any $\epsilon > 0$ there is a continuous function F on $[a,b]$ which is differentiable a.e., $F' = f$ a.e., and $|F(x) - G(x)| < \epsilon$ for all $x \in [a,b]$.

The proof is a little complicated technically; we begin with an observation and two lemmas.

XIX.5.2.27. Let $\epsilon > 0$. If G is continuous on $[a,b]$, there is a continuous function H on $[a,b]$ which is differentiable a.e. and $H' = 0$ a.e. which is uniformly within $\frac{\epsilon}{2}$ of G (XX.10.3.6.). If F_0 is a continuous function on $[a,b]$ which is differentiable a.e. with $F_0' = f$ a.e., with $|F_0(x)| < \frac{\epsilon}{2}$ for all $x \in [a,b]$, then $F = F_0 + H$ is the desired function. Thus it suffices to show that if $\epsilon > 0$, there is a continuous function F on $[a,b]$ which is differentiable a.e., with $F' = f$ a.e. and $|F(x)| < \epsilon$ for all $x \in [a,b]$.

If f is integrable, this is fairly easily accomplished with judicious use of the Cantor function (this is essentially an explicit version of XX.10.3.6., cf. Exercise XIX.5.8.6.):

XIX.5.2.28. Lemma. Let ϕ be an integrable function on an interval $[a,b]$. Then for any $\epsilon > 0$ there is a continuous function Φ on $[a,b]$ with the following properties:

(i) Φ is differentiable a.e. and $\Phi' = \phi$ a.e. on $[a,b]$.

(ii) $\Phi(a) = \Phi(b) = 0$.

(iii) $|\Phi(x)| < \epsilon$ for all $x \in [a,b]$.

Proof: For $x \in [a,b]$, set $\Psi(x) = \int_a^x \phi \, d\lambda$. Then Ψ is absolutely continuous on $[a,b]$, $\Psi' = \phi$ a.e. on $[a,b]$, and $\Psi(a) = 0$. Fix $\epsilon > 0$. Since Ψ is uniformly continuous on $[a,b]$, there is a $\delta > 0$ such that $|\Psi(x) - \Psi(y)| < \epsilon$ whenever $x, y \in [a,b]$ and $|x - y| < \delta$. Let $\mathcal{P} = \{a = x_0, \ldots, x_n = b\}$ be a partition of $[a,b]$ into subintervals of length $< \delta$. On $[x_{k-1}, x_k]$, let H_k be a copy of the Cantor Function scaled to $[x_{k-1}, x_k]$ with $H_k(x_{k-1}) = \Psi(x_{k-1})$ and $H_k(x_k) = \Psi_k(x_k)$. Define $\Phi(x) = \Psi(x) - H_k(x)$ if $x_{k-1} \le x \le x_k$. Then $\Phi(x_k) = 0$ for all k, and hence Φ is well defined and continuous; and $\Phi' = \Psi' = \phi$ a.e. since $H_k' = 0$ a.e. for each k. If $x \in [x_{k-1}, x_k]$, we have $|\Psi(x) - \Psi(x_{k-1})| < \epsilon$ and $|\Psi(x) - \Psi(x_k)| < \epsilon$; since $H_k(x)$ is between $H_k(x_{k-1}) = \Psi(x_{k-1})$ and $H_k(x_k) = \Psi(x_k)$, we also have $|\Phi(x)| = |\Psi(x) - H_k(x)| < \epsilon$. 👍

To handle the more difficult case where f is not integrable, we need the following technical lemma:

XIX.5.2.29. LEMMA. Let ϕ be an integrable function on an interval $[a,b]$, and C a closed subset of $[a,b]$. Then for any $\epsilon > 0$ there is a continuous function Φ on $[a,b]$ with the following properties:

(i) Φ is differentiable a.e. and $\Phi' = \phi$ a.e. on $[a,b] \setminus C$.

(ii) $\Phi(x) = \Phi'(x) = 0$ for all $x \in C$.

(iii) $|\Phi(x+h)| = |\Phi(x+h) - \Phi(x)| < \epsilon|h|$ whenever $x \in C$ and $x + h \in [a,b]$.

PROOF: Fix $\epsilon > 0$. The open set $(a,b) \setminus C$ is a disjoint union of open intervals (a_k, b_k). For each k, fix a set $\{x_{k,n} : n \in \mathbb{Z}\}$ with $x_{k,n} < x_{k,n+1}$ for all n, $\lim_{n\to-\infty} x_{k,n} = a_k$, and $\lim_{n\to+\infty} x_{k,n} = b_k$. For each k and n, let $\Phi_{k,n}$ be a continuous function on $[x_{k,n}, x_{k,n+1}]$ such that

(i) $\Phi_{k,n}$ is differentiable a.e. and $\Phi'_{k,n} = \phi$ a.e. on $[x_{k,n}, x_{k,n+1}]$.

(ii) $\Phi_{k,n}(x_{k,n}) = \Phi_{k,n}(x_{k,n+1}) = 0$.

(iii) $|\Phi_{k,n}(x)| < \min\left(\dfrac{\epsilon(x_{k,n} - a_k)}{k + |n|}, \dfrac{\epsilon(b_k - x_{k,n+1})}{k + |n|}\right)$ for all $x \in [x_{k,n}, x_{k,n+1}]$.

(Lemma XIX.5.2.28.). Define Φ on $[a,b]$ by $\Phi(a) = \Phi(b) = 0$, $\Phi(x) = 0$ for $x \in C$, and $\Phi(x) = \Phi_{k,n}(x)$ if $x \in [x_{k,n}, x_{k,n+1}]$. Then Φ is well defined and continuous, and it is routine to check it has the other required properties (Exercise XIX.5.8.5.). 👍

XIX.5.2.30. We now prove the theorem (in the reduced form $G = 0$). Fix $\epsilon > 0$. Inductively for $n \geq 0$ construct continuous functions Φ_n which are differentiable a.e. and closed subsets (C_n) of $[a,b]$ with $C_n \subseteq C_{n+1}$ for all n, such that, with $F_n = \sum_{k=1}^{n} \Phi_k$, the following conditions are satisfied for $n \geq 1$:

(i) F_n is differentiable at all points of C_n and $F'_n = f$ on C_n.

(ii) $\Phi_n(x) = \Phi'_n(x) = 0$ for all $x \in C_{n-1}$.

(iii) $|\Phi_n(x+h)| = |\Phi_n(x+h) - \Phi_n(x)| \leq \dfrac{\epsilon|h|}{2^n(b-a)}$ whenever $x \in C_{n-1}$ and $x + h \in [a,b]$.

(iv) $\lambda([a,b] \setminus C_n) < \frac{1}{n}$.

Begin with $C_0 = \emptyset$ and $\Phi_0 = 0$. Suppose Φ_k and C_k have been chosen for $k \leq n$. Since F'_n and f are defined a.e., for some sufficiently large M the measurable set

$$A_n = \{x \in [a,b] \setminus C_n : F'_n(x) \text{ and } f(x) \text{ exist and } |F'_n(x)|, |f(x)| \leq M\}$$

satisfies $\lambda([a,b] \setminus [C_n \cup A_n]) < \frac{1}{n+1}$.

Define ϕ_n on $[a,b]$ by $\phi_n = f - F'_n$ on A_n and $\phi_n = 0$ on $[a,b] \setminus A_n$. Then ϕ_n is bounded, hence integrable, so by Lemma XIX.5.2.29. there is a continuous function Φ_{n+1} on $[a,b]$ which is differentiable a.e., $\Phi'_{n+1}(x) = f(x) - F'_n(x)$ for almost all $x \in A_n$, $\Phi_{n+1}(x) = \Phi'_{n+1}(x) = 0$ for all $x \in C_n$, and

$$|\Phi_{n+1}(x+h)| < \frac{\epsilon|h|}{2^{n+1}(b-a)}$$

if $x \in C_n$ and $x + h \in [a, b]$.

By (), there is a closed subset B_n of A_n such that $\Phi'_{n+1}(x) = f(x) - F'_n(x)$ for all $x \in B_n$ and $\lambda([0,1] \setminus [C_n \cup B_n]) < \frac{1}{n+1}$. Set $C_{n+1} = C_n \cup B_n$. This completes the inductive construction, and properties (i)–(iv) obviously hold.

From (iii), we have $|\Phi_n(x)| < \frac{\epsilon}{2^n}$ for all $x \in [a, b]$; thus the series

$$\sum_{n=1}^{\infty} \Phi_n$$

converges uniformly to a continuous function F on $[a, b]$, and $|F(x)| < \epsilon$ for all $x \in [a, b]$. Set $C = \cup_{n=1}^{\infty} C_n$. Then $\lambda([a, b] \setminus C) = 0$, and if $x \in C$, then $x \in C_n$ for sufficiently large n; thus for any h with $x + h \in [a, b]$ we have

$$\left| \frac{F(x+h) - F(x)}{h} - \frac{F_n(x+h) - F_n(x)}{h} \right| = \left| \sum_{k=n+1}^{\infty} \frac{\Phi_k(x+h) - \Phi_k(x)}{h} \right|$$

$$\leq \sum_{k=n+1}^{\infty} \frac{|\Phi_k(x+h) - \Phi_k(x)|}{|h|} < \frac{\epsilon}{2^n(b-a)}$$

for sufficiently large n, and hence

$$\limsup_{h \to 0} \left| \frac{F(x+h) - F(x)}{h} - f(x) \right| \leq \frac{\epsilon}{2^n(b-a)}$$

for all sufficiently large n, i.e. $F'(x) = f(x)$.

This completes the proof of Theorem XIX.5.2.26.. 

XIX.5.2.31. What about uniqueness in XIX.5.2.25.? The F is clearly unique up to adding a constant among absolutely continuous functions. But from XIX.5.2.26. there are many continuous functions which are differentiable a.e. and whose derivative equals f a.e.; in fact such functions are uniformly dense in $C([a, b])$. Thus there is no reasonable uniqueness statement among continuous functions.

XIX.5.3. Signed and Complex Borel Measures on $\mathbb{R}$

We can extend the notions of cumulative distribution function, absolute continuity, and density function to signed and complex measures. The definition of cdf is straightforward:

XIX.5.3.1. Definition. Let μ be a finite signed or complex Borel measure on $\mathbb{R}$. For $x \in \mathbb{R}$, set $F_\mu(x) = \mu((-\infty, x])$. Then F_μ is the *cumulative distribution function (cdf)* for μ.

XIX.5.3.2. Proposition. The function F_μ has the following properties:

(i) F_μ has at most countably many discontinuities, each of which is a jump discontinuity.

(ii) F_μ is continuous from the right.

(iii) $\lim_{x\to-\infty} F_\mu(x) = 0$.

(iv) F_μ is bounded, and $\lim_{x\to+\infty} F_\mu(x) = \mu(\mathbb{R})$.

PROOF: Parts (ii), (iii), and (iv) follow immediately from XVII.9.1.11.. It also follows from XVII.9.1.11. and the Sequential Criterion that for any $x \in \mathbb{R}$,

$$\mu((-\infty, x)) = \lim_{y\to x-} \mu((-\infty, y]) = \lim_{y\to x-} F_\mu(y)$$

so $F_\mu(x-)$ and $F_\mu(x+) = F_\mu(x)$ exist for all $x \in \mathbb{R}$. Thus every discontinuity of F_μ is a jump discontinuity. Furthermore,

$$F_\mu(x+) - F_\mu(x-) = \mu((-\infty, x]) - \mu((-\infty, x)) = \mu(\{x\})$$

for all x. Since μ is finite, it can have only countably many atoms, and the sum of the measures of the atoms is finite. 👍

The direct proof of (i) above is elementary and does not use the Jordan Decomposition Theorem. But using this theorem we get an important result which gives (i) as an immediate corollary:

XIX.5.3.3. PROPOSITION. Let μ be a finite signed Borel measure on $\mathbb{R}$, and let (μ^+, μ^-) be the Jordan decomposition (XVII.9.1.3.) of μ. Then $F_\mu = F_{\mu^+} - F_{\mu^-}$. In particular, since F_{μ^+} and F_{μ^-} are bounded and nondecreasing, F_μ has bounded variation on $\mathbb{R}$. In particular, F_μ is differentiable a.e. and F'_μ is integrable on closed bounded subintervals of $\mathbb{R}$.

XIX.5.3.4. COROLLARY. Let μ be a finite signed Borel measure on $\mathbb{R}$, and let (μ^+, μ^-) be the Jordan decomposition of μ. If $|\mu|$ is the total variation measure of μ (), then $F_{|\mu|} = TF_\mu$, the total variation function of F_μ.

XIX.5.3.5. These results extend immediately to complex measures by considering real and imaginary parts: if μ is a complex Borel measure on $\mathbb{R}$, then F_μ has bounded variation and $F_{|\mu|} = TF_\mu$.

Absolute Continuity

It is slightly tricky to give the proper definition of absolute continuity for signed or complex measures, due to the distinction between null sets and sets of measure zero. The proper definition is:

XIX.5.3.6. DEFINITION. Let μ and ν be signed or complex measures on a measurable space $(X, \mathcal{A})$. Then ν is *absolutely continuous* with respect to μ, written $\nu \ll \mu$, if every μ-null set is a ν-null set, i.e. $|\nu| \ll |\mu|$ in the sense of ().

The next result is an immediate consequence of XIX.5.3.4., XIX.5.2.6., andXIX.5.2.17.:

XIX.5.3.7. PROPOSITION. Let μ be a finite signed or complex Borel measure on $\mathbb{R}$, then the following are equivalent:

(i) $\mu \ll \lambda$.

(ii) TF_μ is absolutely continuous on every closed bounded subinterval of $\mathbb{R}$.

(ii) F_μ is absolutely continuous on every closed bounded subinterval of $\mathbb{R}$.

Density Functions

XIX.5.3.8. DEFINITION. Let μ be a finite signed or complex Borel measure on $\mathbb{R}$. Then μ has a *density function* ϕ if

$$\mu(B) = \int_B \phi \, d\lambda$$

for every Borel set B in $\mathbb{R}$.

A density function, if it exists, is uniquely determined a.e., i.e. two density functions for a measure μ must be equal a.e.

XIX.5.3.9. THEOREM. Let μ be a finite signed or complex Borel measure on $\mathbb{R}$. The following are equivalent:

(i) μ has a density function.

(ii) F'_μ is a density function for μ.

(iii) $|\mu|$ has a density function.

(iv) $|F'_\mu|$ is a density function for $|\mu|$.

(v) $\mu \ll \lambda$.

PROOF: If μ has a density function ϕ, then for any closed bounded interval $[a, b]$,

$$F_\mu(x) = F(a) + \int_a^x \phi \, d\lambda$$

so F_μ is absolutely continuous on $[a, b]$, and hence $F'_\mu = \phi$ a.e. on $\mathbb{R}$. Thus (i) $\Rightarrow$ (ii). (ii) $\Rightarrow$ (i) is trivial, so (i) $\iff$ (ii). Similarly, (iii) $\iff$ (iv). By XIX.5.3.7., (v) is equivalent to $TF_\mu = F_{|\mu|}$ being absolutely continuous, which is equivalent to $|F'|$ being a density function for $|\mu|$ by XIX.5.2.6.; thus (v) is equivalent to (iii) and (iv). (i)–(ii) also imply that F_μ is absolutely continuous on any closed bounded interval, hence $TF_\mu = F_{|\mu|}$ is absolutely continuous by XIX.5.2.17.. We thus have (i) $\iff$ (ii) $\Rightarrow$ (iii) $\iff$ (iv) $\iff$ (v). We need to show (iii)-(v) $\Rightarrow$ (i)-(ii). If (v) holds, then F_μ is absolutely continuous by XIX.5.3.7., so we have $\mu((a, b)) = \mu([a, b]) = \int_a^b F' \, d\lambda$ for any $a, b \in \mathbb{R}$, $a < b$. 👍

XIX.5.4. The Bounded Variation Norm

XIX.5.4.10. Let $[a,b]$ be a closed bounded interval in $\mathbb{R}$. Let $BV([a,b])$ be the set of real-valued functions of bounded variation on $[a,b]$. Then $BV([a,b])$ is a real vector space, and the total variation $V_{[a,b]}$ is a seminorm on $BV([a,b])$ (). It is not a norm since the total variation of a constant function (and only a constant function) is 0. To make a norm, we must add on a "size" term which is another seminorm. It does not much matter what additional seminorm we use so long as it separates constant functions. Here are three standard possibilities:

$$\|f\|_{BV} = |f(a)| + V_{[a,b]}(f) \ .$$

$$\|f\|_{BV1} = \|f\|_1 + V_{[a,b]}(f) = V_{[a,b]}(f) + \int_a^b |f| \, d\lambda \ .$$

$$\|f\|_{BV\infty} = \|f\|_\infty + V_{[a,b]}(f) = V_{[a,b]}(f) + \sup_{a\le t\le b} |f(t)| \ .$$

(Note that a function of bounded variation is bounded and Lebesgue integrable, even Riemann integrable ().)

Note that if f is absolutely continuous on $[a,b]$, then by ()

$$\|f\|_{BV} = |f(a)| + \int_a^b |f'| \, d\lambda \ .$$

In this case, $\|f\|_{BV}$ is usually written $\|f\|_{AC}$. There are similar formulas for the other norms.

XIX.5.4.11. Proposition. The norms $\|\cdot\|_{BV}$, $\|\cdot\|_{BV1}$, and $\|\cdot\|_{BV\infty}$ are equivalent on $BV([a,b])$, and dominate $\|\cdot\|_\infty$, so if $f_n \to f$ in one (hence all) of these norms, then $f_n \to f$ uniformly on $[a,b]$.

Proof: If $f \in BV([a,b])$, we have $|f(a)| \le \|f\|_\infty \le |f(a)| + V_{[a,b]}(f)$, so $\|f\|_{BV} \le \|f\|_{BV\infty} \le 2\|f\|_{BV}$; thus $\|\cdot\|_{BV}$ and $\|\cdot\|_{BV\infty}$ are equivalent. We have $\|f\|_1 \le (b-a)\|f\|_\infty$, so $\|f\|_{BV1} \le K\|f\|_{BV\infty}$ for $K = \max(b-a, 1)$. Let $m = \inf_{a\le t\le b} |f(t)|$; then $|f(a)| \le m + V_{[a,b]}(f)$, so

$$(b-a)|f(a)| \le m(b-a) + (b-a)V_{[a,b]}(f) \le (b-a)V_{[a,b]}(f) + \int_{[a,b]} |f| \, d\lambda$$

and therefore $\|f\|_{BV} \le K\|f\|_{BV1}$ for $K = \max\left(2, \frac{1}{b-a}\right)$. 👍

XIX.5.4.12. It is conventional to take $\|\cdot\|_{BV}$ as the *bounded variation norm*, although we could equally well work with any of these norms. There are even other norms which are equivalent to these, such as

If $c \in [a,b]$, set $\|f\|_{BV(c)} = |f(c)| + V_{[a,b]}(f)$ (so $\|f\|_{BV} = \|f\|_{BV(a)}$).

If $1 < p < \infty$, set $\|f\|_{BVp} = \|f\|_p + V_{[a,b]}(f) = V_{[a,b]}(f) + \left[\int_{[a,b]} |f|^p \, d\lambda\right]^{1/p}$.

XIX.5.4.13. THEOREM. (i) The norm $\|\cdot\|_{BV}$ (hence all the other ones above) is a complete norm on $BV([a,b])$.
(ii) The set $BVC([a,b])$ of continuous functions of bounded variation on $[a,b]$ and the set $AC([a,b])$ of absolutely continuous functions functions on $[a,b]$ are closed subspaces of $BV([a,b])$.
Thus $(BV([a,b]),\|\cdot\|_{BV})$, $(BVC([a,b]),\|\cdot\|_{BV})$, and $(AC([a,b]),\|\cdot\|_{AC})$ are Banach spaces.

PROOF: (i): Let (f_n) be a Cauchy sequence in $BV([a,b])$ for $\|\cdot\|_{BV}$. Then (f_n) is a uniform Cauchy sequence by XIX.5.4.11., hence converges uniformly to a real-valued function f. We also have that the sequence $(V_{[a,b]}(f_n))$ is a Cauchy sequence in $\mathbb{R}$, hence is bounded. So it suffices to prove the following slightly stronger statement: if (f_n) is a sequence in $BV([a,b])$ converging uniformly to f on $[a,b]$, and $V_{[a,b]}(f_n) \le M$ for all n, then $f \in BV([a,b])$ (and $V_{[a,b]}(f) \le M$). To prove this, suppose $V_{[a,b]}(f) > M$, and fix a partition $\mathcal{P} = \{a = x_0, \dots, x_m = b\}$ of $[a,b]$ with $V(f,\mathcal{P}) > M$. Set

$$\epsilon = \frac{V(f,\mathcal{P}) - M}{2m}$$

and choose N such that $\|f_n - f\|_\infty < \epsilon$ for all $n \ge N$. If $n \ge N$, then

$$V(f,\mathcal{P}) = \sum_{k=1}^{m} |f(x_k) - f(x_{k-1})| \le \sum_{k=1}^{m} [|f(x_k) - f_n(x_k)| + |f_n(x_k) - f_n(x_{k-1})| + |f_n(x_{k-1}) - f(x_{k-1})|]$$
$$< \sum_{k=1}^{m} [\epsilon + |f_n(x_k) - f_n(x_{k-1})| + \epsilon] = V(f_n,\mathcal{P}) + 2m\epsilon \le M + (V(f,\mathcal{P}) - M) = V(f,\mathcal{P})$$

a contradiction.
(ii): Closure of $BVC([a,b])$ in $BV([a,b])$ follows immediately from XIX.5.4.11. and (). For $AC([a,b])$, suppose (f_n) is a sequence of absolutely continuous functions on $[a,b]$ which is Cauchy in the $\|\cdot\|_{BV}$ norm. We have

$$V_{[a,b]}(f_n - f_m) = \int_a^b |f_n' - f_m'|\, d\lambda$$

and, since (f_n) is a Cauchy sequence for $V_{[a,b]}$, it follows that (f_n') is a Cauchy sequence for the L^1-norm. Thus $f_n' \to g$ in the L^1-norm for some integrable function g on $[a,b]$. Also, $(f_n(a))$ is a Cauchy sequence in $\mathbb{R}$, hence converges to some y_0. (Actually, (f_n) converges to some $f \in BVC([a,b])$, and $y_0 = f(a)$.) For $x \in [a,b]$, set

$$G(x) = y_0 + \int_a^x g\, d\lambda\ .$$

Then G is absolutely continuous on $[a,b]$, and

$$\|G - f_n\|_{BV} = |y_0 - f_n(a)| + \int_a^b |g - f_n'|\, d\lambda$$

so $f_n \to G$ in the $\|\cdot\|_{BV}$ ($\|\cdot\|_{AC}$) norm. 👍

The following result is "almost" a strengthened form of V.8.5.5.. It is not exactly stronger since the hypotheses of V.8.5.5. on an interval I do not imply that the hypotheses of XIX.5.4.14. hold on closed bounded subintervals of I (under the hypotheses of V.8.5.5., the derivatives are not necessarily locally integrable), and the conclusion is only a.e.; but it is roughly a stronger statement since the convergence hypothesis on the derivatives is weaker and the concluded convergence of the functions is stronger.

XIX.5.4.14. THEOREM. Let (F_n) be a sequence of absolutely continuous functions on a closed bounded interval $[a,b]$, and (f_n) a sequence of integrable functions on $[a,b]$ with $f_n = F_n'$ a.e. Suppose

(a) The sequence (f_n) converges in the $\|\cdot\|_1$ norm on $[a,b]$ to a function f.

(b) There is an $x_0 \in [a,b]$ such that the sequence $(F_n(x_0))$ converges.

Then:

(i) The sequence (F_n) converges in the $\|\cdot\|_{AC}$ norm on $[a,b]$ to an (absolutely continuous) function F.

(ii) F is differentiable a.e. and $F'(x) = f(x)$ a.e. on $[a,b]$.

XIX.5.4.15. COROLLARY. Let $[a,b]$ be a closed bounded interval in $\mathbb{R}$, and (f_n) a sequence of integrable functions on $[a,b]$ converging in the L^1-norm to an (integrable) function f on $[a,b]$. Set

$$F_n(x) = \int_{[a,x]} f_n \, d\lambda \ , \quad F(x) = \int_{[a,x]} f \, d\lambda$$

for each n and each $x \in [a,b]$. Then the F_n and F are absolutely continuous on $[a,b]$, and $F_n \to F$ in the $\|\cdot\|_{AC}$ norm.

In other words, roughly speaking, convergence of a sequence of functions in a fairly weak sense implies convergence of the sequence of antiderivatives in a much stronger sense.

Corollary XIX.5.4.15. is clearly a special case of XIX.5.4.14.. Conversely, we will prove the Corollary and then reduce the proof of XIX.5.4.14. to XIX.5.4.15..

So we first prove the Corollary.

PROOF: Let $[a,b]$, (f_n), (F_n), f, F be as in the statement. We need only show $F_n \to F$ in the $\|\cdot\|_{AC}$ norm. We have $f_n(a) = F(a) = 0$ for all n, so

$$\|F_n - F\|_{AC} = \int_a^b |f_n - f| \, d\lambda$$

which goes to 0 by assumption. 👍

We now prove XIX.5.4.14.. The proof is some simple machinations to take care of the complication that x_0 is not necessarily a, and that the functions do not all agree at x_0.

PROOF: For each n, we have

$$F_n(a) = F_n(x_0) + \int_{x_0}^a f_n \, d\lambda = F_n(x_0) - \int_a^{x_0} f_n \, d\lambda \ .$$

If we set $G_n(x) = F_n(x) - F_n(a)$, so $G_n' = F_n' = f_n$ a.e. and $G_n(a) = 0$ for all n, then the f_n and G_n satisfy the hypotheses of XIX.5.4.15. with G_n in place of F_n, so (G_n) converges in the $\|\cdot\|_{AC}$ norm to the absolutely continuous function G, where

$$G(x) = \int_a^x f \, d\lambda$$

for $x \in [a, b]$. Set $F(x) = G(x) + [y_0 - G(x_0)]$, where

$$y_0 = \lim_{n\to\infty} F_n(x_0)$$

(so $F(x_0) = y_0$, F is absolutely continuous, and $F' = f$ a.e.). For all n we have that

$$\|F_n - F\|_{AC} = |F_n(a) - F(a)| + \int_a^b |f_n - f| \, d\lambda$$

$$= \left| F_n(x_0) - \int_a^{x_0} f_n \, d\lambda - F(x_0) + \int_a^{x_0} f \, d\lambda + \int_a^b |f_n - f| \, d\lambda \right|$$

$$\leq |F_n(x_0) - F(x_0)| + \int_a^{x_0} |f_n - f| \, d\lambda + \int_a^b |f_n - f| \, d\lambda$$

which goes to 0 as $n \to \infty$. 👍

XIX.5.4.16. There are a number of similar results; see () for one. The informal principle illustrated by all these results is that if $f_n \to f$ in a certain sense, and if F_n, F are antiderivatives adjusted by suitable constants so that $F_n(x_0) \to F(x_0)$ for a single x_0, then $F_n \to F$ in a considerably stronger sense than the sense in which $f_n \to f$.

XIX.5.5. Integration by Substitution and Integration by Parts

Using absolute continuity, we can give general versions of integration by substitution and by parts.

Integration by Parts

We first examine integration by parts. We begin with an observation of independent interest:

XIX.5.5.1. PROPOSITION. Let f and g be absolutely continuous functions on $[a,b]$. Then fg is also absolutely continuous on $[a,b]$.

PROOF: Since f and g are continuous on $[a,b]$, they are bounded. Fix positive constants M and N with $|f| \le M$ and $|g| \le N$. Let $\epsilon > 0$, and take δ_1 so that whenever $\{[a_k,b_k] : 1 \le k \le n\}$ is a set of nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta_1$, then $\sum_{k=1}^n |f(b_k) - f(a_k)| < \frac{\epsilon}{2N}$, and δ_2 so that whenever $\{[a_k,b_k] : 1 \le k \le n\}$ is a set of nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta_2$, then $\sum_{k=1}^n |g(b_k) - g(a_k)| < \frac{\epsilon}{2M}$. Set $\delta = \min(\delta_1, \delta_2)$. If $\{[a_k,b_k] : 1 \le k \le n\}$ is a set of nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta$, then, by the usual trick of adding and subtracting,

$$\begin{aligned}
\sum_{k=1}^n |f(b_k)g(b_k) - f(a_k)g(a_k)| &= \sum_{k=1}^n |f(b_k)g(b_k) - f(a_k)g(b_k) + f(a_k)g(b_k) - f(a_k)g(a_k)| \\
&\le \sum_{k=1}^n [|f(b_k)g(b_k) - f(a_k)g(b_k)| + |f(a_k)g(b_k) - f(a_k)g(a_k)|] \\
&= \sum_{k=1}^n |g(b_k)||f(b_k) - f(a_k)| + \sum_{k=1}^n |f(a_k)||g(b_k) - g(a_k)| \\
&\le N \sum_{k=1}^n |f(b_k) - f(a_k)| + M \sum_{k=1}^n |g(b_k) - g(a_k)| < N\frac{\epsilon}{2N} + M\frac{\epsilon}{2M} = \epsilon \ .
\end{aligned}$$

XIX.5.5.2. THEOREM. [INTEGRATION BY PARTS] Let F and G be absolutely continuous functions on $[a,b]$. Then $F'G$ and FG' (defined a.e. on $[a,b]$) are Lebesgue integrable on $[a,b]$, and

$$\int_a^b F'G \, d\lambda = F(b)G(b) - F(a)G(a) - \int_a^b FG' \, d\lambda \ .$$

PROOF: $F'G$ and FG' are integrable since F' and G' are integrable, and a product of an integrable function and a bounded measurable function is integrable. We have that F' exists on $[a,b] \setminus A$ and G' exists on $[a,b] \setminus B$, where A and B are null sets; thus F and G are differentiable on $[a,b] \setminus (A \cup B)$. Therefore by the Product Rule FG is differentiable on $[a,b] \setminus (A \cup B)$ and $(FG)' = F'G + FG'$ on $[a,b] \setminus (A \cup B)$, and in

particular $(FG)' = F'G + FG'$ a.e. (FG may be differentiable on a larger set, but this is irrelevant.) Since FG is absolutely continuous, we thus have

$$F(b)G(b) - F(a)G(a) = \int_a^b (FG)'\,d\lambda = \int_a^b (F'G + FG')\,d\lambda = \int_a^b F'G\,d\lambda + \int_a^b FG'\,d\lambda$$

and the result follows by moving the last term. 👍

XIX.5.5.3. Corollary. Let f and g be integrable functions on $[a,b]$. For $x \in [a,b]$, set $F(x) = \int_a^x f\,d\lambda$ and $G(x) = \int_a^x g\,d\lambda$. Then fG and Fg are integrable on $[a,b]$, and

$$\int_a^b fG\,d\lambda = F(b)G(b) - \int_a^b Fg\,d\lambda\ .$$

See XIX.1.8.2. for a more general Integration by Parts result.

XIX.5.5.4. The hypothesis that both F and G are absolutely continuous is essentially necessary: it is not enough that one is absolutely continuous and the other continuous and differentiable a.e. For example, let F be the constant function 1 and G the Cantor function. Then

$$\int_0^1 F'G\,d\lambda \neq F(1)G(1) - F(0)G(0) - \int_0^1 FG'\,d\lambda$$

since both integrals are zero. Other examples such as taking $F(x) = x$ and G the Cantor function also fail.

Integration by Substitution or Change of Variable

Now we examine integration by substitution. This also seems to have a straightforward argument along the same lines, based on the following general fact:

XIX.5.5.5. Proposition. Let ϕ be an absolutely continuous monotone function from $[a,b]$ to $[c,d]$, and let F be an absolutely continuous function on $[c,d]$. Then $F \circ \phi$ is absolutely continuous on $[a,b]$.

Proof: We prove the result for ϕ nondecreasing; the nonincreasing case is an easy notational modification. Let $\epsilon > 0$, and choose $\eta > 0$ such that if $[c_1,d_1],\ldots,[c_n,d_n]$ are nonoverlapping subintervals of $[c,d]$ with $\sum_{k=1}^n (d_k - c_k) < \eta$, then $\sum_{k=1}^n |F(d_k) - f(c_k)| < \epsilon$. Then choose $\delta > 0$ such that if $[a_1,b_1],\ldots,[a_n,b_n]$ are nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta$, then $\sum_{k=1}^n |\phi(b_k) - \phi(a_k)| < \eta$.

Let $[a_1,b_1],\ldots,[a_n,b_n]$ be nonoverlapping subintervals of $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta$. Set $c_k = \phi(a_k)$ and $d_k = \phi(b_k)$. Since ϕ is nondecreasing, $[c_1,d_1],\ldots,[c_n,d_n]$ are nonoverlapping subintervals of $[c,d]$ (although some may be degenerate). We have $\sum_{k=1}^n (d_k - c_k) = \sum_{k=1}^n |\phi(b_k) - \phi(a_k)| < \eta$, so

$$\sum_{k=1}^n |F(\phi(b_k)) - F(\phi(a_k))| = \sum_{k=1}^n |F(d_k) - F(c_k)| < \epsilon\ .$$

It is not true that a composition of two absolutely continuous functions is necessarily absolutely continuous, even if the inside function is Lipschitz and the outside function is monotone (XIX.5.8.10.). Thus XIX.5.5.5. is rather special.

XIX.5.5.6. THEOREM. [INTEGRATION BY SUBSTITUTION OR CHANGE OF VARIABLE] Let ϕ be an absolutely continuous monotone function on an interval $[a,b]$, with $\phi([a,b]) = [c,d]$.

(i) If f is a nonnegative Lebesgue measurable function on $[c,d]$, then $(f\circ\phi)|\phi'|$ (which is defined a.e. on $[a,b]$, and nonnegative) is Lebesgue measurable on $[a,b]$, and

$$\int_a^b (f\circ\phi)|\phi'|\,d\lambda = \int_c^d f\,d\lambda\ .$$

(ii) If f is a Lebesgue integrable function on $[c,d]$, then $(f\circ\phi)|\phi'|$ (which is defined a.e. on $[a,b]$) is Lebesgue integrable on $[a,b]$, and

$$\int_a^b (f\circ\phi)|\phi'|\,d\lambda = \int_c^d f\,d\lambda\ .$$

XIX.5.5.7. The assumption that ϕ is absolutely continuous is essentially necessary: it is not enough that ϕ is continuous, and differentiable a.e. For example, let ϕ be the Cantor function, and f the constant function 1. Then

$$0 = \int_0^1 \phi'\,d\lambda = \int_0^1 (f\circ\phi)\phi'\,d\lambda \neq \int_0^1 f\,d\lambda = 1\ .$$

XIX.5.5.8. Here is a potential argument for (ii) which looks convincing at first glance: Set

$$F(x) = \int_c^x f\,d\lambda$$

for $x\in[c,d]$. Then F is absolutely continuous on $[c,d]$, so by XIX.5.5.5., $F\circ\phi$ is absolutely continuous, hence differentiable a.e. on $[a,b]$. By the Chain Rule, $(F\circ\phi)' = (F'\circ\phi)\phi'$, so since $F' = f$ a.e. we should have $(F\circ\phi)' = (f\circ\phi)\phi'$ a.e. Thus

$$\int_a^b (f\circ\phi)\phi'\,d\lambda = \int_a^b (F\circ\phi)'\,d\lambda = F(\phi(b)) - F(\phi(a)) = F(d) - F(c) = \int_c^d F'\,d\lambda = \int_a^b f\,d\lambda\ .$$

XIX.5.5.9. Unfortunately, there is a flaw in the argument. What the Chain Rule says is that *if* ϕ is differentiable at x and F is differentiable at $\phi(x)$, then $F\circ\phi$ is differentiable at x and

$$(F\circ\phi)'(x) = (F'\circ\phi)(x)\phi'(x)\ .$$

We have that F is differentiable on $[c,d]\setminus A$ for some null set A, and ϕ is differentiable on $[a,b]\setminus B$ for some null set B. Thus by the Chain Rule $F\circ\phi$ is differentiable on $[a,b]\setminus[\phi^{-1}(A)\cup B]$ and for x in this set,

$$(F\circ\phi)'(x) = (F'\circ\phi)(x)\phi'(x)\ .$$

The problem is that $\phi^{-1}(A)$ is not necessarily a null set! So even though $F\circ\phi$ is differentiable a.e. on $[a,b]$, we cannot conclude from the Chain Rule that it equals $(F'\circ\phi)\phi'$ a.e.

There is an additional problem: although $F'=f$ a.e. on $[c,d]$, it does not follow that $F'\circ\phi = f\circ\phi$ a.e. on $[a,b]$. Thus the argument has a seemingly irreparable flaw.

We will have to do considerable roundabout work to get past the flaw and prove the theorem. After the fact it will indeed turn out that $(F\circ\phi)' = (F'\circ\phi)\phi' = (f\circ\phi)\phi'$ a.e. on $[a,b]$ (XIX.5.8.8.).

We develop the proof of Theorem XIX.5.5.6. in a series of lemmas. We prove the theorem for ϕ nondecreasing (so $\phi'\geq 0$); the proof for ϕ nonincreasing is essentially identical, or see XIX.5.8.7..

XIX.5.5.10. LEMMA. Let ϕ be as in XIX.5.5.6., with ϕ nondecreasing. If D is a G_δ in $[c,d]$, then

$$\lambda(D) = \int_{\phi^{-1}(D)} \phi'\,d\lambda\ .$$

PROOF: First note that if (x,y) is an open interval in $[c,d]$, then $\phi^{-1}((x,y))$ is a relatively open subinterval of $[a,b]$ with endpoints u and v, $u<v$ (possibly containing u or v if $u=a$ or $v=b$), and

$$\int_{\phi^{-1}((x,y))} \phi'\,d\lambda = \int_u^v \phi'\,d\lambda = \phi(v)-\phi(u) = y-x = \lambda((x,y))\ .$$

A similar argument works for a relatively open subinterval with endpoints c and/or d. Thus the formula holds if D is a relatively open interval in $[c,d]$.

Now suppose U is a relatively open subset of $[c,d]$. Then U is a disjoint union of relatively open subintervals $\{I_n : n\in\mathbb{N}\}$. If $J_n=\phi^{-1}(I_n)$, then the J_n are pairwise disjoint relatively open subintervals of $[a,b]$ and $\phi^{-1}(U)=\cup_n J_n$, so

$$\int_{\phi^{-1}(U)} g'\,d\lambda = \int_{\cup_n J_n} \phi'\,d\lambda = \sum_{n=1}^\infty \left[\int_{J_n}\phi'\,d\lambda\right] = \sum_{n=1}^\infty \lambda(I_n) = \lambda(U)$$

so the formula holds if D is relatively open in $[a,b]$.

Finally, suppose $D=\cap_n U_n$ is a G_δ in $[a,b]$, with U_n relatively open and $U_{n+1}\subseteq U_n$ for all n. Then

$$\lambda(D) = \inf_n \lambda(U_n) = \lim_{n\to\infty}\lambda(U_n)$$

and $Y:=\phi^{-1}(D)=\cap_n Y_n$, where $Y_n=\phi^{-1}(U_n)$. If $g_n=\phi'\chi_{Y_n}$, then $g_n\to g:=\phi'\chi_Y$. Since all the g_n are dominated by ϕ', which is integrable, by the DCT (or downward MCT) we have

$$\int_Y \phi'\,d\lambda = \int_a^b g\,d\lambda = \lim_{n\to\infty}\int_a^b g_n\,d\lambda = \lim_{n\to\infty}\int_{Y_n}\phi'\,d\lambda = \lim_{n\to\infty}\lambda(U_n) = \lambda(D)\ .$$

We would like to get a similar formula for an arbitrary Lebesgue measurable subset A of $[c,d]$, but there is a technical difficulty: $\phi^{-1}(A)$ need not be Lebesgue measurable in general. To avoid the problem, we need to work more carefully. In the next lemmas, using the notation of XIX.5.5.6. with ϕ nondecreasing, set

$$P = \{x \in [a,b] : \phi'(x) \text{ exists and } \phi'(x) > 0\}$$

and $Q = [a,b] \setminus P$. Thus P and Q are Lebesgue measurable () and $\phi' = 0$ a.e. on Q.

XIX.5.5.11. LEMMA. Let ϕ be as in XIX.5.5.6., with ϕ nondecreasing. If $N \subseteq [c,d]$ with $\lambda(N) = 0$, then $\lambda^*(\phi^{-1}(N) \cap P) = 0$ (so in particular $\phi^{-1}(N) \cap P$ is Lebesgue measurable).

PROOF: Let D be a G_δ in $[c,d]$ with $N \subseteq D$ and $\lambda(D) = 0$. For $n \in \mathbb{N}$ set

$$P_n = \left\{ x \in [a,b] : \phi'(x) \text{ exists and } \phi'(x) \geq \frac{1}{n} \right\} .$$

Then P_n is measurable and $P = \cup_n P_n$. We have, for each n,

$$0 = \lambda(D) = \int_{\phi^{-1}(D)} \phi' \, d\lambda \geq \int_{\phi^{-1}(D) \cap P_n} \phi' \, d\lambda \geq \frac{1}{n} \lambda(\phi^{-1}(D) \cap P_n)$$

and thus $\lambda(\phi^{-1}(D) \cap P_n)$=0 for all n, and hence

$$\lambda^*(\phi^{-1}(N) \cap P) \leq \lambda(\phi^{-1}(D) \cap P) = \sup_n \lambda(\phi^{-1}(D) \cap P_n) = 0 .$$

XIX.5.5.12. LEMMA. Let ϕ be as in XIX.5.5.6., with ϕ nondecreasing. If $A \subseteq [c,d]$ is measurable, then $\phi^{-1}(A) \cap P$ is measurable, and

$$\int_{\phi^{-1}(A) \cap P} \phi' \, d\lambda = \lambda(A) .$$

PROOF: Write $A = D \setminus N$, where $D \subseteq [c,d]$ is a G_δ and N is a null set. Then $\phi^{-1}(A) = \phi^{-1}(D) \setminus \phi^{-1}(N)$. Since ϕ is continuous, $\phi^{-1}(D)$ is a Borel set (actually a G_δ), so $\phi^{-1}(D) \cap P$ is Lebesgue measurable. Also, $\phi^{-1}(N) \cap P$ is a null set by XIX.5.5.11., so $\phi^{-1}(A) \cap P = [\phi^{-1}(D) \cap P] \setminus [\phi^{-1}(N) \cap P]$ differs from $\phi^{-1}(D) \cap P$ by a null set, hence is Lebesgue measurable, and

$$\int_{\phi^{-1}(A) \cap P} \phi' \, d\lambda = \int_{\phi^{-1}(D) \cap P} \phi' \, d\lambda = \int_{\phi^{-1}(D) \cap P} \phi' \, d\lambda + \int_{\phi^{-1}(D) \cap Q} \phi' \, d\lambda = \int_{\phi^{-1}(D)} \phi' \, d\lambda = \lambda(D) = \lambda(A) .$$

XIX.5.5.13. LEMMA. Let ϕ be as in XIX.5.5.6., with ϕ nondecreasing. If f is a Lebesgue measurable function on $[c,d]$, then $g = (f \circ \phi)\phi'$ (defined a.e.) is Lebesgue measurable on $[a,b]$.

PROOF: We have that $g|_Q$ is zero a.e., hence Lebesgue measurable. If B is a Borel set in $\mathbb{R}$, then

$$(f \circ \phi)^{-1}(B) \cap P = \phi^{-1}(f^{-1}(B)) \cap P \ .$$

Since f is Lebesgue measurable, $f^{-1}(B)$ is a Lebesgue measurable subset of $[c,d]$, and hence $\phi^{-1}(f^{-1}(B)) \cap P$ is Lebesgue measurable by XIX.5.5.12.. Since this is true for all B, $(f \circ \phi)|_P$ is measurable. Since $\phi'|_P$ is also Lebesgue measurable, the product $g|_P$ is Lebesgue measurable by (). Since $g|_P$ and $g|_Q$ are both Lebesgue measurable, g is Lebesgue measurable by ().

XIX.5.5.14. We now finish the proof of XIX.5.5.6. (in the case where ϕ is nondecreasing). There is no issue of measurability by XIX.5.5.13.. We will bootstrap to prove the theorem. First suppose $f = \chi_A$ for some Lebesgue measurable set $A \subseteq [c,d]$. Then $f \circ \phi = \chi_{\phi^{-1}(A)}$, so

$$\int_a^b (f \circ \phi)\phi' \, d\lambda = \int_{\phi^{-1}(A) \cap P} \phi' \, d\lambda = \lambda(A) = \int_c^d \chi_A \, d\lambda = \int_c^d f \, d\lambda \ .$$

If f is a simple function, the formula also holds by linearity. If f is a nonnegative measurable function, then take an increasing sequence (f_n) of nonnegative simple functions converging pointwise to f; then by two applications of the MCT we have

$$\int_a^b (f \circ \phi)\phi' \, d\lambda = \sup_n \int_a^b (f_n \circ \phi)\phi' \, d\lambda = \sup_n \int_c^d f_n \, d\lambda = \int_c^d f \, d\lambda \ .$$

If f is an integrable function, the formula again holds by linearity.

This completes the proof of Theorem XIX.5.5.6. (for ϕ nondecreasing).

See [HS75, 20.5] for a somewhat quicker proof using the Radon-Nikodým Theorem.

XIX.5.6. L^p Versions, $p > 1$

There is an L^p analog of absolute continuity for $p > 1$. Surprisingly, the distinction between absolute continuity and bounded variation disappears in this case. This section is adapted from [**?**].

XIX.5.6.1. THEOREM. Let F be a function from $[a,b]$ to $\mathbb{R}$, and $p > 1$. The following are equivalent:

(i) There is a measurable function f on $[a,b]$ with $\displaystyle\int_a^b |f|^p \, d\lambda < \infty$ (i.e. $f \in L^p([a,b])$) and

$$F(x) = F(a) + \int_a^x f \, d\lambda$$

for all $x \in [a,b]$.

(ii) There is a constant M such that whenever $[a_1, b_1], \ldots, [a_n, b_n]$ are nonoverlapping subintervals of $[a, b]$, with $h_k = b_k - a_k$ for each k, we have

$$\sum_{k=1}^{n} |F(b_k) - F(a_k)|^p h_k^{1-p} \leq M \ .$$

(iii) There is a constant M such that whenever $[a_1, b_1], \ldots, [a_n, b_n]$ are nonoverlapping subintervals of $[a, b]$, with $h_k = b_k - a_k$ for each k, we have

$$\sum_{k=1}^{n} |F(b_k) - F(a_k)|^p h_k^{1-p} \leq M$$

and, for every $\epsilon > 0$, there is a $\delta > 0$ such that whenever $[a_1, b_1], \ldots, [a_n, b_n]$ are nonoverlapping subintervals of $[a, b]$, with $h_k = b_k - a_k$ for each k and $\sum_{k=1}^{n} h_k < \delta$,

$$\sum_{k=1}^{n} |F(b_k) - F(a_k)|^p h_k^{1-p} < \epsilon \ .$$

If these conditions are satisfied, the smallest M in (ii) and (iii) is precisely $\displaystyle\int_a^b |f|^p \, d\lambda$.

XIX.5.6.2. The conditions in (iii) are apparently more restrictive than in (ii). The condition in (i) implies that f is integrable on $[a, b]$, and hence that F is absolutely continuous on $[a, b]$.

If $p = 1$, the condition in (ii) is precisely that F have bounded variation on $[a, b]$, and the second condition in (iii) is that F be absolutely continuous on $[a, b]$, which implies that F has bounded variation and hence satisfies the first condition of (iii). Thus Theorem XIX.5.2.5. says that (i) and (iii) are equivalent also if $p = 1$; however, (ii) is not equivalent to (i) and (iii) in general if $p = 1$ (the Cantor function is a counterexample).

XIX.5.6.3. We now give the proof of XIX.5.6.1..

PROOF: (iii) $\Rightarrow$ (ii) is trivial.

(i) $\Rightarrow$ (iii): By (), for each k we have

$$|F(b_k) - F(a_k)| = \left| \int_{a_k}^{b_k} f \, d\lambda \right| \leq \left[\int_{a_k}^{b_k} |f|^p \, d\lambda \right]^{1/p} \left[\int_{a_k}^{b_k} 1 \, d\lambda \right]^{1-1/p} = h_k^{1-1/p} \left[\int_{a_k}^{b_k} |f|^p \, d\lambda \right]^{1/p}$$

so

$$\sum_{k=1}^{n} |F(b_k) - F(a_k)|^p h_k^{1-p} \leq \sum_{k=1}^{n} h_k^{1-p} \left[h_k^{1-1/p} \right]^p \left[\int_{a_k}^{b_k} |f|^p \, d\lambda \right] = \sum_{k=1}^{n} \left[\int_{a_k}^{b_k} |f|^p \, d\lambda \right] \leq \int_a^b |f|^p \, d\lambda \ .$$

Also, by (), for any $\epsilon > 0$ there is a $\delta > 0$ such that if $\sum_{k=1}^{n} h_k < \delta$,

$$\sum_{k=1}^{n} \left[\int_{a_k}^{b_k} |f|^p \, d\lambda \right] < \epsilon$$

so condition (iii) is satisfied with $M = \int_a^b |f|^p \, d\lambda$.

(ii) $\Rightarrow$ (i): Let $[a_1, b_1], \ldots, [a_n, b_n]$ be nonoverlapping subintervals of $[a, b]$. Then, by Hölder's Inequality (), we have

$$\sum_{k=1}^{n} |F(b_k) - F(a_k)| = \sum_{k=1}^{n} \left[|F(b_k) - F(a_k)| h_k^{1/p-1} \right] h_k^{1-1/p} = \sum_{k=1}^{n} \left[|F(b_k) - F(a_k)|^p h_k^{1-p} \right]^{1/p} h_k^{1-1/p}$$

$$\leq \left(\sum_{k=1}^{n} \left[|F(b_k) - F(a_k)|^p h_k^{1-p} \right] \right)^{1/p} \left(\sum_{k=1}^{n} h_k \right)^{1-1/p} \leq M^{1/p} \left(\sum_{k=1}^{n} h_k \right)^{1-1/p}$$

and thus, for any $\epsilon > 0$, there is a $\delta > 0$ such that if $\sum_{k=1}^{n} h_k < \delta$, $\sum_{k=1}^{n} |F(b_k) - F(a_k)| < \epsilon$. Thus F is absolutely continuous. Hence there is an integrable function f on $[a, b]$ with

$$F(x) = F(a) + \int_a^x f \, d\lambda$$

for all $x \in [a, b]$. It remains to show that $\int_a^b |f|^p \, d\lambda \leq M$.

For each n let $\mathcal{P}_n = \{a = x_{n,0}, x_{n,1}, \ldots, x_{n,n} = b\}$ be a partition of $[a, b]$ into n subintervals of equal length. For $x_{n,k} \leq x < x_{n,k+1}$, set

$$f_n(x) = \frac{F(x_{n,k+1}) - F(x_{n,k})}{x_{n,k+1} - x_{n,k}} \ .$$

Since F is absolutely continuous, it is differentiable a.e. and $F' = f$ a.e. Suppose $x_{n,k} < x < x_{n,k+1}$ and F is differentiable at x. Then

$$f_n(x) = \frac{F(x_{n,k+1}) - F(x)}{x_{n,k+1} - x} \frac{x_{n,k+1} - x}{x_{n,k+1} - x_{n,k}} + \frac{F(x) - F(x_{n,k})}{x - x_{n,k}} \frac{x - x_{n,k}}{x_{n,k+1} - x_{n,k}}$$

$$= (F'(x) + \eta_1) \frac{x_{n,k+1} - x}{x_{n,k+1} - x_{n,k}} + (F'(x) + \eta_2) \frac{x - x_{n,k}}{x_{n,k+1} - x_{n,k}} = F'(x) + \eta_3$$

where η_1, η_2, η_3 depend on x and n; for fixed x and n we have $|\eta_3| \leq |\eta_1| + |\eta_2|$, and for fixed x we have $\eta_1, \eta_2 \to 0$ as $n \to \infty$. So if x is not one of the $x_{n,k}$ for any n and F is differentiable at x, $f_n(x) \to F'(x)$. Thus $f_n \to f$ a.e. By Fatou's Lemma (),

$$\int_a^b |f|^p \, d\lambda \leq \liminf_{n \to \infty} \int_a^b |f_n|^p \, d\lambda = \liminf_{n \to \infty} \left[\sum_{k=1}^{n} \frac{|F(x_{n,k}) - F(x_{n,k-1})|^p}{(x_{n,k} - x_{n,k-1})^p} (x_{n,k} - x_{n,k-1}) \right] \leq M \ .$$

XIX.5.7. The Lebesgue Density Theorem

If A and B are Lebesgue measurable subsets of $\mathbb{R}$, with $0 < \lambda(B) < \infty$, it makes sense to interpret $\frac{\lambda(A \cap B)}{\lambda(B)}$ as the "fraction of the points of B which are in A." We will particularly make this interpretation when B is a finite interval.

If A is a measurable subset of $\mathbb{R}$ and $c \in \mathbb{R}$, we similarly want to carefully define "the fraction of points near c which are in A." There is a way to do this, and it leads to a remarkable result (XIX.5.7.3.): for almost all points x of A, almost all points near x are in A, and for almost all points y of A^c, almost all points near y are in A^c. As a consequence, a Lebesgue measurable subset of $\mathbb{R}$ is "lumpy" and cannot be distributed very evenly throughout $\mathbb{R}$, or an interval in $\mathbb{R}$, unless it is very densely or very sparsely distributed in that interval in a measure-theoretic sense.

XIX.5.7.1. DEFINITION. Let A be a Lebesgue measurable subset of $\mathbb{R}$. If $c \in \mathbb{R}$, define the left and right upper and lower densities of A at c to be

The *left lower density* $d_-(A,c) = \liminf\limits_{x \to c-} \dfrac{\lambda([x,c] \cap A)}{\lambda([x,c])}$.

The *left upper density* $d^-(A,c) = \limsup\limits_{x \to c-} \dfrac{\lambda([x,c] \cap A)}{\lambda([x,c])}$.

The *right lower density* $d_+(A,c) = \liminf\limits_{x \to c+} \dfrac{\lambda([c,x] \cap A)}{\lambda([c,x])}$.

The *right upper density* $d^+(A,c) = \limsup\limits_{x \to c+} \dfrac{\lambda([c,x] \cap A)}{\lambda([c,x])}$.

If $d_-(A,c) = d^-(A,c)$, the *left density* $d_l(A,c)$ is defined and equals the common value.
If $d_+(A,c) = d^+(A,c)$, the *right density* $d_r(A,c)$ is defined and equals the common value.
If $d_l(A,c) = d_r(A,c)$, the *density* $d(A,c)$ is defined and equals the common value.

Note that the left and right upper and lower densities are always defined and are between 0 and 1. It should not be expected that left or right densities, much less densities, always exist (indeed, see XIX.5.8.12.); in fact, it is remarkable that the density exists for almost all c (and even more is true).

Comparing definitions, we immediately get the following characterization of densities as Dini derivatives:

XIX.5.7.2. PROPOSITION. Let $A \subseteq \mathbb{R}$ be Lebesgue measurable, and $c \in \mathbb{R}$. Fix $a < c$, and define

$$F(x) = \int_a^x \chi_A \, d\lambda$$

for $x \geq a$. then $d_-(A,c)$, $d^-(A,c)$, $d_+(A,c)$, $d^+(A,c)$ are the Dini derivatives () $D_-F(c)$, $D^-F(c)$, $D_+F(c)$, $D^+F(c)$ respectively. Thus $d_l(A,c)$ $[d_r(A,c)]$ is defined if and only if F is left [right] differentiable at c, and $d_l(A,c) = D_LF(c)$ $[d_r(A,c) = D_RF(c)]$. The density $d(A,c)$ is defined if and only if F is differentiable at c, and $d(A,c) = F'(c)$.

XIX.5.7.3. THEOREM. [LEBESGUE DENSITY THEOREM] Let A be a Lebesgue measurable subset of $\mathbb{R}$. Then the density of A exists and is 1 for almost all points of A, and exists and is 0 for almost all points of A^c.

PROOF: This is an almost immediate corollary of XIX.5.2.15.. We may assume A is bounded, since for $x \in (a,b)$ the density of A at x is the same as the density of $A \cap (a,b)$ at x. So suppose $A \subseteq (a,b)$. Set

$$F(x) = \int_a^x \chi_A \, d\lambda$$

for $x \in [a,b]$. Then F is differentiable a.e. and $F' = \chi_A$ a.e. on $[a,b]$, i.e. $F'(x) = 1$ for almost all $x \in A$ and $F'(x) = 0$ for almost all $x \in [a,b] \setminus A$. 👍

The next Corollary makes precise the statement that Lebesgue measurable sets are "lumpy" and cannot be evenly distributed.

XIX.5.7.4. COROLLARY. Let A be a measurable subset of $\mathbb{R}$, and I a bounded interval in $\mathbb{R}$.
(i) If $\lambda(A \cap I) > 0$, then for every $\epsilon > 0$ there is a subinterval J of I such that

$$\frac{\lambda(A \cap J)}{\lambda(J)} \geq 1 - \epsilon \ .$$

(ii) If $\lambda(A \cap I) < \lambda(I)$, then for every $\epsilon > 0$ there is a subinterval J of I such that

$$\frac{\lambda(A \cap J)}{\lambda(J)} \leq \epsilon \ .$$

XIX.5.7.5. Thus, for example, there cannot be a Lebesgue measurable set A such that $\lambda(A \cap I) = \frac{1}{2}\lambda(I)$ for every bounded interval I, i.e. such that A contains "half" the points in every interval. In fact, if A is Lebesgue measurable, there is no $\epsilon > 0$ such that

$$\epsilon < \frac{\lambda(A \cap I)}{\lambda(I)} < 1 - \epsilon$$

for every bounded interval I.

XIX.5.7.4. does not hold for $\epsilon = 0$ in general (XIX.5.8.14.)

XIX.5.8. Exercises

XIX.5.8.1. Show that a function $f : [a,b] \to \mathbb{R}$ (or $\mathbb{C}$) is absolutely continuous if and only if for every $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $[a_1,b_1], \ldots, [a_n,b_n]$ are finitely many pairwise disjoint intervals in $[a,b]$ with $\sum_{k=1}^n (b_k - a_k) < \delta$, we have $\sum_{k=1}^n |f(b_k) - f(a_k)| < \epsilon$.

This is the definition of absolute continuity in many references. The "nonoverlapping" version we use is more suitable for some arguments.

XIX.5.8.2. [Sak64] Let A be a Cantor set of positive measure in $[0,1]$, containing 0 and 1. Let $\{I_n : n \in \mathbb{N}\}$ be the open intervals in $[0,1] \setminus A$, in decreasing order of length, and c_n the midpoint of I_n. Let ℓ_n be the length of I_n, and r_n the length of the longest subinterval of $[0,1]$ disjoint from $I_1, \dots, I_n$. Define a continuous function $f : [0,1] \to \mathbb{R}$ by letting f be identically zero on A, $f(c_n) = \ell_n + r_n$, and f piecewise-linear on I_n.

(a) Show that $r_n \to 0$ (obviously $\ell_n \to 0$), and hence f is indeed continuous.

(b) Show that f is absolutely continuous on each $\bar{I}_n$.

(c) Show that f has Property (N). [If N is a null set in $[0,1]$, write $N = \cup_{k=0}^{\infty} N_k$, where $N_0 = N \cap A$ and $N_k = N \cap I_k$ for $k \geq 1$. Show that $\lambda(f(N_k)) = 0$ for all k.] This f is an *ACG function* in the language of [Sak64].

(d) If $x \in A$, show that $D_- f(x) \leq 0$ and $D^+ f(x) \geq 0$, and either $D_- f(x) \leq -1$ or $D^+ f(x) \geq 1$ (or both). Hence f fails to be differentiable anywhere on A, i.e. on a set of positive measure. Conclude that f does not have bounded variation.

(e) Show that if $x > 0$, then $N_f(x)$ is finite. Thus f has Property (S) by XIX.5.1.8..

XIX.5.8.3. Let f be as in XIX.5.8.2., and set $g(x) = x + f(x)$.

(a) Show that g has property (N). [See XIX.5.8.2.(c).]

(b) Show that for almost all $x \in A$, $N_g(x) = +\infty$. Thus N_g is not finite a.e.

(c) By Theorem XIX.5.1.8., g also does not satisfy property (S).

XIX.5.8.4. (a) Show that if f is continuous and real-valued on $[a,b]$, then $V_{[a,b]}(|f|) = V_{[a,b]}(f)$, and in particular f has bounded variation if and only if $|f|$ has bounded variation.

(b) Show that if f is continuous and real-valued, then f is absolutely continuous if and only if $|f|$ is absolutely continuous. [**Caution:** $|f|' \neq |f'|$ in general!]

(c) Show that the statements can fail if f is complex-valued [consider e^{ig} for g real-valued], or if f is not continuous.

XIX.5.8.5. Verify that the function Φ defined in the proof of Lemma XIX.5.2.29. has all the required properties.

XIX.5.8.6. Show that Lemma XIX.5.2.28. is essentially an explicit version of XX.10.3.6., as follows.

(a) Deduce XIX.5.2.28. from XX.10.3.6. by taking H to be a singular function approximating Ψ. [One additional correction with a scaled Cantor function is needed to make $H(a) = \Psi(a)$ and $H(b) = \Psi(b)$.]

(b) Slightly modify the proof of XIX.5.2.28. to obtain XX.10.3.6.. [If G is any continuous function, construct H to approximate $\Psi - G$.]

XIX.5.8.7. Deduce the Integration by Substitution formula for ϕ nonincreasing from the nondecreasing case. [Hint: if ϕ is nonincreasing, set $\psi(x) = \phi(a + b - x)$.]

XIX.5.8.8. Justify the statement in XIX.5.5.9. that $(F \circ \phi)' = (F' \circ \phi)\phi' = (f \circ \phi)\phi'$ a.e. on $[a,b]$ using XIX.5.5.5., XIX.5.5.6., and XIX.5.2.14..

XIX.5.8.9. Let f be continuous and monotone on $[a,b]$, and differentiable except possibly at countably many points of $[a,b]$. Show that f is absolutely continuous on $[a,b]$. [Use XIX.5.2.19..]

XIX.5.8.10. (a) Show that if $f:[a,b]\to[c,d]$ is absolutely continuous and g is Lipschitz on $[c,d]$, then $g\circ f$ is absolutely continuous on $[a,b]$.

(b) Show that $f(x)=x^2\sin^2\frac{1}{x}$ $(f(0)=0)$ is Lipschitz on $[0,1]$ and $f([0,1])\subseteq[0,1]$. [f is differentiable.]

(c) Let $g(x)=\sqrt{x}$. Show that g is absolutely continuous on $[0,1]$ (and obviously increasing). [Use XIX.5.8.9..]

(d) Show that $g\circ f$ does not have bounded variation on $[0,1]$, and in particular is not absolutely continuous. Contrast with (a) and XIX.5.5.5..

XIX.5.8.11. In the situation of XIX.5.5.10., if ϕ is strictly increasing, then

(a) Show that if E is a G_δ in $[a,b]$, then $\phi(E)$ is a G_δ in $[c,d]$.

(b) Show that if B is a Lebesgue measurable subset of $[a,b]$, then

$$\lambda(\phi(B))=\int_B \phi'\,d\lambda$$

(note that $\phi(B)$ is measurable by XIX.5.1.4.).

(c) Does this allow the argument following XIX.5.5.10. to be eliminated or simplified in the case where ϕ is strictly increasing? (In particular, if $A\subseteq[c,d]$ is Lebesgue measurable, is $\phi^{-1}(A)$ necessarily Lebesgue measurable? See XVII.5.2.3..)

XIX.5.8.12. Fix $c\in\mathbb{R}$ and m,M with $0\le m\le M\le 1$. Show that a sequence

$$a_1<b_1<a_2<b_2<\cdots<c$$

of real numbers converging to c can be constructed so that, if $A=\{c\}\cup\bigcup_{n=1}^{\infty}[a_n,b_n]$, then $d_-(A,c)=m$ and $d^-(A,c)=M$. Do the same for right densities. Thus the four densities at a given point can be arbitrary within the obvious constraints, even if A is a closed set (or open set).

XIX.5.8.13. Let A and B be Lebesgue measurable subsets of $\mathbb{R}$. If $\lambda(A\triangle B)=0$, show that $d_-(A,x)=d_-(B,x)$ for all $x\in\mathbb{R}$, and similarly for d^-, d_+, d^+.

XIX.5.8.14. Construct a Lebesgue measurable subset A of $\mathbb{R}$ such that

$$0<\frac{\lambda(A\cap I)}{\lambda(I)}<1$$

for every bounded interval I in $\mathbb{R}$. (Note that these numbers cannot be bounded away from 0 or 1 by XIX.5.7.4..) [Let f be a differentiable function which is not monotone on any interval (V.12.1.7., XIII.12.5.7.), and let $A=\{x:f'(x)>0\}$. Use XIX.5.1.19..]

XIX.5.8.15. Can there be a nonmeasurable subset A of $\mathbb{R}$ with the property that $\lambda^*(A\cap I)=\frac{1}{2}\lambda(I)$ for every bounded interval I?

XIX.6. Approximate Limits and Continuity

Our exposition in this section is largely adapted from [Fed69].

XIX.6.1. The Radon-Nikodým Theorem in $\mathbb{R}^n$

In what sense is the Radon-Nikodým "derivative" a true derivative? It is in the special case of a finite Borel measure on $\mathbb{R}$ absolutely continuous with respect to Lebesgue measure (XVIII.6.1.7.), and it has formal properties of a derivative (XVIII.6.1.8.). But in general it is not really a derivative in the calculus sense.

However, there is a nice interpretation of the Radon-Nikodým derivative in $\mathbb{R}^n$ as a sort of "derivative" in the literal sense, explained in this section. We will work more generally with Borel measures on a controlled (XVII.8.1.1.) metric space (X, ρ) so that the Besicovitch Covering Theorem (XVII.8.3.2.) can be used. Recall that $\mathbb{R}^n$ with the usual metric is controlled (XVII.8.1.6.), so the reader can just take $X = \mathbb{R}^n$ if desired. It is worthwhile to work in greater generality since the argument is identical and there are applications, e.g. in Geometric Measure Theory, where the greater generality is used. We denote by μ^* the outer measure induced by μ (XVII.6.1.6.) (so we can consider μ^*-measurable sets which are not Borel sets).

Recall the following (XVII.6.1.14.):

XIX.6.1.1. Proposition. Let μ be a Borel measure on a separable metrizable (i.e. second countable regular) space X. The following are equivalent:

(i) μ is neighborhood-finite, i.e. every point has a neighborhood of finite measure.

(ii) μ is locally finite (every set of finite measure is contained in an open set of finite measure), and μ has no infinite atoms.

(iii) μ is locally finite and σ-finite.

(iv) μ is regular and σ-finite.

If every closed bounded subset of X is compact (e.g. if $X = \mathbb{R}^n$ with the usual metric), these are also equivalent to

(v) μ is bounded-finite (XVII.6.1.15.).

XIX.6.1.2. Our setup is as follows. Let (X, ρ) be a separable controlled metric space, and μ and ν neighborhood-finite Borel measures on X, with $\nu \ll \mu$. (The reader can just take the most important case $X = \mathbb{R}^n$, or a subset, with the usual metric and μ Lebesgue measure for simplicity if desired.) Since μ and ν are σ-finite, there is a Radon-Nikodým derivative $\frac{d\nu}{d\mu}$. Fix a Radon-Nikodým derivative f, i.e. f is a nonnegative locally integrable Borel-measurable function on X with

$$\nu(E) = \int_E f \, d\mu$$

for each Borel set E.

XIX.6.1.3. There is a largest open set W in X with $\mu(W) = 0$: if $\mathcal{U}$ is a countable base for the topology, W is the union of all basic open sets of μ-measure 0. Since $\nu \ll \mu$, we also have $\nu(W) = 0$. Thus, for almost all $x \in X$ (for all $x \in W^c$), we have that every neighborhood of x has positive μ-measure (and sufficiently small neighborhoods have finite μ- and ν-measure).

XIX.6.1.4. If $x \in W^c$, and $\delta > 0$ is small enough that $\mu(B_\delta(x)) < \infty$, define

$$A(x,\delta) = \frac{\nu(B_\delta(x))}{\mu(B_\delta(x))} = \frac{1}{\mu(B_\delta(x))} \int_{B_\delta(x)} f \, d\mu$$

which can be interpreted as the "average value of f over $B_\delta(x)$." Thus for almost all $x \in X$, $A(x,\delta)$ is defined for all sufficiently small $\delta > 0$.

The main result is:

XIX.6.1.5. THEOREM. For μ-almost all $x \in X$, $\lim_{\delta\to 0} A(x,\delta)$ exists, is finite, and equals f.

XIX.6.1.6. One cannot expect better than an "almost everywhere" result, since for one thing f is only uniquely determined almost everywhere, and for another $A(x,\delta)$ is only defined for almost all x (and small δ), so the limit can only exist almost everywhere in general. There will be additional restrictions too.

The proof of the theorem requires several lemmas. We use the outer measures defined by μ and ν: if $Y \subseteq X$, set

$$\mu^*(Y) = \inf\{\mu(B) : B \text{ Borel}, Y \subseteq B\} = \min\{\mu(B) : B \text{ Borel}, Y \subseteq B\}$$

and similarly for ν^*.

XIX.6.1.7. LEMMA. Use the above notation.
(i) If $c > 0$ and

$$A \subseteq \{x \in W^c : \liminf_{\delta\to 0} A(x,\delta) < c\}$$

then $\nu^*(A) \le c\mu^*(A)$.
(ii) If $c \ge 0$ and

$$A \subseteq \{x \in W^c : \limsup_{\delta\to 0} A(x,\delta) > c\}$$

then $\nu^*(A) \ge c\mu^*(A)$.

PROOF: (i) If $\mu^*(A)$ is ∞ (or 0) there is nothing to prove, so assume $\mu^*(A) < \infty$. Let $\epsilon > 0$. Since μ is regular (XVII.6.1.10.), there is an open set V with $A \subseteq V$ and $\mu(V) < \mu^*(A) + \epsilon$. If $x \in A$, then for sufficiently many small $\delta > 0$, $A(x,\delta) < c$. If $\mathcal{C}$ is the set of open balls B contained in V for which $\nu(B) < c\mu(B)$, then $\mathcal{C}$ is a Besicovitch covering of A, so there is a sequence (B_k) of pairwise disjoint open balls in $\mathcal{C}$ which μ-almost cover A and hence ν-almost cover A. Then we have

$$\nu^*(A) \le \nu(\cup_k B_k) = \sum_{k=1}^{\infty} \nu(B_k) < c \sum_{k=1}^{\infty} \mu(B_k) = c\mu(\cup_k B_k) \le c\mu(V) < c\mu^*(A) + c\epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, the result follows. The proof of (ii) is almost identical (assuming $\mu(A) > 0$). 👍

XIX.6.1.8. LEMMA. With notation as above, $\lim_{\delta\to 0} A(x,\delta)$ exists and is finite for almost all $x \in X$.

PROOF: The set of x such that the limit does not exist or is infinite is the union of the following sets:

The open set W.

The set $Z = \{x \in W^c : \limsup_{\delta>0} A(x,\delta) = +\infty\}$.

The sets $R_{a,b}$ for $a, b \in \mathbb{Q}$, $0 < a < b$, where

$$R_{a,b} = \{x \in W^c : \liminf_{\delta\to 0} A(x,\delta) < a < b < \limsup_{\delta\to 0} A(x,\delta)\} \ .$$

We have $\mu(W) = 0$. To show that $\mu^*(Z) = 0$, let $x \in Z$; then there is a $\delta > 0$ with $\nu(B_\delta(x)) < \infty$. By Lemma XIX.6.1.7., for any c we have $\nu^*(Z \cap B_\delta(x)) \geq c\mu^*(Z \cap B_\delta(x))$; thus $\mu^*(Z \cap B_\delta(x)) = 0$. So, if $\mathcal{U}$ is a countable base for the topology of X, the set of $U \in \mathcal{U}$ such that $\mu^*(Z \cap U) = 0$ covers X. Thus $\mu^*(Z) = 0$. Now fix $a, b \in \mathbb{Q}$, $0 < a < b$. If $x \in R_{a,b}$ and δ is small enough that $0 < \mu(B_\delta(x)) < \infty$, we have by Lemma XIX.6.1.7.

$$b\mu^*(R_{a,b} \cap B_\delta(x)) \leq \nu^*(R_{a,b} \cap B_\delta(x)) \leq a\mu^*(R_{a,b} \cap B_\delta(x))$$

which implies that $\mu^*(R_{a,b} \cap B_\delta(x)) = 0$ (and $\nu^*(R_{a,b} \cap B_\delta(x)) = 0$) since $a < b$. Thus, for the countable base $\mathcal{U}$, the $U \in \mathcal{U}$ such that $\mu^*(R_{a,b} \cap U) = 0$ cover X, and therefore $\mu^*(R_{a,b}) = 0$. 👍

XIX.6.1.9. LEMMA. Using the above notation, set $g(x) = \lim_{\delta>0} A(x,\delta)$ (defined μ-a.e.). Then g is μ^*-measurable, hence equal μ-a.e. to a Borel measurable function.

PROOF: Let $a, b \in \mathbb{R}$, $a < b$, $Y \subseteq X$ with $\mu^*(Y) < \infty$, $A_1 = Y \cap \{x \in X : g(x) < a\}$, $A_2 = Y \cap \{x \in X : g(x) > b\}$. Let B_1 and B_2 be Borel sets with $A_j \subseteq B_j$, $\mu^*(A_j) = \mu(B_j)$, and $\nu^*(A_j) = \nu(B_j)$ for $i = 1, 2$. Then

$$\nu(B_1 \cap B_2) = \nu(A_1 \cap B_2) \leq a\mu(A_1 \cap B_2) \leq a\mu(B_1 \cap B_2)$$

$$\nu(B_1 \cap B_2) \geq \nu(B_1 \cap A_2) \geq b\mu(B_1 \cap A_2) = b\mu(B_1 \cap B_2)$$

by () and XIX.6.1.7., and it follows that $\mu(B_1 \cap B_2) = 0$. Thus

$$\mu^*(Y) = \mu^*(Y \cap B_1) + \mu^*(Y \cap B_2) \geq \mu^*(A_1) + \mu^*(A_2)$$

and so g is μ^*-measurable by XVII.5.1.4.. 👍

XIX.6.1.10. LEMMA. Using the above notation, $g = f$ μ-a.e. on X.

This completes the proof of Theorem XIX.6.1.5.. 💪

XIX.6.1.11. Essentially the same proof works in the case where ν and even μ are signed Borel measures. Details are left to the reader.

XIX.6.1.12. As a closely related matter, if μ is a neighborhood-finite Borel measure on X and f is a locally μ-integrable Borel measurable function on X, define

$$\nu(E) = \int_E f\, d\mu$$

for E a Borel subset of X. Then $\nu \ll \mu$ and f is a Radon-Nikodým derivative for ν with respect to μ. So we have:

XIX.6.1.13. Corollary. Let μ be a neighborhood-finite Borel measure on a separable controlled metric space (X, ρ), and f a locally μ-integrable Borel measurable function on X. Then

$$\lim_{\delta \to 0} \frac{1}{\mu(B_\delta(x))} \int_{B_\delta(x))} f\, d\mu$$

exists and equals $f(x)$ for μ-almost all $x \in X$.

We can actually do a little better:

XIX.6.1.14. Theorem. Let μ be a neighborhood-finite Borel measure on separable controlled metric space (X, ρ), and f a locally μ-integrable Borel measurable function on X. Then

$$\lim_{\delta \to 0} \frac{1}{\mu(B_\delta(x))} \int_{B_\delta(x))} |f(z) - f(x)|\, d\mu(z)$$

exists and equals 0 for μ-almost all $x \in X$. The set of such x is called the *Lebesgue set* of f.

Proof: For each $x \in X$ let $T(x)$ be the set of $y \in \mathbb{R}$ such that

$$\lim_{\delta \to 0} \frac{1}{\mu(B_\delta(x))} \int_{B_\delta(x))} |f(z) - y|\, d\mu(z)$$

exists and equals $|f(x) - y|$. If $y, y' \in \mathbb{R}$, then for any x

$$\frac{1}{\mu(B_\delta(x))} \int_{B_\delta(x))} |f(z) - y|\, d\mu(z) - \frac{1}{\mu(B_\delta(x))} \int_{B_\delta(x))} |f(z) - y'|\, d\mu(z) \leq |y - y'|$$

for any δ, and it follows that $T(x)$ is closed in $\mathbb{R}$. For each $y \in \mathbb{R}$, $y \in T(x)$ for μ-almost all x by XIX.6.1.13. applied to $g(x) = |f(x) - y|$. For $y \in \mathbb{Q}$ let A_y be the set of x for which $y \in T(x)$; then $\mu^*(X \setminus A_y) = 0$. If $A = \cap_{y \in \mathbb{Q}} A_y$, then $\mu^*(X \setminus A) = 0$ and $\mathbb{Q} \subseteq T(x)$ for all $x \in A$. Since $T(x)$ is closed in $\mathbb{R}$, $T(x) = \mathbb{R}$ for all $x \in A$, and in particular $f(x) \in T(x)$ for $x \in A$. 👍

XIX.6.1.15. REMARKS. (i) These results apply in the case $X = \mathbb{R}^n$ (or any subset) and $\mu = \lambda^{(n)}$, and in the case where μ is s-dimensional Hausdorff measure $\mathscr{H}^s$ on $\mathbb{R}^n$ and X is a set with $\mathscr{H}^s(X) < \infty$.

(ii) $\mathbb{R}^n$ with the Euclidean metric can be replaced by any finite-dimensional normed vector space.

(iii) Any separable metrizable topological space (any second countable regular space) X of finite topological dimension can be embedded homeomorphically in a Euclidean space (). But the statement of XIX.6.1.5. requires use of a specific metric. The relative metric from any embedding of X into a finite-dimensional normed vector space will do. However, it is unclear whether an arbitrary metric on X giving its topology will work (to get a version of the Besicovitch Covering Theorem as in XVII.8.3.1., the metric must be "controlled" in a certain sense).

(iv) If X is not finite-dimensional, the statement is probably false in general: the examples in [**?**] likely give, or lead to, a counterexample.

XIX.6.2. Lebesgue Density in $\mathbb{R}^n$

The Lebesgue Density Theorem (XIX.5.7.3.) is more delicate in $\mathbb{R}^n$ for $n > 1$, but is an immediate consequence of the results of the previous section. We work more generally with a neighborhood-finite Borel measure μ on a separable controlled metric space (X, ρ); we assume for simplicity that $\mu(B) > 0$ for every open ball B.

XIX.6.2.1. DEFINITION. Let A be a μ^*-measurable subset of X and $\boldsymbol{c} \in X$ (not necessarily in A). The *μ-upper density* of A at $\boldsymbol{c}$ is

$$\overline{d}(A, \boldsymbol{c}) = \limsup_{\delta \to 0} \frac{\mu(A \cap B_\delta(\boldsymbol{c}))}{\mu(B_\delta(\boldsymbol{c}))} \ .$$

The *μ-lower density* of A at $\boldsymbol{c}$ is

$$\underline{d}(A, \boldsymbol{c}) = \liminf_{\delta \to 0} \frac{\mu(A \cap B_\delta(\boldsymbol{c}))}{\mu(B_\delta(\boldsymbol{c}))} \ .$$

If $\overline{d}(A, \boldsymbol{c}) = \underline{d}(A, \boldsymbol{c})$, i.e. if

$$\lim_{\delta \to 0} \frac{\mu(A \cap B_\delta(\boldsymbol{c}))}{\mu(B_\delta(\boldsymbol{c}))}$$

exists, it is called the *μ-density* of A at $\boldsymbol{c}$, denoted $d(A, \boldsymbol{c})$.

XIX.6.2.2. The $\bar{d}$, etc., depends on μ and should really be written $\bar{d}_\mu$, etc. But the overwhelmingly important case is when μ is Lebesgue measure on $\mathbb{R}^n$, so we generally omit the μ; we even just say "density" instead of "μ-density" when μ is understood (e.g. Lebesgue measure).

We have $0 \le \underline{d}(A, \boldsymbol{c}) \le \overline{d}(A, \boldsymbol{c}) \le 1$ for any A and $\boldsymbol{c}$. Density is monotone: if $A \subseteq B$, then $\overline{d}(A, \boldsymbol{c}) \le \overline{d}(B, \boldsymbol{c})$ and $\underline{d}(A, \boldsymbol{c}) \le \underline{d}(B, \boldsymbol{c})$.

It is not obvious that $d(A, \boldsymbol{c})$ is defined for any $\boldsymbol{c}$ for general A. But we have:

XIX.6.2.3. THEOREM. [LEBESGUE DENSITY THEOREM, GENERAL VERSION] Let μ be a neighborhood-finite Borel measure on a separable controlled metric space (X, ρ), and let A be a μ^*-measurable subset of X. Then the density of A exists and is 1 for almost all points of A, and exists and is 0 for almost all points of A^c.

PROOF: This is an immediate consequence of XIX.6.1.13., taking $f = \chi_A$. 👍

XIX.6.2.4. COROLLARY. [LEBESGUE DENSITY THEOREM IN $\mathbb{R}^n$] Let A be a Lebesgue measurable subset of $\mathbb{R}^n$. Then the density of A exists and is 1 for almost all points of A, and exists and is 0 for almost all points of A^c.

An obvious but useful observation:

XIX.6.2.5. PROPOSITION. Let A and B be μ^*-measurable subsets of X. If $\mu(A \triangle B) = 0$, then $\overline{d}(A, \boldsymbol{c}) = \overline{d}(B, \boldsymbol{c})$ and $\underline{d}(A, \boldsymbol{c}) = \underline{d}(B, \boldsymbol{c})$ for any $\boldsymbol{c}$. Thus the densities of A and B coincide at any point where one (hence the other) is defined.

In particular, if A is μ^*-measurable, there is a Borel set B with the same density at every point.

There is no simple relation for the density of a union or intersection. But we have:

XIX.6.2.6. PROPOSITION. Let A and B be μ^*-measurable subsets of X, and $\boldsymbol{c} \in X$. Then

$$\overline{d}(A \cup B, \boldsymbol{c}) \leq \overline{d}(A, \boldsymbol{c}) + \overline{d}(B, \boldsymbol{c}) \ .$$

If A and B are disjoint (or, more generally, if $\mu(A \cap B) = 0$), and $d(A, c)$ and $d(B, c)$ exist, then $d(A \cup B, \boldsymbol{c})$ exists and equals $d(A, \boldsymbol{c}) + d(B, \boldsymbol{c})$.

Sets of density 0 will be particularly important. The density $d(A, \boldsymbol{c})$ exists and equals 0 if and only if $\overline{d}(A, \boldsymbol{c}) = 0$. Of course $d(A, \boldsymbol{c}) = 0$ if $\boldsymbol{c} \notin \bar{A}$, but this is far from necessary.

XIX.6.2.7. COROLLARY. If $d(A, \boldsymbol{c}) = d(B, \boldsymbol{c}) = 0$, then $d(A \cup B, \boldsymbol{c}) = 0$.

XIX.6.2.6. and XIX.6.2.7. obviously extend to finite unions (but not countable unions in general: in $\mathbb{R}$, let $A_n = [1/n, 1]$ and consider $d(A_n, 0)$).

XIX.6.3. Approximate Limits

We continue to work in the setting where μ is a neighborhood-finite Borel measure on a separable controlled metric space (e.g. Lebesgue measure on $\mathbb{R}^n$ with the usual metric).

XIX.6.3.1. DEFINITION. Let $A \subseteq X$, $f : A \to \mathbb{R}$ a function, and $L \in \mathbb{R}$. Then the *approximate limit* of f at $\boldsymbol{c} \in X$ is L if $d(A, \boldsymbol{c}) > 0$ and, for every $\epsilon > 0$. the set

$$A_\epsilon = \{x \in A : |f(\boldsymbol{x}) - L| \geq \epsilon\}$$

has density 0 at $\boldsymbol{c}$. We write

$$L = ap \lim_{\boldsymbol{x} \to \boldsymbol{c}} f(\boldsymbol{x}) = L$$

if L is the approximate limit of f at $\boldsymbol{c}$.

The approximate limit of course need not exist. For the approximate limit to be defined, $\boldsymbol{c}$ must be in $\bar{D}$ (but this is not sufficient). The definition is most commonly used if D is a neighborhood or deleted neighborhood of $\boldsymbol{c}$.

XIX.6.3.2. EXAMPLE. (i) Let $f : \mathbb{R} \to \mathbb{R}$ be

$$f(x) = \begin{cases} 1 & \text{if} \quad x \geq 0 \\ 0 & \text{if} \quad x < 0 \end{cases} .$$

Then $ap \lim_{x \to c} f(x) = 1$ if $c > 0$, $ap \lim_{x \to c} f(x) = 0$ if $c < 0$, and $ap \lim_{x \to 0} f(x)$ does not exist.
(ii) The Lebesgue Density Theorem can be rephrased: if $A \subseteq X$ is μ^*-measurable, then $ap \lim_{\boldsymbol{x} \to \boldsymbol{c}} \chi_A(x)$ exists and equals 1 for almost all $\boldsymbol{c} \in A$, and exists and is 0 for almost all $\boldsymbol{c} \in A^c$.

We have said "the" approximate limit. This is justified by the next observation (this is where $d(D, \boldsymbol{c}) > 0$ is needed):

XIX.6.3.3. PROPOSITION. Let $A \subseteq X$, $f : A \to \mathbb{R}$, and $\boldsymbol{c} \in X$ with $d(A, \boldsymbol{c}) > 0$. If $ap \lim_{\boldsymbol{x} \to \boldsymbol{c}} f(\boldsymbol{x}) = L$ and $ap \lim_{\boldsymbol{x} \to \boldsymbol{c}} f(\boldsymbol{x}) = L'$, then $L = L'$.

PROOF: If $L \neq L'$ and $\epsilon < |L - L'|$, $A_\epsilon = \{x \in A : |f(\boldsymbol{x}) - L| \geq \epsilon\}$, and $B_\epsilon = \{x \in A : |f(\boldsymbol{x}) - L'| \geq \epsilon\}$, then $A_\epsilon \cup B_\epsilon = A$. Apply XIX.6.2.7. to obtain a contradiction. 👍

The definition is consistent with the usual limit definition:

XIX.6.3.4. PROPOSITION. Let $A \subseteq X$, $f : A \to \mathbb{R}$, and $\boldsymbol{c} \in X$ with $d(A, \boldsymbol{c}) > 0$. If $\lim_{\boldsymbol{x} \to \boldsymbol{c}} f(x)$ exists and equals L, then $ap \lim_{\boldsymbol{x} \to \boldsymbol{c}} f(x)$ exists and equals L.

PROOF: For any $\epsilon > 0$, a deleted neighborhood of $\boldsymbol{c}$ is contained in A_ϵ^c. 👍

XIX.6.3.5. Approximate limits are much more general than (ordinary) limits: in $\mathbb{R}$, $\lim_{x \to c} \chi_{\mathbb{Q}}(x)$ does not exist anywhere, but $ap \lim_{x \to c} \chi_{\mathbb{Q}}(x)$ exists (and is 0) for every c. But there is a useful rephrasing of the definition:

XIX.6.3.6. PROPOSITION. Let $A \subseteq \mathbb{R}^n$, $f : A \to \mathbb{R}$, and $\boldsymbol{c} \in \mathbb{R}^n$ with $d(A, \boldsymbol{c}) > 0$. Then $ap\lim_{\boldsymbol{x}\to\boldsymbol{c}} f(x)$ exists and equals L if and only if there is a $B \subseteq A$ with $d(A \setminus B, \boldsymbol{c}) = 0$ such that $\lim_{\boldsymbol{x}\to\boldsymbol{c}} f|_B(x)$ exists and equals L.

XIX.6.4. Approximate Continuity

The main goal of this section is to make precise and justify the statement that "a Lebesgue measurable function is almost continuous almost everywhere."

The next definition is obvious:

XIX.6.4.1. DEFINITION. Let (X, ρ) be a metric space, μ a neighborhood-finite Borel measure on X, $A \subseteq X$, and $f : A \to \mathbb{R}$ a function. Then f is *approximately continuous* at $a \in A$ if $d(A, a) > 0$ and $ap\lim_{x\to a} f(x)$ exists and equals $f(a)$.

Luzin's Theorem

We begin with a theorem of LUZIN (who considered only the case of $\mathbb{R}$ with Lebesgue measure):

XIX.6.4.2. THEOREM. [LUZIN'S THEOREM] Let X be a metrizable space, and μ a locally finite Borel measure on X. Let f be a real-valued μ^*-measurable function on X, and $A \subseteq X$ a μ^*-measurable set with $\mu(A) < \infty$. Then for any $\epsilon > 0$ there is a closed set $E \subseteq A$ with $\mu(A \setminus E) < \epsilon$ and $f|_E$ continuous on E. If X is Polish (e.g. $\mathbb{R}^n$), then E can be chosen compact.

PROOF: Let $\epsilon > 0$. For each $n \in \mathbb{N}$ and $k \in \mathbb{Z}$ let $I_{n,k} = \left[\frac{k}{n}, \frac{k+1}{n}\right)$ and set

$$A_{n,k} = A \cap f^{-1}(I_{n,k}) \ .$$

For fixed n the sets $A_{n,k}$ are pairwise disjoint μ^*-measurable sets of finite measure. Thus by () for each n and k there is a closed set $E_{n,k} \subseteq A_{n,k}$ with

$$\mu(A_{n,k} \setminus E_{n,k}) < 2^{-n-|k|-1}\epsilon \ .$$

For each n we have that

$$A \setminus \bigcup_{k\in\mathbb{Z}} E_{n,k} = \bigcup_{k\in\mathbb{Z}} (A_{n,k} \setminus E_{n,k})$$

(disjoint union), so

$$\mu\left(A \setminus \bigcup_{k\in\mathbb{Z}} E_{n,k}\right) = \sum_{k\in\mathbb{Z}} \mu(A_{n,k} \setminus E_{n,k}) < \sum_{k\in\mathbb{Z}} 2^{-n-|k|-1}\epsilon < 2^{-n}\epsilon \ .$$

Thus there is an $m(n)$ such that, if

$$E_n = \bigcup_{k=-m(n)}^{m(n)} E_{n,k}$$

we have

$$\mu(A \setminus E_n) < 2^{-n}\epsilon$$

and the set E_n is closed.

Define a continuous function g_n on E_n by setting $g_n(x) = \frac{k}{n}$ if $x \in E_{n,k}$ ($|k| \leq m(n)$). We have $|f(x) - g_n(x)| < \frac{1}{n}$ for $x \in E_n$.

Set $E = \cap_n E_n$. Then E is closed, and

$$\mu(A \setminus E) \leq \sum_{n=1}^{\infty} \mu(A \setminus E_n) < \sum_{n=1}^{\infty} 2^{-n}\epsilon = \epsilon \ .$$

The continuous functions g_n converge uniformly to $f|_E$ on E, hence $f|_E$ is continuous on E.

For the last statement, if X is Polish, find E as above with $\mu(A \setminus E) < \epsilon/2$; then by XVII.6.1.22. there is a compact $K \subseteq E$ with $\mu(E \setminus K) < \epsilon/2$, so $\mu(A \setminus K) < \epsilon$ and $f|_K$ is continuous on K. 👍

XIX.6.4.3. **Caution:** The theorem asserts that the *restriction* of f to E is continuous, not that f is continuous at points of E. In fact a measurable function need not be continuous anywhere, such as $\chi_{\mathbb{Q}}$ (in this case the E would be a subset of the irrational numbers). ✋

Approximate Continuity of Measurable Functions

XIX.6.4.4. THEOREM. Let (X, ρ) be a separable controlled metric space and μ a neighborhood-finite Borel measure on X. If $f : X \to \mathbb{R}$ is μ^*-measurable, then f is approximately continuous μ-almost everywhere on X.

PROOF: By XIX.6.4.2. there is a sequence (E_n) of closed sets in X with $\mu(X \setminus \cup E_n) = 0$ and $f|_{E_n}$ continuous on E_n. By XIX.6.2.3. we have $d(X \setminus E_n, x) = 0$ for almost all $x \in E_n$, so f is approximately continuous at almost all points of E_n for each n. 👍

XIX.6.4.5. Since the conclusion does not depend on the metric, the result holds for any separable metrizable space which is topologically finite-dimensional (XVII.8.1.15.).

XIX.6.5. Approximate Differentiability

In this section, we consider only $\mathbb{R}^n$ with Lebesgue measure $\lambda = \lambda^{(n)}$.

XIX.6.5.1. DEFINITION. Let A be a subset of $\mathbb{R}^n$, $\boldsymbol{a} \in A$ with $d(A, \boldsymbol{a}) > 0$. A function $\boldsymbol{f} : A \to \mathbb{R}^m$ is *approximately differentiable* at $\boldsymbol{a}$ if there is a linear map $L : \mathbb{R}^n \to \mathbb{R}^m$ with

$$ap \lim_{\boldsymbol{x} \to \boldsymbol{a}} \frac{\|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{f}(\boldsymbol{a}) - L(\boldsymbol{x} - \boldsymbol{a})\|}{\|x - a\|} = 0 \ .$$

The linear map L, if it exists, is the *approximate derivative* of $\boldsymbol{f}$ at $\boldsymbol{a}$, denoted *ap-*$d\boldsymbol{f}(\boldsymbol{a})$ and its matrix denoted *ap-*$D\boldsymbol{f}(\boldsymbol{a})$.

XIX.6.5.2. The L, if it exists, is unique, just as in the differentiable case () (since $d(A, \boldsymbol{a}) > 0$). If $\boldsymbol{f} = (f_1, \ldots, f_m)$ with $f_k : A \to \mathbb{R}$, then $\boldsymbol{f}$ is approximately differentiable at $\boldsymbol{a}$ if and only if each f_k is approximately differentiable at $\boldsymbol{a}$, and the linear functions $ap\text{-}df_k$ are the coordinate functions of $ap\text{-}d\boldsymbol{f}$. Thus in analyzing approximate differentiability we may assume $m = 1$.

XIX.6.5.3. PROPOSITION. Let A be a subset of $\mathbb{R}^n$, $\boldsymbol{a} \in A$ with $d(A, \boldsymbol{a}) > 0$, $\boldsymbol{f} : A \to \mathbb{R}^m$. If $\boldsymbol{f}$ is approximately differentiable at $\boldsymbol{a}$, then $\boldsymbol{f}$ is approximately continuous at $\boldsymbol{a}$.

There is a companion definition:

XIX.6.5.4. DEFINITION. Let A be a subset of $\mathbb{R}^n$, $\boldsymbol{a} = (a_1, \ldots, a_n) \in A$, and $\boldsymbol{f} : A \to \mathbb{R}$ a function. Fix k, $1 \leq k \leq n$. If the intersection

$$A_k = A \cap \{(a_1, \ldots, a_{k-1}, t, a_{k+1}, \ldots, a_n) : t \in \mathbb{R}$$

has positive 1-dimensional density at $\boldsymbol{a}$ and

$$ap \lim_{t \to a_k} \frac{f(a_1, \ldots, a_{k-1}, t, a_{k+1}, \ldots, a_n) - f(a_1, \ldots, a_{k-1}, a_k, a_{k+1}, \ldots, a_n)}{t}$$

exists, it is called the *approximate partial derivative* of f at $\boldsymbol{a}$ with respect to x_k, denoted $ap\frac{\partial f}{\partial x_k}$.

XIX.6.5.5. If f is approximately differentiable at $\boldsymbol{a}$, the domain A of f need not have any point other than $\boldsymbol{a}$ itself on lines in coordinate directions through $\boldsymbol{a}$ (although A must contain points near $\boldsymbol{a}$ very close to such a coordinate line by density), so the approximate partial derivatives of f at $\boldsymbol{a}$ do not necessarily exist and the geometric interpretation of the entries of the matrix entries of $ap\text{-}Df(\boldsymbol{a})$ is a little obscure. But if the 1-dimensional densities of the intersection of A with lines in the coordinate directions through $\boldsymbol{a}$ are positive, the approximate partial derivatives exist at $\boldsymbol{a}$ and they are the entries of $ap\text{-}Df(\boldsymbol{a})$. Thus, modulo delicate questions about domain, approximate differentiability implies existence of approximate partial derivatives in each coordinate direction.

The converse is false in general, just as in the exact case: existence of approximate partial derivatives is not sufficient for approximate differentiability. Even existence and approximate continuity of exact partial derivatives is not sufficient:

XIX.6.5.6. EXAMPLE. Theorem VIII.3.3.1. does not hold if continuity and differentiability are replaced by approximate continuity and approximate differentiability. In $\mathbb{R}^2$, let L_1 and L_2 be rays from $\mathbf{0}$ in the open first quadrant with L_2 above L_1, and C_1 and C_2 curves in the open first quadrant below L_1 and above L_2 respectively and asymptotic to the rays approaching $\mathbf{0}$ (see Figure ()). Let $f : \mathbb{R}^2 \to [0, 1]$ be a function which is 1 at points of the open first quadrant between L_1 and L_2, zero on points of the first quadrant below C_1 or above C_2 and on the other three (closed) quadrants, and $\mathcal{C}^\infty$ on $\mathbb{R}^2 \setminus \{\mathbf{0}\}$. Then the first-order partials of f exist everywhere and are continuous everywhere except at $\mathbf{0}$. If C_1 and C_2 approach L_1 and L_2 rapidly enough, the first-order partials are approximately continuous at $\mathbf{0}$ since they are identically 0 except between C_1 and L_1 and between L_2 and C_2. But f is not even approximately continuous at $\mathbf{0}$, hence not approximately differentiable at $\mathbf{0}$.

XIX.7. Lipschitz Functions

Lipschitz functions are especially important on Euclidean spaces, where they are a generalization of smooth functions with many of the same properties; but the definition makes sense for functions between general metric spaces

XIX.7.1. Lipschitz Functions Between Metric Spaces

XIX.7.1.1. DEFINITION. Let (X, ρ) and (Y, σ) be metric spaces. A function $f : X \to Y$ is *Lipschitz* if there is a constant C such that $\sigma(f(x_1), f(x_2)) \leq C\rho(x_1, x_2)$ for all $x_1, x_2 \in X$. The smallest such C is called the *Lipschitz constant* of f, denoted $Lip(f)$.

XIX.7.1.2. Note that this is strictly a metric notion, and depends on the choice of metrics (which should technically be incorporated into the notation and terminology, although it is conventional not to since generally only Lipschitz functions between subsets of Euclidean spaces are considered).

XIX.7.1.3. PROPOSITION. A Lipschitz function is uniformly continuous (and in particular continuous).

PROOF: Let $f : (X, \rho) \to (Y, \sigma)$ be Lipschitz, with constant C; we may assume $C > 0$. Let $\epsilon > 0$, and set $\delta = \frac{\epsilon}{C}$. Then if $\rho(x_1, x_2) < \delta$, then $\sigma(f(x_1), f(x_2)) < \epsilon$. 👍

XIX.7.2. Locally Lipschitz Functions

DEFINITION. Let (X, ρ) and (Y, σ) be metric spaces. A function $f : X \to Y$ is *locally Lipschitz (LL)* if, for each $a \in X$, there is an open ball B around a such that $f|_B$ is a Lipschitz function from B to Y. In other words, for every $a \in X$ there is an $\epsilon > 0$ and $C \geq 0$ such that $\sigma(f(x_1), f(x_2)) \leq C\rho(x_1, x_2)$ for any $x_1, x_2 \in X$ with $\rho(x_1, a), \rho(x_2, a) < \epsilon$.

An LL function is locally uniformly continuous, hence continuous.

XIX.7.2.1. EXAMPLE. In this definition it is not enough that $\sigma(f(x), f(a)) \leq C\rho(x, a)$ whenever $\rho(x, a) < \epsilon$. Let $X \subseteq \mathbb{R}^2$ consist of $\mathbf{0}$ and two sequences (p_n), (q_n), where

$$p_n = \left(\frac{1}{n}, \frac{1}{n^2}\right) \quad , \quad q_n = \left(\frac{1}{n}, -\frac{1}{n^2}\right) .$$

Define $f : X \to \mathbb{R}$ by $f(\mathbf{0}) = 0$, $f(p_n) = \frac{1}{n}$, and $f(q_n) = -\frac{1}{n}$ for all n. Then f is continuous,

$$|f(p_n) - f(\mathbf{0})| = |f(q_n) - f(\mathbf{0})| < \|p_n - \mathbf{0}\| = \|q_n - \mathbf{0}\|$$

for all n, but f is not Lipschitz on any neighborhood of $\mathbf{0}$ since $|f(p_n) - f(q_n)| = n\|p_n - q_n\|$ for all n.

XIX.7.2.2. PROPOSITION. Let (X, ρ) and (Y, σ) be metric spaces. A function $f : X \to Y$ is LL if and only if its restriction to every compact subset of X is Lipschitz.

PROOF: Suppose f is not LL. Then there is an $a \in X$ and sequences (p_n), (q_n) in X with $\rho(p_n, a), \rho(q_n, a) < \frac{1}{n}$ and $\sigma(f(p_n), f(q_n)) > n\rho(p_n, q_n)$ for each n. Then $K = \{p_n, q_n : n \in \mathbb{N}\} \cup \{a\}$ is a compact subset of X, and $f|_K$ is not Lipschitz.

Conversely, suppose f is LL, and let K be a compact subset of X. Since f is continuous, the function $g(x_1, x_2) = \sigma(f(x_1), f(x_2))$ is a continuous function from $X \times X$ to $\mathbb{R}$, hence is bounded on the compact set $K \times K$, say by M.

For each $a \in K$, there is an open ball B_a around a such that $f|_{B_a}$ is Lipschitz. The B_a cover K, so there is a finite subcover $\{B_{a_1}, \ldots, B_{a_n}\}$. Let C_i be the Lipschitz constant of $f|_{B_{a_i}}$, and $C = \max(C_1, \ldots, C_n)$.

Let δ be a Lebesgue number () for the open cover $\{B_{a_1}, \ldots, B_{a_n}\}$ of K, and set $N = \max\left(C, \frac{M}{\delta}\right)$. Let $x_1, x_2 \in K$. If $\rho(x_1, x_2) < \delta$, then x_1 and x_2 are in the same B_{a_i} and hence

$$\sigma(f(x_1), f(x_2)) \leq C_i \rho(x_1, x_2) \leq N\rho(x_1, x_2) \ .$$

And if $\rho(x_1, x_2) \geq \delta$, then

$$\frac{\sigma(f(x_1), f(x_2))}{\rho(x_1, x_2)} \leq \frac{\sigma(f(x_1), f(x_2))}{\delta} \leq \frac{M}{\delta} \leq N \ .$$

XIX.7.3. Lipschitz Functions Between Euclidean Spaces

We now specialize to the case of functions from $\mathbb{R}^n$, or an open set in $\mathbb{R}^n$, to $\mathbb{R}^m$. We will always use the standard metric on a Euclidean space, or any subset.

XIX.7.3.1. PROPOSITION. Let U be a subset of $\mathbb{R}^n$, and $\boldsymbol{f} : U \to \mathbb{R}^m$ a function. Then $\boldsymbol{f}$ is Lipschitz (resp. LL) if and only if each coordinate function is a Lipschitz (resp. LL) function from U to $\mathbb{R}$.

XIX.7.3.2. If $[a, b]$ is a closed bounded interval in $\mathbb{R}$ and $f : I \to \mathbb{R}$ is a function, then by () f is Lipschitz if and only if it is absolutely continuous and f' (defined a.e.) is bounded. Thus, if I is an interval in $\mathbb{R}$ and $f : I \to \mathbb{R}$, then f is LL if and only if f is locally absolutely continuous (absolutely continuous on each closed bounded subinterval of I) and f' is locally bounded. In particular, if f is $\mathcal{C}^1$ on I, then f is LL on I. Thus LL functions are slightly more special than locally absolutely continuous functions, and generalize smooth functions. By considering coordinate functions, the same statements apply to functions from I to $\mathbb{R}^m$ for any m.

XIX.7.3.3. There is no natural analog of absolute continuity for real-valued functions on a rectangle in $\mathbb{R}^n$ for $n > 1$. But Lipschitz makes sense and is a good substitute. So if $U \subseteq \mathbb{R}^n$ is open, it makes sense to consider LL functions from U to $\mathbb{R}$, or to $\mathbb{R}^m$ for any m.

XIX.7.3.4. PROPOSITION. Let $U \subseteq \mathbb{R}^n$ be open, and $\boldsymbol{f} : U \to \mathbb{R}^m$ be a $\mathcal{C}^1$ function. Then $\boldsymbol{f}$ is LL on U.

PROOF: Let $\boldsymbol{a} \in U$, and B an open ball around $\boldsymbol{a}$ whose closure is contained in U. Then all partial derivatives of $\boldsymbol{f}$ are bounded on B. Set

$$M = \sum_{i,j} \sup_{\boldsymbol{x} \in B} \left| \frac{\partial f_i}{\partial x_j}(\boldsymbol{x}) \right| .$$

If $\boldsymbol{x}, \boldsymbol{y} \in B$, set $\boldsymbol{g}(t) = \boldsymbol{f}(t\boldsymbol{x} + (1-t)\boldsymbol{y})$. Then $\boldsymbol{g}$ is $\mathcal{C}^1$ on $[0,1]$, and $\|\boldsymbol{g}'(t)\| \leq M\|\boldsymbol{x} - \boldsymbol{y}\|$ a.e. by the Chain Rule, so $\|\boldsymbol{f}(\boldsymbol{x}) - \boldsymbol{f}(\boldsymbol{y})\| = \|\boldsymbol{g}(1) - \boldsymbol{g}(0)\| \leq M\|\boldsymbol{x} - \boldsymbol{y}\|$. 👍

The next key result extending () is a partial converse.

XIX.7.3.5. THEOREM. [RADEMACHER'S THEOREM] Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f}$ a Lipschitz function from U to $\mathbb{R}^m$. Then $\boldsymbol{f}$ is differentiable a.e., and $\|D\boldsymbol{f}(\boldsymbol{a})\| \leq Lip(\boldsymbol{f})$ for all $\boldsymbol{a}$ for which it is defined (i.e. for all $\boldsymbol{a}$ where $\boldsymbol{f}$ is differentiable).

XIX.7.3.6. COROLLARY. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f}$ an LL function from U to $\mathbb{R}^m$. Then $\boldsymbol{f}$ is differentiable a.e., and $D\boldsymbol{f}$ is locally bounded.

The proof of Rademacher's Theorem uses several lemmas.

XIX.7.3.7. LEMMA. Let U be an open set in $\mathbb{R}^n$, and $\boldsymbol{f}$ a Lipschitz function from U to $\mathbb{R}^m$. Then, for each i, $\frac{\partial \boldsymbol{f}}{\partial x_i}$ exists a.e. on U with respect to n-dimensional Lebesgue measure; in fact, on any line segment within U parallel to $\boldsymbol{e}_i$, $\frac{\partial \boldsymbol{f}}{\partial x_i}$ exists a.e. with respect to 1-dimensional Lebesgue measure (1-dimensional Hausdorff measure on $\mathbb{R}^n$). $\left\| \frac{\partial \boldsymbol{f}}{\partial x_i}(\boldsymbol{a}) \right\| \leq Lip(\boldsymbol{f})$ whenever it is defined.

PROOF: We may assume $m = 1$ by considering coordinate functions (so we write f instead of $\boldsymbol{f}$). Let $\boldsymbol{a}_0 \in U$, and set $g(t) = f(\boldsymbol{a}_0 + t\boldsymbol{e}_i)$. Then g is a Lipschitz function on the largest open interval I around 0 whose image is contained in U, whose constant is less than or equal to $Lip(f)$, and hence is differentiable a.e. in I with $|g'(t)| \leq Lip(f)$ wherever defined. We have

$$\frac{\partial f}{\partial x_i}(\boldsymbol{a}_0 + t\boldsymbol{e}_i) = g'(t)$$

for any t where the right side is defined. It then follows from the Junior Tonelli Theorem that $\frac{\partial f}{\partial x_i}$ exists a.e. on U with respect to n-dimensional Lebesgue measure (the set on which it is defined is a Borel set, cf. ()). 👍

XIX.7.3.8. More generally, if L is any line in $\mathbb{R}^n$ and I is any line segment contained in U parallel to L, then the directional derivative of $\boldsymbol{f}$ in the direction L is defined a.e. on I with respect to 1-dimensional Hausdorff measure, with the same bound $Lip(\boldsymbol{f})$. With care, this can be extended to any smooth curve in U.

XIX.7.4. Hölder Continuity

Chapter XX

Functional Analysis

Functional analysis is, in a nutshell, the study of topological vector spaces and operators on them. The name arose in part because historically (and still today), many of the most important topological vector spaces are function spaces. Another reason for the name is that one of the main underlying philosophies of functional analysis is that spaces can be studied by means of real- or complex-valued functions (*functionals*) on them.

Functional analysis combines linear algebra with analysis and topology. The interaction makes for a rich and powerful theory that has many applications in both pure and applied mathematics.

If a scientist wants to study a forest, there are two principal ways to examine it. First, one can walk through the forest. In this way, the small-scale properties can be studied in detail: the individual trees and the local ecosystems. But it is not easy to determine the large-scale structure of the forest this way, its overall extent and shape, the relative distribution of tree species and open spaces, etc. The other way is to fly over the forest (https://www.youtube.com/watch?v=EqFmLgK_H9s). If you do this, the small-scale structure is not easily seen: individual trees are almost reduced to points in the overall picture; but the large-scale structure can be easily seen at a glance. A full study of the forest would undoubtedly include both methods.

Calculus and traditional elementary analysis give the basic tools necessary to do small-scale analysis of spaces of functions. Functional analysis provides the way to do large-scale analysis. Individual functions, although they have a rich internal structure of their own, are just points in an overall space from the functional analysis point of view. Flying over the function space using functional analysis is often a powerful way of easily establishing properties or solving problems related to function spaces.

Functional analysis reaches its full development and power in combination with measure theory, and many if not most texts assume familiarity with measure theory. But the essentials of functional analysis can be done without measure theory, so we will go as far as possible without weaving measure theory into the picture.

XX.1. Preliminaries

In this section, we introduce important results and terminology about vector spaces over the real or complex numbers. No topology will be used in this section (actually there is some, hidden in the structure of the field $\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$); the subject matter is entirely linear algebra. However, the applications will be (almost) all to the study of topological vector spaces.

In this section, all vector spaces will be vector spaces over $\mathbb{F}$, which could be either $\mathbb{R}$ or $\mathbb{C}$. We will specify which when it matters.

XX.1.1. Properties of Subsets

Set Arithmetic

XX.1.1.1. If A and B are subsets of a vector space X, then

$$A + B = \{x + y : x \in A, y \in B\} \ .$$

If $y \in X$, then $A + y = A + \{y\} = \{x + y : x \in A\}$.

If $\alpha \in \mathbb{F}$, define $\alpha A = \{\alpha x : x \in A\}$.

These can be combined, e.g. $\alpha A + \beta B$, $A - B$, etc.

Special Types of Sets

XX.1.1.2. Definition. Let X be a vector space over $\mathbb{F}$, and $A \subseteq X$. Then

(i) A is *balanced* if $\lambda \in \mathbb{F}$, $|\lambda| \leq 1$, implies $\lambda A \subseteq A$, i.e. $x \in A$ and $|\lambda| \leq 1$ imply $\lambda x \in A$.

(ii) A is *radial* if for every $x \in X$ there is an $M > 0$ such that $x \in \lambda A$ for all $\lambda \in \mathbb{F}$, $|\lambda| \geq M$. Equivalently, A is radial if for every $x \in X$ there is an $\epsilon > 0$ such that $\alpha x \in A$ for all $\alpha \in \mathbb{F}$, $0 < |\alpha| \leq \epsilon$.

(iii) More generally, A *absorbs* a subset B of X if there is an $M > 0$ such that $B \subseteq \lambda A$ for all $\lambda \in \mathbb{F}$, $|\lambda| \geq M$.

XX.1.1.3. Being balanced depends on the field $\mathbb{F}$ (being radial or absorbing does not). In some references the term *circled* is used to mean *balanced*. The term *balanced* seems better, especially if $\mathbb{F} = \mathbb{R}$ (not to mention that there is a mathematical distinction between a circle and a disk). A balanced set, if nonempty, always contains 0.

A set is radial if and only if it absorbs every singleton (hence every finite subset of X). A radial set always contains 0 (thus is nonempty); hence A is radial if and only if for every $x \in X$, there is an $\epsilon > 0$ such that $\alpha x \in A$ for all $\alpha \in \mathbb{F}$, $|\alpha| \leq \epsilon$.

Being balanced and being radial seem like similar concepts, but neither implies the other. For example, a proper vector subspace is balanced but not radial. And since any set containing a radial set is radial, a set can be radial but not balanced.

XX.1.1.4. Definition. Let A be a subset of a vector space A. Then x is an *internal point* of A if the set $A - x$ is radial, i.e. for every $y \in X$ there is an $\epsilon > 0$ such that $x + \alpha y \in A$ for all α, $|\alpha| \leq \epsilon$.

An internal point is an algebraic version of an interior point (note that there is no topology involved).

Balanced Hull

XX.1.1.5. Let X be a vector space. Any intersection of balanced subsets of X is balanced. Thus if $A \subseteq X$, there is a smallest balanced set B containing A, the intersection of all balanced sets containing A (there is at least one such set, X). B is called the *balanced hull* (some references call it the *circled hull*) of A, denoted $bal(A)$. We have $bal(A) = \cup_{|\alpha| \leq 1} \alpha A$.

XX.1.2. Convex Sets

Convexity is hard to categorize mathematically. It is essentially a purely algebraic concept; but it is defined only in vector spaces, or affine spaces, over the real numbers (or over a field containing the real numbers, notably $\mathbb{C}$), and the primary applications are in analysis.

XX.1.2.1. Definition. Let X be a vector space over $\mathbb{R}$. If $x, y \in X$, the *interval* between x and y is

$$[x, y] = \{\alpha x + (1 - \alpha)y : 0 \leq \alpha \leq 1\} .$$

A subset C of X is *convex* if, whenever $x, y \in C$, then $[x, y] \subseteq C$.

XX.1.2.2. Geometrically, the interval $[x, y]$ is the "straight line segment" between x and y ($[x, y] = [y, x]$; $[x, y] = \{x\}$ if $x = y$). Thus a set is convex if and only if it contains the straight line segment between any two of its points; thus it can have no "dents" or "holes."

XX.1.2.3. Examples. (i) Any singleton set is convex.

(ii) An affine subspace is convex.

(iii) In a normed vector space, any ball (open or closed) is convex by the triangle inequality.

(iv) In $\mathbb{R}^2$, any regular polygon (including the interior!) is convex. Many nonregular polygons are convex: for example, any triangle or trapezoid is convex. But not every quadrilateral is convex (the interior angles must be less than 180°). In $\mathbb{R}^3$, (solid) regular polyhedra are convex, as are many, but far from all, nonregular polyhedra. A convex set in $\mathbb{R}^2$ contained in a two-dimensional affine subspace of $\mathbb{R}^3$ is convex (more generally, the property of being convex is intrinsic and largely independent of the containing vector space, e.g. if Y is an affine subspace of X, a subset of Y is convex as a subset of X if and only if it is convex as a subset of Y.)

(v) The empty set is vacuously convex. (Not all authors call $\emptyset$ convex, but it is convenient to allow it.) ✋

XX.1.2.4. Proposition. Let X be a vector space, and A and B convex subsets of X. Then αA is convex for any $\alpha \in \mathbb{F}$, and $A + B$ is convex. Hence $A - B$, etc., are convex.

Convex Combinations

Convex Hull

XX.1.2.5. Let X be a vector space. Any intersection of convex subsets of X is convex. Thus if $A \subseteq X$, there is a smallest convex set C containing A, the intersection of all convex sets containing A (there is at least one such set, X). C is called the *convex hull* of A, denoted $co(A)$. We have that $co(A)$ is the set of all convex combinations of elements of A.

XX.1.2.6. If A is a subset of a vector space X, there is also a smallest balanced convex set containing A, called the *balanced convex hull* of A, denoted $bc(A)$. It can be shown that

$$bc(A) = co(bal(A)) = \left\{ \sum_{k=1}^{n} \alpha_k x_k \right\}$$

where n can vary, $x_1, \ldots, x_n \in A$, $\alpha_1, \ldots, \alpha_n \in \mathbb{F}$, $\sum_{k=1}^{n} |\alpha_k| \leq 1$. (It is not $bal(co(A))$ in general, e.g. if A consists of two linearly independent points in $\mathbb{R}^2$.)

Affine Functions

XX.1.2.7. DEFINITION. Let C and D be convex sets in vector spaces X and Y respectively. An *affine map* from C to D is a function $f : C \to D$ such that

$$f(\alpha x + (1-\alpha)y) = \alpha f(x) + (1-\alpha) f(y)$$

for all $x, y \in C$ and all α, $0 \leq \alpha \leq 1$.

XX.1.2.8. An affine map from C to D is a function which preserves the convex structure. If f is an affine map from X to Y in the usual sense of (), and $f(C) \subseteq D$, then $f|_C$ is an affine map from C to D in the sense of XX.1.2.7.. It can be shown that every affine map from C to D arises in this way (), so the terminology is consistent.

XX.1.2.9. DEFINITION. Let C and D be convex sets in vector spaces X and Y respectively. An *isomorphism* from C to D is an affine bijection from C to D.

Thus an isomorphism from C to D is a bijection which preserves the convex structure.

XX.1.3. Faces and Extreme Points

The crucial notion underlying the whole analysis of convex sets is that of a face.

XX.1.3.1. DEFINITION. Let K be a convex set in a (real) vector space. A nonempty subset F of K is a *face* of K if, whenever $x, y \in K$ and $\alpha x + (1-\alpha)y \in F$ for some α, $0 < \alpha < 1$, then both x and y are in F. A one-point face is called an *extreme point* of K. More precisely, p is an extreme point of K if $\{p\}$ is a face of K. Thus an extreme point of K is a point which cannot be written as a nontrivial convex combination of two distinct points in K.

Note that this definition makes no use of any topology. However, faces and extreme points are most interesting for closed convex sets in topological vector spaces. A face is automatically convex.

In some references, faces are called *extreme subsets* or *supports*.

XX.1.3.2. K itself is a face of K; we are mainly interested in *proper faces* of K. Roughly (imprecisely, and not quite correctly) speaking, a proper face of K is a subset of the "boundary" of K.

XX.1.3.3. EXAMPLES. (i) In $\mathbb{R}$, convex subsets are intervals. If I is an interval, the only proper faces are the extreme points; the extreme points of I are the endpoints of I which are contained in I (by definition, a face of a convex set is a subset of the convex set). Thus a nondegenerate closed bounded interval has two extreme points, an open interval has no extreme points, and other intervals have one extreme point.

(ii) Let K be a closed convex (solid) polygon in $\mathbb{R}^2$, e.g. a (solid) triangle or rectangle. Each closed edge of K is a face of K, and each vertex is an extreme point, and these are all the proper faces.

(iii) Let K be a closed convex (solid) polyhedron in $\mathbb{R}^3$, e.g. a tetrahedron or cube. There are two-dimensional faces, the closed bounding (solid) polygons (which are usually called the "faces" of the polyhedron); one-dimensional faces, the closed edges; and 0-dimensional faces (extreme points), the vertices. These are all the proper faces. This example is undoubtedly the origin of the term "face" for general convex sets.

(iv) Let K be the closed unit ball in $\mathbb{R}^n$. Then the only proper faces of K are the extreme points, which are precisely all the points on the unit sphere. Thus if $n > 1$ there are uncountably many extreme points.

(v) An open ball in $\mathbb{R}^n$ has no extreme points. A nontrivial subspace of $\mathbb{R}^n$ has no extreme points.

XX.1.3.4. PROPOSITION. Let K be a convex set in a vector space, and F a nonempty subset of K. The following are equivalent:

(i) Whenever $x, y \in K$ and $\frac{1}{2}(x+y) \in F$, then $x, y \in F$.

(ii) Whenever $x_1, \ldots, x_n \in K$, $0 < \alpha_1, \ldots, \alpha_n < 1$, $\sum_{k=1}^n \alpha_k = 1$, and $\sum_{k=1}^n \alpha_k x_k \in F$, then $x_1, \ldots, x_n$ are all in F.

(iii) F is a face of K.

In particular, F is automatically convex.

PROOF: (ii) $\Rightarrow$ (iii) $\Rightarrow$ (i) are trivial.

(i) $\Rightarrow$ (iii): Suppose $x, y \in K$, $0 < \alpha < 1$, $z_0 := \alpha x + (1-\alpha)y \in F$. We may assume without loss of generality that $\alpha \leq \frac{1}{2}$. Set $z_1 = 2\alpha x + (1-2\alpha)y$. Then $z_1 \in K$ and $z_0 = \frac{1}{2}(y + z_1) \in F$ and thus $y, z_1 \in F$. If $2\alpha \geq \frac{1}{2}$, repeat the argument with x and y reversed and α replaced by 2α to conclude that $x \in F$. If $2\alpha < \frac{1}{2}$, set $z_2 = 4\alpha x + (1-4\alpha)y \in K$; then $z_1 = \frac{1}{2}(y + z_2)$, so $z_2 \in F$. Repeat the argument as many times as necessary; after a finite number of steps (at most $-\log_2 \alpha$) we obtain $x \in F$.

(iii) $\Rightarrow$ (ii): Suppose $x_1, \ldots, x_n, \alpha_1, \ldots, \alpha_n$ are as in (ii), and set

$$z = \sum_{k=1}^{n} \alpha_k x_k \ .$$

For $1 \leq k \leq n-1$ set $\beta_k = \frac{\alpha_k}{1-\alpha_n}$. Then $\sum_{k=1}^{n-1} \beta_k = 1$. Set

$$y = \sum_{k=1}^{n-1} \beta_k x_k \in K$$

so that $z = \alpha_n x_n + (1-\alpha_n)y$. Since K is a face, x_n and y are in F. Repeat the argument with y in place of z, and iterate $n-1$ times (or prove by induction on n). 👍

XX.1.3.5. Corollary. Let K be a convex set in a vector space, and $z \in K$. The following are equivalent:

(i) Whenever $x, y \in K$ and $\frac{1}{2}(x+y) = z$, then $x = y = z$.

(ii) Whenever $x_1, \ldots, x_n \in K$, $0 < \alpha_1, \ldots, \alpha_n < 1$, $\sum_{k=1}^n \alpha_k = 1$, and $\sum_{k=1}^n \alpha_k x_k = z$, then $x_k = z$ for all k.

(iii) z is an extreme point of K.

XX.1.3.6. Proposition. Let K be a convex set in a vector space.

(i) Let $\{F_i : i \in I\}$ be a collection of faces of K. If $\cap_i F_i \neq \emptyset$, then it is a face of K.

(ii) A face of a face of K is a face of K.

(iii) If C is a convex subset of K, F is a face of K, and $F \cap C \neq \emptyset$, then $F \cap C$ is a face of C.

Proof: Straightforward and left to the reader. 👍

XX.1.3.7. Thus, if S is any nonempty subset of K, there is a smallest face $F(S)$ containing S, called the *face generated by* S. $F(S)$ is the intersection of all faces containing S.

We can define an *inner point* of K to be any point p of K such that $F(\{p\}) = K$. Note that such a p is not necessarily an interior point in the topological sense in general (indeed, there may be no topology in the picture!); but if K is a convex set in a topological vector space which has a nonempty interior, then points in the topological interior are inner points (XX.9.1.3.).

A nonempty convex need not have any inner points (). But if it has one, it has a lot:

XX.1.3.8. Proposition. Let C be a convex set in a vector space X. If x is an inner point of C, then for any $y \in C$ the set $[x, y) = \{\alpha x + (1-\alpha)y : 0 < \alpha \leq 1\}$ consists entirely of inner points.

Images and Preimages

XX.1.3.9. Proposition. Let X and Y be vector spaces, and $T : X \to Y$ a linear transformation. If K is a convex set in Y and F is a face of K, then $T^{-1}(F)$ is a face in $T^{-1}(K)$.

The simple proof is again left to the reader.

XX.1.3.10. The same result does not hold for images in general: if $T : X \to Y$ is linear, K is a convex set in X, and F is a face in K, then $T(F)$ is not necessarily a face in $T(K)$ (consider the case where Y is one-dimensional). ✋

XX.1.3.11. A particularly important case of XX.1.3.9. is when $Y = \mathbb{R}$. If ϕ is a linear functional on X, K is a convex subset of X, $I = \phi(K)$ (an interval in $\mathbb{R}$), and c is an endpoint of I contained in I, then the intersection of K with the hyperplane $\phi^{-1}(\{c\})$ is a face of K (cf. XX.1.3.6.(iii)). In other words, if $\phi(x) \geq c$ (or $\phi(x) \leq c$) for all $x \in K$, and there is an $x \in K$ with $\phi(x) = c$, then the set

$$\{x \in K : \phi(x) = c\}$$

is a face of K. In this case, the hyperplane $\phi^{-1}(\{c\})$ is called a *support hyperplane* for K, and the intersection with K a *support face*. Such a support face is frequently, although far from always, an extreme point of K.

XX.1.4. Minkowski Functionals

XX.1.4.1. Definition. Let X be a vector space, and A a subset of X. The *Minkowski functional*, or *gauge*, of A is the function $m_A : X \to [0, \infty]$ defined by

$$m_A(x) = \inf\{\alpha > 0 : x \in \alpha A\} = \inf\left\{\alpha > 0 : \frac{1}{\alpha}x \in A\right\}$$

(where $\inf \emptyset = \infty$).

XX.1.4.2. Proposition. Let A be a subset of a vector space X, and m_A its Minkowski functional. Then

(i) If $x \in X$, then $m_A(\alpha x) = \alpha m_A(x)$ for $\alpha > 0$. If $0 \in A$, this holds also for $\alpha = 0$.

(ii) If A is radial, then $m_A(x) < \infty$ for all $x \in X$.

(iii) If A is balanced, then $m_A(\alpha x) = |\alpha| m_A(x)$ for all $x \in X$, $\alpha \in \mathbb{F}$.

(iv) If A is convex, then $m_A(x + y) \leq m_A(x) + m_A(y)$ for all $x, y \in X$.

Proof: (i)–(iii) are obvious; only (iv) needs proof. Suppose A is convex, and let $x, y \in X$. Let $\alpha > m_A(x)$ and $\beta > m_A(y)$ and $x \in \alpha A$, $y \in \beta A$. We have

$$\alpha A + \beta A = (\alpha + \beta)\left[\frac{\alpha}{\alpha + \beta}A + \frac{\beta}{\alpha + \beta}A\right] \subseteq (\alpha + \beta)A$$

since A is convex, so $x + y \in (\alpha + \beta)A$ and $m_A(x + y) \leq \alpha + \beta$. It follows that m_A is subadditive. 👍

XX.2. Normed Vector Spaces

XX.2.1. Completeness

XX.2.1.1. Proposition. Let X be a normed vector space and Y a (necessarily closed) subspace of X. If Y is complete, and X/Y is complete in the quotient norm, then X is complete.

Proof: Let $\bar{X}$ be the completion of X. Then Y is closed in $\bar{X}$ since Y is complete. Thus the quotient map from X to X/Y extends to a (bounded) quotient map π from $\bar{X}$ to $\bar{X}/Y$; so X/Y is naturally a subspace of $\bar{X}/Y$. On the one hand, X/Y is dense in $\bar{X}/Y$ since X is dense in $\bar{X}$ and π is continuous; on the other hand, X/Y is complete, hence closed in $\bar{X}/Y$. Thus $X/Y = \bar{X}/Y$, and hence $X = \bar{X}$ [if $z \in \bar{X}$, let $x \in X$ with $\pi(x) = \pi(z)$; then $z - x \in Y \subseteq X$, so $z = x + (z - x) \in X$]. 👍

Since finite-dimensional normed spaces are complete, we obtain:

XX.2.1.2. Corollary. Let X be a normed vector space and Y a (necessarily closed) subspace of X. If Y is complete, and X/Y is finite-dimensional, then X is complete.

XX.2.2. Isometries of Normed Vector Spaces

In this section, we prove the following theorem due to Mazur and Ulam []:

XX.2.2.1. Theorem. Let $\mathcal{V}$ and $\mathcal{W}$ be normed vector spaces over $\mathbb{R}$. Then any isometry from $\mathcal{V}$ onto $\mathcal{W}$ is an $\mathbb{R}$-affine function.

XX.2.2.2. This result is false if $\mathbb{R}$ is replaced by $\mathbb{C}$. For example, $\alpha \mapsto \bar{\alpha}$ is an isometry on the complex vector space $\mathbb{C}$ which is not $\mathbb{C}$-affine (it is, of course, $\mathbb{R}$-affine).

We begin with a simple observation:

XX.2.2.3. Proposition. Let $\mathcal{V}$ and $\mathcal{W}$ be Hausdorff topological vector spaces over $\mathbb{R}$, and $f : \mathcal{V} \to \mathcal{W}$ a continuous function. Then f is $\mathbb{R}$-affine if and only if, for every $x, y \in \mathcal{V}$, we have

$$f\left(\frac{x+y}{2}\right) = \frac{f(x)+f(y)}{2}$$

(i.e. f preserves midpoints).

Proof: It is obvious that an affine function preserves midpoints. Conversely, suppose f preserves midpoints. By composing f with a translation, we may assume $f(0) = 0$. It then follows that

$$f\left(\frac{x}{2}\right) = \frac{f(x)}{2}$$

for every $x \in \mathcal{V}$ by taking $y = 0$ in the midpoint property. Thus $f(2x) = 2f(x)$ for every $x \in \mathcal{V}$, and thus, for any $x, y \in \mathcal{V}$, we have

$$f(x+y) = f\left(\frac{2x+2y}{2}\right) = \frac{f(2x)+f(2y)}{2} = \frac{2f(x)+2f(y)}{2} = f(x)+f(y)$$

so f is additive. Then by iteration we get that $f(\alpha x) = \alpha f(x)$ for any dyadic rational α and any x. If $\alpha \in \mathbb{R}$ is arbitrary, let (α_n) be a sequence of dyadic rationals converging to α. Then, for any x,

$$f(\alpha x) = \lim_{n\to\infty} f(\alpha_n x) = \lim_{n\to\infty} \alpha_n f(x) = \alpha f(x)$$

since $\mathcal{W}$ is Hausdorff, i.e. the (translated) function f is linear. 👍

The special case of XX.2.2.1. for $\mathcal{V} = \mathcal{W} = \mathbb{R}^n$ follows almost immediately:

XX.2.2.4. THEOREM. Every isometry of $\mathbb{R}^n$ (with the usual Euclidean norm) is affine.

PROOF: Let f be an isometry of $\mathbb{R}^n$, and let $x, y \in \mathbb{R}^n$. Let $z = \frac{x+y}{2}$ be the midpoint of x and y. Then z is the unique point of $\mathbb{R}^n$ with the property that

$$\rho_2(x,z) = \rho_2(z,y) = \frac{1}{2}\rho_2(x,y)$$

where ρ_2 is the standard metric coming from the norm. It follows that $f(z)$ must satisfy

$$\rho_2(f(x),f(z)) = \rho_2(f(z),f(y)) = \frac{1}{2}\rho_2(f(x),f(y))$$

since f is an isometry. Thus $f(z)$ must be the midpoint of $f(x)$ and $f(y)$. Since f is continuous, it is affine by XX.2.2.3.. 👍

XX.2.2.5. This proof works more generally for XX.2.2.1. if $\mathcal{V}$ and $\mathcal{W}$ are strictly convex (). For the general case of XX.2.2.1., we need a subtler argument:

PROOF: Write ρ and σ for the norm metrics on $\mathcal{V}$ and $\mathcal{W}$ respectively. Fix x and y in $\mathcal{V}$, and set $z = \frac{x+y}{2}$. By XX.2.2.3. it suffices to show that

$$f(z) = \frac{f(x)+f(y)}{2} \ .$$

Let A_1 be the set of all $a \in \mathcal{V}$ such that

$$\rho(x,a) = \rho(a,y) = \frac{1}{2}\rho(x,y) \ .$$

Then A_1 is a subset of $\mathcal{V}$ containing z. We show that A_1 is symmetric around z, i.e. if $a \in A_1$, then $b = a + 2(z-a) = 2z - a$ is also in A_1 (b is the point for which z is the midpoint of a and b). We have $2z = x + y$, and thus $b - x = y - a$ and $b - y = x - a$, so

$$\rho(x,b) = \rho(y,a) = \rho(a,x) = \rho(b,y) = \frac{1}{2}\rho(x,y)$$

and $b \in A_1$.

Let δ_1 be the diameter of A_1. Then δ_1 is finite since if $a, b \in A_1$, we have

$$\rho(a,b) \leq \rho(a,x) + \rho(x,b) = \rho(x,y) \ .$$

For any $a \in A_1$, set $b = 2z - a \in A_1$. Since z is the midpoint of a and b, we have

$$\rho(a,z) = \frac{1}{2}\rho(a,b) \leq \delta_1 \ .$$

Now let A_2 be the set of $c \in A_1$ such that $\rho(a,c) \leq \frac{1}{2}\delta_1$ for all $a \in A_1$. Then $z \in A_2$. If $c \in A_2$, set $d = 2z - c$. If $a \in A_1$, set $b = 2z - a \in A_1$. We then have $2z = a + b$, so $d - a = c - b$ and hence $\rho(a,d) = \rho(b,c) \leq \frac{1}{2}\delta_1$, so $d \in A_2$ and A_2 is also symmetric around z. Also, if $c, d \in A_2$, then $c \in A_1$ so $\rho(c,d) \leq \frac{1}{2}\delta_1$. Thus the diameter δ_2 of A_2 satisfies $\delta_2 \leq \frac{1}{2}\delta_1$.

If $c \in A_2$, then $d = 2z - c \in A_2$, so we have

$$\rho(c,z) = \rho(z,d) = \frac{1}{2}\rho(c,d) \leq \frac{1}{2}\delta_2 \ .$$

Let A_3 be the set of $v \in A_2$ for which $\rho(c,v) \leq \frac{1}{2}\delta_2$ for all $c \in A_2$. Then $z \in A_3$ and, as before, A_3 is symmetric around z and the diameter δ_3 of A_3 satisfies $\delta_3 \leq \frac{1}{2}\delta_2$.

Iterating the process, we obtain a decreasing sequence (A_n) of sets containing z, symmetric around z, with diameter

$$\delta_n \leq \frac{1}{2}\delta_{n-1} \leq \frac{1}{2^{n-1}}\delta_1$$

and hence $\cap_n A_n = \{z\}$.

Let w be the midpoint of $f(x)$ and $f(y)$ in $\mathcal{W}$. Similarly, using σ construct a decreasing sequence (B_n) of subsets of $\mathcal{W}$ containing w. Since the A_n and B_n are constructed using just the metrics ρ and σ, and f is an isometry, we must have $f(A_n) = B_n$ for all n. Thus we have that

$$f(\{z\}) = f(\cap_n A_n) = \cap_n B_n = \{w\} \ .$$

XX.2.3. Exercises

XX.2.3.1. Use the Baire Category Theorem to give an alternate proof that that no Banach space has vector space dimension $\aleph_0$ (). [If $\{\xi_n : n \in \mathbb{N}\}$ is a Hamel basis for X, consider $X_n = span\{\xi_1, \ldots, \xi_n\}$.]

XX.3. Banach Spaces

"Banach started modestly enough from a class consisting of at least two completely arbitrary elements, and postulated that the class is closed under addition and under multiplication by real numbers subject to certain simple, almost trivial postulates. Again it seemed superficially to be the device of putting in what you want to get out. He also postulated an absolute value for which the triangular [sic] inequality holds. [This description leaves out the crucial notion of completeness.] It might seem that from such slavish copying of the rudiments of elementary algebra and elementary geometry nothing really new could issue. But this appears to have been contradicted by experience. In spite of Banach's professional rivals who say he put into his space the trivialities he wished to get out of it, 'Banach space' has at least unified the underlying concepts of several 'spaces' of interest to geometers."

E. T. Bell[1]

[1] [Bel87, p. 161-162].

XX.4. Topological Vector Spaces

Just as topological spaces are a generalization of metric spaces, topological vector spaces are a generalization of normed vector spaces. Throughout this section, $\mathbb{F}$ will denote either $\mathbb{R}$ or $\mathbb{C}$ (we will be specific in the few cases where it matters which), and "vector space" will mean "vector space over $\mathbb{F}$".

XX.4.1. Basic Definitions and Properties

XX.4.1.1. DEFINITION. A *topological vector space* (over $\mathbb{F}$) is a vector space X over $\mathbb{F}$ with a topology $\mathcal{T}$ satisfying

(i) $(x, y) \mapsto x+y$ is a continuous function from $(X, \mathcal{T}) \times (X, \mathcal{T})$ to $(X, \mathcal{T})$ ("addition is jointly continuous").

(i) $(\lambda, x) \mapsto \lambda x$ is a continuous function from $(\mathbb{F}, \mathcal{S}) \times (X, \mathcal{T})$ to $(X, \mathcal{T})$, where $\mathcal{S}$ is the usual topology on $\mathbb{F}$ ("scalar multiplication is jointly continuous").

In both cases, the topology on the product is the product topology. A topology on a vector space making it a topological vector space is called a *TVS topology*. Thus a topological vector space is a pair $(X, \mathcal{T})$, where X is a vector space and $\mathcal{T}$ a TVS topology on X.

XX.4.1.2. The topology $\mathcal{T}$ is part of the definition of a topological vector space (as is the field $\mathbb{F}$); thus it is technically incorrect to say "Let X be a topological vector space." But, as usual, we frequently abuse language by saying this when the topology is understood.

XX.4.1.3. EXAMPLES. (i) If $\|\cdot\|$ is a norm on a vector space X, the topology $\mathcal{T}$ defined by the corresponding metric $\rho(x, y) = \|x - y\|$ is a TVS topology on X, which is Hausdorff and even normal. [Note that it is technically incorrect to say a normed vector space *is* a topological vector space, just as it is incorrect to say that a metric space *is* a topological space. For one thing, different norms can define the same topology. But we frequently abuse language here too.] In particular, the ordinary topology on $\mathbb{F}$, or $\mathbb{F}^n$ for any $n \in \mathbb{N}$, is a TVS topology.

(ii) Let $\{(X_i, \mathcal{T}_i) : i \in I\}$ be a family of topological vector spaces (over the same field $\mathbb{F}$). Let $X = \prod_i X_i$. Then X is a vector space under coordinatewise operations, and the product topology on X is a TVS topology. In particular, if I is any set, then $\mathbb{F}^I$ is a topological vector space under the product topology from the ordinary topology on $\mathbb{F}$. If I is infinite, this topology does not come from a norm (XX.4.4.15.). If I is uncountable, this topology is not even first countable.

(iii) Let X be any vector space. Then the indiscrete topology on X is a (not very interesting) TVS topology. (We will primarily be concerned with Hausdorff topological vector spaces.)

We will see many more interesting examples.

XX.4.1.4. PROPOSITION. Let $(X, \mathcal{T})$ be a topological vector space, and Y a subspace of X. Then the relative topology $\tilde{\mathcal{T}}$ on Y is a TVS topology on Y.

XX.4.1.5. PROPOSITION. Let $(X, \mathcal{T})$ be a topological vector space, and Y a subspace of X. Then the closure $\bar{Y}$ of Y is also a subspace.

This is an easy consequence of the continuity of addition and scalar multiplication, and is left to the reader.

XX.4.1.6. If the scalar multiplication is ignored, a vector space is an abelian group under addition. If $(X, \mathcal{T})$ is a topological vector space, then by (i) it is a topological group under addition. Thus all results about abelian topological groups apply to topological vector spaces. For one thing, translation is a homeomorphism, i.e. the topology on a topological vector space is homogeneous (XXIII.1.2.9.). In fact:

XX.4.1.7. PROPOSITION. Let X be a topological vector space over $\mathbb{F}$. Then
(i) For any $y \in X$, the translation function $\tau_y : x \mapsto x + y = y + x$ is a homeomorphism from X to X.
(ii) For any $\lambda \in \mathbb{F}$, $\lambda \neq 0$, the scaling function $\sigma_\lambda : x \mapsto \lambda x$ is a homeomorphism from X to X.

PROOF: The functions τ_y and σ_λ are continuous by joint continuity (which implies separate continuity), and have inverses τ_{-y} and $\sigma_{\lambda^{-1}}$ respectively. 👍

In contrast to general abelian topological groups, we have:

XX.4.1.8. PROPOSITION. A topological vector space is path-connected.

PROOF: Let X be a topological vector space, and $x, y \in X$. Then the function $[0,1] \to X$ given by $\alpha \mapsto \alpha y + (1-\alpha)x$ is continuous and gives a path from x to y. 👍

This can be taken much further. The path is the "straight line segment" from x to y, and is the beginning of the theory of convex sets (), which is a crucial part of topological vector space theory. See also XX.4.1.17..

In fact, a topological vector space is contractible: the function $h : [0,1] \times X \to X$, $h(\alpha, x) = \alpha x$, is a contraction.

XX.4.1.9. If X is a topological vector space, $A \subseteq X$, an interior point of A in an internal point, by continuity of addition and scalar multiplication. In particular, any neighborhood of 0 is radial. The converse is false in general (XX.4.8.4.(b)).

We have (cf. XXIII.1.2.26.):

XX.4.1.10. PROPOSITION. Let $(X, \mathcal{T})$ be a topological vector space. Then the following are equivalent:

(i) $(X, \mathcal{T})$ is T_0.

(ii) $(X, \mathcal{T})$ is Hausdorff.

(iii) $(X, \mathcal{T})$ is completely regular.

(iv) For any $x \in X$, $x \neq 0$, there is an open neighborhood U of 0 with $x \notin U$.

We also have, in analogy with XXIII.1.2.29.:

XX.4.1.11. PROPOSITION. Let $(X, \mathcal{T})$ be a topological vector space, and Y a subspace of X. Let $\bar{\mathcal{T}}$ be the quotient topology () on the vector space X/Y. Then

(i) $\bar{\mathcal{T}}$ is a TVS topology on X/Y.

(ii) $(X/Y, \bar{\mathcal{T}})$ is Hausdorff if and only if Y is closed in X.

We will primarily be interested in Hausdorff topological vector spaces. Indeed, some authors require topological vector spaces to be Hausdorff. We will not since some natural topological vector spaces are not Hausdorff (). But there is a painless way to reduce to the Hausdorff case, an analogy (almost a special case) of XXIII.1.2.31.:

XX.4.1.12. PROPOSITION. Let X be a topological vector space, and $Y = \overline{\{0\}}$. Then Y is a (closed) subspace of X, and the quotient topology on X/Y is Hausdorff. X/Y is the maximal T_0 quotient of X in the sense of XIII.8.3.10., and the maximal Hausdorff quotient in the sense of XIII.8.5.6..

In fact, see XX.4.8.1..

Specification by Fundamental Neighborhoods

Just as in a topological group, TVS topology on a vector space can be described by giving a fundamental family of neighborhoods of 0.

XX.4.1.13. DEFINITION. Let X be a vector space. A *fundamental system of neighborhoods of* 0 is a nonempty collection $\mathcal{F}$ of subsets of X, satisfying:

(i) Each $U \in \mathcal{F}$ is radial and balanced (and thus contains 0).

(ii) If $U, V \in \mathcal{F}$, there is a $W \in \mathcal{F}$ with $W \subseteq U \cap V$.

(iii) For each $U \in \mathcal{F}$ there is a $V \in \mathcal{F}$ with $V + V \subseteq U$.

Note that in this definition, there is no specified topology on X, so the sets in $\mathcal{F}$ are not "neighborhoods" of 0 in X in the usual sense of the term. But the terminology is justified by:

XX.4.1.14. THEOREM. Let X be a vector space, and let $\mathcal{F}$ be a fundamental system of neighborhoods of 0 in X. Then there is a (unique) TVS topology $\mathcal{T}$ on X such that $\mathcal{F}$ forms a local base for $\mathcal{T}$ at 0 (consisting of not necessarily open sets). Conversely, if $\mathcal{T}$ is a TVS topology on X, then there is a fundamental system of neighborhoods of 0 in X forming a local base for $\mathcal{T}$; in fact, the set of all balanced neighborhoods of 0 is a fundamental system of neighborhoods of 0 forming a local base for $\mathcal{T}$.

PROOF: If $\mathcal{F}$ is a fundamental system of neighborhoods of 0 in X, then $\mathcal{F}$ satisfies the conditions of XXIII.1.2.18., and thus is a local base for a topology $\mathcal{T}$ on X making X into a topological group under addition, i.e. addition is jointly continuous for $\mathcal{T}$.

To show that scalar multiplication is jointly continuous, fix $\lambda_0 \in \mathbb{F}$ and $x_0 \in X$. If $U \in \mathcal{F}$, then $\lambda_0 x_0 + U$ is a basic neighborhood of $\lambda_0 x_0$. Choose $V \in \mathcal{F}$ with $V + V \subseteq U$. Since V is radial, there is an $\epsilon > 0$ such that $(\lambda - \lambda_0)x \in V$ whenever $|\lambda - \lambda_0| \leq \epsilon$. Fix $n \in \mathbb{N}$ with $n \geq |\lambda_0| + \epsilon$, and by repeatedly using XX.4.1.13., there is a $W \in \mathcal{F}$ with $W + \cdots + W$ (n terms) contained in V; so $nW \subseteq V$. Then $x - x_0 \in W$ and $|\lambda - \lambda_0| \leq \epsilon$ imply $\lambda(x - x_0) \in V$ since V is balanced; so

$$\lambda x = \lambda_0 x_0 + (\lambda - \lambda_0)x_0 + \lambda(x - x_0) \in \lambda_0 x_0 + V + V \subseteq \lambda_0 x_0 + U \ .$$

For the converse, let $\mathcal{T}$ be a TVS topology on X. Any neighborhood of 0 is radial by (separate) continuity of scalar multiplication. Let U be a neighborhood of 0. By continuity of scalar multiplication, there is an $\epsilon > 0$ and a neighborhood V of 0 such that $\lambda V \subseteq U$ whenever $|\lambda| \leq \epsilon$. Set $W = \cup_{|\lambda| \leq \epsilon} \lambda V$; then W is a balanced neighborhood of 0 contained in U. Thus the set $\mathcal{F}$ of balanced neighborhoods of 0 is a local base for $\mathcal{T}$, and satisfies XX.4.1.13.(i) and (ii). If $U \in \mathcal{F}$, by continuity of addition there is a $\mathcal{T}$-neighborhood V of 0 with $V + V \subseteq U$, and V contains a balanced neighborhood W of 0, which satisfies $W + W \subseteq U$. Thus $\mathcal{F}$ satisfies XX.4.1.13.(iii). 👍

This proof is adapted from [SW99], one of the standard references for topological vector spaces.

XX.4.1.15. Corollary. Let $\mathcal{T}$ be a translation-invariant topology on a vector space X (i.e. for which translations are homeomorphisms). If there is a fundamental system $\mathcal{F}$ of neighborhoods of 0 in X forming a local base at 0 for $\mathcal{T}$, then $\mathcal{T}$ is a TVS topology on X.

Proof: There is a TVS topology $\mathcal{S}$ on X for which $\mathcal{F}$ forms a local base at 0; so $\mathcal{S}$ and $\mathcal{T}$ have identical local bases at every point since $\mathcal{T}$ is translation-invariant. Thus $\mathcal{S} = \mathcal{T}$. 👍

Finite-Dimensional Topological Vector Spaces

We also have the following generalization of (). We have designated this as a theorem since it is a little more than just a corollary of XX.4.1.14., although XX.4.1.14. (converse direction) is the crucial tool in the proof.

XX.4.1.16. Theorem. Let $n \in \mathbb{N}$. Then the ordinary topology on $X = \mathbb{F}^n$ is the unique Hausdorff TVS topology on $\mathbb{F}^n$.

Proof: We may assume $\mathbb{F} = \mathbb{R}$ and $X = \mathbb{R}^n$. Let $\mathcal{T}$ be a Hausdorff TVS topology on $\mathbb{R}^n$, and $\mathcal{S}$ the ordinary topology, i.e. $\mathcal{S}$ comes from a norm on $\mathbb{R}^n$ (any norm will do, but it will be convenient to use $\| \cdot \|_1$. Reference to balls in this proof will be with respect to this norm.)

Let $\mathcal{F}$ be a fundamental system of neighborhoods of 0 for $\mathcal{T}$, and $U \in \mathcal{F}$. Let B be the set consisting of the standard basis vectors in $\mathbb{R}^n$ and their negatives. Then B is a finite set with $2n$ elements. The convex hull C of B is an $\mathcal{S}$-neighborhood of 0 (it is the closed unit ball). By repeated use of XX.4.1.14.(iii), there is a $V \in \mathcal{F}$ with $V + \cdots + V$ ($2n$ terms) contained in U. Since V is radial, V absorbs B, i.e. there is an $\epsilon > 0$ such that $\epsilon B \subseteq V$. Since V is balanced, it follows that ϵC, which is an $\mathcal{S}$-neighborhood of 0, is contained in U. So every $\mathcal{T}$-neighborhood of 0 contains an $\mathcal{S}$-neighborhood, i.e. $\mathcal{S}$ is stronger than $\mathcal{T}$.

Let S be the unit sphere in $\mathbb{R}^n$. Then S is $\mathcal{S}$-compact, hence $\mathcal{T}$-compact, so S is $\mathcal{T}$-closed since $\mathcal{T}$ is Hausdorff. Thus $Z = \mathbb{R}^n \setminus S$ is a $\mathcal{T}$-open neighborhood of 0, so contains a $W \in \mathcal{F}$. Let $x \in W$. Since W is

balanced, the line segment $\{\lambda x : 0 \leq \lambda \leq 1\}$ is contained in W. This line segment cannot cross S, so x is in the open unit ball of $\mathbb{R}^n$, i.e. W is contained in the open unit ball. Thus every $\mathcal{S}$-neighborhood of 0 contains a $\mathcal{T}$-neighborhood (cf. XX.4.1.7.(ii)), i.e. $\mathcal{T}$ is stronger than $\mathcal{S}$. Therefore $\mathcal{T} = \mathcal{S}$. 👍

XX.4.1.17. Corollary. Let X be a Hausdorff topological vector space, and Y a finite-dimensional affine subspace of X. Then there is an affine homeomorphism from Y to $\mathbb{F}^n$, where $n = dim(Y)$. In particular, if X is finite-dimensional, there is a unique Hausdorff TVS topology on X.

Thus, although a vector space can have many Hausdorff TVS topologies, they cannot be drastically different: they must all agree on every finite-dimensional affine subspace.

XX.4.2. Locally Convex Topological Vector Spaces

> "The theory of general topological vector spaces ... remains on the whole an unsatisfactory theory, devoid of a great number of valuable results both from pure and applied viewpoints. The concept of topological vector space ... is too general to support a rich theory just as, on the other hand, the concept of Banach space is too narrow. The notion on which a satisfactory and applicable theory can be built is that of local convexity ..."
>
> *H. Schaefer*[2]

As pointed out in [KN76], the main extra feature in topological vector spaces distinguishing them from general (abelian) topological groups is convexity. See XX.1.2.1..

XX.4.2.1. Definition. Let $(X, \mathcal{T})$ be a topological vector space. Then $(X, \mathcal{T})$ is *locally convex* if it is Hausdorff and there is a base for $\mathcal{T}$ consisting of convex sets.

XX.4.2.2. Some authors do not require a locally convex topological vector space to be Hausdorff, but it will be convenient for us to make this assumption to avoid verbosity, and since essentially all interesting topological vector spaces are Hausdorff. We call a locally convex TVS topology an *LCS topology*.

XX.4.2.3. Examples. (i) Any normed vector space is locally convex (balls are convex by the triangle inequality). In particular, the unique TVS topology on a finite-dimensional vector space is locally convex.

(ii) If X is a normed vector space and Y a total subspace of X^*, then the $\sigma(X, Y)$ topology () is an LCS topology on X.

(iii) The inductive limit topology on a directed inductive limit (XX.4.8.2.) of LCS topologies is LCS (if Hausdorff). In particular, the maximal TVS topology on a vector space is locally convex.

[2] [SW99, p. 36].

XX.4.2.4. PROPOSITION. Let $(X, \mathcal{T})$ be a Hausdorff topological vector space. The following are equivalent:

(i) $(X, \mathcal{T})$ is locally convex.

(ii) There is a local base at 0 consisting of convex sets.

(iii) There is a local base at 0 consisting of balanced convex open sets.

XX.4.2.5. The importance of local convexity is, in part, due to the fact that the following are equivalent:

(i) $(X, \mathcal{T})$ is locally convex.

(ii) The topology $\mathcal{T}$ is defined by a separating family of seminorms (XX.4.4.5.).

(iii) There are "sufficiently many" continuous linear functionals on X ().

In fact, a Hausdorff topological vector space which is not locally convex can fail to have any nonzero continuous linear functionals (XX.4.5.5.). Important theorems such as the Krein-Milman Theorem () can fail in Hausdorff topological vector spaces which are not locally convex.

XX.4.3. Paranorms and Fréchet Spaces

There is a useful extension of the notion of a norm:

XX.4.3.1. DEFINITION. Let X be a vector space over $\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$. A function $p : X \to [0, \infty)$ is a *paranorm* if it satisfies:

(i) $p(x) = 0$ if and only if $x = 0$.

(ii) $p(x + y) \leq p(x) + p(y)$ for all $x, y \in X$.

(iii) $p(-x) = p(x)$ for all $x \in X$.

(iv) Scalar multiplication in X is jointly continuous for the metric ρ defined by $\rho(x, y) = p(x - y)$.

The paranorm p is *balanced* if $p(\alpha x) \leq p(x)$ for all $x \in X$ and all $\alpha \in \mathbb{F}$, $|\alpha| \leq 1$. This implies that $p(\alpha x) \leq p(\beta x)$ for all $x \in X$ and all $\alpha, \beta \in \mathbb{F}$, $|\alpha| \leq |\beta|$ (see the proof of XX.4.3.5.). As with norms, we say a paranorm is *complete* if its corresponding metric is complete.

It follows from (iv) that X with the metric topology is a Hausdorff topological vector space (from (ii), addition is jointly continuous).

XX.4.3.2. A paranorm is really the same thing as a translation-invariant metric satisfying (iv): if p is a paranorm, then ρ defined by $\rho(x, y) = p(x - y)$ is a translation-invariant metric. Conversely, if ρ is a translation-invariant metric satisfying (iv), set $p(x) = \rho(x, 0)$; then p is a paranorm defining ρ. Thus, if $(X, \mathcal{T})$ is a topological vector space, then the topology $\mathcal{T}$ comes from a paranorm if and only if it is Hausdorff and first countable (XX.4.4.1.).

XX.4.3.3. The main difference between a paranorm and a norm is that it is not assumed that $p(\alpha x) = |\alpha| p(x)$ for $x \in X$, $\alpha \in \mathbb{F}$. In fact a norm is precisely a paranorm with this additional homogeneity property (from which (iv) is automatic for scalar multiplication, and which is automatically balanced).

It turns out that paranorms are more common than norms, and there are many important topological vector spaces whose topology is given by a paranorm but not a norm. **Caution:** because of the lack of homogeneity in general, a topological vector space whose topology is defined by a paranorm is not necessarily locally convex (XX.4.3.7.(iii)).

XX.4.3.4. A function satisfying (ii)–(iv), and

(i′) $p(0) = 0$.

is called an *indefinite paranorm* (we will avoid the terms *semiparanorm* or *paraseminorm*). A standard example is a seminorm.

Most natural paranorms are balanced, and any paranorm is equivalent to a balanced one (in the sense that the corresponding metrics are uniformly equivalent):

XX.4.3.5. Proposition. Let p be a paranorm on a vector space X. Then there is a balanced paranorm $\tilde{p}$ on X inducing the same topology as p.

Proof: Since $\mathbb{D} := \{\alpha \in \mathbb{F} : |\alpha| \leq 1\}$ is compact and p is continuous for the induced metric, for any $x \in X$ there is an M_x such that $p(\alpha x) \leq M_x$ for all $\alpha \in \mathbb{D}$. So we set

$$\tilde{p}(x) = \sup_{\alpha \in \mathbb{D}} p(\alpha x) \ .$$

It is easily checked that $\tilde{p}$ satisfies (i)–(iii), and clearly $\tilde{p}$ is balanced and $p(x) \leq \tilde{p}(x)$ for any $x \in X$.

We show that if (x_n) is a sequence in X and $p(x_n) \to 0$, then $\tilde{p}(x_n) \to 0$. Suppose not; passing to a subsequence, there is an $\epsilon > 0$ and, for each n, an $\alpha_n \in \mathbb{D}$, with $p(\alpha_n x_n) \geq \epsilon$. Passing to a further subsequence, we may assume $\alpha_n \to \alpha$ for some $\alpha \in \mathbb{D}$; then $p(\alpha_n x_n) \to \alpha \cdot 0 = 0$ by joint continuity of scalar multiplication for p, a contradiction.

If $|\alpha| \leq |\beta|$, $\beta \neq 0$, and $x \in X$, then

$$\tilde{p}(\alpha x) = \sup_{|\gamma| \leq 1} p(\gamma \cdot \alpha x) = \sup_{|\gamma| \leq |\frac{\alpha}{\beta}|} p\left(\gamma \cdot \beta x\right) \leq \sup_{|\gamma| \leq 1} p\left(\gamma \cdot \beta x\right) = \tilde{p}(\beta x) \ .$$

It remains to note that scalar multiplication is jointly continuous for $\tilde{p}$. It suffices to show that if $\alpha_n \to \alpha$ and $x_n \to 0$, then $p(\alpha_n x_n) \to 0$. For any $m \in \mathbb{N}$ and $x \in X$, we have $p(x) \leq m p\left(\frac{x}{m}\right)$ by the triangle inequality. Choose m so that $m \geq |\alpha_n|$ for all n. Then we have

$$\tilde{p}(\alpha_n x_n) = \sup_{|\gamma| \leq 1} p(\gamma \alpha_n x_n) \leq m \sup_{|\gamma| \leq 1} p\left(\gamma \frac{\alpha_n}{m} x_n\right) \leq m \tilde{p}(x_n) \to 0 \ .$$

XX.4.3.6. From now on, for economy of exposition we will take "paranorm" to mean "balanced paranorm" unless specifically stated otherwise. Many of the results also apply to unbalanced paranorms (which rarely arise in practice); the interested reader can work out the details.

XX.4.3.7. EXAMPLES. (i) Any norm is a paranorm. Any positive multiple of a paranorm is a paranorm. Any (finite) sum of paranorms is a paranorm.

(ii) If p is a paranorm, so is $\sqrt{p}$ (or p^α for $0 < \alpha < 1$), defining the same topology as p. If p is a norm, then p^α $(0 < \alpha < 1)$ is not a norm.

(iii) Similarly, if $0 < q < 1$, the vector space ℓ^q of q'th power summable sequences has a paranorm

$$p((x_k)) = \sum_{k=1}^{\infty} |x_k|^q \ .$$

The corresponding TVS topology on ℓ^q is not locally convex. More generally, if $(X, \mathcal{A}, \mu)$ is a measure space, then $L^q(X, \mathcal{A}, \mu)$ $(0 < q < 1)$ has a paranorm

$$p(f) = \int_X |f(x)|^q \, d\mu(x) \ .$$

The corresponding TVS topology on $L^q(X, \mathcal{A}, \mu)$ is rarely locally convex.

(iv) Here is a crucial construction which can be done with paranorms but not norms. Let p be a paranorm on X, and $\lambda > 0$. For $x \in X$ set

$$\tilde{p}_\lambda(x) = \min(p(x), \lambda)$$

$$\bar{p}(x) = \frac{p(x)}{1 + p(x)}$$

(cf. ()). Then p_λ and $\bar{p}$ are paranorms on X defining the same topology as p. These paranorms are bounded, hence can never be norms. These constructions can also be done with indefinite paranorms.

Here is an important construction which follows from (iv). The proof is essentially the same as the proof of ().

XX.4.3.8. PROPOSITION. Let (p_k) be a sequence of paranorms on a vector space X, and for $x \in X$ set

$$p(x) = \sum_{k=1}^{\infty} 2^{-k} \bar{p}_k(x) \ .$$

Then p is a paranorm on X. The p-topology is the weakest topology stronger than the p_k-topology for all k, i.e. $x_n \to x$ in the p-topology if and only if $x_n \to x$ in the p_k-topology for all k.

XX.4.3.9. Instead of $\sum_k 2^{-k} \bar{p}_k(x)$, we could have used $\sum_k 2^{-k} (\widetilde{p_k})_1$ or $\sum_k (\widetilde{p_k})_{2^{-k}}$, which are also paranorms giving the same topology. More generally, instead of paranorms we could use a separating sequence of indefinite paranorms, e.g. a separating sequence of seminorms.

Completion

XX.4.3.10. If p is a paranorm on a vector space X, then the completion $\bar{X}$ of X with respect to the corresponding metric has a natural structure as a vector space, and p extends naturally to a function $\bar{p}$ on $\bar{X}$. It is routine to show that the completion with respect to the metric is the same (isomorphic to) the completion as a topological vector space (), and hence (using ()) that $\bar{p}$ is a paranorm on $\bar{X}$ giving its topology (only joint continuity of multiplication is an issue; a direct proof is somewhat simpler than the general proof of ()).

F-Spaces and Fréchet Spaces

XX.4.3.11. Definition. An *F-space* is a topological vector space whose topology is given by a complete paranorm.

A *Fréchet space* is a locally convex F-space.

XX.4.3.12. **Caution:** Terminology in this subject is not standardized. Some references use the terms F-space and Fréchet space interchangeably, with or without the locally convex requirement. It is also not standard whether the paranorm is part of the definition of an F-space or Fréchet space (i.e. there are "isometric" and "isomorphic" theories). Even the term *paranorm* is not entirely standard. Check the definitions in any reference.

XX.4.3.13. Examples. (i) Any Banach space is a Fréchet space (more precisely, the underlying topological vector space of a Banach space is a Fréchet space).

(ii) If $0 < q < 1$, ℓ^q (XX.4.3.7.(iii)) is an F-space which is not a Fréchet space.

(iii) A Hausdorff topological vector space is an F-space if and only if it is complete and first countable (). It is a Fréchet space if and only if it is complete, first countable, and locally convex. Thus the completion of any first countable Hausdorff topological vector space is an F-space, and the completion of any Hausdorff first countable locally convex topological vector space is a Fréchet space.

There are many Fréchet spaces whose topology does not come from a norm, so Fréchet spaces are considerably more general than Banach spaces.

XX.4.3.14. Remark. We can relax the definition of paranorm. Say a function p on a vector space X is a *weak paranorm* (nonstandard term) if it satisfies XX.4.3.1.(i)–(iii) and

(iv′) Scalar multiplication is separately continuous for the corresponding metric.

It turns out that a complete weak paranorm is automatically a paranorm (Exercise XX.4.8.3.). However, completeness seems to be necessary: it is unclear whether XX.4.3.10. holds for a weak paranorm (the issue is whether the scalar multiplication is separately continuous in the completion). The notion of weak paranorm has limited application in practice. See [DS88].

XX.4.3.15. Here is an important standard construction of Fréchet spaces. Let X be a vector space, and (p_k) an increasing sequence of paranorms on X. Let X_1 be the completion of X with respect to p_1. Since the p_k are stronger than p_1, the completion X_k of X with respect to p_k can be identified with a subspace of X_1. The X_k form a decreasing sequence of subspaces of X_1, and $X \subseteq \cap_k X_k$. Form the paranorm p on X from the p_k as in XX.4.3.7.(iv). Then the completion $\bar{X}$ of X is naturally a subspace of X_1.

XX.4.3.16. Proposition. We have $\bar{X} = \cap_k X_k$, and $\bar{X}$ is an F-space. If all the X_k are Fréchet spaces (e.g. if the p_k are norms), then $\bar{X}$ is a Fréchet space. In particular, if $X = \cap X_k$, then X is an F-space from p.

Proof: We have $\bar{X} \subseteq \cap_k X_k$. Conversely, if $x \in \cap_k X_k$, then for each k there is a sequence x_{kn} in X with $p_k(x_{kn} - x) < 2^{-n}$. The diagonal subsequence (x_{kk}) is a p-Cauchy sequence which converges to x, so $x \in \bar{X}$. 👍

XX.4.3.17. Example. Let $[a, b]$ be an interval in $\mathbb{R}$, and let $X = \mathcal{C}^\infty([a, b])$. For $f \in X$, let

$$p_k(f) = \max_{0 \le r \le k} \max_{x \in [a,b]} |f^{(r)}(x)| \ .$$

Then $X_k = \mathcal{C}^k([a, b])$, and $X = \cap_k X_k$. Each p_k is a norm, and X_k is a Banach space; so X is a Fréchet space. We have that $f_n \to f$ in $\mathcal{C}^\infty([a, b])$ if and only if $f_n^{(r)} \to f^{(r)}$ uniformly on $[a, b]$ for each $r \ge 0$. This is the standard topology on $\mathcal{C}^\infty([a, b])$. This topology is also the topology determined by the seminorms $s_k(f) = \|f^{(k)}\|_\infty$, or the paranorm constructed from these. It turns out that this topology does not come from a norm (XX.4.4.14.).

XX.4.3.18. A somewhat similar construction is also common. Let X be a vector space, and (p_k) a sequence of indefinite paranorms (e.g. seminorms) on X which is separating, i.e. $p_k(x) = 0$ for all k implies $x = 0$. Replacing p_k by the supremum or sum of the first k, we may assume the p_k are increasing. Let $Y_k = \{x \in X : p_k(x) = 0\}$. Then Y_k is a subspace of X, and p_k drops to a paranorm $\bar{p}_k$ on X/Y_k. The Y_k are decreasing, and the quotient map π_k from X/Y_j to X/Y_k is continuous (for the induced topologies) for $j > k$. The p_k define a paranorm p on X by XX.4.3.7.(iv).

XX.4.3.19. Proposition. Using the above notation, suppose

(a) X/Y_k is $\bar{p}_k$-complete for each k.

(b) If $(x^{(k)})$ is a coherent sequence, i.e. $x^{(k)} \in X/Y_k$ and $x^{(k)} = \pi_k(x^{(j)})$ for all $j > k$, there is a (necessarily unique) $x \in X$ with $x^{(k)} = \pi_k(x)$ for all k (in other words, $X = \lim_{\leftarrow} X/Y_k$ ()).

Then X is complete under p, i.e. X is an F-space. If the p_k are seminorms, X is a Fréchet space. A sequence (x_n) is X is p-Cauchy if and only if $(\pi_k(x_n))$ is a $\bar{p}_k$-Cauchy sequence in X/Y_k for all k.

Proof: Let (x_n) be a p-Cauchy sequence in X. Set $x_n^{(k)} = \pi_k(x_n)$ for all n and k. Then $(x_n^{(k)})$ is a $\bar{p}_k$-Cauchy sequence in X/Y_k, hence converges to some $x^{(k)} \in X/Y_k$. Since the quotient maps are continuous, the $x^{(k)}$ form a coherent sequence, so there is a (unique) $x \in X$ with $\pi(x) = x^{(k)}$ for all k; and $x_n \to x$. 👍

XX.4.3.20. Condition (b) is not automatic, even if condition (a) holds: for example, let $X = C([0,1])$, and (t_k) a dense sequence in $[0,1]$. Set $Y_k = \{f \in X : f(t_j) = 0 \text{ for } 1 \le j \le k\}$ and $p_k(f) = \max\{|f(t_1)|, \dots, |f(t_k)|\}$. Any function from the t_k to $\mathbb{F}$ gives a coherent sequence, but most such functions do not extend to a continuous function on $[0,1]$. The p-topology on X is the topology of pointwise convergence on the t_k.

XX.4.3.21. EXAMPLE. Let s be the vector space of all sequences in $\mathbb{F}$, i.e. $s = \mathbb{F}^{\mathbb{N}}$. The sequence (p_k) of seminorms defined by $p_k((x_n)) = |x_k|$ defines a paranorm p on s as in XX.4.3.7.(iv). It is easily checked directly that s is complete with respect to p (a sequence in s is p-Cauchy if and only if the sequence of k'th terms is Cauchy for each k), so is a Fréchet space. The topology on s is the topology of coordinatewise convergence (the product topology on $\mathbb{F}^{\mathbb{N}}$). We could replace $\mathbb{F}$ here by any Banach space (or, more generally, any Fréchet spaces X_k, which could vary from coordinate to coordinate, i.e. a countable product of Fréchet spaces is a Fréchet space with the product topology).

XX.4.3.22. EXAMPLE. Let Z be a locally compact, σ-compact Hausdorff space, e.g. $Z = \mathbb{R}^n$. Let (U_k) be an increasing sequence of open sets in Z with compact closure E_k, with $Z = \cup_k U_k$. On the vector space $X = C(Z)$ of all continuous functions from Z to $\mathbb{F}$, set

$$p_k(f) = \max_{x \in E_k} |f(x)| \ .$$

Then $Y_k = \{f \in C(Z) : f = 0 \text{ on } E_k\}$. We have $\cap_k Y_k = \{0\}$ and $X/Y_k \cong C(E_k)$, and $\bar{p}_k = \| \cdot \|_\infty$; thus X/Y_k is a Banach space. If $(f^{(k)})$ is a coherent sequence, i.e. $f^{(k)}$ is a continuous function on E_k which is the restriction of a continuous function on E_j for $j > k$, there is a continuous function f on Z whose restriction to E_k is $f^{(k)}$ for all k. Thus the hypotheses of XX.4.3.19. are satisfied, so $C(Z)$ with the p-paranorm is a Fréchet space. The topology on $C(Z)$ is the topology of u.c. convergence.

The two constructions can be combined:

XX.4.3.23. EXAMPLE. Let $X = \mathcal{C}^\infty(\mathbb{R}^m)$ for some m. For each k let

$$p_k(f) = \max_{0 \le |\alpha| \le k} \max_{\|\boldsymbol{x}\| \le k} |f^{(\alpha)}(\boldsymbol{x})| \ .$$

Then (p_k) is an increasing sequence of seminorms on X which is separating. If p is the induced paranorm on X, a p-Cauchy sequence (f_n) gives a $\bar{p}_k$-Cauchy sequence in $\mathcal{C}^k(B_k)$ for each k, where B_k is the closed ball of radius k in $\mathbb{R}^m$, which converges to some f^k, and the f^k form a coherent sequence. There is a unique $f \in X$ which restricts to f^k for each k, and $f_n \to f$. Thus X is p-complete, hence a Fréchet space. A sequence (f_n) in $\mathcal{C}^\infty(\mathbb{R}^m)$ converges to f in this topology if and only if $(f_n^{(\alpha)})$ converges to $f^{(\alpha)}$ u.c. for all α.

Many similar examples and constructions are possible.

XX.4.4. Metrizability and Normability

In this section, we describe the conditions under which a topological vector space is metrizable and/or normable.

Metrizability

The next theorem is a special case of (), but we give a proof here to keep this section independent of ().

XX.4.4.1. THEOREM. A topological vector space which is Hausdorff and first countable has a paranorm (equivalently, an invariant metric) inducing its topology and uniform structure.

We will give an alternate proof in the locally convex case in XX.4.4.6..

Minkowski Functionals

In the locally convex case, the key tool for further analysis is Minkowski functionals ().

The next result is an immediate corollary of XX.1.4.2.:

XX.4.4.2. COROLLARY. Let X be a vector space, and $A \subseteq X$ be radial, balanced, and convex. Then the Minkowski functional m_A is a seminorm on X.

In general, under the hypotheses m_A is only a seminorm.

EXAMPLE. Let X be a normed vector space, and A the unit ball of X (open or closed). Then $m_A(x) = \|x\|$ for all $x \in X$. More generally, if A is the ball of radius r, then $m_A(x) = \frac{1}{r}\|x\|$.

XX.4.4.3. If A is radial, balanced, and convex, we have

$$\{x \in X : m_A(x) < 1\} \subseteq A \subseteq \{x \in X : m_A(x) \leq 1\}$$

but this is the best that can be said in general: if X is a topological vector space, we have $m_A = m_{\bar{A}}$, and if A has nonempty interior (which is not automatic), then $m_A = m_{A^\circ}$. (And note that the definition of Minkowski functional applies in any vector space X and does not presuppose a topology on X.)

XX.4.4.4. PROPOSITION. Let $(X, \mathcal{T})$ be a topological vector space, and A a radial, balanced, convex subset of X. Then the following are equivalent:

(i) $m_A : X \to [0, \infty)$ is $\mathcal{T}$-continuous at 0.

(ii) m_A is $\mathcal{T}$-uniformly continuous.

(iii) A is a $\mathcal{T}$-neighborhood of 0 in X.

(iv) $U_A := \{x \in X : m_A(x) < 1\}$ is a $\mathcal{T}$-neighborhood of 0 in X.

(v) $E_A := \{x \in X : m_A(x) \leq 1\}$ is a $\mathcal{T}$-neighborhood of 0 in X.

PROOF: (ii) ⇒ (iv) since $U_A = m_A^{-1}([0,1))$, which is open in $[0,\infty)$. (iv) ⇒ (iii) ⇒ (v) by the previous remark.

(i) ⇒ (ii): If m_A is continuous at 0, then for any $\epsilon > 0$ there is a $\mathcal{T}$-neighborhood V of 0 such that $m_A(x) < \epsilon$ for all $x \in V$. Then, for any $x, y \in X$, $m_A(x-y) < \epsilon$ whenever $x - y \in V$, so m_A is uniformly continuous.

(v) ⇒ (i): If m_A is not continuous at 0, there is a net (x_i) $\mathcal{T}$-converging to 0 such that $m_A(x_i) \not\to 0$. Passing to a subnet, there is an $\epsilon > 0$ such that $m_A(x_i) > \epsilon$ for all i. Then $\frac{1}{\epsilon}x_i \to 0$, but $m_A\left(\frac{1}{\epsilon}x_i\right) > 1$ for all i, so no x_i is in E_A. Thus E_A is not a $\mathcal{T}$-neighborhood of 0. 👍

XX.4.4.5. THEOREM. Let $(X, \mathcal{T})$ be a (Hausdorff) topological vector space. Then the topology $\mathcal{T}$ is determined by a (separating) family of seminorms if and only if X is locally convex. The topology $\mathcal{T}$ is determined by a countable (separating) family of seminorms if and only if X is locally convex and first countable.

PROOF: If $\mathcal{T}$ is determined by a family (s_i) of seminorms, then finite intersections of sets of the form $\{x \in X : s_i(x) < \epsilon\}$ form a local base for $\mathcal{T}$ at 0 of convex sets, so $(X, \mathcal{T})$ is locally convex.

Conversely, suppose X is locally convex, and let $\mathcal{F}$ be a fundamental system of neighborhoods of 0 consisting of convex sets (). For each $V \in \mathcal{F}$ let m_V be the corresponding Minkowski functional. Then the m_V are seminorms on X, and we claim $\mathcal{T}$ is the topology determined by $\{m_V : V \in \mathcal{F}\}$. Each m_V is $\mathcal{T}$-continuous, so if $x_i \to 0$, then $m_V(x_i) \to 0$. On the other hand, suppose (x_i) is a net in X and $m_V(x_i) \to 0$ for all $V \in \mathcal{F}$. Let U be a $\mathcal{T}$-neighborhood of 0. There is a $V \in \mathcal{F}$ with $V \subseteq U$. There is an i_0 such that $m_V(x_i) < 1$ for all $i > i_0$, hence $x_i \in V \subseteq U$ for $i > i_0$; thus $x_i \to 0$ in $(X, \mathcal{T})$.

If $(X, \mathcal{T})$ is Hausdorff, for each $x \in X$, $x \neq 0$, there is a $V \in \mathcal{F}$ with $x \notin V$, so $m_V(x) \geq 1$ and $m_V(x) \neq 0$. Thus the m_V are a separating family of seminorms on X.

If X is first countable, we may take $\mathcal{F}$ to be countable. Conversely, if $\mathcal{T}$ is determined by a countable family (s_k) of seminorms, finite intersections of sets of the form $U_{k,n} = \left\{x \in X : s_k(x) < \frac{1}{n}\right\}$ form a countable local base for $\mathcal{T}$ at 0. 👍

XX.4.4.6. Since a separating sequence of seminorms can be combined into a single paranorm by XX.4.3.8., we obtain another proof of XX.4.4.1. in the locally convex case (and even a somewhat better result).

Bounded Sets

XX.4.4.7. DEFINITION. Let X be a topological vector space. A subset A of X is *bounded* ($\mathcal{T}$-bounded) if every $\mathcal{T}$-neighborhood of 0 absorbs A, i.e. for every $\mathcal{T}$-neighborhood U of 0 there is a λ with $A \subseteq \lambda U$, i.e. $\epsilon A \subseteq U$ for some $\epsilon > 0$.

Clearly, to check that A is bounded it suffices to let U run over a base for the topology. Any subset of a bounded set is bounded.

XX.4.4.8. EXAMPLES. (i) Let $(X, \|\cdot\|)$ be a normed vector space. Then, since the balls B_r around 0 are a base for the topology, and $B_r = rB_1$ for any $r > 0$, the following are equivalent for a subset A of X:

(a) A is bounded (in the sense of XX.4.4.7.).

(b) B_r absorbs A for every $r > 0$.

(c) B_1 absorbs A.

(d) A is bounded in the norm sense, i.e. there is an M such that $\|x\| \leq M$ for all $x \in A$.

(ii) Similarly, let $0 < q < 1$ and $X = \ell^q$, with topology from the paranorm p of XX.4.3.7.(iii). Let $B_r = \{x \in X : p(x) < r\}$. Then the B_r form a base for the topology, and $B_r = r^{1/q}B_1$ for any r. Then a subset A of X is bounded if and only if it is contained in B_r for some r. In particular, the B_r are bounded.

XX.4.4.9. PROPOSITION. Let $(X, \mathcal{T})$ be a topological vector space, and s a $\mathcal{T}$-continuous seminorm on X. If A is a bounded subset of X, then $s(A)$ is a bounded subset of $[0, \infty)$, i.e. s is bounded on A.

PROOF: $\{x \in X : s(x) < 1\}$ is a $\mathcal{T}$-neighborhood of 0 in X, so absorbs A. 👍

There is a simple criterion for normability of a topological vector space:

XX.4.4.10. THEOREM. A topological vector space is normable if and only if it is Hausdorff and has a bounded convex neighborhood of 0.

PROOF: If X is a normable topological vector space, then X is Hausdorff and the open unit ball is a bounded convex neighborhood of 0.

Conversely, suppose X is Hausdorff and U is a bounded convex neighborhood of 0. There is a balanced neighborhood V of 0 contained in U, and the convex hull W of V is a balanced convex neighborhood of 0 contained in U since U is convex. Then the sets $\left\{\frac{1}{n}W : n \in \mathbb{N}\right\}$ form a base for the topology of X since W is bounded. If $x \in X$, $x \neq 0$, there is a neighborhood Z of 0 not containing x, and Z absorbs W, so there is an $\epsilon > 0$ with $x \notin \epsilon W$, i.e. $m_W(x) \geq \epsilon$. It follows that the seminorm m_W is a norm. If $W_n = \frac{1}{n}W$, then the m_{W_n} define the topology of X. But m_{W_n} is just nm_W, so the norm m_W determines the topology of X. 👍

XX.4.4.11. Note that convexity of the bounded neighborhood cannot be eliminated: ℓ^q $(0 < q < 1)$ is Hausdorff and has a neighborhood base of bounded open sets, but is not normable since it is not locally convex.

XX.4.4.12. It follows from (the easy direction of) XX.4.4.10. that if X is a normable topological vector space and $\mathcal{B}$ is a local base for the topology at 0, then $\mathcal{B}$ contains a bounded neighborhood. (**Caution:** this only applies to a *base*, not a subbase.) ✋

Nonnormability

We can then get a criterion which shows that many natural topological vector spaces are not normable:

XX.4.4.13. PROPOSITION. Let $(X, \mathcal{T})$ be a topological vector space, and (s_k) an increasing sequence of seminorms defining $\mathcal{T}$. Set $U_k = \{x \in X : s_k(x) < 1\}$. If for every k there is an $n > k$ such that s_n is unbounded on U_k, then $(X, \mathcal{T})$ is not normable. [If $\mathcal{T}$ is not defined by a sequence of seminorms, then $(X, \mathcal{T})$ is trivially not normable; if it is defined by a sequence of seminorms, we may assume the s_k are increasing by replacing s_k by the supremum or sum of the first k for each k.]

PROOF: The sets ϵU_k for $\epsilon > 0$ and $k \in \mathbb{N}$ form a local base for $\mathcal{T}$ at 0 since the s_k are increasing. If $(X, \mathcal{T})$ is normable, one of these is bounded, so for some ϵ and k, s_n is bounded on ϵU_k for all n by XX.4.4.9.. 👍

XX.4.4.14. EXAMPLE. Let $X = \mathcal{C}^\infty([a, b])$, with the seminorms (actually norms) p_k of XX.4.3.17.. For each k, it is easy to construct an $f \in \mathcal{C}^\infty([a, b])$ with $|f^{(r)}(x)| < 1$ for $0 \leq r \leq k$ and all $x \in [a, b]$, and $\max_{x \in [a,b]} |f^{(k+1)}(x)|$ arbitrarily large. Thus p_{k+1} is not bounded on $U_k = \{x \in X : p_k(x) < 1\}$ for any k, and therefore $\mathcal{C}^\infty([a, b])$ is not normable.

XX.4.4.15. Similarly, the examples from XX.4.3.21. (if all the X_k are nonzero), XX.4.3.22., and XX.4.3.23. are not normable.

XX.4.5. Continuous Linear Functionals and the Dual Space

In keeping with the basic philosophy of functional analysis, we want to describe and analyze topological vector spaces by means of their continuous linear functionals. This can be done satisfactorily in the (Hausdorff) locally convex case (and only in this case).

We will need to use the AC, or at least the Hahn-Banach Theorem, in this section. In fact, without the AC even the algebraic dual of a vector space can be $\{0\}$ ().

XX.4.5.1. DEFINITION. Let $(X, \mathcal{T})$ be a topological vector space. The *(topological) dual space* X^* of X is the set of all continuous linear functionals on X.

XX.4.5.2. The space X^* is a subspace of the algebraic dual X^d (). It is typically much smaller, but in good cases is large enough to reflect the TVS structure of X.

XX.4.5.3. EXAMPLES. (i) If X is a normed vector space, then X^* is the set of bounded linear functionals $\mathcal{B}(X, \mathbb{F})$ (). (So the notation is consistent.)

(ii) If $\mathcal{T}$ is the largest TVS topology on a vector space X (), then every linear functional on X is continuous. So $X^* = X^d$.

(iii) Let X be a vector space with the indiscrete topology. Then $X^* = \{0\}$.

XX.4.5.4. Because of XX.4.5.3.(iii), the theory of dual spaces is only good in the Hausdorff case. Thus for the rest of this section we will assume all topological vector spaces are Hausdorff.

The dual space can be degenerate even in the Hausdorff case:

XX.4.5.5. EXAMPLE. Fix q, $0 < q < 1$, and let $X = L^q([0,1])$. Then X is an F-space, and in particular Hausdorff. ($L^q([0,1])$ is not locally convex; in fact, see XX.4.5.10.).

We have that $L^1([0,1]) \subseteq L^q([0,1])$, and the 1-topology on $L^1([0,1])$ is stronger than the q-topology. Thus the restriction to $L^1([0,1])$ of any linear functional ϕ on $L^q([0,1])$ which is q-continuous is 1-continuous, hence is given by integration against an L^∞ function g, i.e.

$$\phi(f) = \int_0^1 fg\, d\lambda$$

for $f \in L^1([0,1])$ by the Riesz Representation Theorem ().

If p is the paranorm defining the topology of $L^q([0,1])$ (), and for $r > 0$

$$B_r^p = \{f \in L^q([0,1]) : p(f) \leq r\} = \left\{f \in L^q([0,1]) : \int_0^1 |f|^q\, d\lambda \leq r\right\}$$

is the closed ball of radius r around 0, we have that the B_r^p form a local base for the q-topology at 0, and $B_r^p = r^q B_1^p$ for any $r > 0$. It follows that if ϕ is a q-continuous linear functional on $L^q([0,1])$, then ϕ must be bounded on each B_r^p, and in particular on B_1^p.

Now suppose ϕ is a nonzero q-continuous linear functional on $L^q([0,1])$, and let g be the corresponding L^∞ function for the restriction of ϕ to $L^1([0,1])$. Then there is an $\epsilon > 0$ such that $A = \{t \in [0,1] : |g(t)| \geq \epsilon\}$ has $\lambda(A) > 0$. Let (A_n) be a sequence of measurable subsets of A with $\lambda(A_n) > 0$ for all n and $\lambda(A_n) \to 0$. Set

$$f_n = \frac{|g|}{g}[\lambda(A_n)]^{-1/q}\chi_{A_n} \in L^1([0,1]) \subseteq L^q([0,1])$$

for each n (this is well defined since $g \neq 0$ on A_n). Then

$$p(f_n) = \int_0^1 |f_n|^q\, d\lambda = \int_{A_n} [\lambda(A_n)]^{-1}\, d\lambda = 1$$

for all n. But

$$|\phi(f_n)| = \left|\int_0^1 g\frac{|g|}{g}[\lambda(A_n)]^{-1/q}\chi_{A_n}\, d\lambda\right| = \int_0^1 |g|[\lambda(A_n)]^{-1/q}\chi_{A_n}\, d\lambda \geq \epsilon[\lambda(A_n)]^{1-1/q} \to \infty$$

which is a contradiction.

Thus $L^q([0,1])$ has no nonzero q-continuous linear functionals. This argument works more generally in any (nonzero) finite, or even semifinite, measure space with no atoms, i.e. where every measurable set of positive measure contains measurable subsets of arbitrarily small (finite) positive measure. (Conversely, if $(X, \mathcal{A}, \mu)$ has an atom A, then $L^q(X, \mathcal{A}, \mu)$ has a one-dimensional topological direct summand spanned by χ_A and hence a nonzero continuous linear functional.)

However, a topological vector space which is not locally convex can have a lot of continuous linear functionals (although not "enough" – see ()):

XX.4.5.6. Example. Fix q, $0 < q < 1$, and let $X = \ell^q$. Then X is an F-space, and in particular Hausdorff. (ℓ^q is not locally convex; cf. ().)

We have $\ell^q \subseteq \ell^1$, and the q-topology is stronger than the 1-topology. Thus any 1-continuous linear functional is q-continuous. There are a lot of 1-continuous linear functionals, one for each sequence $(y_n) \in \ell^\infty$, given by

$$\phi((x_n)) = \sum_{n=1}^{\infty} x_n y_n \ .$$

In particular, the q-continuous linear functionals on ℓ^q separate points (and even more).

Actually, these are all the q-continuous linear functionals on ℓ^q. The linear combinations of the standard basis vectors $\boldsymbol{e}_n$ are dense in ℓ^q, so any q-continuous linear functional ϕ is determined by the sequence $(\phi(\boldsymbol{e}_n))$. But as in XX.4.5.5., every q-continuous linear functional is bounded on

$$B_1^p = \left\{ (x_n) \in \ell^q : \sum_{n=1}^{\infty} |x_n|^q \leq 1 \right\}$$

and $\boldsymbol{e}_n \in B_1^p$ for all n, so the sequence $(\phi(\boldsymbol{e}_n))$ is bounded, i.e. ϕ is 1-continuous, not just q-continuous. Thus there are not enough q-continuous linear functionals on ℓ^q to distinguish the q-topology from the 1-topology.

The main result of this section is:

XX.4.5.7. Theorem. [Geometrical Hahn-Banach Theorem] Let X be a topological vector space over $\mathbb{F}$, and A and B disjoint nonempty convex sets in X. If one of A, B has nonempty interior, then there is a nonzero continuous linear functional ϕ on X separating A and B. Equivalently in the real case, there is a closed hyperplane in X separating A and B.

Proof: Since an interior point is an internal point (), the theorem follows immediately from XX.6.4.6., or XX.6.4.9. in the complex case, and the following result. 👍

XX.4.5.8. Proposition. Let X be a topological vector space, and ϕ a linear functional on X. If $Re(\phi)$ is bounded above or below on a neighborhood of 0, then ϕ is continuous.

Proof: Let $Re(\phi)$ be bounded above on a neighborhood U of 0, i.e. there is a $c > 0$ such that $Re(\phi(x)) \leq c$ for all $c \in U$ (if $Re(\phi)$) is bounded below, replace ϕ by $-\phi$). There is a balanced neighborhood V of 0 contained in U. If $x \in V$, there is an $\alpha \in \mathbb{F}$, $|\alpha| = 1$, with $\phi(\alpha x) \geq 0$. Then $\alpha x \in V \subseteq U$, so

$$|\phi(x)| = |\alpha||\phi(x)| = |\phi(\alpha x)| = Re(\phi(\alpha x)) \leq c \ .$$

If $\epsilon > 0$, set $\beta = \frac{\epsilon}{c}$. Then βV is a neighborhood of 0 and if $x \in \beta V$, $|\phi(x)| \leq \epsilon$. 👍

XX.4.5.9. Corollary. Let X be a locally convex topological vector space over $\mathbb{R}$. Then the continuous linear functionals on X separate points of X, i.e. if $x, y \in X$, $x \neq y$, there is a continuous linear functional ϕ on X with $\phi(x) \neq \phi(y)$.

XX.4.5.10. Example. This is a continuation of (). The F-space $L^q([0,1])$ is not locally convex. In fact, if U is any neighborhood of 0, set $C = \overline{co}(U)$. If $C \neq X$ and $x \in X \setminus C$, then there is a nonzero continuous linear functional ϕ with $\phi(x) \geq \sup_{y \in C} \phi(y)$, a contradiction. Thus $C = X$, i.e. $co(U)$ is dense in X.

The next result is sometimes called *Mazur's Theorem*. It has a direct proof using Zorn's Lemma (consider a maximal subspace containing Y disjoint from C; cf. e.g. [SW99, II.3.1]), and can be used to prove the standard form of the Hahn-Banach Theorem XX.6.2.1. (Exercise ()).

XX.4.5.11. Corollary. Let X be a topological vector space over $\mathbb{R}$, Y an affine subspace, and C a nonempty convex open set in X disjoint from Y. Then there is a closed hyperplane H in X containing Y and disjoint from C.

Proof: There is a nonzero continuous linear functional ϕ separating Y and C. Then ϕ is bounded on Y. But a linear functional bounded on an affine subspace is constant on that subspace, i.e. ϕ is identically c on Y for some C. Set $H = \{x \in X : \phi(x) = c\}$. Since ϕ is not constant, $\phi(C)$ is open in $\mathbb{R}$, and contained in $[c, \infty)$, so is contained in (c, ∞) and C is disjoint from H. 👍

There is another separation theorem in the locally convex case, with compact subsets:

XX.4.5.12. Theorem. Let X be a locally convex topological vector space, and A and B disjoint nonempty closed convex subsets. If at least one of A, B is compact, then A and B are strictly separated.

Proof: Strictly separating A and B is the same as strictly separating 0 and $C = A - B$. C is closed by XXIII.1.2.20., and convex, and $0 \notin C$. Thus $X \setminus C$ is a neighborhood of 0. There is a balanced convex neighborhood V of 0 contained in $X \setminus C$ since X is locally convex, and there is a nonzero continuous linear functional ϕ with $\sup_{x \in V} Re(\phi(x)) \leq \inf_{y \in C} Re(\phi(y))$ by XX.4.5.7.. Then ϕ is not identically 0 on V, so since V is balanced there is an $z \in V$ with $\phi(z) > 0$. Then

$$\phi(0) = 0 < \phi(z) \leq \sup_{x \in V} Re(\phi(x)) \leq \inf_{y \in C} Re(\phi(y)) \ .$$

👍

XX.4.6. Duality and the Weak and Weak-* Topologies

We can define the weak topology on any topological vector space and the weak-* topology on its dual in a manner identical to the normed case. These topologies have reasonable properties only in the locally convex case.

The Weak Topology

XX.4.6.1. Let $(X, \mathcal{T})$ be a topological vector space, and X^* its topological dual. We define the *weak topology* $\mathcal{T}_w$ on X to be the topology of pointwise convergence for X^*, i.e. $x_i \to x$ if and only if $\phi(x_i) \to \phi(x)$ for all $\phi \in X^*$. The sets

$$U_{\{\phi_1,\ldots,\phi_n\},\epsilon} = \{x \in X : |\phi_k(x)| < \epsilon \text{ for } 1 \leq k \leq n\}$$

form a fundamental system of neighborhoods of 0 for $\mathcal{T}_w$.

XX.4.6.2. The weak topology $\mathcal{T}_w$ is clearly weaker than $\mathcal{T}$. If $\mathcal{T}$ is an LCS topology, so is $\mathcal{T}_w$. If $\mathcal{T}$ is normable, then $\mathcal{T}_w$ is the weak topology defined in ().

XX.4.6.3. Proposition. Let $(X, \mathcal{T})$ be a topological vector space. Then a linear functional is $\mathcal{T}_w$-continuous if and only if it is $\mathcal{T}$-continuous, i.e. the dual space $(X, \mathcal{T}_w)^*$ is the same as $X^* = (X, \mathcal{T})^*$ (as a subset of X^d).

This result is a special case of XX.4.6.11..

The Weak-* Topology

XX.4.6.4. Let $(X, \mathcal{T})$ be a topological vector space, and X^* its topological dual. We define the *weak-* topology* $\mathcal{T}_{w*}$ on X^* to be the topology of pointwise convergence for X, i.e. $\phi_i \to \phi$ if and only if $\phi_i(x) \to \phi(x)$ for all $x \in X$. The sets

$$U_{\{x_1,\ldots,x_n\},\epsilon} = \{\phi \in X^* : |\phi(x_k)| < \epsilon \text{ for } 1 \leq k \leq n\}$$

form a fundamental system of neighborhoods of 0 for $\mathcal{T}_{w*}$.

XX.4.6.5. If $\mathcal{T}$ is an LCS topology, so is $\mathcal{T}_{w*}$. If $\mathcal{T}$ is normable, then $\mathcal{T}_{w*}$ is the weak-* topology defined in (). (In the general case, this is the first topology we have defined on X^*.)

XX.4.6.6. Proposition. Let $(X, \mathcal{T})$ be a topological vector space. Then a linear functional on X^* is $\mathcal{T}_{w*}$-continuous if and only if it is of the form $\hat{x}$ for $x \in X$, where $\hat{x}(\phi) = \phi(x)$, i.e. the dual space $(X^*, \mathcal{T}_{w*})^*$ is X (regarded as a subset of X^{dd}).

This result is also a special case of XX.4.6.11..

Duality

This can all be put in a more general framework.

XX.4.6.7. Definition. Let X and Y be vector spaces over $\mathbb{F}$ (with no assumed topology). A *duality* between X and Y, denoted $\langle X, Y\rangle$ is a bilinear form $\langle \cdot, \cdot \rangle$ from $X \times Y$ to $\mathbb{F}$ which is separating in both X and Y, i.e. for fixed $x \in X$, $\langle x, y\rangle = 0$ for all $y \in Y$ implies $x = 0$ and for fixed $y \in Y$, $\langle x, y\rangle = 0$ for all $x \in X$ implies $y = 0$.

XX.4.6.8. Although the situation is completely symmetric in X and Y, notationally we consider the first space X as the basic space and elements of Y as giving linear functionals on X, i.e. $Y \subseteq X^d$.

XX.4.6.9. Example. If X is a locally convex topological vector space, the bilinear form $\langle x, \phi \rangle = \phi(x)$ gives a duality $\langle X, X^* \rangle$ between X and X^*. This can be written also in reverse order: $\langle \phi, x \rangle = \phi(x)$ gives a duality $\langle X^*, X \rangle$ between X^* and X.

XX.4.6.10. Let X and Y be vector spaces over $\mathbb{F}$, and $\langle X, Y \rangle$ a duality. The duality defines a topology $\sigma(X, Y)$ on X of pointwise convergence: $x_i \to x$ if and only if $\langle x_i, y \rangle \to \langle x, y \rangle$ for all $y \in Y$. The sets

$$U_{\{y_1,\dots,y_n\},\epsilon} = \{x \in X : |\langle x, y_k \rangle| < \epsilon \text{ for } 1 \leq k \leq n\}$$

form a fundamental system of neighborhoods of 0 for $\sigma(X, Y)$. This is an LCS topology on X.

Although the notation does not reflect it, the $\sigma(X, Y)$-topology depends on the bilinear form $\langle \cdot, \cdot \rangle$ and not just on X and Y. In applications there is generally a natural bilinear form which is understood.

For example, if X is a locally convex topological vector space, the $\sigma(X, X^*)$-topology is the weak topology on X, and the $\sigma(X^*, X)$-topology is the weak-* topology on X^*. The notations $\sigma(X, X^*)$ and $\sigma(X^*, X)$ are standard for these topologies.

Here is the general form of (). The proof is essentially identical.

XX.4.6.11. Proposition. Let X and Y be vector spaces over $\mathbb{F}$, and $\langle X, Y \rangle$ a duality. The $\sigma(X, Y)$-continuous linear functionals on X are precisely the linear functionals in Y (regarded as a subset of X^d). Thus $(X, \sigma(X, Y))^* = Y$. The topology $\sigma(X, Y)$ is the weakest LCS topology $\mathcal{T}$ on X for which $(X, \mathcal{T})^* = Y$.

XX.4.6.12. If $\langle X, Y \rangle$ is a duality, an LCS topology $\mathcal{T}$ on X is *consistent* for the duality if $(X, \mathcal{T})^* = Y$ (as a subset of X^d). Thus $\sigma(X, Y)$ is the weakest consistent topology. If $(X, \mathcal{T})$ is a locally convex topological vector space, the topology $\mathcal{T}$ is consistent for $\langle X, X^* \rangle$.

There is always a largest consistent topology $\tau(X, Y)$ for any duality $\langle X, Y \rangle$, called the *Mackey topology* of the duality. This topology is the topology of uniform convergence on all $\sigma(Y, X)$-compact convex balanced subsets of Y. If $(X, \mathcal{T})$ is a locally convex topological vector space, the Mackey topology on X is stronger than $\mathcal{T}$, and coincides with $\mathcal{T}$ in reasonable cases, e.g. if X is barrelled () or bornological (), and in particular if X is metrizable (first countable) [SW99, IV.3.2].

XX.4.7. Uniform Topologies on X^* and the Bidual

We give only a brief survey of the problem of defining a "uniform" topology on the dual of a locally convex topological vector space. For a full treatment see e.g. [SW99].

XX.4.7.1. If X is a normed vector space, besides the weak and weak-* topologies on the dual X^* there is a norm topology defined by the operator norm. It is a delicate and complicated matter to generalize the norm topology to general locally convex topological vector spaces, and there are several reasonable candidates and no obvious one, and none with all the properties desirable. (These topologies are often called *strong topologies* in the literature, but I prefer the term *uniform topologies* for reasons explained in ().)

Even worse, although the dual space X^* of a locally convex topological vector space $(X, \mathcal{T})$ is at least well defined as a set (subset of X^d) by $\mathcal{T}$, the bidual space $X^{**} = (X^*)^*$ is not even determined as a set (subset of $(X^*)^d$) by $\mathcal{T}$, but depends on what topology is chosen for the uniform topology on X^*. This is to be expected: the uniform topology on X^* should not generally be consistent for $\langle X^*, X\rangle$ (this even fails if X is a nonreflexive Banach space).

XX.4.7.2. We work more generally with a duality $\langle X, Y\rangle$. The general idea is that if $\mathcal{B}$ is a collection of subsets of Y with suitable properties (e.g. closed under finite unions), we can define on X the "topology of uniform convergence on sets in $\mathcal{B}$" by $x_i \to x$ if and only if $\langle x_i, y\rangle \to \langle x, y\rangle$ uniformly on B, for every $B \in \mathcal{B}$. The sets

$$U_{B,\epsilon} = \{x \in X : |\langle x, y\rangle| < \epsilon \text{ for all } y \in B\}$$

form a fundamental set of neighborhoods of 0. One can of course interchange X and Y.

For a uniform topology, there are several reasonable choices for $\mathcal{B}$:

All equicontinuous sets in Y.

All $\sigma(Y, X)$-compact subsets of Y.

All $\sigma(Y, X)$-bounded subsets of Y.

Even the weak topology fits into this picture, taking $\mathcal{B}$ to be the collection of finite subsets of Y, and the Mackey topology, taking $\mathcal{B}$ to be the set of $\sigma(Y, X)$-compact convex balanced subsets of Y.

XX.4.7.3. Fortunately, under mild hypotheses, all these topologies coincide, e.g. if X is barrelled () or bornological (), and in particular if X is metrizable (first countable).

XX.4.7.4. There is a standard choice: let $\beta(X, Y)$ be the topology of uniform convergence on all $\sigma(Y, X)$-bounded subsets of Y. We call this the *uniform topology* on X from $\langle X, Y\rangle$ (many references call it the *strong topology*).

In particular, if $(X, \mathcal{T})$ is a locally convex topological vector space, we call $\beta(X, X^*)$ the *uniform topology* on X, and $\beta(X^*, X)$ the *uniform topology* on X^*.

XX.4.7.5. If $(X, \mathcal{T})$ is a locally convex topological vector space, then the uniform topology $\beta(X, X^*)$ is stronger than $\mathcal{T}$. It can be strictly stronger, but the topologies coincide if $(X, \mathcal{T})$ is barrelled ().

The Bidual

XX.4.7.6. Definition. Let $(X, \mathcal{T})$ be a locally convex topological vector space. The *uniform bidual* of $(X, \mathcal{T})$ is the dual space $(X^*, \beta(X^*, X))^*$, denoted X^{**}.

XX.4.7.7. There is a natural embedding of X into X^{**}. One can put the uniform topology $\beta(X^{**}, X^*)$ on X^{**}, but the inclusion of X into X^{**} is not continuous in general for this topology. There is a weaker topology on X^{**}, the *natural topology*, the topology of uniform convergence on equicontinuous subsets of X^*; the inclusion of X into X^{**} is a homeomorphism for this topology. The uniform and natural topologies on X^{**} coincide in reasonable cases, e.g. if X is barrelled or bornological, and in particular if X is metrizable (first countable).

XX.4.8. Exercises

XX.4.8.1. Let $(X, \mathcal{T})$ be a topological vector space. Let $Y = \overline{\{0\}}$, and let Z be a subspace of X complementary to Y (III.11.2.38.; the AC is needed to insure the existence of such a Z). Then $X \cong Y \oplus Z = Y \times Z$ as a vector space (III.11.2.36.).

(a) Show that the restriction to Z of the quotient map from X to X/Y is a linear homeomorphism, where Z has the relative topology and X/Y the quotient topology. [See XX.4.1.12..]

(b) Show that X is linearly homeomorphic to $Y \oplus Z = Y \times Z$ with the product topology (the relative topology on Y is the indiscrete topology). Thus every topological vector space is (uniquely) the direct sum (product) of a Hausdorff topological vector space and a vector space with the indiscrete topology.

(c) Although Y is closed in X by definition, Z is not closed in X if X is not Hausdorff; in fact, Z is dense in X. (If X is Hausdorff, then $Y = \{0\}$ and $Z = X$.)

(d) The result in (a) is not true in general if Y is just a closed subspace of X and Z is a complementary subspace: the restriction to Z of the quotient map from X to X/Y is a continuous linear bijection, but not a linear homeomorphism in general. [Consider the case where X is a Banach space and Z is not closed in X.] The result in (a) (and also (b)) is true if Z is closed in X.

XX.4.8.2. Let $\{(X_i, \mathcal{T}_i) : i \in I\}$ be an inductive system () of topological vector spaces, and $(X, \mathcal{T})$ the inductive limit (). The important case is where X is a vector space, the X_i are subspaces directed by inclusion, each with a topology $\mathcal{T}_i$, such that whenever $i < j$, X_i is a closed subspace of X_j and the relative $\mathcal{T}_j$-topology on X_i is $\mathcal{T}_i$, and $X = \cup_i X_i$; such an inductive limit is called *strict*.

(a) Show that $(X, \mathcal{T})$ has a natural structure as a topological vector space, and that $\mathcal{T}$ is the strongest TVS topology on X making the natural maps from the X_i to X continuous. If each $\mathcal{T}_i$ is Hausdorff and the connecting maps are injective, $\mathcal{T}$ is Hausdorff. [Replace "Hausdorff" by "T_1".]

(b) In the strict case, show that the relative $\mathcal{T}$-topology on X_i is $\mathcal{T}_i$ for all i.

(c) In the strict case with $I = \mathbb{N}$, show that if (x_n) is a sequence in X, then $x_n \to x$ in the $\mathcal{T}$-topology if and only if there is an i such that x and all the x_n are contained in $\mathcal{T}_i$ and $x_n \to x$ in the $\mathcal{T}_i$-topology. (This is true only for *sequences*, and not nets in general. Is it true for sequences for general I?)

(d) Show that $(X, \mathcal{T})$ is not metrizable if I is infinite and the images of the X_i in X are distinct. If $\mathcal{T}$ is Hausdorff, it is not first countable.

(e) If X is any vector space, then X has a strongest TVS topology, and it is the inductive limit topology from its finite-dimensional subspaces (directed by inclusion) with their unique Hausdorff TVS topologies. If X is infinite-dimensional, this topology is Hausdorff and not first countable (it is of course the unique Hausdorff TVS topology if X is finite-dimensional).

XX.4.8.3. [DS88, II.1.12] Let p be a complete weak paranorm (XX.4.3.14.) on a vector space X. Use the Uniform Boundedness Theorem () to show that p is a paranorm, i.e. that scalar multiplication is jointly continuous.

XX.4.8.4. A subset B of a topological vector space $(X, \mathcal{T})$ is a *barrel* if it is closed, radial, balanced, and convex. The space X is *barreled* if every barrel in X is a neighborhood of 0.

(a) Show that every topological vector space which is a Baire space is barreled. In particular, every F-space (e.g. every Fréchet space, hence every Banach space) is barreled.

(b) Give c_{00} () the topology from the supremum norm (i.e. the relative topology from c_0). Show that c_{00} with this norm is not barreled. [Let B be the subset

$$\left\{(x_n) \in c_{00} : |x_n| \leq \frac{1}{n} \text{ for all } n\right\} .$$

Then B is a barrel in c_{00}. Note that the closure of B in c_0 is not radial.] Thus a normed vector space need not be barreled, and a subspace of a barreled space need not be barreled. Even a closed subspace of a barreled space need not be barreled [SW99, Exercise IV.10].

(c) The topological vector space $X = L^q([0,1])$ $(0 < q < 1)$ is barreled by (a), but contains no barrels other than X itself (so is vacuously barreled). [A nontrivial barrel gives rise to at least one nonzero continuous linear functional.]

(d) Show that any barrel B in a topological vector space X absorbs any subset A of X which is balanced, convex, bounded, and complete. [Consider the norm m_A on $\cup_n nA$.]

(e) A barreled vector space need not be bornological (XX.4.8.5.) ([**?**], [**?**]).

XX.4.8.5. A locally convex topological vector space $(X, \mathcal{T})$ is *bornological* if every balanced convex subset of X which absorbs every bounded subset of X is a neighborhood of 0. (This condition is really only interesting if $\mathcal{T}$ is Hausdorff. For example, any vector space with the indiscrete topology is bornological, since every subset is bounded.)

(a) Show that every metrizable locally convex topological vector space is bornological.

(b) Show that if $(X, \mathcal{T})$ is a locally convex topological vector space, there is a strongest locally convex TVS topology $\mathcal{T}_0$ with the same bounded sets as $\mathcal{T}$, and $(X, \mathcal{T}_0)$ is bornological. $\mathcal{T}_0 = \mathcal{T}$ if and only if $(X, \mathcal{T})$ is bornological.

(c) Let $(X, \mathcal{T})$ be a bornological space, Y a locally convex topological vector space, and $T : X \to Y$ a linear transformation. Show that the following are equivalent:

(i) T is continuous.

(ii) T is sequentially continuous, i.e. if $x_n \to x$, then $Tx_n \to Tx$.

(iii) If $x_n \to 0$, then $Tx_n \to 0$.

(iv) T sends bounded sets in X to bounded sets in Y.

(We have (i) $\Rightarrow$ (ii) $\Rightarrow$ (ii) $\Rightarrow$ (iv) if X and Y are any topological vector spaces. The bornological condition is only needed for (iv) $\Rightarrow$ (i).]

(d) Let $(X, \mathcal{T})$ be a locally convex topological vector space. Show that the following are equivalent:

(i) $(X, \mathcal{T})$ is bornological.

(ii) Any seminorm on X which is bounded on bounded sets is continuous.

(iii) For any locally convex topological vector space Y and linear $T : X \to Y$ sending bounded sets in X to bounded sets in Y, T is continuous.

If X is Hausdorff, these are equivalent to

(iv) $(X, \mathcal{T})$ is the inductive limit of a family of normed vector spaces.

XX.5. Bounded Operators

When considering normed vector spaces, or more generally topological vector spaces, the most natural and important functions between them should preserve both the algebraic structure, i.e. be linear, and the topological structure, i.e. be continuous. Thus we usually want to work with continuous linear operators. In the case of normed vector spaces, continuity is equivalent to another property, boundedness, which is usually easier to work with directly.

XX.5.1. Bounded Operators on Normed Vector Spaces

XX.5.1.6. DEFINITION. Let X and Y be vector spaces over $\mathbb{F}$. A *(linear) operator* from X to Y is a linear transformation () from X to Y.

Thus *operator* and *linear transformation* are synonymous. The term *operator* is primarily used in the case $X = Y$, in which case we call it an operator on X. If $T : X \to Y$ is an operator, we usually write Tx instead of $T(x)$ for the image of $x \in X$ under T.

XX.5.1.7. DEFINITION. Let $(X, \|\cdot\|_X)$ and $(Y, \|\cdot\|_Y)$ be normed vector spaces over $\mathbb{F}$, and $T : X \to Y$ an operator (linear transformation). Then T is *bounded*, or a *bounded operator*, if there is a constant M such that

$$\|Tx\|_Y \leq M\|x\|_X$$

for all $x \in X$. The smallest such M is called the *operator norm* of T, written $\|T\|_{op}$ or usually just $\|T\|$ when there is no possibility of confusion.

Although the notation does not reflect it, boundedness of T and its operator norm depend on the choices of norms on X and Y. Thus, although we often write $T : X \to Y$ by slight abuse of notation, there must be understood norms on X and Y.

XX.5.1.8. If T is a bounded operator from X to Y, we have

$$\|T\| = \sup_{x \neq 0} \frac{\|Tx\|_Y}{\|x\|_X} = \sup_{\|x\|_X = 1} \|Tx\|_Y$$

since T is linear and any vector is a scalar multiple of a unit vector. The 0 operator is bounded, and $\|0\| = 0$; if T is bounded, then $\|T\| \geq 0$, and $\|T\| = 0$ if and only if $T = 0$.

The most important feature of boundedness is that it is equivalent to continuity:

XX.5.1.9. PROPOSITION. Let $(X, \|\cdot\|_X)$ and $(Y, \|\cdot\|_Y)$ be normed vector spaces over $\mathbb{F}$, and $T : X \to Y$ a linear transformation. The following are equivalent:

(i) T is continuous at 0.

(ii) T is continuous.

(iii) T is uniformly continuous.

(iv) T is bounded.

PROOF: (iii) $\Rightarrow$ (ii) $\Rightarrow$ (i) is trivial.

(iv) $\Rightarrow$ (iii): Suppose T is bounded. We may assume $T \neq 0$, so $\|T\| > 0$. Let $\epsilon > 0$, and set $\delta = \frac{\epsilon}{\|T\|}$. If $x_1, x_2 \in X$ with $\|x_2 - x_1\|_X < \delta$, then

$$\|Tx_2 - Tx_1\|_Y = \|T(x_2 - x_1)\|_Y \leq \|T\|\|x_2 - x_1\|_X < \|T\|\delta = \epsilon \ .$$

Thus T is uniformly continuous.

(i) $\Rightarrow$ (iv): Suppose T is not bounded. Then for every n there is a $v_n \in X$, $v_n \neq 0$, with $\|Tv_n\|_Y > n\|v_n\|_X$. Set $x_n = \frac{1}{n\|v_n\|_X} v_n$. Then $\|x_n\|_X = \frac{1}{n}$ and

$$\|Tx_n\|_Y = \left\| T\left(\frac{1}{n\|v_n\|_X} v_n\right)\right\|_Y = \left\|\frac{1}{n\|v_n\|_X} Tv_n\right\|_Y = \frac{1}{n\|v_n\|_X}\|Tv_n\|_Y > 1$$

for all n. Thus $x_n \to 0$ in X but $Tx_n \not\to 0$ in Y, so T is not continuous at 0. 👍

XX.5.1.10. Let X and Y be vector spaces over $\mathbb{F}$. The set $\mathcal{L}(X, Y)$ of linear transformations from X to Y is a vector space over $\mathbb{F}$ under the usual operations ().

XX.5.1.11. PROPOSITION. Let $(X, \|\cdot\|_X)$ and $(Y, \|\cdot\|_Y)$ be normed vector spaces over $\mathbb{F}$, and S and T bounded operators from X to Y. Then

(i) $S + T$ is a bounded operator from X to Y, and $\|S + T\| \leq \|S\| + \|T\|$.

(ii) If $\alpha \in \mathbb{F}$, then αT is bounded and $\|\alpha T\| = |\alpha|\|T\|$.

PROOF: (i): If $x \in X$, we have

$$\|(S + T)x\|_Y = \|Sx + Tx\|_Y \leq \|Sx\|_Y + \|Tx\|_Y \leq \|S\|\|x\|_X + \|T\|\|x\|_X = (\|S\| + \|T\|)\|x\|_X \ .$$

(ii): We have

$$\|\alpha T\| = \sup_{\|x\|_X = 1} \|(\alpha T)x\|_Y = \sup_{\|x\|_X = 1} \|\alpha(Tx)\|_Y = \sup_{\|x\|_X = 1} |\alpha|\|Tx\|_Y = |\alpha| \sup_{\|x\|_X = 1} \|Tx\|_Y = |\alpha|\|T\| \ .$$

👍

XX.5.1.12. COROLLARY. Let X and Y be normed vector spaces over $\mathbb{F}$. Then the set $\mathcal{B}(X, Y)$ of bounded operators from X to Y is a vector subspace of $\mathcal{L}(X, Y)$, and the operator norm is a norm on $\mathcal{B}(X, Y)$.

The operator norm has one more simple but important property:

XX.5.1.13. PROPOSITION. Let X, Y, Z be normed vector spaces over $\mathbb{F}$, $T \in \mathcal{B}(X,Y)$, $S \in \mathcal{B}(Y,Z)$. Then $ST = S \circ T \in \mathcal{B}(X,Z)$ and $\|ST\| \leq \|S\|\|T\|$.

PROOF: If $x \in X$, we have

$$\|(ST)x\|_Z = \|S(Tx)\|_Z \leq \|S\|\|Tx\|_Y \leq \|S\|\|T\|\|x\|_X \ .$$

Simple examples with 2×2 matrices show that the inequality can be strict; if fact, we can have $ST = 0$ even if S and T are both nonzero, if the range of T is contained in the null space of S.

Completeness

XX.5.1.14. THEOREM. Let X and Y be normed vector spaces over $\mathbb{F}$. If Y is complete (a Banach space), then $\mathcal{B}(X,Y)$ is complete (a Banach space) in the operator norm.

PROOF: The proof follows the standard pattern of completeness proofs. Suppose (T_n) is a Cauchy sequence in $\mathcal{B}(X,Y)$. We first find a candidate for the limit T.

Fix $x \in X$. We have, for $n, m \in \mathbb{N}$,

$$\|T_n x - T_m x\|_Y = \|(T_n - T_m)x\|_Y \leq \|T_n - T_m\|\|x\|_X$$

so the sequence $(T_n x)$ is a Cauchy sequence in Y. Since Y is complete, the sequence $(T_n x)$ converges to an element of Y we may call Tx. As x varies over X, this procedure defines a function $T : X \to Y$, and $T_n \to T$ pointwise.

We must show that T is a bounded operator and that $T_n \to T$ in operator norm. If $x_1, x_2 \in X$, then $T_n x_1 \to T x_1$, $T_n x_2 \to T x_2$, and $T_n(x_1 + x_2) \to T(x_1 + x_2)$. But $T_n(x_1 + x_2) = T_n x_1 + T_n x_2$ by linearity, and $T_n x_1 + T_n x_2 \to T x_1 + T x_2$ by continuity of addition in Y. Thus $T(x_1 + x_2) = T x_1 + T x_2$ by uniqueness of limits in Y. Similarly, if $\alpha \in F$, we have $T_n(\alpha x) \to T(\alpha x)$ and $T_n(\alpha x) = \alpha(T_n x) \to \alpha(Tx)$, so $T(\alpha x) = \alpha(Tx)$. Thus T is linear.

To show that T is bounded, note that the sequence (T_n), being a Cauchy sequence, is bounded, say $\|T_n\| \leq M$ for all n. Fix x with $\|x\| = 1$. Then $\|T_n x\|_Y \leq M\|x\|_X = M$, and since $T_n x \to Tx$, we also have $\|Tx\|_Y \leq M$. This is true for every x of norm 1, so T is bounded and $\|T\| \leq M$.

Finally, let $\epsilon > 0$. Since (T_n) is a Cauchy sequence, there is an N such that $\|T_n - T_m\| < \epsilon$ for all $n, m \geq N$. Fix $x \in X$, $\|x\|_X = 1$. Then

$$\|T_n x - T_m x\|_Y = \|(T_n - T_m)x\|_Y \leq \|T_n - T_m\|\|x\|_X < \epsilon$$

for all $n, m \geq N$. Fix $n \geq N$; since $T_m x \to Tx$, we have $\|(T_n - T)x\|_Y = \|T_n x - Tx\|_Y \leq \epsilon$. This is true for all such x, so $\|T_n - T\| \leq \epsilon$. This is true for all $n \geq N$, so $T_n \to T$ in operator norm.

XX.5.1.15. Note that completeness of X is not needed for this result. But if Y is complete, any bounded operator from X to Y extends uniquely to a bounded operator from the completion $\bar{X}$ to Y with the same norm, so $\mathcal{B}(X,Y) \cong \mathcal{B}(\bar{X},Y)$:

XX.5.1.16. PROPOSITION. Let X and Y be normed vector spaces, with Y complete, and let Z be a dense subspace of X. If T is a bounded operator from Z to Y, then T extends uniquely to a bounded operator $\bar{T} : X \to Y$, and $\|\bar{T}\| = \|T\|$.

PROOF: Since T is uniformly continuous (XX.5.1.9.) and Y is complete, T extends uniquely to a continuous function $\bar{T}$ from X to Y (). If $x_1, x_2 \in X$, there are sequences (z_{n1}) and (z_{n2}) in Z converging to x_1 and x_2 respectively. Then $z_{n1} + z_{n2} \to x_1 + x_2$, so $\bar{T}(z_{n1} + z_{n2}) = T(z_{n1} + z_{n2}) \to \bar{T}(x_1 + x_2)$. On the other hand, $\bar{T}z_{n1} = Tz_{n1} \to \bar{T}x_1$ and $\bar{T}z_{n2} = Tz_{n2} \to \bar{T}x_2$, so

$$\bar{T}(z_{n1} + z_{n2}) = T(z_{n1} + z_{n2}) = Tz_{n1} + Tz_{n2} \to \bar{T}x_1 + \bar{T}x_2$$

so $\bar{T}(x_1 + x_2) = \bar{T}x_1 + \bar{T}x_2$ by uniqueness of limits in Y. Similarly, if $\alpha \in \mathbb{F}$, $\bar{T}(\alpha z_{n1})$ converges to both $\bar{T}(\alpha x_1)$ and $\alpha(\bar{T}x_1)$, so $\bar{T}(\alpha x_1) = \alpha(\bar{T}x_1)$ and $\bar{T}$ is linear.

Let $x \in X$, $\|x\|_X = 1$. There is a sequence (z_n) in Z converging to x. Then $\|z_n\|_X \to \|x\|_X = 1$, so if $w_n = \frac{z_n}{\|z_n\|_X}$, then $w_n \in Z$ for all n, $\|w_n\|_X = 1$ for all n, and $w_n \to x$ by joint continuity of scalar multiplication. We have $\|Tw_n\|_Y \leq \|T\|$ for all n, and since $\bar{T}w_n = Tw_n \to \bar{T}x$, we also have $\|\bar{T}x\|_Y \leq \|T\|$. This is true for all such x, so $\bar{T}$ is bounded and $\|\bar{T}\| \leq \|T\|$.

For the opposite inequality, let $\epsilon > 0$. There is a $z \in Z$ with $\|z\|_X = 1$ and $\|Tz\|_Y > \|T\| - \epsilon$. We then have

$$\|T\| - \epsilon < \|Tz\|_Y = \|\bar{T}z\|_Y \leq \|\bar{T}\|\|z\|_X = \|\bar{T}\| \ .$$

The extreme inequality is true for all $\epsilon > 0$, and thus $\|T\| \leq \|\bar{T}\|$. 👍

XX.5.2. Bounded Linear Functionals

XX.5.2.17. DEFINITION. Let X be a vector space over $\mathbb{F}$. A *linear functional* on X is a linear transformation from X to $\mathbb{F}$. If X is a normed vector space, a linear functional ϕ on X is *bounded* if it is bounded as a linear transformation (regarding $\mathbb{F}$ as a normed vector space with norm $|\cdot|$), i.e. if there is a constant M such that $|\phi(x)| \leq M\|x\|$ for all $x \in X$. The smallest such M is the *norm* of ϕ, denoted $\|\phi\|$.

XX.5.2.18. **Notation:** If X is a vector space over $\mathbb{F}$, we will write X' for the set $\mathcal{L}(X, \mathbb{F})$ of linear functionals on X. If X is normed, write X^* for the set $\mathcal{B}(X, \mathbb{F})$ of bounded linear functionals on X. Then X' is a vector space over $\mathbb{F}$, and by XX.5.1.12., X^* is a subspace which is normed by $\|\cdot\|$; X^* is a Banach space by XX.5.1.14.. X' is called the *algebraic dual space* of X, and X^* the *(topological) dual space* of X.

There is no uniformity of notation for dual spaces. Many authors use X' for the topological dual space, and some of these (e.g. [**?**]) even use X^* to denote the algebraic dual. We use what seems to be the most common notation. We usually use ϕ, ψ, etc. to denote linear functionals; some authors use x^* to denote a general element of X^*, leading to poor and confusing expressions like $x^*(x)$ where x denotes a general element of X and x^* a general element of X^*, with no relation between them. ✋

XX.5.2.19. By XX.5.1.9., a linear functional on a normed vector space is continuous if and only if it is bounded. The null space of any bounded operator is closed (). The converse does not hold in general, e.g. there are unbounded one-to-one linear transformations. However:

XX.5.2.20. PROPOSITION. Let X be a normed vector space over $\mathbb{F}$, and $\phi : X \to \mathbb{F}$ a linear functional on X. If the null space N_ϕ is closed in X, then ϕ is bounded.

PROOF: Suppose ϕ is unbounded. Then for each $n \in \mathbb{N}$ there is a $y_n \in X$ with $\|y_n\| = 1$ but $|\phi(y_n)| > n$. Set $x_n = \frac{1}{\phi(y_n)} y_n$. Then $\|x_n\| < 1/n$ and $\phi(x_n) = 1$ for all n. Fix $v \in X$ with $\phi(v) = 1$. We have $x_n \to 0$, so $v - x_n \to v$. But $v - x_n \in N_\phi$ for all n, so $v \in \overline{N_\phi} \setminus N_\phi$, and N_ϕ is not closed. 👍

In fact, this argument shows that if ϕ is unbounded, then N_ϕ is dense in X. (Actually it would have to be either closed or dense since it has codimension 1.)

XX.5.3. Operators on Finite-Dimensional Normed Spaces

XX.5.4. Bounded Operators on Hilbert Spaces

XX.5.5. Algebras of Operators

XX.5.5.1. DEFINITION. A *(concrete) operator algebra* is a *-subalgebra of $\mathcal{B}(\mathcal{H})$ which is topologically closed in a suitable sense (there is also a subject of non-self-adjoint operator algebras, but it is outside the scope of this volume.) A *von Neumann algebra* is a (necessarily unital) *-subalgebra M of $\mathcal{B}(\mathcal{H})$ such that $M = M''$.

A von Neumann algebra is weakly (hence strongly, norm-, $\cdots$) closed, and in particular is a concrete C*-algebra (XX.16.1.3.), albeit of a very special kind.

Commutant and Bicommutant

One of the first, yet still one of the most crucial basic theorems of operator algebra theory is VON NEUMANN'S Bicommutant Theorem [**?**]. We say a *-algebra A of operators on a Hilbert space $\mathcal{H}$ *acts nondegenerately* if $T\xi = 0$ for all $T \in A$ implies $\xi = 0$. Since A is a *-algebra, this is equivalent to the condition that the subspace

$$A\mathcal{H} = span\{T\xi : T \in A, \xi \in \mathcal{H}\}$$

is dense in $\mathcal{H}$. If $I \in A$, then A obviously acts nondegenerately.

XX.5.5.2. THEOREM. [BICOMMUTANT THEOREM] Let A be a *-subalgebra of $\mathcal{B}(\mathcal{H})$ acting nondegenerately. Then A is σ-strongly dense in A''.

PROOF: Using **??**, the proof reduces to showing that if $\xi \in \mathcal{H}$ and $T \in A''$, there is a sequence (T_n) in A with $T_n\xi \to T\xi$. If $\mathcal{X} = \{S\xi : S \in A\}^-$, then $P_\mathcal{X} \in A'$ (since both $\mathcal{X}$ and $\mathcal{X}^\perp$ are invariant under A), so T commutes with $P_\mathcal{X}$, i.e. T leaves $\mathcal{X}$ invariant. It remains to show that $\xi \in \mathcal{X}$, so that $T\xi \in \mathcal{X}$. This is trivial if $I \in A$. In the general nondegenerate case, for each $S \in A$,

$$S[(I - P_\mathcal{X})\xi] = (I - P_\mathcal{X})[S\xi] = 0$$

since $S\xi \in \mathcal{X}$, so $(I - P_\mathcal{X})\xi = 0$. 👍

The Bicommutant Theorem relates a topological closure property with the simple, natural, and purely algebraic property of being the bicommutant (or just commutant) of a *-closed set of operators.

XX.5.5.3. Corollary. Let A be a unital (or just nondegenerate) *-subalgebra of $\mathcal{B}(\mathcal{H})$. The following are equivalent:

(i) A is strongly closed.

(ii) A is σ-strongly closed.

(iii) A is weakly closed.

(iv) A is σ-weakly closed.

(v) A is a von Neumann algebra, i.e. A''.

XX.6. The Hahn-Banach Theorem

The Hahn-Banach Theorem is one of the most fundamental results of functional analysis. In various forms it asserts the existence of "many" linear functionals on real or complex vector spaces. Indeed, this theorem underlies and justifies the whole philosophy of functional analysis: that a space can be completely studied via the scalar-valued functionals on the space.

There are many slightly different forms in which this theorem is commonly expressed. All the general versions require use of some form of the Axiom of Choice, but versions for vector spaces which are "not too large" can be proved directly without using the AC.

XX.6.1. Sublinear Functionals and Version 1

The first version of the Hahn-Banach Theorem concerns existence of linear functionals on a real vector space which are trapped between a sublinear functional and a superlinear functional, and more generally extensions to the whole vector space of such a linear functional already defined on a subspace.

XX.6.1.1. DEFINITION. Let V be a real vector space. A function $p : V \to (-\infty, +\infty]$ is a *sublinear functional* on V if

(i) $p(x + y) \leq p(x) + p(y)$ for all $x, y \in V$.

(ii) $p(\alpha x) = \alpha p(x)$ for all $\alpha > 0$.

A function $q : V \to [-\infty, +\infty)$ is a *superlinear functional* on V if

(i) $q(x + y) \geq q(x) + q(y)$ for all $x, y \in V$.

(ii) $q(\alpha x) = \alpha q(x)$ for all $\alpha > 0$.

A sublinear or superlinear functional taking only real values is called *finite*.

Note that a sublinear functional can take the value $+\infty$ but not $-\infty$, and a superlinear functional can take the value $-\infty$ but not $+\infty$. In most applications, sublinear or superlinear functionals are finite.

XX.6.1.2. EXAMPLES. (i) Any linear functional is both sublinear and superlinear.

(ii) The function $p(x) = +\infty$ for all x is sublinear; the function $q(x) = -\infty$ for all x is superlinear.

(iii) Any seminorm () is a finite sublinear functional taking only nonnegative values.

(iv) Let C be a convex set in V containing 0. For $x \in V$, set

$$m_C(x) = \inf\{\alpha > 0 : \alpha^{-1}x \in C\}$$

(where $\inf(\emptyset) = +\infty$). Then m_C is a sublinear functional on V, called the *Minkowski functional* of C (). It takes only nonnegative values, and is finite if C is radial.

(v) If p is a sublinear functional, then $-p$ is a superlinear functional, and vice versa.

The first version of the Hahn-Banach Theorem is:

XX.6.1.3. Theorem. [Hahn-Banach Theorem, Version 1] Let V be a real vector space, p a sublinear functional on V, and q a superlinear functional on V satisfying $q(x) \leq p(x)$ for all $x \in V$. Assume at least one of p and q is finite. Let W be a subspace of V, and ψ a linear functional on W satisfying $q(y) \leq \psi(y) \leq p(y)$ for all $y \in W$. Then there is a linear functional ϕ on V extending ψ with

$$q(x) \leq \phi(x) \leq p(x)$$

for all $x \in V$.

Taking $q(x) = -\infty$ for all x, we get the following commonly-stated version of the theorem:

XX.6.1.4. Corollary. [Hahn-Banach Theorem, Version 1A] Let V be a real vector space, and p a finite sublinear functional on V. Let W be a subspace of V, and ψ a linear functional on W satisfying $\psi(y) \leq p(y)$ for all $y \in W$. Then there is a linear functional ϕ on V extending ψ with

$$\phi(x) \leq p(x)$$

for all $x \in V$.

There is an analogous result with inequalities reversed for a superlinear functional.

XX.6.1.5. If p is a sublinear functional on V, then $p(0) = \alpha p(0)$ for all $\alpha > 0$. Thus $p(0)$ is either 0 or $+\infty$. Similarly, if q is superlinear, then $q(0)$ is either 0 or $-\infty$. Thus, if p is sublinear and q superlinear, then $q(0) \leq 0 \leq p(0)$, so the hypotheses of XX.6.1.3. and XX.6.1.4. are automatically satisfied if W is the zero subspace and ψ the zero functional. Thus we obtain:

XX.6.1.6. Corollary. Let V be a real vector space, p a sublinear functional on V, and q a superlinear functional on V satisfying $q(x) \leq p(x)$ for all $x \in V$. Assume at least one of p and q is finite. Then there is a linear functional ϕ on V with

$$q(x) \leq \phi(x) \leq p(x)$$

for all $x \in V$.

There are also one-sided versions of this result.

XX.6.1.7. The proof of Theorem XX.6.1.3. consists of two steps:

(1) Show that ψ can be extended to a subspace spanned by W and one additional element.

(2) "Iterate" step 1 to extend ψ all the way to V.

The first step is elementary and straightforward, but takes some work. The second step in general requires some form of the Axiom of Choice.

We begin with step 1.

XX.6.1.8. LEMMA. Let V be a real vector space, p a sublinear functional on V, and q a superlinear functional on V satisfying $q(x) \leq p(x)$ for all $x \in V$. Assume at least one of p and q is finite. Let W be a subspace of V, and ψ a linear functional on W satisfying $q(y) \leq \psi(y) \leq p(y)$ for all $y \in W$. Let $x_0 \in V \setminus W$, and let X be the subspace of V spanned by W and x_0. Then there is a linear functional θ on X extending ψ with

$$q(x) \leq \theta(x) \leq p(x)$$

for all $x \in X$.

PROOF: Every $x \in X$ can be uniquely written as $y + \alpha x_0$, where $y \in W$ and $\alpha \in \mathbb{R}$. Any linear functional on X extending ψ is of the form

$$\theta(y + \alpha x_0) = \psi(y) + \alpha c$$

for some $c \in \mathbb{R}$, so we must choose c so that $q(x) \leq \theta(x) \leq p(x)$ for all $x \in X$, i.e.

$$q(y + \alpha x_0) \leq \psi(y) + \alpha c \leq p(y + \alpha x_0)$$

for all $y \in W$ and $\alpha \in \mathbb{R}$. To show this is possible, we obtain some inequalities.

First, if $y, z \in W$, we have

$$\psi(y) - \psi(z) = \psi(y - z) \leq p(y - z) = p([y + x_0] + [-x_0 - z]) \leq p(y + x_0) + p(-x_0 - z)$$

$$-p(-x_0 - z) - \psi(z) \leq p(y + x_0) - \psi(y) \tag{XX.1}$$

and similarly we obtain

$$q(y + x_0) - \psi(y) \leq -q(-x_0 - z) - \psi(z) \ . \tag{XX.2}$$

Finally, we have

$$\psi(y) - \psi(z) = \psi(y + x_0) - \psi(x_0 + z) \leq p(y + x_0) - q(x_0 + z)$$

$$q(x_0 + z) - \psi(z) \leq p(y + x_0) - \psi(y) \tag{XX.3}$$

and we similarly obtain

$$-p(-x_0 - z) - \psi(z) \leq -q(-x_0 - y) - \psi(y) \ . \tag{XX.4}$$

Now define

$$\sigma_1 = \sup\{-p(-x_0 - y) - \psi(y) : y \in W\}$$

$$\sigma_2 = \sup\{q(x_0 + y) - \psi(y) : y \in W\}$$

$$\tau_1 = \inf\{p(x_0 + y) - \psi(y) : y \in W\}$$

$$\tau_2 = \inf\{-q(-x_0 - y) - \psi(y) : y \in W\} \ .$$

We have $\sigma_1 \leq \tau_1$ by XX.1, $\sigma_2 \leq \tau_2$ by XX.2, $\sigma_2 \leq \tau_1$ by XX.3, and $\sigma_1 \leq \tau_2$ by XX.4. Thus

$$\max(\sigma_1, \sigma_2) \leq \min(\tau_1, \tau_2) \ .$$

If there is a $y \in W$ with $p(x_0 + y) < +\infty$, then τ_1 is not $+\infty$, so σ_1 and σ_2 are not $+\infty$; if there is a $y \in W$ with $p(-x_0 - y) < +\infty$, then σ_1 is not $-\infty$, so τ_1 and τ_2 are not $-\infty$. A similar statement holds for q. Thus, if p or q is finite, we have that $\max(\sigma_1, \sigma_2) \neq +\infty$ and $\min(\tau_1, \tau_2) \neq -\infty$.

Choose any $c \in \mathbb{R}$ such that

$$\max(\sigma_1, \sigma_2) \leq c \leq \min(\tau_1, \tau_2)$$

(to avoid making a choice, just set $c = \min(\tau_1, \tau_2)$). We will show that this c works, i.e. that $\theta(y + \alpha x_0) = \psi(y) + \alpha c$ satisfies

$$q(y + \alpha x_0) \leq \psi(y) + \alpha c \leq p(y + \alpha x_0)$$

for all $y \in W$ and $\alpha \in \mathbb{R}$.

Let $x \in X$. Write $x = y + \alpha x_0$. If $\alpha = 0$, then $x = y \in W$ and $q(x) \leq \theta(x) = \psi(x) \leq p(x)$ by assumption. If $\alpha > 0$, we have $\alpha^{-1} y \in W$, so

$$c \leq \tau_1 \leq p(x_0 + \alpha^{-1} y) - \psi(\alpha^{-1} y)$$

$$\alpha c \leq \alpha p(x_0 + \alpha^{-1} y) - \alpha \psi(\alpha^{-1} y) = p(\alpha x_0 + y) - \psi(y) = p(x) - \psi(y)$$

$$\theta(x) = \psi(y) + \alpha c \leq p(x) \ .$$

Similarly using σ_2 we obtain $q(x) \leq \theta(x)$.

If $\alpha < 0$, we similarly have

$$-p(-x_0 - \alpha^{-1} y) - \psi(\alpha^{-1} y) \leq \sigma_1 \leq c$$

$$-p(x) + \psi(y) = -p(\alpha x_0 + y) + \psi(y) = (-\alpha)[-p(-x_0 - \alpha^{-1} y)] - (-\alpha)\psi(\alpha^{-1} y) \leq -\alpha c$$

$$\theta(x) = \psi(y) + \alpha c \leq p(x) \ .$$

In the same manner using τ_2 we have $q(x) \leq \theta(x)$. 

XX.6.1.9. In the case of XX.6.1.3. where V/W is countably generated, we can iterate XX.6.1.8. inductively to extend ψ to all of V (the Countable AC is technically needed to do this; if V itself is countably generated, the Countable AC can be dispensed with since we can take c to have a definite formula at each step). The same construction can be done transfinitely if a set of generators for V/W can be well ordered; assuming the Well-Ordering Principle (i.e. assuming AC: cf. ()), the proof of the general version of XX.6.1.3. can be completed this way.

XX.6.1.10. We will give an alternate argument using Zorn's Lemma to finish the proof of XX.6.1.3. in the general case. Let $\mathcal{E}$ be the set of pairs (X, θ), where X is a subspace of V containing W and θ is a linear functional on X extending ψ, with $q(x) \leq \theta(x) \leq p(x)$ for all $x \in X$. Put a partial ordering $\precsim$ on $\mathcal{E}$ by setting $(X_1, \theta_1) \precsim (X_2, \theta_2)$ if and only if $X_1 \subseteq X_2$ and θ_2 extends θ_1.

If $\mathcal{C} = \{(X_i, \theta_i : i \in I\}$ is a chain in $\mathcal{E}$, set $X = \cup_i X_i$. If $x, y \in X$, then $x \in X_i$ and $y \in X_j$ for some i, j; but either $X_i \subseteq X_j$ or $X_j \subseteq X_i$ since $\mathcal{C}$ is a chain, so either $x, y \in X_i$ or $x, y \in X_j$; in either case $x + y \in X$, so X is closed under addition. X is obviously closed under scalar multiplication, so X is a subspace of V. Define $\theta : X \to \mathbb{R}$ by $\theta(x) = \theta_i(x)$ if $x \in X_i$; this function is well defined since the θ_i all agree wherever they are defined. It is routine to check that θ is linear. Thus (X, θ) is an upper bound for $\mathcal{C}$ in $\mathcal{E}$.

Thus Zorn's lemma applies to give a maximal element (X, θ) in $\mathcal{E}$. But we must have $X = V$, for otherwise if $x_0 \in V \setminus X$ Lemma XX.6.1.8. gives an extension of θ to the span of X and x_0 with the right properties, contradicting maximality of (X, θ). Then $\phi = \theta$ is the desired extension.

This completes the proof of Theorem XX.6.1.3.. 

XX.6.1.11. The proof we have given of the Hahn-Banach Theorem uses the AC. But the full AC is not necessary; one can get away with weaker assumptions such as the BPI (). Even this assumption is not necessary: the Hahn-Banach Theorem is logically equivalent (over ZF) to the Measure Extension Property (), which is strictly weaker than the BPI []. The Hahn-Banach Theorem is not a theorem of ZF, i.e. some form of Choice is necessary.

XX.6.2. Extension of Bounded Linear Functionals

One of the most common special cases of XX.6.1.4. is extension of bounded linear functionals from subspaces of normed vector spaces without increasing the norm:

XX.6.2.1. THEOREM. [HAHN-BANACH THEOREM, VERSION 2] Let V be a real vector space, and $\|\cdot\|$ a norm on V. Let W be a subspace of V, and ψ a bounded linear functional on W. Then there is a bounded linear functional ϕ on V extending ψ with $\|\phi\| = \|\psi\|$.

PROOF: Apply XX.6.1.4. with $p(x) = \|\psi\|\|x\|$. 👍

XX.6.2.2. Note that no completeness is assumed in this result, and the subspace W need not be closed in V. (This is not a significant observation, though, since a bounded linear functional can automatically be extended to the completion or closure without increase in norm by uniform continuity ().)

XX.6.2.3. COROLLARY. Let $V \neq \{0\}$ be a normed real vector space, and $x \in V$. Then there is a bounded linear functional ϕ of norm 1 on V with $\phi(x) = \|x\|$.

PROOF: Suppose $x \neq 0$. Let W be the one-dimensional subspace of V spanned by x. Define $\psi : W \to \mathbb{R}$ by $\psi(\alpha x) = \alpha\|x\|$. Then ψ is a bounded linear functional of norm 1 on W with $\psi(x) = \|x\|$. Extend ψ to a bounded linear functional of norm 1 on V.

If $x = 0$, let ϕ be any bounded linear functional on V of norm 1 (such a linear functional exists by the first part of the proof applied to any nonzero vector in V). 👍

XX.6.2.4. This result shows that if V is a normed vector space, then the dual space V^* () is "large" (large enough to determine the norm on V). Without this result it is not obvious that a normed vector space has any nonzero bounded linear functionals.

XX.6.2.5. Theorem XX.6.2.1. requires some version of the AC (XX.6.1.11.). However, if V is separable, or more generally contains a well-ordered total subset, no version of the AC is necessary. Thus this version of the Hahn-Banach Theorem holds for separable Banach spaces with no Choice needed.

The Canonical Embedding into the Second Dual

XX.6.2.6. If V is a normed (real) vector space, then V^* is a Banach space (). V^* itself has a dual space $V^{**} = (V^*)^*$. If $x \in V$, then there is a canonically associated $\hat{x} \in V^{**}$ defined by

$$\hat{x}(\phi) = \phi(x)$$

for $\phi \in V^*$. It is easily checked that $\hat{x}$ is a linear functional on V^*, and that $x \mapsto \hat{x}$ is linear in x. Since $|\hat{x}(\phi)| = |\phi(x)| \leq \|x\|\|\phi\|$ for any $\phi \in V^*$, $\hat{x}$ is bounded and $\|\hat{x}\| \leq \|x\|$. By XX.6.2.3., we actually have $\|\hat{x}\| = \|x\|$. So:

XX.6.2.7. Corollary. Let V be a normed real vector space. The map $x \mapsto \hat{x}$ is an isometric linear embedding of V into V^{**}, called the *canonical embedding*.

XX.6.2.8. V is said to be *reflexive* if the canonical map from V to V^{**} is surjective. Since V^{**} is a Banach space, if V is reflexive it must be complete (a Banach space). Some Banach spaces are reflexive (), () while others are not ().

XX.6.3. The Complex Hahn-Banach Theorem

The complex case of the Hahn=Banach Theorem is slightly different: since a nonzero complex-linear functional takes all values in $\mathbb{C}$, the statement of XX.6.1.3. does not make sense. But there is a simple modification, based on the following observation:

XX.6.3.1. Proposition. Let V be a vector space over $\mathbb{C}$, and ϕ a complex-linear functional on X. Let $\theta = Re(\phi)$. Then θ is a real-linear functional on V, and

$$\phi(x) = \theta(x) - i\theta(ix)$$

for all $x \in V$. Conversely, if θ is any real-linear functional on V, define ϕ by this formula; then ϕ is a complex-linear functional on V. Thus every real linear functional on V is the real part of a unique complex-linear functional.

Proof: if ϕ is complex-linear and θ and λ are the real and imaginary parts, so $\phi(x) = \theta(x) + i\lambda(x)$, we have

$$\theta(ix) + i\lambda(ix) = \phi(ix) = i\phi(x) = i\theta(x) + i^2\lambda(x) = -\lambda(x) + i\theta(x)$$

for $x \in V$, so $\lambda(x) = -\theta(ix)$. Conversely, if θ is a real-linear functional on V, and $\phi(x) = \theta(x) - i\theta(ix)$, then ϕ is real-linear, and for $x \in V$ we have

$$\phi(ix) = \theta(ix) - i\theta(i^2x) = \theta(ix) - i\theta(-x) = \theta(ix) + i\theta(x)$$

$$i\phi(x) = i\theta(x) - i^2\theta(x) = i\theta(x) + \theta(ix)$$

so ϕ is complex-linear. 👍

XX.6.3.2. Theorem. [Complex Hahn-Banach Theorem, Version 1] Let V be a complex vector space, p a sublinear functional on V, and q a superlinear functional on V satisfying $q(x) \leq p(x)$ for all $x \in V$. Assume at least one of p and q is finite. Let W be a subspace of V, and ψ a linear functional on W satisfying $q(y) \leq Re(\psi(y)) \leq p(y)$ for all $y \in W$. Then there is a linear functional ϕ on V extending ψ with

$$q(x) \leq Re(\phi(x)) \leq p(x)$$

for all $x \in V$.

Proof: Let $\lambda = Re(\psi)$, and extend λ to a real linear functional θ on V satisfying $q(x) \leq \theta(x) \leq p(x)$ for all $x \in V$ by XX.6.1.3.. Set $\phi(x) = \theta(x) - i\theta(ix)$. 👍

Taking $q(x) = -\infty$ for all x, we get the following commonly-stated version of the theorem:

XX.6.3.3. Corollary. [Complex Hahn-Banach Theorem, Version 1A] Let V be a complex vector space, and p a finite sublinear functional on V. Let W be a subspace of V, and ψ a linear functional on W satisfying $Re(\psi(y)) \leq p(y)$ for all $y \in W$. Then there is a linear functional ϕ on V extending ψ with

$$Re(\phi(x)) \leq p(x)$$

for all $x \in V$.

There is an analogous result with inequalities reversed for a superlinear functional.

XX.6.3.4. Corollary. Let V be a complex vector space, p a sublinear functional on V, and q a superlinear functional on V satisfying $q(x) \leq p(x)$ for all $x \in V$. Assume at least one of p and q is finite. Then there is a linear functional ϕ on V with

$$q(x) \leq Re(\phi(x)) \leq p(x)$$

for all $x \in V$.

There are also one-sided versions of this result.

XX.6.3.5. Theorem. [Complex Hahn-Banach Theorem, Version 2] Let V be a complex vector space, and $\|\cdot\|$ a norm on V. Let W be a subspace of V, and ψ a bounded linear functional on W. Then there is a bounded linear functional ϕ on V extending ψ with $\|\phi\| = \|\psi\|$.

Proof: Apply XX.6.3.3. with $p(x) = \|\psi\|\|x\|$. We have $Re(\phi(x)) \leq \|\psi\|\|x\|$ for all $x \in V$. For any $x \in V$, there is an $\alpha \in \mathbb{C}$, $|\alpha| = 1$, such that $\phi(\alpha x) \geq 0$. Thus

$$|\phi(x)| = |\alpha||\phi(x)| = |\phi(\alpha x)| = Re(\phi(\alpha x)) \leq \|\psi\|\|\alpha x\| = \|\psi\|\|x\|$$

so $\|\phi\| \leq \|\psi\|$, and the opposite inequality is obvious. 👍

XX.6.3.6. Note that no completeness is assumed in this result, and the subspace W need not be closed in V. (This is not a significant observation, though, since a bounded linear functional can automatically be extended to the completion or closure without increase in norm by uniform continuity ().)

XX.6.3.7. COROLLARY. Let $V \neq \{0\}$ be a normed complex vector space, and $x \in V$. Then there is a bounded linear functional ϕ of norm 1 on V with $\phi(x) = \|x\|$.

PROOF: Suppose $x \neq 0$. Let W be the one-dimensional subspace of V spanned by x. Define $\psi : W \to \mathbb{C}$ by $\psi(\alpha x) = \alpha\|x\|$. Then ψ is a bounded linear functional of norm 1 on W with $\psi(x) = \|x\|$. Extend ψ to a bounded linear functional of norm 1 on V.

If $x = 0$, let ϕ be any bounded linear functional on V of norm 1 (such a linear functional exists by the first part of the proof applied to any nonzero vector in V). 👍

XX.6.3.8. This result shows that if V is a normed vector space, then the dual space V^* () is "large" (large enough to determine the norm on V). Without this result it is not obvious that a normed vector space has any nonzero bounded linear functionals.

XX.6.3.9. Theorem XX.6.3.5. requires some version of the AC (XX.6.1.11.). However, if V is separable, or more generally contains a well-ordered total subset, no version of the AC is necessary. Thus this version of the Hahn-Banach Theorem holds for separable Banach spaces with no Choice needed.

XX.6.3.10. Actually the statements of the various versions of the complex Hahn-Banach Theorem apply verbatim to real vector spaces, since $\phi = Re(\phi)$ for a real linear functional. But it seems clearer to state the real and complex cases separately, especially since the real case is used to prove the complex case.

The Canonical Embedding into the Second Dual

XX.6.3.11. If V is a normed complex vector space, then V^* is a Banach space (). V^* itself has a dual space $V^{**} = (V^*)^*$. If $x \in V$, then there is a canonically associated $\hat{x} \in V^{**}$ defined by

$$\hat{x}(\phi) = \phi(x)$$

for $\phi \in V^*$. It is easily checked that $\hat{x}$ is a linear functional on V^*, and that $x \mapsto \hat{x}$ is linear in x. Since $|\hat{x}(\phi)| = |\phi(x)| \leq \|x\|\|\phi\|$ for any $\phi \in V^*$, $\hat{x}$ is bounded and $\|\hat{x}\| \leq \|x\|$. By XX.6.2.3., we actually have $\|\hat{x}\| = \|x\|$. So:

XX.6.3.12. COROLLARY. Let V be a normed complex vector space. The map $x \mapsto \hat{x}$ is an isometric linear embedding of V into V^{**}, called the *canonical embedding*.

XX.6.4. Separation of Convex Sets and Version 3

The Hahn-Banach Theorem can be rephrased as a statement that disjoint convex sets can be separated by linear functionals or hyperplanes under mild additional hypotheses.

We will first work in real vector spaces, and then give the (slight) modifications necessary in the complex case.

XX.6.4.1. DEFINITION. Let X be a vector space over $\mathbb{R}$, and $A, B \subseteq X$. Then A and B are *separated* (in X) if there is a nonzero linear functional ϕ on X with $\phi(x) \leq \phi(y)$ for all $x \in A$, $y \in B$, i.e.

$$\sup_{x \in A} \phi(x) \leq \inf_{y \in B} \phi(y) \ .$$

We say ϕ *separates* A and B. The sets A and B are *strictly separated* if there is a (necessarily nonzero) linear functional ϕ on X with

$$\sup_{x \in A} \phi(x) < \inf_{y \in B} \phi(y) \ .$$

We say ϕ *strictly separates* A and B.

The definition is symmetric in A and B: if ϕ (strictly) separates A and B, then $-\phi$ (strictly) separates B and A.

XX.6.4.2. Strictly separated sets must be disjoint. Separated sets (by this definition) are not necessarily disjoint, but must be "almost disjoint." We will usually only consider separation for disjoint sets. Indeed, some references require separated sets to be disjoint.

Separation can be rephrased "geometrically" in terms of hyperplanes:

XX.6.4.3. DEFINITION. Let X be a vector space over $\mathbb{R}$. A *hyperplane* in X is an affine subspace of X of codimension 1.

XX.6.4.4. If H is a hyperplane in X, then there is a (nonunique, necessarily nonzero) linear functional ϕ and a constant c such that $H = \{x \in X : \phi(x) = c\}$: fix $x_0 \in H$, and let $Y = H - x_0$; then Y is a subspace of X of codimension 1. If $z \in X \setminus Y$, then X is spanned by Y and z; for $x = y + \alpha z \in X$, where $y \in Y$, set $\phi(x) = \alpha$ and $c = \phi(x_0)$. (Conversely, if ϕ is a nonzero linear functional, and $c \in \mathbb{R}$, then $\{x \in X : \phi(x) = c\}$ is a hyperplane in X.)

As a result, X splits into two *closed half-spaces* $H^+ = \{x \in X : \phi(x) \geq c\}$ and $H^- = \{x \in X : \phi(x) \leq c\}$, whose intersection is H, and two disjoint *open half-spaces* $H_0^+ = \{x \in X : \phi(x) > c\}$ and $H_0^- = \{x \in X : \phi(x) < c\}$ with H^+ the disjoint union of H_0^+ and H, and H^- the disjoint union of H_0^- and H. These half-spaces are independent of the choice of ϕ except that $+$ and $-$ can be interchanged if ϕ is changed.

Thus separation can be rephrased:

XX.6.4.5. PROPOSITION. Let X be a vector space over $\mathbb{R}$, and $A, B \subseteq X$. Then A and B are separated if and only if there is a hyperplane H in X such that $A \subseteq H^-$ and $B \subseteq H^+$. (We say A and B are *separated by* H.)

Strict separation cannot be quite so cleanly stated; see Exercise XX.6.5.1..

Hahn-Banach Theorem Version 3

There is an important rephrasing of the Hahn-Banach Theorem in terms of separation of convex sets, called Version 3 or the *Hahn-Banach Separation Theorem*:

XX.6.4.6. THEOREM. [HAHN-BANACH SEPARATION THEOREM] Let X be a vector space over $\mathbb{R}$, and A, B disjoint nonempty convex sets in X. If one of A, B has an internal point, then A and B are separated (by a linear functional or hyperplane).

PROOF: Suppose without loss of generality that A has an internal point z. Separating A and B is equivalent to separating $A - z$ and $B - z$, so we may assume $z = 0$. And separating A and B is the same as separating $A - B$ (which is convex, and $0 \notin A - B$) and $\{0\}$.

Fix $y \in B$. Then $-y$ is an internal point of $A - B$, so 0 is an internal point of the convex set $C = A - B + y$, i.e. C is radial. We have $y \notin C$ since $0 \notin A - B$.

Let m_C be the Minkowski functional of C. Then m_C is subadditive since C is convex; $m_C \leq 1$ on C, and $m_C(y) \geq 1$ since $y \notin C$. Define a linear functional ψ on the one-dimensional subspace spanned by y by $\psi(\alpha y) = \alpha$. Then $\psi(\alpha y) \leq m_C(\alpha y)$ for all $\alpha \in \mathbb{R}$. By the Hahn-Banach Theorem Version 1A (), there is a linear functional ϕ on X extending ψ with $\phi(x) \leq m_C(x)$ for all $x \in X$. Thus $\phi(x) \leq 1$ for $x \in C$ and $\phi(y) \geq 1$, so ϕ separates C and y and therefore separates $A - B$ and 0, i.e. separates A and B. 👍

XX.6.4.7. EXAMPLE. Here is an interesting "folklore" example of a pair of convex sets which cannot be separated by a linear functional, showing that the hypothesis of an internal point cannot be eliminated.

Let $X = c_{00}$ (). Let A be the set of nonzero sequences in X whose last nonzero term is positive. It is obvious that A is convex. Similarly, let $B = -A$ be the set of nonzero sequences whose last nonzero term is negative. Then B is convex, and X is the disjoint union of A, B, and $\{0\}$.

If X is given the uniform norm () (or any vector space topology), then A and B are dense in X: if $x \in X$, fix a k larger than the index of the last nonzero term in x, and then $x + \epsilon \mathbf{e}_k \in A$ for any $\epsilon > 0$, where $\mathbf{e}_k$ is the k'th standard basis vector (). A similar argument shows that A and B have no interior (or internal) points.

Since A and B are dense in X, it is obvious they cannot be separated by a bounded linear functional. But in fact they cannot be separated by *any* nonzero linear functional, bounded or not, i.e. there is no nonzero linear functional ϕ on X such that $\phi(x) \geq 0$ for all $x \in A$ (a separating linear functional or its negative would have to have this property). For if ϕ is such a linear functional, and $x \in X$ is arbitrary, fix k larger than the index of the last nonzero term in x. Then $x + \epsilon \mathbf{e}_k \in A$ for any $\epsilon > 0$, so

$$0 \leq \phi(x + \epsilon \mathbf{e}_k) = \phi(x) + \epsilon \phi(\mathbf{e}_k)$$

for any $\epsilon > 0$. Letting $\epsilon \to 0$, we obtain $\phi(x) \geq 0$. Since $x \in X$ is arbitrary, we also have $\phi(-x) \geq 0$, so $\phi(x) = 0$ for any x and ϕ is the zero linear functional.

Note that we have referred to a norm topology on X, but actually this example is purely algebraic and can be written (except for the density of A and B) without any reference to a topology on X.

The Complex Case

Just as with the previous versions of the Hahn-Banach Theorem, there is a similar statement for complex vector spaces. Separation must be defined slightly differently:

XX.6.4.8. Definition. Let X be a vector space over $\mathbb{C}$, and $A, B \subseteq X$. Then A and B are *separated* (in X) if there is a nonzero linear functional ϕ on X with $Re(\phi(x)) \leq Re(\phi(y))$ for all $x \in A$, $y \in B$, i.e.

$$\sup_{x \in A} Re(\phi(x)) \leq \inf_{y \in B} Re(\phi(y)) \ .$$

We say ϕ *separates* A and B. The sets A and B are *strictly separated* if there is a (necessarily nonzero) linear functional ϕ on X with

$$\sup_{x \in A} Re(\phi(x)) < \inf_{y \in B} Re(\phi(y)) \ .$$

We say ϕ *strictly separates* A and B.

There is not a good rephrasing in terms of hyperplanes.

XX.6.4.9. Theorem. [Complex Hahn-Banach Separation Theorem] Let X be a vector space over $\mathbb{C}$, and A, B disjoint nonempty convex sets in X. If one of A, B has an internal point, then A and B are separated.

XX.6.5. Exercises

XX.6.5.1. Here are two natural separation properties between separation and strict separation.

(a) If X is a topological vector space and A and B disjoint convex sets in X, then A and B are *completely separated* if there is a hyperplane H such that A and B are contained in distinct open half-spaces for H.

(b) If X is a topological vector space and A and B disjoint convex sets in X, then A and B are *fully separated* if there is a hyperplane H such that one of A and B is contained in an open half-space for H and the other in the complementary closed half-space.

(c) Observe that strict separation $\Rightarrow$ complete separation $\Rightarrow$ full separation $\Rightarrow$ separation.

(d) Show that A and B are fully separated if and only if there is a continuous linear functional ϕ on X such that $\phi(a) < \phi(b)$ for all $a \in A$, $b \in B$, and that A and B are completely separated if and only if there is a continuous linear functional ϕ and a real number m such that $f(a) < m < f(b)$ for all $a \in A$, $b \in B$.

(e) Show that if A and B are separated convex sets in a topological vector space, and if one is open, then A and B are fully separated. If both are open, then they are completely separated. If A and $\bar{B}$ are not disjoint, then A and B cannot be completely separated, and if $\bar{A}$ and B are also not disjoint, then A and B cannot be fully separated.

(f) Let $X = \mathbb{R}^2$, A the open upper half-plane along with the positive x-axis, and B the lower half-plane along with the negative x-axis. Show that A and B are disjoint, convex, separated, but not fully separated.

(g) Let $X = \mathbb{R}^2$, A the x-axis, and $B = \left\{(x, y) : x > 0, y \geq \frac{1}{x}\right\}$. Show that A and B are disjoint closed convex sets which are fully separated but not completely separated.

(h) Show that if A and B are disjoint closed convex subsets of $\mathbb{R}^2$, then A and B are fully separated.

(i) [KN76, 3G] Let $X = \mathbb{R}^3$,

$$A = \{(x, y, z) : x \geq 0, y \geq 0, z \geq 0, z^2 \leq xy\}$$

$$B = \{(0, y, 1) : y \in \mathbb{R}\} \ .$$

Show that A and B are disjoint, closed, convex, and separated, but not fully separated.

Thus full or complete separation is not always possible, even in finite-dimensional spaces.

XX.7. Dual Spaces and Weak Topologies

One of the core tenets of functional analysis is that spaces can be studied via the scalar-valued continuous functions on them. This section describes the linear version of this philosophy.

XX.7.1. Bounded Linear Functionals

XX.7.1.1. Definition. Let X be a vector space over $\mathbb{F}$. A *linear functional* on X is a linear transformation from X to $\mathbb{F}$. If X is a normed vector space, a linear functional ϕ on X is *bounded* if it is bounded as a linear transformation, i.e. if there is a constant M such that $|\phi(x)| \leq M\|x\|$ for all $x \in X$. The smallest such M is the *norm* of ϕ, denoted $\|\phi\|$.

XX.7.1.2. **Notation:** If X is a vector space over $\mathbb{F}$, we will write X^d for the set of linear functionals on X. If X is normed, write X^* for the set $\mathcal{B}(X, \mathbb{F})$ of bounded linear functionals on X. We have that X^d is a vector space over $\mathbb{F}$ in the obvious way, and by (), X^* is a subspace which is normed by $\|\cdot\|$; X^* is a Banach space by (). X^d is called the *algebraic dual space* of X, and X^* the *(topological) dual space* of X.

There is no uniformity of notation for dual spaces. Many authors use X' for the topological dual space, and some use X^* or X' to denote the algebraic dual. We use what seems to be the most common notation for the topological dual, although the notation X^d is not standard for the algebraic dual. We usually use ϕ, ψ, etc. to denote linear functionals; some authors use x^* to denote a general element of X^*, leading to poor and confusing expressions like $x^*(x)$ where x denotes a general element of X and x^* a general element of X^*, with no relation between them.

XX.7.1.3. By (), a linear functional on a normed vector space is continuous if and only if it is bounded. The null space of any bounded operator is closed (). The converse does not hold in general, e.g. there are unbounded one-to-one linear transformations. However:

XX.7.1.4. Proposition. Let X be a normed vector space over $\mathbb{F}$, and $\phi : X \to \mathbb{F}$ a linear functional on X. If the null space N_ϕ is closed in X, then ϕ is bounded.

Proof: Suppose ϕ is unbounded. Then for each $n \in \mathbb{N}$ there is a $y_n \in X$ with $\|y_n\| = 1$ but $|\phi(y_n)| > n$. Set $x_n = \frac{1}{\phi(y_n)} y_n$. Then $\|x_n\| < 1/n$ and $\phi(x_n) = 1$ for all n. Fix $v \in X$ with $\phi(v) = 1$. We have $x_n \to 0$, so $v - x_n \to v$. But $v - x_n \in N_\phi$ for all n, so $v \in \overline{N_\phi} \setminus N_\phi$, and N_ϕ is not closed.

In fact, this argument shows that if ϕ is unbounded, then N_ϕ is dense in X. (Actually it would have to be either closed or dense since it has codimension 1.)

Without the Hahn-Banach Theorem, it is not obvious that a normed vector space has any nonzero bounded linear functionals. But by XX.6.2.3. and (), we have:

XX.7.1.5. Corollary. Let $X \neq \{0\}$ be a normed vector space, and $x \in X$. Then

$$\|x\| = \max\{|\phi(x)| : \phi \in X^*, \|\phi\| = 1\} = \sup\{|\phi(x)| : \phi \in X^*, \|\phi\| = 1\} .$$

Here is a simple but useful consequence:

XX.7.1.6. PROPOSITION. Let X be a normed vector space and Y a proper closed subspace. Then there is a bounded linear functional ϕ on X with $\|\phi\| = 1$ and $Y \subseteq \mathcal{N}(\phi)$ (i.e. $\phi(y) = 0$ for all $y \in Y$).

PROOF: The normed vector space X/Y has a nonzero bounded linear functional ψ. Let $\pi : X \to X/Y$ be the quotient map; then $\|\pi\| \leq 1$ (in fact $\|\pi\| = 1$ by ()). Then $\psi \circ \pi$ is a nonzero bounded linear functional on X whose null space contains Y, and can be normalized to ϕ. 👍

Subspaces and Quotients

We can be more specific. Let X be a normed space and Y a closed subspace. What is the relation between X^*, Y^*, and $(X/Y)^*$?

XX.7.1.7. We define the *annihilator* $Y^\perp$ to be

$$Y^\perp = \{\phi \in X^* : \phi(y) = 0 \ \forall y \in Y\} .$$

Then $Y^\perp$ is a closed subspace of X^*. By XX.7.1.6., $Y^\perp = \{0\}$ if and only if $Y = X$. At the other extreme, $\{0\}^\perp = X^*$.

XX.7.1.8. Let ρ be the restriction map from X^* to Y^*. Then ρ is surjective by the Hahn-Banach Extension Theorem (), and its null space is exactly $Y^\perp$. Thus ρ drops to a vector space isomorphism $\bar{\rho}$ from $X^*/Y^\perp$ to Y^*.

XX.7.1.9. PROPOSITION. The map $\bar{\rho} : X^*/Y^\perp \to Y^*$ is an isometric isomorphism.

PROOF: It is convenient to show that $\eta = \bar{\rho}^{-1} : Y^* \to X^*/Y^\perp$ is an isometry. If $\psi \in Y^*$, then $\eta(\psi)$ is the equivalence class of all extensions of ψ to X, and $\|\eta(\phi)\|$ is by definition the infimum of the norms of all extensions. Each extension ϕ has $\|\phi\| \geq \|\psi\|$, so $\|\eta(\psi)\| \geq \|\psi\|$, and by the Hahn-Banach Extension Theorem there is a ϕ with $\|\phi\| = \|\psi\|$, so $\|\eta(\psi)\| \leq \|\psi\|$. 👍

XX.7.1.10. Let $\pi : X \to X/Y$ be the quotient map. Since π is bounded, every $\psi \in (X/Y)^*$ defines a bounded linear functional $\psi \circ \pi$ on X, which vanishes on Y, i.e. $\psi \circ \pi \in Y^\perp$. The map $\psi \mapsto \psi \circ \pi$ is a linear map σ from $(X/Y)^*$ to $Y^\perp$.

XX.7.1.11. PROPOSITION. The map $\sigma : (X/Y)^* \to Y^\perp$ is an isometric isomorphism.

PROOF: The map σ is clearly injective. Any $\phi \in Y^\perp$ has null space containing Y and thus drops to a linear functional $\bar{\phi}$ on X/Y. If $z \in X/Y$, $\|z\| = 1$, then for any $\alpha > 1$ there is an $x \in X$ with $\pi(x) = z$ and $\|x\| < \alpha$. Thus

$$|\bar{\phi}(z)| = |\phi(x)| \leq \|\phi\|\|x\| < \alpha\|\phi\|$$

and since this holds for all z and all $\alpha > 1$, $\|\bar{\phi}\| \leq \|\phi\|$. In particular, $\bar{\phi}$ is bounded, hence in $(X/Y)^*$; thus σ is surjective. The map $\omega : \phi \mapsto \bar{\phi}$ is exactly σ^{-1}, and this argument shows that $\|\omega\| \leq 1$. Conversely, if $\psi \in (X/Y)^*$, let $\phi = \sigma(\psi)$. If $x \in X$, we have

$$|\phi(x)| = |\psi(\pi(x))| \leq \|\psi\|\|\pi(x)\| \leq \|\psi\|\|x\|$$

so $\|\phi\| \leq \|\psi\|$. Therefore $\|\sigma\| \leq 1$. 👍

XX.7.1.12. Thus the dual of a subspace of X is a quotient of X^*, and the dual of a quotient of X is a subspace of X^*. The correspondence between X and X^* is an important example of a *duality* (). In a duality, subobjects correspond to quotients and vice versa.

XX.7.1.13. The duality between X and X^* is not complete, even if we restrict to Banach spaces (i.e. assume X is complete): not every closed subspace of X^* is $Y^\perp$ for a closed subspace Y of X in general. See XX.7.4.13. for further discussion of this.

XX.7.2. The Weak Topology

If X is a normed vector space, then X of course has a norm topology. But it also has another natural and important topology, the weak topology.

XX.7.2.1. Let X be a normed vector space. If $\phi_1, \ldots, \phi_n \in X^*$ and $\epsilon > 0$, set

$$U_{\{\phi_1,\ldots,\phi_n\},\epsilon} = \{x \in X : |\phi_1(x)| < \epsilon, \ldots, |\phi_n(x)| < \epsilon\} .$$

Note that $U_{\{\phi_1,\ldots,\phi_n\},\epsilon}$ is an open neighborhood of 0 (in the norm topology) and is convex and circled (). These sets form a local base at 0 for a topology making X into a locally convex topological vector space. In fact, by scaling the ϕ_k, it suffices to take basic open sets with $\epsilon = 1$; and it suffices to take basic open sets with the ϕ_k linearly independent (Exercise XX.7.5.7.).

XX.7.2.2. Definition. This topology is called the *weak topology* on X (from X^*).

Since the basic open sets for the weak topology are norm-open, the weak topology is weaker than the norm topology. It is almost always strictly weaker (XX.7.2.6.).

XX.7.2.3. Proposition. The weak topology on X is Hausdorff.

Proof: It suffices to show that the intersection of the basic open sets is $\{0\}$. Let $x \in X$, $x \neq 0$, and let ϕ be a bounded linear functional on X with $\phi(x) = \|x\|$. Set $\epsilon = \|x\|/2$. Then $U_{\{\phi\},\epsilon}$ is a basic open neighborhood of 0 not containing x. 👍

The weak topology is the "topology of pointwise convergence":

XX.7.2.4. PROPOSITION. Let X be a normed vector space, (x_i) a net in X, and $x \in X$. Then $x_i \to x$ in the weak topology if and only if $\phi(x_i) \to \phi(x)$ for every $\phi \in X^*$.

PROOF: Replacing x_i by $x_i - x$, we may assume $x = 0$. Suppose $x_i \to 0$ in the weak topology. Let $\phi \in X^*$ and $\epsilon > 0$. Then $x_i \in U_{\{\phi\},\epsilon}$ for all sufficiently large i, so $\phi(x_i) \to 0$. Conversely, if $\phi(x_i) \to 0$ for all $\phi \in X^*$, let $\phi_1, \ldots, \phi_n \in X^*$ and $\epsilon > 0$. Then for each k, $1 \leq k \leq n$, there is an i_k such that $|\phi(x_i)| < \epsilon$ for all $i > i_k$. Since the index set of the net is directed, there is an i_0 with $i_0 > i_k$ for $1 \leq k \leq n$. If $i > i_0$, then $x_i \in U_{\{\phi_1,\ldots,\phi_n\},\epsilon}$. Thus $x_i \to 0$ in the weak topology. 👍

XX.7.2.5. In light of XX.7.1.5., the norm topology can be called "the topology of uniform convergence." In many references, the norm topology is called the *strong topology*, but this is too easily confused with the strong operator topology () when X is a space of operators, so we will avoid this terminology.

XX.7.2.6. PROPOSITION. Let X be a normed vector space. Then the weak topology on X coincides with the norm topology if and only if X is finite-dimensional.

PROOF: If X is finite-dimensional, then all Hausdorff TVS topologies on X coincide (). Conversely, if the norm and weak topologies on X coincide, the open unit ball of X is a weak neighborhood of 0, hence contains a basic neighborhood $U_{\{\phi_1,\ldots,\phi_n\},1}$, i.e. there are $\phi_1, \ldots, \phi_n \in X^*$ such that $|\phi_k(x)| < 1$ for all k implies $\|x\| < 1$. Then for any $\epsilon > 0$, $|\phi_k(x)| < \epsilon$ for all k implies $\|x\| < \epsilon$, so $\phi_k(x) = 0$ for all k implies $x = 0$. Thus the linear map $T : X \to \mathbb{F}^n$, $T(x) = (\phi_1(x), \ldots, \phi_n(x))$, has $\mathcal{N}(T) = \{0\}$ and is therefore injective, so $dim(X) \leq n$. 👍

XX.7.2.7. Existence of the weak topology distinct from the norm topology reinforces the warning in (): spaces in analysis can have more than one natural topology, and it is crucial to always keep track of what topology is being considered. We sometimes need to even consider delicate interactions of two or more topologies (e.g. ()).

Since the norm and weak topologies are distinct in general, a norm-closed subset of a normed vector space is not generally weakly closed. But there is an important case where this holds:

XX.7.2.8. PROPOSITION. Let X be a normed vector space. Every norm-closed convex subset of X is weakly closed.

PROOF: Let C be a norm-closed convex subset of X. If $x \in X$, $x \notin C$, then by the Hahn-Banach Separation Theorem () there is a bounded linear functional ϕ on X with

$$|\phi(x)| > \sup\{|\phi(y)| : y \in C\} .$$

By XX.7.2.4., x is not in the weak closure of C. Since this is true for every $x \in X \setminus C$, C is weakly closed. 👍

XX.7.2.9. Corollary. Every norm-closed subspace Y of X is weakly closed. The weak topology on Y is the relative topology from the weak topology on X.

Proof: For the last statement, every basic open neighborhood for the weak topology of Y is the intersection with Y of a basic open neighborhood for the weak topology of X by the Hahn-Banach Extension Theorem. 👍

Here is a nice consequence:

XX.7.2.10. Corollary. Let X be a normed vector space. If $S \subseteq X$ and $C = Conv(S)$, then any x in the weak closure of S is in the norm-closure of C, and is thus a norm-limit of a sequence in C. In particular, if (x_i) is a net in X converging weakly to $x \in X$, then there is a sequence in the convex hull of the x_i which converges to x in norm.

Proof: The norm-closed convex hull $\bar{C}$ of S is norm-closed and convex, hence weakly closed. Since $S \subseteq C$, $x \in \bar{C}$. Since X is a metric space, there is a sequence in C converging to x in norm. 👍

XX.7.2.11. Note that the result of Proposition XX.7.2.8. does not hold with "closed" replaced by "open." Indeed, open balls in X are norm-open convex subsets which are not generally weakly open (if they were, the topologies would coincide!) ✋

Similarly, we have:

XX.7.2.12. Proposition. Let X be a normed vector space. Then a linear functional on X is weakly continuous if and only if it is norm-continuous (i.e. bounded).

Proof: Since the weak topology is weaker than the norm topology, a weakly continuous linear functional is norm-continuous. Conversely, let ϕ be norm-continuous, i.e. $\phi \in X^*$. Then $U_{\{\phi\},\epsilon} = \{x \in X : |\phi(x)| < \epsilon\}$ is weakly open for every $\epsilon > 0$, so ϕ is weakly continuous at 0, hence everywhere. 👍

XX.7.2.13. If X is a normed vector space with completion $\bar{X}$, then X^* can be naturally identified with $(\bar{X})^*$, and it follows that the weak topology on X is just the relative topology from the weak topology on $\bar{X}$.

XX.7.2.14. In the infinite-dimensional case, weak (and weak-*) topologies cannot be entirely described by convergence of sequences (XX.7.2.17.; cf. Exercise XX.7.5.4.). But in most applications, one considers only convergence of sequences, so it is important to have results about weak (or weak-*) convergence of sequences. Thus we will have various results about sequences, such as the following.

XX.7.2.15. PROPOSITION. Let X be a normed vector space. Then every weakly convergent sequence in X is norm-bounded.

PROOF: Let (x_k) be a weakly convergent sequence in X. Then, for every ϕ in X^*, the sequence $(\phi(x_k))$ is convergent in $\mathbb{F}$, hence bounded (). For each k, define $T_k : X^* \to \mathbb{F}$ by $T_k(\phi) = \phi(x_k)$. The T_k are pointwise bounded. Thus by the Uniform Boundedness Theorem () there is an M such that $\|T_k\| \leq M$ for all k, i.e. $|\phi(x_k)| \leq M$ for all k and all $\phi \in X^*$, $\|\phi\| \leq 1$. This implies that $\|x_k\| \leq M$ for all k (XX.7.1.5.). 👍

XX.7.2.16. Note that this result only applies to *sequences*, not nets. In fact, if X is infinite-dimensional, weak neighborhoods of 0 are always unbounded, and it is easy to construct an unbounded net (indexed by basic open neighborhoods) converging to 0. ✋

When the weak topology does not coincide with the norm topology, it is somewhat pathological:

XX.7.2.17. PROPOSITION. Let X be an infinite-dimensional normed vector space. Then the weak topology on X is not first countable (hence not metrizable).

PROOF: Suppose there is a decreasing sequence (U_k) of weakly open neighborhoods of 0 forming a local base. Since each weak neighborhood of 0 is unbounded, for each k there is an $x_k \in U_k$ with $\|x_k\| \geq k$. Then $x_k \to 0$ weakly, but is unbounded, contradicting XX.7.2.15.. 👍

However, in good cases the restriction of the weak topology to norm-bounded sets is metrizable (note that no weak neighborhood of 0 is norm-bounded if X is infinite-dimensional):

XX.7.2.18. PROPOSITION. Let X be a normed vector space. If X^* is separable (in the norm topology), then for any norm-bounded subset A of X, the relative weak topology on A is metrizable.

PROOF: It suffices to prove the statement when A is the unit ball of X. Let (ψ_k) be a countable norm-dense subset of X^*. For each k let ρ_k be the pseudometric on A defined by the seminorm $\|x\|_k = |\psi_k(x)|$. If $\phi_1, \ldots, \phi_n \in X^*$ and $\epsilon > 0$, for each k, $1 \leq k \leq n$, choose ψ_k with $\|\phi_k - \psi_k\| < \frac{\epsilon}{2}$. Then the basic open set $U_{\{\psi_1,\ldots,\psi_n\},\epsilon/2} \cap A$ is contained in $U_{\{\phi_1,\ldots,\phi_n\},\epsilon} \cap A$. It follows that the relative weak topology on A is defined by the pseudometrics ρ_k. Thus the topology is metrizable (). 👍

XX.7.2.19. Note that in this proof, $U_{\{\psi_1,\ldots,\psi_n\},\epsilon/2}$ is not generally contained in $U_{\{\phi_1,\ldots,\phi_n\},\epsilon}$; only the intersection with the unit ball has the containment. Thus there is no contradiction with XX.7.2.17.. ✋

In connection with XX.7.2.18., we have:

XX.7.2.20. PROPOSITION. Let X be a normed vector space. If X^* is (norm-)separable, then X is (norm-)separable.

PROOF: Let (ψ_k) be a norm-dense sequence in X^*. For each k let $x_k \in X$ with $\|x_k\| = 1$ and $|\psi_k(x_k)| > \frac{1}{2}\|\psi_k\|$. Let Y be the closed span of the x_k. If Y is a proper subspace of X, then there is a $\phi \in X^*$ with $\|\phi\| = 1$ and $Y \subseteq \mathcal{N}(\phi)$ (XX.7.1.6.), so $\phi(x_k) = 0$ for all k. Fix k with $\|\psi_k - \phi\| < \frac{1}{3}$; then $\|\psi_k\| > \frac{2}{3}$, so $|\psi_k(x_k)| > \frac{1}{3}$. But

$$|\psi_k(x_k)| = |\psi_k(x_k) - \phi(x_k)| \leq \|\psi_k - \phi\|\|x_k\| < \frac{1}{3}$$

which is a contradiction. Thus $Y = X$, so finite linear combinations of the x_k are (norm-)dense in X, hence finite linear combinations with coefficients in $\mathbb{Q}$ ($\mathbb{Q} + \mathbb{Q}i$ if $\mathbb{F} = \mathbb{C}$) form a countable norm-dense set in X. 👍

XX.7.2.21. The converse of this result is false: many (perhaps "most") separable Banach spaces, e.g. ℓ^1 (), have nonseparable duals. ✋

XX.7.3. The Second Dual

XX.7.3.1. Let X be a normed vector space. Then X^* is also a normed vector space, even a Banach space, so has a dual space $(X^*)^*$, denoted X^{**} and called the *second dual* of X.

The Canonical or Natural Embedding

XX.7.3.2. If $x \in X$, there is a natural linear functional $\hat{x}$ on X^* given by evaluation:

$$\hat{x}(\phi) = \phi(x) \ .$$

Since $|\hat{x}(\phi)| = |\phi(x)| \leq \|\phi\|\|x\|$ for any ϕ, we have that $\hat{x}$ is bounded, i.e. $\hat{x} \in X^{**}$, and $\|\hat{x}\| \leq \|x\|$. On the other hand, by () there is a ϕ with $\|\phi\| = 1$ and $|\hat{x}(\phi)| = \|x\|$, so $\|\hat{x}\| \geq \|x\|$; thus $\|\hat{x}\| = \|x\|$.

XX.7.3.3. Thus the map $\iota : x \mapsto \hat{x}$ is an isometric embedding of X into X^{**}, called the *canonical embedding* or *natural embedding*. So we can, and often will, regard X as a subspace of X^{**}.

XX.7.3.4. The canonical embedding is not surjective in general. If X is not complete, it cannot be surjective since X^{**} is complete. But even if X is complete, ι is not surjective in general; indeed, X^{**} is often *much* larger than X (it is often nonseparable even if X is separable).

XX.7.3.5. EXAMPLE. Let $X = c_0$ (), the Banach space of sequences (in $\mathbb{F}$) converging to 0, with the supremum norm. Then X^* can be naturally identified with ℓ^1, the absolutely summable sequences. Then X^{**} can be identified with the dual of ℓ^1, which is ℓ^∞, the Banach space of bounded sequences. The canonical embedding of X into X^{**} is just the natural embedding of c_0 as a subspace of ℓ^∞. Note that in this case c_0 is separable but $\ell^\infty = c_0^{**}$ is nonseparable. In this case $c_0^* = \ell^1$ is separable. We also have that $(\ell^1)^{**} = (\ell^\infty)^*$ is nonseparable by XX.7.2.20., so the canonical map from ℓ^1 to $(\ell^1)^{**}$ is far from surjective.

Reflexive Banach Spaces

XX.7.3.6. There are Banach spaces for which the canonical embedding is surjective, hence an isometric isomorphism. Such a Banach space is called *reflexive*. Reflexive Banach spaces are exactly the ones for which the duality between X and X^* is complete ().

XX.7.3.7. Examples. (i) Any finite-dimensional normed vector space is reflexive (by dimension counting).

(ii) Any Hilbert space is reflexive ().

(iii) If $(X, \mathcal{A}, \mu)$ is a measure space, then $L^p(X, \mathcal{A}, \mu)$ is reflexive for $1 < p < \infty$ (). In particular, ℓ^p is reflexive for $1 < p < \infty$.

(iv) c_0, ℓ^1, ℓ^∞ are not reflexive. More generally, $L^1(X, \mathcal{A}, \mu)$ and $\ell^\infty(X, \mathcal{A}, \mu)$ are not reflexive for most measure spaces $(X, \mathcal{A}, \mu)$ (the exact condition is a little tricky).

(iv) If X is a compact Hausdorff space, then $C(X)$ is not reflexive unless X is a finite discrete space (). More generally, no infinite-dimensional C*-algebra is reflexive ().

Reflexivity will be discussed in more detail in ().

Higher Duals

XX.7.3.8. Why stop at two? X^{**} has a dual space, denoted X^{***}. We can go on *ad infinitum*.

XX.7.3.9. There is a canonical embedding of X^* into X^{***}, and of X^{**} into X^{****}, etc. The canonical embedding of X^* into X^{***} is surjective (i.e. X^* is reflexive) if and only if X is reflexive; the same holds for higher duals (cf. XX.7.1.6.). In general, the duals get much larger at every step.

The duals form two towers: $X \subseteq X^{**} \subseteq X^{****} \subseteq \cdots$ and $X^* \subseteq X^{***} \subseteq X^{*****} \subseteq \cdots$. The two towers are in duality.

XX.7.3.10. If the n'th dual of X is separable, then X and the k'th dual of X for $k < n$ are also separable by repeated application of XX.7.2.20.. But they can become nonseparable at some step (cf. XX.7.3.5.).

XX.7.4. The Weak-* Topology

If X is a normed vector space, the dual space X^* is itself a Banach space, so has a weak topology (and of course also a norm topology). But it also has a more important topology, the weak-* topology.

XX.7.4.1. If $x_1, \ldots, x_n \in X$ and $\epsilon > 0$, we let

$$U_{\{x_1,\ldots,x_n\},\epsilon} = \{\phi \in X^* : |\phi(x_1)| < \epsilon, \ldots, |\phi(x_n)| < \epsilon\} .$$

This is a norm-open convex circled neighborhood of 0 in X^*, and the set of all these basic open sets forms a base for a TVS topology on X^*.

XX.7.4.2. Definition. This topology is called the *weak-* topology* on X^* (from X).

XX.7.4.3. The basic open neighborhoods and the weak-* topology are defined without reference to the second dual X^{**}. But the definition can be rephrased to look more like the definition of the weak topology: $U_{\{x_1,\dots,x_n\},\epsilon} = U_{\{\hat{x}_1,\dots,\hat{x}_n\},\epsilon}$, where $\hat{x}_k$ is the linear functional on X^* corresponding to x_k. Thus the basic open neighborhoods for the weak-* topology are basic open neighborhoods for the weak topology, so it follows that the weak-* topology is weaker than the weak topology on X^*. If X is reflexive, the basic open neighborhoods are the same, so the weak and weak-* topologies coincide (the converse also holds (XX.7.4.21.), i.e. the weak-* topology is strictly weaker than the weak topology unless X is a reflexive Banach space).

XX.7.4.4. The weak-* topology on X^* has a very natural interpretation: it is exactly the topology of pointwise convergence on X, i.e. a net (ϕ_i) in X^* converges weak-* to ϕ if and only if $\phi_i(x) \to \phi(x)$ for all $x \in X$. (The proof is almost identical to the proof of XX.7.2.4. and is left to the reader.)

XX.7.4.5. If $\phi \in X^*$, $\phi \neq 0$, let $x \in X$ with $\phi(x) \neq 0$. Then $U_{\{x\},|\phi(x)|}$ is an open neighborhood of 0 not containing ϕ. It follows that the weak-* topology is Hausdorff.

The most important fact about the weak-* topology, the main reason it is so useful, is Alaoglu's Theorem:

XX.7.4.6. Theorem. [Alaoglu's Theorem] Let X be a normed vector space. Then the norm-closed unit ball B of X^* is compact in the relative weak-* topology.

Proof: If $\alpha > 0$, let D_α be the closed ball in $\mathbb{F}$ of radius α around 0 (either $[-\alpha, \alpha]$ if $\mathbb{F} = \mathbb{R}$ or the closed disk of radius α around 0 if $\mathbb{F} = \mathbb{C}$). Then D_α is compact. Each $\phi \in B$ defines a function on X whose value at x is in $D_{\|x\|}$, which can be thought of as a point in the product

$$P := \prod_{x \in X} D_{\|x\|}$$

so we can regard B as a subset of P. The relative weak-* topology is the topology of coordinatewise convergence, i.e. the product topology. P is compact in the product topology by Tikhonov's Theorem (). So it suffices to show that B is a closed subset of P.

Suppose (ϕ_i) is a net in B converging to $\phi \in P$. Then ϕ can be regarded as a function from X to $\mathbb{F}$: $\phi(x) = \lim \phi_i(x)$ for all $x \in X$. If $x, y \in X$, we have

$$\phi(x+y) = \lim \phi_i(x+y) = \lim(\phi_i(x) + \phi_i(y)) = \phi(x) + \phi(y)$$

by continuity. Similarly, $\phi(\alpha x) = \alpha\phi(x)$ for $\alpha \in \mathbb{F}$, $x \in X$. So ϕ is a linear functional. For any x, $\phi(x) = \lim \phi_i(x) \in D_{\|x\|}$ since $D_{\|x\|}$ is closed in $\mathbb{F}$; thus ϕ is bounded and $\|\phi\| \leq 1$, i.e. $\phi \in B$. 👍

XX.7.4.7. Proposition. Let X be a separable normed vector space. Then norm-bounded subsets of X^* are metrizable in the relative weak-* topology from X.

The proof is almost identical to the proof of XX.7.2.18..

Combining the last two results and XIII.11.2.2., we obtain:

XX.7.4.8. Corollary. Let X be a separable normed vector space. Then the closed unit ball of X^* is sequentially compact in the weak-* topology, i.e. any norm-bounded sequence in X^* has a weak-* convergent subsequence.

This result is sometimes called *Helly's Theorem* since it was obtained in [].

The weak-* analogs of XX.7.2.15. and XX.7.2.8. are not unrestrictedly true. We have:

XX.7.4.9. Proposition. Let X be a Banach space. Then every weak-* convergent sequence in X is norm-bounded.

XX.7.4.10. The proof is almost identical to the proof of XX.7.2.15., except that the T_n are defined on X, not X^*, so completeness of X is needed to apply the Uniform Boundedness Theorem. In fact, the result can fail if X is not complete (Exercise XX.7.5.1.).

Not every norm-closed convex set in X^*, not even every closed subspace of X^*, is weak-* closed in general (XX.7.4.14.). In fact:

XX.7.4.11. Proposition. Let X be a normed vector space. Then a linear functional on X^* is weak-* continuous if and only if it is of the form $\hat{x}$ for some $x \in X$ (i.e. if and only if it is in the canonical image of X in X^{**}).

We will prove a more general result in XX.7.4.20..

XX.7.4.12. Let X be a normed vector space, and Z a subspace of X^*. Set

$$Z_\perp = \{x \in X : \phi(x) = 0 \ \forall \phi \in Y\} \ .$$

$Z_\perp$ is the *annihilator* of Z in X, a norm-closed subspace of X. Then

$$(Z_\perp)^\perp = \{\phi \in X^* : \phi(x) = 0 \ \forall x \in Z_\perp\}$$

is a norm-closed subspace of X^* containing Z. We have $[(Z_\perp)^\perp]_\perp \subseteq Z_\perp$ since $Z \subseteq (Z_\perp)^\perp$; on the other hand, if $x \in Z_\perp$, then $\phi(z) = 0$ for all $\phi \in (Z_\perp)^\perp$, so $x \in [(Z_\perp)^\perp]_\perp$, i.e. $[(Z_\perp)^\perp]_\perp = Z_\perp$.

XX.7.4.13. Proposition. The subspace $(Z_\perp)^\perp$ is the weak-* closure of the subspace Z. In particular, Z is weak-* closed if and only if $Z = (Z_\perp)^\perp$, if and only if $Z = Y^\perp$ for some (closed) subspace Y of X.

Proof: If ϕ is in the weak-* closure of $(Z_\perp)^\perp$, i.e. there is a net (ϕ_i) in $(Z_\perp)^\perp$ with $\phi_i \to \phi$ in the weak-* topology, then if $x \in Z_\perp$, $0 = \phi_i(x) \to \phi(x)$, so $\phi(x) = 0$; thus $\phi \in (Z_\perp)^\perp$. Therefore $(Z_\perp)^\perp$ is weak-* closed.

Conversely, if Z is weak-* closed and $\phi \in X^* \setminus Z$, then since the weak-* topology is locally convex there is a weak-* continuous linear functional f on X^* with $Z \subseteq \mathcal{N}(f)$ and $f(\phi) = 1$. By XX.7.4.11., $f = \hat{x}$ for some $x \in X$, i.e. $\phi(x) = 1$ and $\psi(x) = 0$ for all $\psi \in Z$. Then $x \in Z_\perp$, so $\phi \notin (Z_\perp)^\perp$. Therefore $(Z_\perp)^\perp = Z$. 👍

XX.7.4.14. Corollary. Let X be a normed vector space, canonically embedded in X^{**}. Then X is weak-* dense in X^{**}.

Proof: $X_\perp = \{0\}$ (in X^*). 👍

See Exercise XX.7.5.5. for a direct proof.

XX.7.4.15. The weak topology on a normed vector space X is intrinsic to X. But the weak-* topology on a Banach space Y is not intrinsic to Y: it depends on whether, and how, Y is realized as the dual of a normed space X. Not every Banach space is the dual of another Banach space (see ()). And there can be nonisomorphic Banach spaces X_1 and X_2 with X_1^* and X_2^* isometrically isomorphic, and in this case there may not be an isomorphism which is a homeomorphism for the weak-* topologies (see ()). As a related matter, if X is not complete, we have $\bar{X}^*$ naturally isomorphic to X^*, but the weak-* topologies from X and $\bar{X}$ are subtly different (XX.7.4.21.; see XX.7.5.1. for an example). The difference is indeed quite subtle: the relative topologies on norm-bounded sets agree (XX.7.5.2.).

Unified Notation

There is a nice alternate notation which describes both the weak and weak-* topologies, and carries more information including the distinctions of XX.7.4.15..

XX.7.4.16. Definition. Let X be a normed vector space and Y a subspace of X^* (not necessarily closed). The $\sigma(X,Y)$-*topology* on X is the topology of pointwise convergence of functionals in Y, i.e. $x_i \to x$ in the $\sigma(X,Y)$-topology if and only if $\phi(x_i) \to \phi(x)$ for all $\phi \in Y$.

XX.7.4.17. A system of basic neighborhoods of 0 for the $\sigma(X,Y)$-topology is the set of $U_{\{\phi_1,\ldots,\phi_n\},\epsilon}$ as in XX.7.2.1. with the $\phi_k \in Y$.

XX.7.4.18. We have that the weak topology on X is the $\sigma(X,X^*)$-topology and the weak-* topology on X^* from X is the $\sigma(X^*,X)$-topology, where X is regarded as the canonically embedded subspace of X^{**}.

XX.7.4.19. Proposition. (i) Let X be a normed vector space and Y a subspace of X^*. Then the $\sigma(X,Y)$-topology is Hausdorff if and only if Y separates the points of X, i.e. for any $x \in X$, $x \neq 0$, there is a $\phi \in Y$ with $\phi(x) \neq 0$. Such a subspace is called *total* in some references since Y separates points of X if and only if it is weak-*dense in X^* (XX.7.4.13.), although it need not be norm-dense.

(ii) If X is a normed vector space and $Y_1 \subseteq Y_2 \subseteq X^*$, then the $\sigma(X,Y_1)$-topology is weaker than the $\sigma(X,Y_2)$-topology.

(iii) If $X_1 \subseteq X_2$ are normed vector spaces, Y a subspace of X_2^*, and Z the set of restrictions of Y to X_1 (so $Z \cong Y/X_1^\perp$), then the $\sigma(X_1,Z)$-topology on X_1 is the relative $\sigma(X_2,Y)$-topology.

Continuity of Linear Functionals

XX.7.4.20. THEOREM. Let X be a normed vector space, and Y a subspace of X^*. Then the linear functionals on X which are $\sigma(X,Y)$-continuous are precisely the linear functionals in Y.

PROOF: Since the $\sigma(X,Y)$-topology is weaker than the norm topology, any $\sigma(X,Y)$-continuous linear functional is norm-continuous, i.e. in X^*.

If $\phi \in Y$, then $U_{\{\phi\},\epsilon}$ is a $\sigma(X,Y)$-open neighborhood of 0 for any $\epsilon > 0$; thus ϕ is $\sigma(X,Y)$-continuous at 0, hence everywhere.

Conversely, suppose ϕ is $\sigma(X,Y)$-continuous. Then $V = \{x \in X : |\phi(x)| < 1\}$ is a $\sigma(X,Y)$-open neighborhood of 0, so there are $\psi_1, \dots, \psi_n \in Y$ such that $U_{\{\psi_1,\dots,\psi_n\},1} \subseteq V$, i.e. $|\psi_k(x)| < 1$ for $1 \le k \le n$ implies $|\phi(x)| < 1$. Then, for any $\epsilon > 0$, $|\psi_k(x)| < \epsilon$ for $1 \le k \le n$ implies $|\phi(x)| < \epsilon$. Thus $\psi_k(x) = 0$ for $1 \le k \le n$ implies $\phi(x) = 0$. So ϕ is a linear combination of $\{\psi_1, \dots, \psi_n\}$ by III.11.5.16. and therefore $\phi \in Y$. 👍

XX.7.4.21. COROLLARY. Let X be a normed linear space, and Y_1 and Y_2 distinct subspaces of X^*. Then the $\sigma(X,Y_1)$-topology and $\sigma(X,Y_2)$-topology on X are different. If $Y_1 \subseteq Y_2$, then the $\sigma(X,Y_1)$-topology is strictly weaker than the $\sigma(X,Y_2)$-topology. In particular:

(i) If X is not reflexive, the weak-* topology on X^* from X is strictly weaker than the weak topology.

(ii) If X is not complete, the $\sigma(X^*,X)$-topology is strictly weaker than the $\sigma(X^*,\bar{X})$-topology.

PROOF: The topologies must be distinct since different linear functionals are continuous. 👍

This shows that there are an enormous number of weak-type topologies on any infinite-dimensional normed vector space (one for each weak-* dense subspace of X^*), although only a few are useful in practice.

XX.7.5. Exercises

XX.7.5.1. Let c_0 be the Banach space of sequences in $\mathbb{F}$ converging to 0 with supremum norm, and c_{00} the dense subspace of sequences eventually 0 (). Then $c_{00}^* = c_0^* \cong \ell^1$. Let $(\boldsymbol{e}_k)$ denote the standard basis vectors of ℓ^1.

(a) Show that the $\sigma(\ell^1, c_{00})$-topology on ℓ^1 is the topology of coordinatewise convergence. In particular, if (α_k) is any sequence of scalars, then the sequence $(\alpha_k \boldsymbol{e}_k)$ converges to 0 in the $\sigma(\ell^1, c_{00})$-topology. Since (α_k) need not be bounded, the conclusion of XX.7.4.9. does not hold for the weak-* topology from c_{00}.

(b) Show that a sequence $(\boldsymbol{x}_k)$ in ℓ^1 converges to $\boldsymbol{x} \in \ell^1$ in the $\sigma(\ell^1, c_0)$-topology if and only if the sequence is uniformly bounded and converges coordinatewise.

(c) The $\sigma(\ell^1, c_{00})$-topology and the $\sigma(\ell^1, c_0)$-topology are distinct but agree on norm-bounded sets.

(d) A sequence $(\boldsymbol{x}_k)$ in ℓ^1 converges weakly to $\boldsymbol{x} \in \ell^1$ if and only if it converges in norm to $\boldsymbol{x}$ [**?**]. (This does not mean the norm and weak topologies are the same!) ✋

XX.7.5.2. Show that if X is a normed vector space and $\bar{X}$ its completion, then the $\sigma(X^*,X)$- and $\sigma(X^*,\bar{X})$-topologies agree on norm-bounded subsets. [Use (), XX.7.4.19.(ii), and Alaoglu's Theorem.]

XX.7.5.3. (a) Let X be a Banach space. The closed unit ball B of X^* is weak-* compact by Alaoglu's Theorem, thus is the weak-* closed convex hull of its extreme points by the Krein-Milman Theorem (). In particular, B has many extreme points.

(b) The closed unit ball of the Banach space c_0 has no extreme points. Thus there is no Banach space X with $X^* \cong c_0$.

(c) Show that if X is reflexive, then the closed unit ball of X is the norm-closed convex hull of its extreme points. [X is the dual of X^*. Use (a), XX.7.2.8., and that the weak and weak-* topologies coincide.]

(d) The closed unit ball of ℓ^1 is the norm-closed convex hull of its extreme points, although ℓ^1 is not reflexive. But this is false for most dual spaces, e.g. $C([0,1])^*$.

(e) The closed unit ball of the Banach space c of convergent sequences is also the norm-closed convex hull of its extreme points, although c is not the dual of any Banach space. (Any unital C*-algebra has this convex hull property (), but is rarely a dual space ()).

XX.7.5.4. Let X be an infinite-dimensional normed space, and let (X_m) be an increasing sequence of subspaces of X with $dim(X_m) = m$. Set $Y = \overline{\cup_n X_n}$ (norm-closure). For each m let S_m be a finite set of points x_{mj} in X_m of norm m such that every $x \in X_m$, $\|x\| = m$, is within $\frac{1}{m}$ of some x_{mj}. Set $S = \cup_m S_m \subseteq Y$.

(a) Show that S is weakly closed (resp. weakly sequentially closed) in X if and only if it is weakly closed (resp. weakly sequentially closed) in Y. [Use XX.7.2.9.,]

(b) Fix a basic weakly open neighborhood $U := U_{\{\phi_1,\dots,\phi_n\},\epsilon}$ of 0 in Y, with $\|\phi_k\| = 1$ for all k. For sufficiently large $m > n$, there is an $x_m \in X_m$ with $\|x_m\| = m$ and $\phi_k(x_m) = 0$ for all k. [Use III.11.5.17.(iii).]

(c) Fix j with $\|x_m - x_{mj}\| < \frac{1}{m}$. Then $|\phi_k(x_{mj})| < \frac{1}{m}$ for all k. Thus for sufficiently large $m > \frac{1}{\epsilon}$, $x_{mj} \in U$.

(d) Conclude from (c) that 0 is in the weak closure of S. Since $0 \notin S$, S is not weakly closed.

(e) For any M, S contains only finitely many points of norm $\leq M$. Thus the only weakly convergent sequences in S are sequences which are eventually constant. In particular, S is weakly sequentially closed.

This construction is in [Lax02], but is not quite correct there.

XX.7.5.5. Let X be a normed vector space.

(a) Use III.11.5.17. to show that if $f \in X^{**}$, then for any $\phi_1, \dots, \phi_n \in X^*$ there is an $x \in X$ such that $\phi_k(x) = f(\phi_k)$ for all k, $1 \leq k \leq n$. [The values of f on the ϕ_k are determined by the values on a linearly independent subset with the same span.]

(b) Use (a) to give a direct proof that X is weak-* dense in X^{**}.

XX.7.5.6. (a) Show that if X is separable, then the closed unit ball of X^* is sequentially compact in the weak-* topology.

(b) The closed unit ball of $(\ell^\infty)^*$ is not sequentially compact. [Let $\phi_k((x_n)) = x_k$. The sequence (ϕ_k) has no weak-* convergent subsequence.]

(c) If X is reflexive, then the closed unit ball of X^* is weak-* (weakly) sequentially compact. [Every sequence in X^* is contained in a separable closed subspace.] Applying this to X^*, the closed unit ball of X is weakly sequentially compact. Conversely, if the closed unit ball of a Banach space Y is weakly sequentially compact, then Y is reflexive.

XX.7.5.7. Show that in the definition of the $\sigma(X, Y)$-topology (and, in particular, for the weak and weak-* topologies), it suffices to consider basic open sets $U_{\{\phi_1,\ldots,\phi_n\},\epsilon}$ (even with $\epsilon = 1$) for which $\{\phi_1, \ldots, \phi_m\}$ is linearly independent.

XX.7.5.8. Let X be a normed vector space, and Y a subspace of X^*. Give a characterization of the subspaces of X which are $\sigma(X, Y)$-closed generalizing XX.7.4.13. and XX.7.2.9..

XX.7.5.9. Let X be a vector space over $\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$, and let Y be a subspace of X^d. Define a $\sigma(X, Y)$-topology on X in an analogous manner to the definition for normed vector spaces. To what extent do the results of this section hold in this situation? Generalize to vector spaces over other topological fields.

XX.8. The Open Mapping Theorem, Closed Graph Theorem, and Uniform Boundedness Theorem

These are three of the most basic theorems of functional analysis. The first two are essentially one theorem, in the sense that either of them can be derived relatively easily from the other. The Uniform Boundedness Theorem is a consequence of the other two, or can be proved independently (it is apparently a "lower-level theorem" since the other two theorems cannot be obviously deduced from Uniform Boundedness). All of them are a consequence of the Baire Category Theorem, although they are not immediate corollaries and take some considerable additional work to prove. We may work over either $\mathbb{R}$ or $\mathbb{C}$ (denoted $\mathbb{F}$, which will usually just be understood); in fact, it suffices to work over $\mathbb{R}$.

XX.8.1. Open Mappings

XX.8.1.1. Recall () that if f is a function from a topological space X to a topological space Y, then f is an *open mapping* if $f(U)$ is open in Y for every open set U in X. An open mapping does not have to be continuous. It is unusual for a continuous function, even a surjective one, to be an open mapping; however, we will show that a surjective bounded linear transformation between Banach spaces is an open mapping. In this subsection, we give alternate characterizations of when linear transformations are open mappings. The arguments make repeated use of the following principle which is an immediate result of linearity:

XX.8.1.2. [Basic Principle of Open Balls] Let X and Y be normed vector spaces, and $T : X \to Y$ a linear transformation. Then the images under T of all open balls in X look essentially the same, up to scaling and translation.

XX.8.1.3. Proposition. Let X and Y be normed vector spaces, and $T : X \to Y$ a linear transformation (not necessarily bounded). The following are equivalent:

(i) T is an open mapping.

(ii) The image under T of some open ball in X contains an open ball in Y.

(iii) The image under T of every open ball in X contains an open ball in Y.

(iv) The image under T of some open ball in X centered at 0 contains an open ball in Y centered at 0.

(v) The image under T of every open ball in X centered at 0 contains an open ball in Y centered at 0.

Proof: (i) $\Rightarrow$ (iii) $\Rightarrow$ (ii) and (i) $\Rightarrow$ (v) $\Rightarrow$ (iv) $\Rightarrow$ (ii) are trivial (since $T(0) = 0$). (ii) $\Rightarrow$ (iii) is an instance of the Basic Principle of Open Balls: if $T(B_r(x_0))$ contains $B_\epsilon(y_0)$, then for any x_1 we have that $T(B_r(x_1))$ contains $B_\epsilon(y_1)$, where $y_1 = y_0 + T(x_1 - x_0)$. In particular, $T(B_r(0))$ contains $B_\epsilon(y_2)$, where $y_2 = y_0 - T(x_0)$. Then, for any s, we have $T(B_s(0))$ contains $B_\delta(\frac{s}{r}y_2)$, where $\delta = \frac{s}{r}\epsilon$, and, for any x_1, $T(B_s(x_1))$ contains $B_\delta(T(x_1) + \frac{s}{r}y_2)$. The proof of (iv) $\Rightarrow$ (v) is similar but easier.

To prove (iii) $\Rightarrow$ (iv), suppose $T(B_r(0))$ contains $B_\epsilon(y_0)$. Then there is an $x_0 \in B_r(0)$ with $T(x_0) = y_0$. Then $T(B_r(-x_0))$ contains $B_\epsilon(0)$. If $s = r + \|x_0\|$, then $B_r(-x_0) \subseteq B_s(0)$, so $T(B_s(0))$ contains $B_\epsilon(0)$.

To finish the proof, it suffices to show (v) $\Rightarrow$ (i). Let U be an open set in X, and $y_0 \in T(U)$. Let $x_0 \in U$ with $T(x_0) = y_0$, and $\delta > 0$ for which $B_\delta(x_0) \subseteq U$. There is an $\epsilon > 0$ such that $T(B_\delta(0))$ contains $B_\epsilon(0)$ by

(v). Then $T(B_\delta(x_0))$ contains $B_\epsilon(y_0)$, so $T(U)$ contains $B_\epsilon(y_0)$. Since $y_0 \in T(U)$ is arbitrary, $T(U)$ is open. 👍

A slight modification of a subset of the proof of XX.8.1.3. (adding the words "the closure of" in a few places) gives the following:

XX.8.1.4. Proposition. Let X and Y be normed vector spaces, and $T : X \to Y$ a linear transformation (not necessarily bounded). The following are equivalent:

(ii) The closure of the image under T of some open ball in X contains an open ball in Y.

(iii) The closure of the image under T of every open ball in X contains an open ball in Y.

(iv) The closure of the image under T of some open ball in X centered at 0 contains an open ball in Y centered at 0.

(v) The closure of the image under T of every open ball in X centered at 0 contains an open ball in Y centered at 0.

XX.8.2. The Open Mapping Theorem

The main result of this subsection is:

XX.8.2.1. Theorem. [Open Mapping Theorem] Let X and Y be Banach spaces, and $T : X \to Y$ a surjective bounded operator. Then T is an open mapping.

A crucial special case is when T is injective as well as surjective:

XX.8.2.2. Corollary. [Bounded Inverse Theorem] Let X and Y be Banach spaces, and $T : X \to Y$ a bijective bounded operator. Then $T^{-1} : Y \to X$ is also bounded. Equivalently, T is bounded below, i.e. a homeomorphism.

Proof: T^{-1} is continuous, hence bounded by (), if and only if T is an open mapping, which follows from the Open Mapping Theorem. 👍

XX.8.2.3. We can derive the Open Mapping Theorem from the Bounded Inverse Theorem, as follows. Let X and Y be Banach spaces and $T : X \to Y$ a surjective bounded operator. Let N be the null space of T; then N is a closed subspace of X, so we may form the quotient space X/N which is a Banach space under the quotient norm (). Let $P : X \to X/N$ be the projection map. Then there is an injective bounded operator $\tilde{T} : X/N \to Y$ with $T = \tilde{T} \circ P$ (). $\tilde{T}$ is an open mapping by the Bounded Inverse Theorem. P is also an open mapping: this is a general fact about quotient spaces (), but in this instance it is also an immediate corollary of XX.8.1.3., since it follows from the definition of the quotient norm () that the image of the open unit ball in X is exactly the open unit ball in X/N. Thus T is a composition of two open mappings, hence also an open mapping. Hence the Open Mapping Theorem and the Bounded Inverse Theorem are equivalent.

Although the Open Mapping Theorem can be easily deduced from the Bounded Inverse Theorem, there does not appear to be a proof of the Bounded Inverse Theorem which is simpler than the proof of the Open Mapping Theorem.

XX.8.2.4. Examples. All the hypotheses of the Open Mapping Theorem are necessary in general, as the following examples show. These examples illustrate that the statement of the Open Mapping Theorem is a nontrivial assertion which may even be considered somewhat surprising.

(i) Let $X = Y = \ell^2$, and define $T : X \to Y$ by

$$T((\xi_1, \xi_2, \dots)) = \left(\xi_1, \frac{1}{2}\xi_2, \dots, \frac{1}{n}\xi_n, \dots\right) .$$

Then T is injective and has dense range, but is not surjective. T is bounded ($\|T\| = 1$). T is not an open map since no positive scalar multiple of $(1, \frac{1}{2}, \dots, \frac{1}{n}, \dots)$ is in the range. Thus the hypothesis that T is surjective is necessary. (In fact, a linear map which is not surjective can never be an open map, since the range is a subspace and a proper subspace can never be an open set.)

(ii) Take the same example as in (i) but let Y be the range of T. Y is a dense subspace of ℓ^2 and inherits a norm from ℓ^2, but is not complete. T is now a bijection from $X = \ell^2$ to Y, but T^{-1} is not bounded since T is not bounded below. Thus the hypothesis that Y be complete is necessary.

(iii) It is trickier to give an example showing that the hypothesis that X be a Banach space is necessary. Let Z be a Banach space and N a closed subspace of Z. Set $Y = Z/N$ with the quotient norm (), and $P : Z \to Z/N$ the quotient map (). Suppose X is a subspace of Z complementary to N which is not closed (e.g. X is the null space of a discontinuous linear functional on Z and N a complementary one-dimensional subspace; cf. also ()). X is a normed vector space with norm inherited from Z, and $T = P|_X$ is an injective bounded operator from X onto Y. But $T^{-1} : Y \to X$ cannot be bounded, since if it were X would be complete, hence closed in Z.

(iv) The hypothesis that T be bounded is also necessary. Expand the standard orthonormal basis of ℓ^2 to a Hamel basis, and take a permutation of the Hamel basis interchanging the orthonormal basis with a subset of the remaining Hamel basis vectors. This permutation extends to a bijective but unbounded operator T from ℓ^2 to ℓ^2. If T were an open mapping, then T^{-1} would be continuous, hence bounded, so T would be bounded by the Bounded Inverse Theorem, a contradiction.

Note that some form of the Axiom of Choice is needed in (iii) and (iv). (Actually, some form of Choice is even needed for the Open Mapping Theorem, since the Baire Category Theorem depends on DC ().)

XX.8.2.5. We now give the proof of the Open Mapping Theorem.

PROOF: Write B_r^X and B_r^Y for the open balls of radius r around 0 in X and Y respectively. We have that

$$\cup_{n=1}^{\infty} T(B_n^X) = T(X) = Y$$

since T is surjective. Thus, since Y is a Banach space, by the Baire Category Theorem $T(B_n^X)$ is not nowhere dense in Y for some n, i.e. $\overline{T(B_n^X)}$ contains an open ball in Y. Thus by XX.8.1.4., $\overline{T(B_r^X)}$ contains an open ball around 0 in Y for any r. In particular, there is an $\epsilon > 0$ such that $\overline{T(B_1^X)}$ contains B_ϵ^Y. We will show that $T(B_2^X)$ contains B_ϵ^Y; it will then follow from XX.8.1.3. that T is an open mapping.

Let $y \in B_\epsilon^Y$; we will construct an $x \in X$ with $\|x\| < 2$ and $Tx = y$. A key observation is that $\overline{T(B_r^X)}$ contains $B_{\epsilon r}^Y$ for every $r > 0$. Since y is in the closure of $T(B_1^X)$, for any $\delta > 0$ we can find an $x_0 \in X$, $\|x_0\| < 1$, with $\|y - Tx_0\| < \delta$. Let $x_1 \in X$, $\|x_1\| < 1$, with

$$\|y - Tx_1\| < \frac{\epsilon}{2} .$$

Since $y - Tx_1$ is in the closure of $T(B_{1/2}^X)$, there is an $x_2 \in X$, $\|x_2\| < \frac{1}{2}$, with

$$\|(y - Tx_1) - Tx_2)\| < \frac{\epsilon}{4} .$$

Continuing inductively, we obtain for each n an $x_n \in X$ with $\|x_n\| < 2^{-n+1}$ and

$$\|y - Tx_1 - Tx_2 - \cdots - Tx_n\| < 2^{-n}\epsilon .$$

The infinite series

$$\sum_{k=1}^{\infty} x_k$$

converges absolutely, hence converges to some $x \in X$ since X is a Banach space (). We have

$$\|x\| < \sum_{k=1}^{\infty} 2^{-k+1} = 2 .$$

Since T is continuous, we have

$$Tx = \sum_{k=1}^{\infty} Tx_k$$

in Y (). But we have

$$\left\| y - \sum_{k=1}^{n} Tx_k \right\| < 2^{-n}\epsilon$$

for all n, and thus the infinite series

$$\sum_{k=1}^{\infty} Tx_k$$

converges to y, i.e. $Tx = y$, completing the proof. 👍

XX.8.3. The Closed Graph Theorem

XX.8.3.1. Recall () that if X and Y are sets and $f : X \to Y$ is a function, the set

$$\Gamma(f) = \{(x, y) \in X \times Y : y = f(x)\}$$

is the *graph* of f. (Technically, using the ordered pair definition of function, a function *is* its graph.) If X and Y are topological spaces, then f has *closed graph* if $\Gamma(f)$ is closed in $X \times Y$.

XX.8.3.2. PROPOSITION. If X and Y are topological spaces and $f : X \to Y$ is a function, then f has closed graph if and only if, whenever (x_i) is a net in X with $x_i \to x$ and $f(x_i) \to y$ for some $x \in X$ and $y \in Y$, we have $y = f(x)$.

PROOF: By definition, f has closed graph if and only if, whenever $((x_i, y_i))$ is a net in $\Gamma(f)$ converging to $(x, y) \in X \times Y$, we have $(x, y) \in \Gamma(f)$. The statement of the proposition is a simple rephrasing. 👍

A continuous function between Hausdorff spaces has closed graph (), but a function between Hausdorff spaces which has closed graph need not be continuous (). However, we have the following, which is the main result of this subsection:

XX.8.3.3. THEOREM. [CLOSED GRAPH THEOREM] Let X and Y be Banach spaces, and $T : X \to Y$ be a linear transformation. Then T is bounded (continuous) if and only if T has closed graph.

PROOF: If T is continuous, it has closed graph by (). Conversely, suppose T has closed graph. We have that $X \times Y$ is a Banach space under a number of equivalent norms (). Fix one of these norms, say

$$\|(x, y)\| = \max(\|x\|, \|y\|) \ .$$

Since T is linear, $\Gamma(T)$ is a subspace of $X \times Y$; by assumption, it is closed, hence a Banach space under the induced norm. The map $S : \Gamma(T) \to X$ given by $S((x, Tx)) = x$ is bijective and linear, and bounded ($\|S\| \leq 1$). Thus by the Bounded Inverse Theorem $S^{-1} : X \to \Gamma(T)$ is bounded. If P is the projection from $X \times Y$ to Y, then P is bounded, and hence $T = P \circ S^{-1}$ is also bounded. 👍

XX.8.3.4. The proof shows that the Closed Graph Theorem is a simple corollary of the Bounded Inverse Theorem. The converse is true too: if X and Y are Banach spaces and $T : X \to Y$ is a continuous (bounded) bijection, then $\Gamma(T)$ is closed. Thus $\Gamma(T^{-1})$ is also closed since it is essentially the same as $\Gamma(T)$ with coordinates reversed. So T^{-1} is bounded by the Closed Graph Theorem.

We thus obtain that the Open Mapping Theorem, the Bounded Inverse Theorem, and the Closed Graph Theorem are equivalent statements by simple arguments.

XX.8.3.5. The importance of the Closed Graph Theorem is that it is often much easier to prove that a map $T : X \to Y$ has closed graph than to directly prove that it is continuous or bounded. To prove directly that T is continuous, it must be shown that if (x_n) is a sequence in X with $x_n \to x$, then the sequence (Tx_n) converges to Tx. The sequence (Tx_n) cannot be assumed to converge or even to have a convergent subsequence. But to show that T has closed graph, one only needs to show that if (x_n) is a sequence in X with $x_n \to x$, *and* $Tx_n \to y$ *for some* $y \in Y$, then $y = Tx$, i.e. the sequence (Tx_n) can be assumed to converge to something. The next result is a good illustration of the use of the Closed Graph Theorem.

XX.8.3.6. PROPOSITION. Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be Hilbert spaces, and $T : \mathcal{H}_1 \to \mathcal{H}_2$ a linear operator. If T has an adjoint $T^* : \mathcal{H}_2 \to \mathcal{H}_1$, i.e. T^* is a function (which is automatically a linear operator) satisfying

$$\langle x, T^* y\rangle_{\mathcal{H}_1} = \langle Tx, y\rangle_{\mathcal{H}_2}$$

for all $x \in \mathcal{H}_1$, $y \in \mathcal{H}_2$, then T is bounded (and hence T^* is also bounded).

PROOF: We need only show that T has closed graph. Suppose (x_n) is a sequence in $\mathcal{H}_1$ with $x_n \to x$ and $Tx_n \to y$ for some $y \in \mathcal{H}_2$. Then, for any $z \in \mathcal{H}_2$, we have

$$\langle Tx_n, z\rangle_{\mathcal{H}_2} \to \langle y, z\rangle_{\mathcal{H}_2}$$

by continuity of the inner product in $\mathcal{H}_2$ (). On the other hand, we have

$$\langle Tx_n, z\rangle_{\mathcal{H}_2} = \langle x_n, T^* z\rangle_{\mathcal{H}_1} \to \langle x, T^* z\rangle_{\mathcal{H}_1} = \langle Tx, z\rangle_{\mathcal{H}_2}$$

by continuity of the inner product in $\mathcal{H}_1$. Thus by uniqueness of limits we have

$$\langle y, z\rangle_{\mathcal{H}_2} = \langle Tx, z\rangle_{\mathcal{H}_2}$$

for every $z \in \mathcal{H}_2$, and so $y = Tx$ by ().

XX.8.3.7. **Caution:** Our convention is that "T is a linear map from X to Y" means that the domain of T is all of X. In some references, this phrase means only that the domain of T is a subspace (usually dense) of X. The Closed Graph Theorem does *not* apply in this situation; in fact, such an operator can be unbounded but have closed graph. Densely defined unbounded operators with closed graph, called *closed operators*, are very important; see section (). Proposition XX.8.3.6. is also false in general for operators which are just densely defined (with densely defined adjoint); cf. ().

XX.8.3.8. Since in the statement of the Closed Graph Theorem T is not required to be surjective, one might think the hypothesis that Y be complete is unnecessary: Y could just be replaced by its completion $\bar{Y}$. But this is incorrect. The graph of T can be a closed subset of $X \times Y$ but not closed in $X \times \bar{Y}$.

For a counterexample, let X, Y, T be as in XX.8.2.4.(iii). Then the graph of T is closed in $X \times Y$ since T is continuous, so the graph of $T^{-1} : Y \to X$ is closed in $Y \times X$. But T^{-1} is not bounded.

XX.8.4. The Uniform Boundedness Theorem

The Uniform Boundedness Theorem is a theorem which states that a family of bounded operators on a Banach space which is "pointwise bounded" is actually uniformly bounded. This result, like the Open Mapping Theorem and Closed Graph Theorem, has many uses. It can be obtained as a simple consequence of the Closed Graph Theorem or proved directly from scratch; we will give three arguments.

XX.8.4.1. THEOREM. [UNIFORM BOUNDEDNESS THEOREM] Let X be a Banach space, $\{Y_i : i \in I\}$ a collection of normed vector spaces, and $T_i : X \to Y_i$ a bounded operator for each i. Suppose, for each $x \in X$, the set

$$\{\|T_i(x)\| : i \in I\}$$

is bounded (the bound may depend on x). Then the set

$$\{\|T_i\| : i \in I\}$$

is bounded.

XX.8.4.2. In other words, if for each $x \in X$ there is a constant M_x such that $\|T_i x\| \leq M_x$ for all $i \in I$, then there is a single constant M such that $\|T_i\| \leq M$ for all $i \in I$.

The theorem is commonly applied in the case where all the Y_i are the same, and/or when $I = \mathbb{N}$, but these restrictions do not make the proof any easier.

The theorem is sometimes stated in the contrapositive, where it is called the *Resonance Theorem*:

XX.8.4.3. THEOREM. [RESONANCE THEOREM] Let X be a Banach space, $\{Y_i : i \in I\}$ a collection of normed vector spaces, and $T_i : X \to Y_i$ a bounded operator for each i. If $\sup_i \|T_i\| = +\infty$, then there is an $x \in X$ such that $\sup_i \|T_i(x)\| = +\infty$.

The idea, and origin of the name, is that if the T_i "blow up" globally, then there is at least one specific point ("point of resonance") where the T_i blow up.

XX.8.4.4. PROOF: Our first proof deduces the theorem from the Closed Graph Theorem.

First note that since the T_i are not assumed to be surjective, there is no harm in replacing Y_i by its completion. Thus we may assume without loss of generality that each Y_i is a Banach space.

Let Y be the ℓ^∞ product of the Y_i (). Then Y is a Banach space. Define $T : X \to Y$ by

$$T(x) = (\cdots T_i(x) \cdots)$$

(the pointwise boundedness hypothesis exactly means that $T(x) \in Y$ for all $x \in X$). Then T is a linear operator; T is bounded if and only if the T_i are uniformly bounded (in fact, $\|T\| = \sup_i \|T_i\|$).

To show T is bounded, it suffices to show that T has closed graph. But this is easy. Suppose (x_n) is a sequence in X and $x_n \to x$ and $Tx_n \to y$ for some $x \in X$, $y \in Y$. Set $y = (\cdots y_i \cdots)$. Since convergence in Y implies coordinatewise convergence, we have $T_i x_n \to y_i$ for all i. But since T_i is bounded, we have $T_i x_n \to T_i x$, i.e. $y_i = T_i x$ for all i, and thus $y = Tx$. 👍

XX.8.4.5. PROOF: We give a second direct proof from the Baire Category Theorem.

For $n \in \mathbb{N}$, define

$$A_n = \{x \in X : \|T_i x\| \leq n \text{ for all } i \in I\}$$

and note that A_n is a closed subset of X ($A_n = \cap_{i \in I} T_i^{-1}(\{y \in Y_i : \|y\| \leq n\})$).

By the pointwise boundedness assumption, $\cup_n A_n = X$, so by the Baire Category Theorem some A_n has nonempty interior. Thus there is an $x_0 \in X$ and $\epsilon > 0$ such that $\|T_i x\| \leq n$ whenever $\|x - x_0\| < \epsilon$. Let m be a number such that $\|T_i(x_0)\| \leq m$ for all $i \in I$. Then, if $\|x\| < \epsilon$, we have $\|[x + x_0] - x_0\| < \epsilon$, so, for all i,

$$\|T_i(x + x_0)\| \leq n$$

$$\|T_i x\| = \|T_i([x + x_0] - x_0)\| = \|T_i(x + x_0) - T_i(x_0)\| \leq \|T_i(x + x_0)\| + \|T_i(x_0)\| \leq n + m$$

which implies that

$$\|T_i\| \leq \frac{n + m}{\epsilon}$$

for all i. 👍

XX.8.4.6. PROOF: Our third proof is the most elementary, using a "gliding hump" argument. This proof is due to HAUSDORFF [Hau32] (cf. [Hen80]).

Suppose $\{\|T_i\| : i \in I\}$ is unbounded. Inductively define sequences (x_n) in X and $i_n \in I$ as follows. Suppose x_k and i_k have been defined for $k < n$. Set $M_0 = 0$, and if $n > 1$ set

$$M_{n-1} = \sup_i \{T_i(x_1 + \cdots + x_{n-1})\} .$$

Now choose i_n such that

$$\|T_{i_n}\| > 3 \cdot 4^n [n + M_{n-1}]$$

and x_n such that

$$\|x_n\| = 4^{-n}$$

$$\|T_{i_n} x_n\| > \frac{2}{3} \|T_{i_n}\| \|x_n\| .$$

Set

$$x = \sum_{n=1}^{\infty} x_n$$

(note that the series converges absolutely, hence converges since X is complete). For each n set

$$z_n = x_1 + \cdots + x_{n-1}$$

(set $z_1 = 0$)

$$y_n = \sum_{k=n+1}^{\infty} x_k$$

and note that $\|y_n\| \leq \frac{4^{-n}}{3} = \frac{1}{3}\|x_n\|$. We then have

$$\|T_{i_n} x_n\| > 2[n + M_{n-1}]$$

$$\|T_{i_n} y_n\| \leq \|T_{i_n}\| \|y_n\| \leq \frac{1}{3}\|T_{i_n}\| \|x_n\| < \frac{1}{2}\|T_{i_n} x_n\|$$

for each n. Thus for each n we have

$$\|T_{i_n} x\| = \|T_{i_n}(x_n + y_n + z_n)\| \geq [\|T_{i_n} x_n\| - \|T_{i_n} y_n\|] - \|T_{i_n} z_n\| > [n + M_n] - M_n = n$$

which contradicts that $\{\|T_i x\| : i \in I\}$ is bounded. 👍

Here is a typical application of the Uniform Boundedness Theorem:

XX.8.4.7. PROPOSITION. Let X be a Banach space. If (ϕ_n) is a weak-* convergent sequence in X^*, then (ϕ_n) is uniformly bounded, i.e. there is a K such that $\|\phi_n\| \leq K$ for all n.

PROOF: We have $X^* = \mathcal{B}(X, \mathbb{F})$. For each $x \in X$, the sequence $(\phi_n(x))$ is a convergent sequence in $\mathbb{F}$, hence bounded (). 👍

This is only true for *sequences*, not nets! In fact, even a convergent net of real numbers is not necessarily bounded. ✋

XX.8.5. Exercises

XX.8.5.1. Let X and Y be normed vector spaces, with X complete, and $T : X \to Y$ a linear operator.
(a) Show that T is bounded if and only if $T^{-1}(B_Y)$ is closed, where B_Y is the closed unit ball of Y. [One direction is trivial from continuity. Conversely, suppose $T^{-1}(B_Y)$ is closed. Then $T^{-1}(B)$ is closed for every closed ball B in Y. Apply the Baire Category Theorem to conclude that $T^{-1}(B_Y)$ contains an open ball.]
(b) Let $T : c_{00} \to c_{00}$ () be defined by

$$T(\xi_1, \xi_2, \dots) = (\xi_1, 2\xi_2, \dots, n\xi_n, \dots) \ .$$

Show that $T^{-1}(B_{c_{00}})$ is closed. Thus the result does not necessarily hold if X is not complete.
(c) What is the relation between this property of T and having closed graph?

XX.9. Compact Convex Sets

A fairly detailed analysis can be given of the structure of compact convex sets in locally convex topological vector spaces. We describe the basics of this theory in this section; for more detailed analyses, see [Alf71], [**?**],

We will work throughout this section with *real* topological vector spaces. The results will immediately apply also to complex topological vector spaces, since a complex topological vector space has an underlying structure as a real topological vector space and none of the statements or proofs of the results make use of complex scalar multiplication. To avoid unnecessary subscripts, if K is a compact Hausdorff space, in this section write $C(K)$ for the set $C_{\mathbb{R}}(K)$ of real-valued continuous functions on K.

XX.9.1. Convex Sets in Topological Vector Spaces

The notion of convexity makes sense in any vector space over the real numbers (or field containing the real numbers such as $\mathbb{C}$), but the primary applications in analysis concern convex sets in topological vector spaces, usually with additional topological properties.

The first simple observation is a consequence of the continuity of addition and scalar multiplication:

XX.9.1.1. Proposition. Let C be a convex set in a topological vector space X. Then the closure $\bar{C}$ and the interior C° of C are also convex (C° may be empty in general).

XX.9.1.2. A convex set with empty (topological) interior (e.g. $[x, y]$ for $x \neq y$ in $\mathbb{R}^2$) can have inner points in the sense of XX.1.3.7.. However:

XX.9.1.3. Proposition. Let C be a convex set in a topological vector space X. Any internal point of C (in particular, any interior point of C) is an inner point.

We modify the definition of isomorphism of convex sets (XX.1.2.9.) to one more appropriate in topological vector spaces:

XX.9.1.4. Definition. Let C and D be convex sets in topological vector spaces X and Y respectively. An *isomorphism* from C to D is an affine homeomorphism from C to D.

Thus an isomorphism from C to D is a bijection which preserves both the convex structure and the topology.

XX.9.2. Faces and Extreme Points

The crucial notion underlying the whole analysis of compact convex sets is that of a face (XX.1.3.1.).

Closed Faces

Let X be a topological vector space, and K a convex subset of X. The faces of K which are relatively closed in K are particularly important, and are called the *closed faces* of K. This situation is especially important if K is closed in X, although we do not make this assumption in the definition. Note that (if X is Hausdorff) every extreme point is a closed face.

XX.9.2.1. It looks at first from the definition that a face should be closed; in fact, if F is a face in K and Y is a one-dimensional (more generally, finite-dimensional) affine subspace of X, then $F \cap Y$ is always relatively closed in $K \cap Y$. However, a face of a convex set, even a compact convex set (Choquet simplex), need not be closed in general, and the closure of a face is not necessarily a face (XX.9.8.2.). ✋

XX.9.2.2. As in XX.1.3.6.(i), an arbitrary intersection of closed faces of a convex set K, if nonempty, is a closed face (the other parts of XX.1.3.6. have straightforward analogs for closed faces too, with "face" replaced by "closed face" throughout). Thus if S is an arbitrary nonempty subset of K, there is a smallest closed face $\bar{F}(S)$ of K containing S, the intersection of all closed faces containing S.

XX.9.2.3. Similarly, if K is a convex set in a topological vector space X, and ϕ is a continuous linear functional on X, a support face for K from ϕ (XX.1.3.11.) is a closed face of K.

Convex Hulls and Extreme Points

XX.9.2.4. PROPOSITION. Let X be a topological vector space, and $K_1, \ldots, K_n$ a finite collection of compact convex sets in X. Let K be the convex hull of $\cup_{j=1}^n K_j$. Then K is compact.

PROOF: Since each K_j is convex, it is easy to check that

$$\left\{ \sum_{j=1}^n \alpha_j x_j : x_j \in K_j, \alpha_j \geq 0, \sum_{j=1}^n \alpha_j = 1 \right\}$$

is convex; since it is contained in K and contains each K_j, it equals K. Set

$$S = \left\{ (\alpha_1, \ldots, \alpha_n) : \alpha_j \geq 0, \sum_{j=1}^n \alpha_j = 1 \right\} .$$

Then S is a compact subset of $\mathbb{R}^n$ (it is an $(n-1)$-simplex), so the map

$$(\alpha_1, \ldots, \alpha_n, x_1, \ldots, x_n) \mapsto \sum_{j=1}^n \alpha_j x_j$$

is a continuous function from the compact set $S \times K_1 \times \cdots \times K_n$ onto K. Thus K is compact by (). 👍

The next result is known as *Milman's (partial) converse to the Krein-Milman Theorem*. Our proof is adapted from [SW99].

XX.9.2.5. THEOREM. Let S be a subset of a locally convex (Hausdorff) topological vector space X such that the closed convex hull K of S is compact. Then all extreme points of K lie in $\bar{S}$.

PROOF: Since $\bar{S}$ is a subset of K, it is compact. Let U be an open convex neighborhood of 0 in X. For $x \in \bar{S}$, set $U_x = x + U$. The U_x form an open cover of $\bar{S}$, so there is a finite subcover $\{U_{x_1}, \ldots, U_{x_n}\}$. Let K_j be the closed convex hull of $S \cap \bar{U}_{x_j}$. Then $K_j \subseteq K$ for all j. The convex hull K' of $\cup_{j=1}^n K_j$ contains S, $K' \subseteq K$, and K' is compact by XX.9.2.4.; thus $K' = K$. So if p is an extreme point of K, we have $p = \sum_{j=1}^n \alpha_j y_j$ for some α_j's in S and $y_j \in K_j$; since p is extreme, we must have $p = y_j$ for some j, i.e. $p \in K_j$. Since $\bar{U}_{x_j}$ is closed and convex, $K_j \subseteq \bar{U}_{x_j} \subseteq \bar{S} + \bar{U}$. Thus $p \in \bar{S} + \bar{U}$. This is true for every U, so $p \in \bar{S}$. 👍

XX.9.3. Compact Convex Sets in Finite-Dimensional Spaces

We now look at compact convex sets in finite-dimensional topological vector spaces. A finite-dimensional real vector space has a unique topology making it a Hausdorff topological vector space, which can be identified with $\mathbb{R}^n$ for some n. So without loss of generality we will work in Euclidean space. We can thus use geometric arguments in our analysis.

XX.9.3.1. If K is a convex set in $\mathbb{R}^n$, then K spans an m-dimensional affine subspace of $\mathbb{R}^n$ for some $m \leq n$; we say K is *m-dimensional* (this terminology is justified in **??**). By replacing $\mathbb{R}^n$ with this subspace and identifying it with $\mathbb{R}^m$, we may if desired for analysis of K assume it spans all of $\mathbb{R}^n$ as an affine space (i.e. is n-dimensional), although we will not routinely make this restriction. Dimension in this sense is an isomorphism invariant of K.

XX.9.3.2. PROPOSITION. If K is an n-dimensional convex set in $\mathbb{R}^n$, then K has nonempty (topological) interior K°; in fact K° is an open convex set in $\mathbb{R}^n$ which is dense in K.

PROOF: K contains $n+1$ points $\boldsymbol{x}_0, \ldots, \boldsymbol{x}_n$ which span $\mathbb{R}^n$ as an affine space (any set which spans $\mathbb{R}^n$ as an affine space contains $n+1$ points which also span it). Set $\boldsymbol{x} = \frac{1}{n+1}\sum_{k=0}^n \boldsymbol{x}_k$. Every point $\boldsymbol{y}$ of $\mathbb{R}^n$ can be uniquely written as $\sum_{k=0}^n \alpha_k \boldsymbol{x}_k$ for $\alpha_k \in \mathbb{R}$, $\sum_{k=0}^n \alpha_k = 1$; if $\boldsymbol{y}$ is sufficiently close to $\boldsymbol{x}$, each α_k is close to $\frac{1}{n+1}$ and is hence positive. Thus $\boldsymbol{y} \in K$ if $\boldsymbol{y}$ is sufficiently close to $\boldsymbol{x}$, i.e. K contains an open ball around $\boldsymbol{x}$. Thus $\boldsymbol{x}$ is in K°, so $K^\circ \neq \emptyset$. The density and convexity of K° follow from (). 👍

This result fails for infinite-dimensional compact convex sets, since it implies that the spanned affine subspace contains a nonempty open set with compact closure.

Combining this with the geometric version of the Hahn-Banach Theorem in () (which is elementary in a finite-dimensional vector space, not requiring any form of Choice), we obtain:

XX.9.3.3. PROPOSITION. Let K be an n-dimensional convex set in $\mathbb{R}^n$. If $\boldsymbol{x} \in K$ is in the topological boundary of K, then $\boldsymbol{x}$ is contained in a proper face of K, and hence is not an interior point in the sense of XX.1.3.7..

PROOF: By () applied to K° and $\boldsymbol{x}$, there is a linear functional ϕ on $\mathbb{R}^n$, which is automatically continuous, and a number r such that $\phi(\boldsymbol{x}) \geq r$ and $\phi(\boldsymbol{y}) < r$ for all $\boldsymbol{y} \in K^\circ$. Since ϕ is continuous, $\phi(\boldsymbol{y}) \leq r$ for

all $\boldsymbol{y} \in \overline{K^\circ}$, and in particular $\phi(\boldsymbol{x}) = r$ and $\phi(\boldsymbol{y}) \leq r$ for all $\boldsymbol{y} \in K$ since K° is dense in K. The set $F = \{\boldsymbol{y} \in K : \phi(\boldsymbol{y}) = r\}$ is thus a proper face of K containing $\boldsymbol{x}$. 👍

This result fails in the infinite-dimensional case, and even in the finite-dimensional case if the dimension of the convex set is strictly smaller than the dimension of the space.

Extreme Points

Our next goal is to show that a compact convex set K in a finite-dimensional vector space has "many" extreme points, enough that K is the convex hull of its extreme points. This result is a special case of the Krein-Milman Theorem, although we will obtain a sharper result with a more elementary proof in the finite-dimensional case.

XX.9.3.4. Example. It can be shown that if K is a compact convex set in $\mathbb{R}^2$, then the set of extreme points of K is closed in K, hence also compact. But this fails in $\mathbb{R}^3$. Let K be the convex hull of the points of $C = \{(x, y, 0) : (x-1)^2 + y^2 = 1\}$ and the points $(0, 0, 1)$ and $(0, 0, -1)$; see Fig. (). The extreme points of K are the points of C except the origin, and the points $(0, 0, 1)$ and $(0, 0, -1)$. The origin is in the closure of the set of extreme points but is not itself an extreme point.

XX.9.3.5. Proposition. An n-dimensional compact convex set K has at least $n + 1$ extreme points. The extreme points of K span the same affine subspace as K.

XX.9.3.6. Lemma. A nonempty compact convex set in $\mathbb{R}^n$ has an extreme point.

Proof: Let K be a compact convex set in $\mathbb{R}^n$, and $\boldsymbol{x} \in K$. There is a point $\boldsymbol{y} \in K$ of maximum distance d from $\boldsymbol{x}$ by compactness ($\boldsymbol{y}$ is not necessarily unique). Then $\boldsymbol{y}$ is an extreme point of the ball $\bar{B}_d(\boldsymbol{x})$, which contains K, so $\boldsymbol{y}$ is an extreme point of K. 👍

In fact, if K contains more than one point, it contains a second extreme point too, any point of maximum distance from $\boldsymbol{y}$. This result and proof hold more generally in any strictly convex Banach space. The result is true in much greater generality (XX.9.4.1.), but requires a different proof.

Proof: Proof of XX.9.3.5.: let K be an n-dimensional compact convex subset of $\mathbb{R}^n$. Let A be the affine subspace spanned by the extreme points of K (there is at least one extreme point by XX.9.3.6.). If A does not contain K, then there is a point $\boldsymbol{x}$ of K of maximum distance $d > 0$ from A. If S is the set of points of K of distance d from A, then the face $F(\{\boldsymbol{x}\})$ of K generated by $\boldsymbol{x}$ is contained in S. $F(\{\boldsymbol{x}\})$ is a compact convex set and thus has an extreme point $\boldsymbol{y}$ (XX.9.3.6.), which must be an extreme point of K also. But $\boldsymbol{y} \in S$, so $\boldsymbol{y} \notin A$, a contradiction. The first statement then follows since the affine subspace spanned by m points has dimension $\leq m - 1$. 👍

The next result is the main theorem of this subsection, due first to Minkowski without the $n + 1$, and in the sharp form with $n + 1$ by Carathéodory.

XX.9.3.7. THEOREM. Let K be a compact convex set in $\mathbb{R}^n$. Then every point of K is a convex combination of at most $n+1$ extreme points of K.

PROOF: By complete induction on the dimension m of K. If $m = 1$, K is isomorphic to a closed bounded interval and is the convex hull of its two endpoints (and the case $m = 0$ is trivial). For a general K of dimension m, let $\boldsymbol{x} \in K$. If $\boldsymbol{x}$ is in the topological boundary of K, then $\boldsymbol{x}$ lies in a proper face F of K (XX.9.3.3.), and thus $\boldsymbol{x}$ is a convex combination of at most m extreme points of F by the inductive hypothesis, all of which are extreme points of K. If $\boldsymbol{x}$ is an interior point of K, let $\boldsymbol{y}$ be an extreme point of K. The ray from $\boldsymbol{y}$ through $\boldsymbol{x}$ intersects the boundary of K in a (unique) point $\boldsymbol{z}$, which is in K since K is compact. Then as before $\boldsymbol{z}$ is a convex combination of at most m extreme points in a proper face of K. Since $\boldsymbol{x}$ is a convex combination of $\boldsymbol{z}$ and $\boldsymbol{y}$, $\boldsymbol{x}$ is a convex combination of $\boldsymbol{y}$ and these at most m other extreme points of K. 👍

Combining this result with XX.9.2.5., we get:

XX.9.3.8. COROLLARY. Let E be a compact subset of $\mathbb{R}^n$. Then the convex hull K of E is also compact.

PROOF: Let

$$S = \left\{ (\alpha_0, \ldots, \alpha_n) : \alpha_j \geq 0, \sum_{j=0}^{n} \alpha_j = 1 \right\} \subseteq \mathbb{R}^{n+1}$$

and consider the map $f : S \times E^{n+1} \to K$ defined by

$$f(\alpha_0, \ldots, \alpha_n, \boldsymbol{x}_0, \ldots, \boldsymbol{x}_n) = \sum_{j=0}^{n} \alpha_j \boldsymbol{x}_j \ .$$

Then f is continuous. Each extreme point of K is in E by XX.9.2.5., and every element of K is a convex combination of at most $n+1$ extreme points by XX.9.3.7., so f is surjective. $S \times E^{n+1}$ is compact, so K is compact by (). 👍

XX.9.4. The Krein-Milman Theorem

XX.9.4.1. THEOREM. [KREIN-MILMAN THEOREM] Let K be a nonempty compact convex set in a locally convex (Hausdorff) topological vector space X. Then K is the closed convex hull of its extreme points (and in particular has extreme points).

PROOF: Recall that we regard X as a *real* topological vector space by ignoring the complex structure if necessary, since all relevant notions (convexity, compactness, etc.) depend only on the real topological vector space structure. Let $\mathcal{F}$ be the collection of all closed faces of K. Partially order $\mathcal{F}$ by reverse inclusion: if $E, F \in \mathcal{F}$, then $E \leq F$ if $F \subseteq E$. If $\mathcal{C} = \{F_i : i \in I\}$ is a chain in $\mathcal{F}$, then $\mathcal{C}$ has an upper bound, namely $F = \cap_i F_i$, which is a closed face (XX.9.2.2.) since it is nonempty because $\mathcal{C}$ is a nested family of compact subsets of K (this is the first of several places compactness of K is used).

Thus, by Zorn's Lemma, $\mathcal{F}$ has a maximal element, i.e. K has a minimal closed face E. We must have that E is a singleton: if $x, y \in E$, $x \neq y$, there is a continuous linear functional ϕ on X with $\phi(x) \neq \phi(y)$ (this is the first place where we need that X is locally convex and Hausdorff). Then $\{\phi(z) : z \in E\}$ is a compact subset of $\mathbb{R}$ (actually a closed bounded interval) since E is compact. If λ is the largest number in this set, then $F = \{z \in E : \phi(z) = \lambda\}$ is a closed face of E and hence of K, and is a proper subset of E since x and y cannot both be in F, contradicting that E is a minimal closed face of K. Thus $E = \{p\}$ for an extreme point p of K, and K has an extreme point. A stronger conclusion also holds: if F is any closed face of K, then F is itself a nonempty compact convex set in X, and so has a point which is an extreme point of F and thus an extreme point of K. Therefore every closed face of K contains an extreme point of K.

Now let L be the closed convex hull of the extreme points of K. If $L \neq K$, let $x \in K \setminus L$. Then, since L is compact and convex, there is a continuous linear functional ψ on X with

$$\psi(x) > \sup\{\psi(y) : y \in L\}$$

by the geometrical Hahn-Banach Theorem () (we again use that X is locally convex and Hausdorff). The set $\{\psi(z) : z \in K\}$ is a compact subset of $\mathbb{R}$ (actually a closed bounded interval), so has a largest number μ. Then $F = \{z \in K : \psi(z) = \mu\}$ is a closed face in K disjoint from L. But F contains an extreme point of K by the previous proof, contradicting that all extreme points of K are in L. Thus $L = K$. 👍

XX.9.4.2. The local convexity hypothesis in the Krein-Milman Theorem is to insure that there are sufficiently many continuous linear functionals, or equivalently enough closed supporting hyperplanes. There exists a compact convex set in a topological vector space which is complete and metrizable, but not locally convex, which has no extreme points [Rob77]. (In a non-Hausdorff topological vector space, there is a trivial counterexample: the closure of $\{0\}$.)

XX.9.4.3. The hypotheses of the Krein-Milman Theorem are not necessary. If A is a unital C*-algebra (), then every element of the open unit ball of A is a convex combination of unitaries, which are extreme points of the closed unit ball [Bla06]. Thus the closed unit ball of a unital C*-algebra is the closed convex hull of its extreme points, even though there is no (Hausdorff) topological vector space topology on A in general under which the closed unit ball is compact. (The closed unit ball of a nonunital C*-algebra has no extreme points.) A closed bounded set in a Banach space with the Radon-Nikodym Property () is the closed convex hull of its extreme points ([Phe74], [Edg75]).

XX.9.5. Choquet's Theorem

There is an important sharpening of the Krein-Milman Theorem for metrizable compact convex sets, due to G. Choquet [Cho56]. Our exposition is adapted from [Phe66].

Representing Measures

XX.9.5.1. Definition. Let X be a topological vector space, and E a compact subset of X. Let μ be a Borel probability measure on E, and $x \in X$. Then μ *represents* x, or x is the *barycenter*, *resultant*, or *moment* of μ, if for every continuous linear functional ϕ on X we have

$$\phi(x) = \mu(\phi) := \int_E \phi \, d\mu$$

(note that ϕ is Borel measurable and bounded on E, so the integral is defined; the notation $\mu(\phi)$ comes from regarding μ as a bounded linear functional on $C(E)$ by the Riesz Representation Theorem ()).

The point x, if it exists, is the weak integral $\int_E \iota \, d\mu$ (), where ι is the identity map on E, regarded as a continuous function from E to X.

XX.9.5.2. Examples. (i) If $x \in X$ and E is any compact subset of X containing x, then the point mass δ_x (regarded as a Borel probability measure on E) represents x. The measure δ_x is called ϵ_x in some references.

(ii) Let K be the convex hull of n extreme points $\{p_1, \ldots, p_n\}$ in a Hausdorff topological vector space X. Then K is compact. If $x \in K$, then $x = \sum_{j=1}^n \alpha_j p_j$ for some $\alpha_1, \ldots, \alpha_n \geq 0$ with $\sum_{j=1}^n \alpha_j = 1$. If μ is the purely atomic Borel probability measure on K with $\mu(p_j) = \alpha_j$ (i.e. $\mu = \sum_{j=1}^n \alpha_j \delta_{p_j}$), then μ represents x (x is the barycenter of μ). Thus every point of K is the barycenter of a Borel probability measure on K supported on the extreme points of K. (Since the convex combination giving x is not necessarily unique, the representing measure for x is not unique in general.)

Choquet's Theorem extends (ii) to an arbitrary metrizable compact convex set K, giving a representing measure (not unique in general) for any point of K which is supported on the extreme points of K.

XX.9.5.3. Proposition. If X is locally convex (Hausdorff), and μ is a Borel probability measure on a compact subset E of X, then μ represents at most one point of X.

Proof: If μ represents x and y, then $\phi(x) = \mu(\phi) = \phi(y)$ for all $\phi \in X^*$. Thus $x = y$ since X^* separates the points of X. 👍

XX.9.5.4. Proposition. If K is a compact convex set in a topological vector space X, and μ is a Borel probability measure on K, of X, then μ represents at least one point of X (exactly one point x_μ if X is locally convex), and the barycenter is in K. If X is locally convex, the function $\mu \mapsto x_\mu$ is weak-* continuous, i.e. if $\mu_i \to \mu$ weak-* in $C(K)^*$, then $x_{\mu_i} \to x_\mu$ in K.

Proof: If $x \in X$ is represented by μ, then for any $\phi \in X^*$,

$$\phi(x) = \mu(\phi) \leq \sup\{\phi(y) : y \in K\}$$

and thus by the geometrical Hahn-Banach Theorem () $x \in K$ since it is closed and convex.

For existence, for each $\phi \in X^*$ let $H_\phi = \{x \in K : \phi(x) = \mu(\phi)\}$. Then H_ϕ is a closed hyperplane in X, and we wish to show that

$$\left[\bigcap_\phi H_\phi\right] \cap K \neq \emptyset \ .$$

Since these sets are compact, it suffices to show that for any $\phi_1, \ldots, \phi_n \in X^*$,

$$H_{\phi_1} \cap \cdots \cap H_{\phi_n} \cap K \neq \emptyset \ .$$

Define a bounded linear map $T : X \to \mathbb{R}^n$ by

$$T(x) = (\phi_1(x), \ldots, \phi_n(x)) \ .$$

Then $T(K)$ is a compact convex subset of $\mathbb{R}^n$. Set $\boldsymbol{y} = (\mu(\phi_1), \ldots, \mu(\phi_n)) \in \mathbb{R}^n$. It suffices to show $\boldsymbol{y} \in T(K)$. If $\boldsymbol{y} \notin T(K)$, there is a linear functional ψ on $\mathbb{R}^n$ with $\psi(\boldsymbol{y}) > \sup\{\psi(\boldsymbol{z}) : \boldsymbol{z} \in T(K)\}$. There is a vector $\boldsymbol{a} \in \mathbb{R}^n$ such that $\psi(\boldsymbol{z}) = \langle \boldsymbol{a}, \boldsymbol{z} \rangle$ for all $\boldsymbol{z} \in \mathbb{R}^n$ (). Set $\boldsymbol{a} = (a_1, \ldots, a_n)$. We have

$$\psi(\boldsymbol{y}) = \langle \boldsymbol{a}, \boldsymbol{y} \rangle > \sup\{\langle \boldsymbol{a}, T(x) \rangle : x \in K\} \ .$$

If $\theta \in X^*$ is defined by $\theta = \sum_{j=1}^n a_j \phi_j$, we have

$$\int_K \theta \, d\mu = \psi(\boldsymbol{y}) > \sup\{\theta(x) : x \in K\} \ .$$

This is impossible since μ is a probability measure. Thus $\boldsymbol{y} \in T(K)$.

Now suppose X is locally convex (Hausdorff), and (μ_i) is a net of Borel probability measures on K with $\mu_i \to \mu$ weak-*. Set $x_i = x_{\mu_i}$ and $x = x_\mu$. To show $x_i \to x$, we use the hard-to-state criterion XIII.3.2.13.. Fix a subnet (x_j) of (x_i). Then (x_j) has a convergent subnet by compactness of K. Fix a convergent subnet (x_r), say $x_r \to y \in K$. Then, for any $\phi \in X^*$, $\phi(x_r) \to \phi(y)$ by continuity of ϕ. On the other hand,

$$\phi(x_i) = \mu_i(\phi) \to \mu(\phi) = \phi(x)$$

and so the subnet $(\phi(x_r))$ also converges to $\phi(x)$. Thus $\phi(y) = \phi(x)$. This is true for all $\phi \in X^*$, so $y = x$ since X^* separates the points of X. So (x_j) has a subnet converging to x, and so $x_i \to x$ by XIII.3.2.13.. 🖒

XX.9.5.5. Corollary. If E is a compact set in a locally convex topological vector space X, and the closed convex hull K of E is also compact (this is automatic if X is topologically complete, e.g. if X is a Banach space in the norm topology, or the dual of a Banach space in the weak-* topology, cf. ()), then every Borel probability measure μ on E has a unique barycenter x_μ in X, and $x_\mu \in K$. The map $\mu \mapsto x_\mu$ is weak-* continuous.

XX.9.5.6. Proposition. If E is a compact set in a locally convex topological vector space X, and $x \in X$, then x is in the closed convex hull $\overline{co}(E)$ if and only if x is represented by a Borel probability measure on E.

Proof: One direction generalizes part of XX.9.5.5. (since it is not assumed that $\overline{co}(E)$ is compact), and has the same proof: if x is represented by μ, then for any $\phi \in X^*$,

$$\phi(x) = \mu(\phi) \leq \sup\{\phi(y) : y \in E\} = \sup\{\phi(y) : y \in \overline{co}(E)\}$$

and thus $x \in \overline{co}(E)$ since it is closed and convex.

For the converse, suppose $x \in \overline{co}(E)$. Then there is a net (x_i) in $co(E)$ with $x_i \to x$. Each x_i can be represented by a Borel probability measure μ_i on E which is a finite convex combination of point masses as in XX.9.5.2.(ii). Since the set of Borel probability measures on E is a weak-* compact subset of $C(E)^*$, there

is a subnet (μ_j) of the net (μ_i) which converges weak-* to a Borel probability measure μ. Then $x_j \to x$, and for any $\phi \in X^*$ we have

$$\phi(x_j) \to \phi(x)$$

$$\phi(x_j) = \mu_j(\phi) \to \mu(\phi)$$

and thus $\phi(x) = \mu(\phi)$. Since this holds for all $\phi \in X^*$, μ represents x. 👍

The Krein-Milman Theorem Revisited

The Krein-Milman Theorem can thus be rephrased using XX.9.5.6.:

XX.9.5.7. Theorem. [Krein-Milman Theorem, Representing Measure Form] Let K be a compact convex set in a locally compact (Hausdorff) topological vector space X, and E the closure of the set $\partial_e(K)$ of extreme points of K. Then every point of K is the barycenter of a Borel probability measure on E.

For the proof, just note that $\overline{co}(E) = \overline{co}(\partial_e(K))$, and apply XX.9.4.1. and XX.9.5.6.. Conversely, XX.9.4.1. follows from XX.9.5.7. and XX.9.5.6., so XX.9.4.1. and XX.9.5.7. are equivalent via XX.9.5.6..

XX.9.5.8. This form of the Krein-Milman Theorem is not optimally useful, since E can be a rather large subset of K; in fact, E is "generically" the whole set K (i.e. the set of extreme points of K is generically dense in K)! [Kle59].

It would be far better to have representing measures supported on the set $\partial_e(K)$ of extreme points of K itself, not just on the closure.

XX.9.5.9. In order for the desired statement to even make sense, we need the set $\partial_e(K)$ to be a Borel set. Although it is not closed in general, even if K is a metrizable Choquet simplex (), in the metrizable case we do have:

XX.9.5.10. Proposition. Let K be a metrizable compact convex set in a topological vector space X. Then the set $\partial_e(K)$ of extreme points of K is a G_δ, and in particular a Borel set.

Proof: Fix a metric ρ giving the topology of K. For $n \in \mathbb{N}$, let A_n be the set of all $x \in K$ such that there exist $y, z \in K$ with $x = \frac{1}{2}(y+z)$ and $\rho(y,z) \geq \frac{1}{n}$. Then $\cup_{n=1}^{\infty} A_n$ is the complement of $\partial_e(K)$, so it suffices to show that each A_n is a closed set.

Fix $n \in \mathbb{N}$, and let (x_j) be a sequence in A_n with $x_j \to x \in K$. For each j, there are $y_j, z_j \in K$ with $x_j = \frac{1}{2}(y_j + z_j)$ and $\rho(y_j, z_j) \geq \frac{1}{n}$. By compactness of K, there are convergent subsequences (y_{r_j}) and (z_{r_j}) of (y_j) and (z_j), which can be taken to have the same indices (), say $y_{r_j} \to y$, $z_{r_j} \to z$. Then

$$\frac{1}{2}(y_{r_j} + z_{r_j}) \to \frac{1}{2}(y+z) \ .$$

But

$$\frac{1}{2}(y_{r_j} + z_{r_j}) = x_{r_j} \to x$$

and thus $x = \frac{1}{2}(y+z)$ since K is Hausdorff. Since $\rho(y,z) \geq \frac{1}{n}$ by continuity of ρ, we have $x \in A_n$ and A_n is closed. 👍

We then have the following strengthening of XX.9.5.7. in the metrizable case:

XX.9.5.11. THEOREM. [CHOQUET'S THEOREM] Let K be a metrizable compact convex set in a locally convex (Hausdorff) topological vector space X. Then every $x \in K$ is represented by a measure which is supported on the set $\partial_e(K)$ of extreme points of K.

XX.9.5.12. We give a nice proof due to BONSALL [Bon63] (cf. [Phe66]) based on the Hahn-Banach Theorem. The argument will be a series of lemmas. To begin, fix a point $x_0 \in K$; we will show that x_0 is represented by a measure supported on $\partial_e(K)$. We will work with the subspace $\mathrm{Aff}(K)$ of $C(K)$ of real-valued continuous affine functions on K. Since K is metrizable, $\mathrm{Aff}(K)$ is separable; fix a sequence (h_n) which is dense in the unit sphere of $\mathrm{Aff}(K)$, and set

$$f = \sum_{n=1}^{\infty} 2^{-n} h_n^2 \in C(K) \ .$$

XX.9.5.13. LEMMA. The function f is strictly convex on K, i.e. $f(tx+(1-t)y) < tf(x)+(1-t)f(y)$ for $x, y \in K$, $x \neq y$, $0 < t < 1$.

PROOF: Each h_n^2 is clearly convex, so f is convex. If $x \neq y$, there is an h_n with $h_n(x) \neq h_n(y)$, so h_n is affine and not constant on the segment between x and y, and therefore h_n^2 is strictly convex on this segment. Hence f is too. 👍

XX.9.5.14. DEFINITION. If $g \in C(K)$, write

$$\bar{g} = \inf\{h : h \in \mathrm{Aff}(K), g \leq h\} \ .$$

The function $\bar{g}$ is called the *upper envelope* of g.

XX.9.5.15. LEMMA. Let $g, g_1, g_2 \in C(K)$. Then

(i) $\bar{g}$ is concave, i.e. $\bar{g}(tx+(1-t)y) \geq t\bar{g}(x)+(1-t)\bar{g}(y)$ for $x, y \in K$, $0 < t < 1$.

(ii) $\bar{g}$ is bounded and upper semicontinuous, hence Borel measurable.

(iii) $g \leq \bar{g}$, and $g = \bar{g}$ if and only if g is concave.

(iv) $\overline{g_1+g_2} \leq \bar{g}_1 + \bar{g}_2$, and $\overline{g_1+g_2} = \bar{g}_1 + \bar{g}_2 = \bar{g}_1 + g_2$ if $g_2 \in \mathrm{Aff}(K)$.

(v) $|\bar{g}_1 - \bar{g}_2| \leq \|g_1 - g_2\|$.

(vi) If $\alpha \geq 0$, then $\overline{\alpha g} = \alpha \bar{g}$.

The simple proof is straightforward and left to the reader.

XX.9.5.16. Let Y be the subspace of $C(K)$ spanned by $\mathrm{Aff}(K)$ and f (defined above). Define a linear functional ψ on Y by $\psi(h+\alpha f) = h(x_0) + \alpha \bar{f}(x_0)$.

XX.9.5.17. Lemma. For $g \in C(K)$, define $p(g) = \bar{g}(x_0)$. Then

(i) p is subadditive and positive-homogeneous.

(ii) If $h + \alpha f \in Y$, then $\psi(h+\alpha f) \leq p(h+\alpha f)$.

Proof: (i) follows immediately from XX.9.5.15.(iv) and (vi).
(ii): If $\alpha \geq 0$, then $\overline{h+\alpha f} = h + \alpha \bar{f}$ by XX.9.5.15.(iv) and (vi), and in particular

$$\psi(h+\alpha f) = h(x_0) + \alpha \bar{f}(x_0) = \overline{h+\alpha f}(x_0) = p(h+\alpha f)$$

and if $\alpha < 0$, then $h + \alpha f$ is concave, so $\overline{h+\alpha f} = h + \alpha f \geq h + \alpha \bar{f}$ and in particular

$$\psi(h+\alpha f) = h(x_0) + \alpha \bar{f}(x_0) \leq h(x_0) + \alpha f(x_0) = \overline{h+\alpha f}(x_0) = p(h+\alpha f)\ .$$

XX.9.5.18. Thus by the Hahn-Banach Theorem there is a linear functional ϕ on $C(K)$ with

$$\phi(g) \leq p(g) = \bar{g}(x_0)$$

for all $g \in C(K)$, which extends ψ.

XX.9.5.19. Lemma. The linear functional ϕ is a state (positive linear functional of norm 1) on $C(K)$.

Proof: If $g \in C(K)$, $g \leq 0$, then since the constant function 0 is in $\mathrm{Aff}(K)$, $\bar{g} \leq 0$, and in particular $\phi(g) \leq p(g) = \bar{g}(x_0) \leq 0$. Taking negatives, ϕ is a positive linear functional. Since the constant function 1 is in $\mathrm{Aff}(K)$, we have $\phi(1) = \psi(1) = 1(x_0) = 1$.

XX.9.5.20. Thus, by the Riesz Representation Theorem, there is a Borel probability measure μ on K with

$$\phi(g) = \mu(g) := \int_K g\, d\mu$$

for all $g \in C(K)$. We have $\mu(f) = \bar{f}(x_0)$. Since $f \leq \bar{f}$, $\mu(f) \leq \mu(\bar{f})$ (note that $\mu(\bar{f}) = \int_K \bar{f}\, d\mu$ is defined even though $\bar{f}$ may not be continuous, since it is bounded and Borel measurable); but if $h \in \mathrm{Aff}(K)$, $h \geq f$, we have $h \geq \bar{f}$, so

$$h(x_0) = \psi(h) = \phi(h) = \mu(h) \geq \mu(\bar{f})\ .$$

Taking the infimum over all such h, we get

$$\bar{f}(x_0) \geq \mu(\bar{f}) \geq \mu(f) = \bar{f}(x_0)$$

and thus equality holds, i.e.

$$\int_K \bar{f}\, d\mu = \mu(\bar{f}) = \mu(f) = \int_K f\, d\mu$$

and so

$$\int_K (\bar{f} - f)\, d\mu = 0 \ .$$

Thus μ vanishes on the complement of the set

$$S = \{x \in K : f(x) = \bar{f}(x)\} \ .$$

XX.9.5.21. LEMMA. The set S is contained in $\partial_e(K)$.

PROOF: If x, y, z are distinct points of K with $x = \frac{1}{2}(y + z)$, then by the strict convexity of f we have

$$f(x) < \frac{1}{2}f(y) + \frac{1}{2}f(z) \leq \frac{1}{2}\bar{f}(y) + \frac{1}{2}\bar{f}(z) \leq \bar{f}(x)$$

since $\bar{f}$ is concave. 

This completes the proof of XX.9.5.11.. 

XX.9.5.22. In fact, the set S is exactly $\partial_e(K)$; cf. [Phe66, 3.1].

The Nonmetrizable Case

XX.9.5.23. There is a generalization of Choquet's Theorem to nonmetrizable compact convex sets, the Bishop-de Leeuw Theorem [BdL59]. This theorem is considerably more difficult to prove, and is even somewhat tricky to state, because (among other things) the set of extreme points in a nonmetrizable compact convex set, even a nonmetrizable Choquet simplex, need not be a Borel set. See e.g. [Phe66] or [Alf71] for details.

XX.9.5.24. The Bishop of Bishop-de Leeuw is the Errett Bishop of constructivism fame (I.7.1.20.). Karel de Leeuw is known (besides for his work) for a darker reason: he was murdered in his office by a graduate student.

XX.9.6. Regular Embeddings, Cones, and Affine Functions

XX.9.7. Choquet Simplexes

XX.9.7.1. A compact convex set can be thought of as being defined by "generators" and "relations." The "generators" are the set of extreme points, and the "relations" are pairs of measures which represent the same point. For example, a square (or parallelogram, cf. XX.9.8.1.(b)) has four generators v_1, v_2, v_3, v_4 and one relation

$$\frac{1}{2}(v_1 + v_3) = \frac{1}{2}(v_2 + v_4) \ .$$

From this (somewhat imprecise) point of view, a Choquet simplex is a "free" compact convex set, i.e. one with no relations, although this should not be taken too literally unless the set of extreme points is closed (cf. XX.9.8.6.).

Bauer Simplexes

XX.9.7.2. Definition. A Choquet simplex Δ in which the set of extreme points is closed in Δ is a *Bauer simplex*.

XX.9.7.3. Since a Bauer simplex is compact, its set of extreme points is a compact Hausdorff space. Every compact Hausdorff space X is the set of extreme points of a Bauer simplex Δ_X, which is unique up to isomorphism. Δ_X can be concretely described as the state space of $C(X)$ (), which by the Riesz Representation Theorem can be identified with the set of Radon probability measures on X. The extreme points are just the point masses, which can be identified with X (). The representing measure of a point is just the point itself; thus uniqueness is essentially tautological, so Δ_X is a Choquet simplex. Δ_X is metrizable if and only if X is metrizable, i.e. $C(X)$ is separable (). All finite-dimensional simplexes are, of course, Bauer simplexes.

Other Simplexes

XX.9.7.4. "Most" Choquet simplexes are not Bauer simplexes. The simplest example of a Choquet simplex which is not a Bauer simplex is given in Exercise XX.9.8.2.. The construction can be modified to give far more complicated examples.

In fact, if X is any Polish space, there is a metrizable Choquet simplex Δ such that $\partial_e(\Delta)$ is homeomorphic to X (); the set of extreme points of a metrizable Choquet simplex is always a G_δ, hence a Polish space

in the relative topology). The simplex Δ is highly nonunique in general; for example, the set of extreme points for each of the Δ_c ($0 < c \leq 1$) of XX.9.8.2.(f) is a countable discrete space (and there are much more complicated simplexes with the same space of extreme points).

XX.9.7.5. The most extreme case is the Poulsen simplex. There is a metrizable Choquet simplex Δ, unique up to isomorphism, called the *Poulsen simplex*, for which the set of extreme points of Δ is dense in Δ [Pou61]. Every metrizable Choquet simplex is isomorphic to a face of the Poulsen simplex.

The set of extreme points of the Poulsen simplex is thus a Polish space in which every Polish space can be embedded as a closed subset. It can be shown that $\partial_e(\Delta)$ is homeomorphic to $\mathbb{R}^\infty$ (), the underlying topological space of every separable infinite-dimensional Banach space ().

The Facial Topology

XX.9.7.6. Let Δ be a Choquet simplex. The collection

$$\{\emptyset\} \cup \{F \cap \partial_e(\Delta) : F \text{ a closed face of } \Delta\}$$

of subsets of $\partial_e(\Delta)$ contains $\emptyset$ and $\partial_e(\Delta)$ and is closed under finite unions and arbitrary intersections (this is nontrivial to prove and uses the notion of a *split face*; every closed face in a Choquet simplex is split, cf. [Alf71]), and is thus the collection of closed sets for a topology on $\partial_e(\Delta)$ called the *facial topology*. Each of these sets is closed in the relative topology from Δ, and thus the facial topology is weaker than the relative topology. Since extreme points of Δ are singleton closed faces, the facial topology is T_1. But it is not necessarily Hausdorff. See XX.9.8.2.–XX.9.8.4..

The facial topology was defined and first studied in [Eff67]. A facial topology can be defined more generally on the set of extreme points of any compact convex set, using the notion of split face, although it will often be the indiscrete topology on sets which are not simplexes.

XX.9.8. Exercises

XX.9.8.1. (a) Show that all (solid) triangles are isomorphic as compact convex sets.

(b) Show that all parallelograms are isomorphic as convex sets. Show that a convex quadrilateral which is not a parallelogram is not isomorphic to a parallelogram. Describe the isomorphism classes of convex quadrilaterals. [Consider how the diagonals intersect.]

XX.9.8.2. Give ℓ^1 the weak-* topology as c_0^* (). Then the closed unit ball is compact (), metrizable (), and convex. Let $(\boldsymbol{e}_n)$ be the standard Schauder basis. Let Δ be the set of sequences $\boldsymbol{x} = (\lambda_1, \lambda_2, \dots)$ such that $\|\boldsymbol{x}\| \leq 1$, $-1 \leq \lambda_1 \leq 1$, and $\lambda_n \geq 0$ for all $n > 1$.

(a) Show that Δ is the closed convex hull of $E = \{\boldsymbol{e}_1, -\boldsymbol{e}_1, \boldsymbol{e}_2, \boldsymbol{e}_3, \dots\}$, and that E is the set of extreme points of Δ. Thus Δ is compact (and metrizable).

(b) Show that Δ is a Choquet simplex. [Use ().]

(c) Show that E is not closed in Δ: $\bar{E} = E \cup \{\mathbf{0}\}$. Note that $\mathbf{0}$ is the midpoint of the segment between $\boldsymbol{e}_1$ and $-\boldsymbol{e}_1$.

(d) Let F be the set of sequences in Δ for which $\lambda_1 = 0$ and $\sum_{k=2}^\infty \lambda_k = 1$. Show that F is a face of Δ.

(e) Show that $\bar{F}$ is the set of sequences in Δ with $\lambda_1 = 0$, which is not a face of Δ.

(f) More generally, fix c, $0 \leq c \leq 1$, and let Δ_c be the closed convex hull of $\{\boldsymbol{e}_1, -c\boldsymbol{e}_1, \boldsymbol{e}_2, \boldsymbol{e}_3, \dots\}$. Then each Δ_c is a metrizable Choquet simplex with a sequence of extreme points converging to $\mathbf{0}$. No two of the Δ_c are isomorphic. Δ_0 is a Bauer simplex ($\mathbf{0}$ is an extreme point).

(g) In all these examples except Δ_0, the relative topology on $\partial_e(\Delta_c)$ is the discrete topology. The facial topology on $\partial_e(\Delta_c)$ is the T_1 topology consisting of a sequence of isolated points ($\boldsymbol{e}_n$ for $n \geq 2$) converging simultaneously to $\boldsymbol{e}_1$ and $-c\boldsymbol{e}_1$. The relative and facial topologies on $\partial_e(\Delta_0)$ coincide and consist of a sequence of isolated points (the $\boldsymbol{e}_n$) converging to $\mathbf{0}$.

XX.9.8.3. Let Δ_0 be the simplex of XX.9.8.2.(f), and let π be the quotient map from ℓ^1 onto ℓ^1/X, where X is the one-dimensional subspace of ℓ^1 spanned by $\boldsymbol{x} = (2^{-1}, 2^{-2}, 2^{-3}, \dots)$. Set $\Delta = \pi(\Delta_0)$.

(a) Show that Δ is a Choquet simplex, and that $\partial_e(\Delta)$ consists of $\{\boldsymbol{f}_n : n \in \mathbb{N}\}$, where $\boldsymbol{f}_n = \pi(\boldsymbol{e}_n)$.

(b) The relative topology on $\partial_e(\Delta)$ is the discrete topology, while the facial topology is the finite complement topology.

This Δ is a *prime simplex* (cf. XX.9.8.4.(b)).

XX.9.8.4. Let Δ be a Choquet simplex.

(a) Prove that the following are equivalent:

(i) The facial topology on $\partial_e(\Delta)$ is the same as the relative topology from Δ.

(ii) The facial topology on $\partial_e(\Delta)$ is Hausdorff.

(iii) $\mathrm{Aff}(\Delta)$ is a lattice.

(iv) Every bounded uniformly continuous function from $\partial_e(\Delta)$ to $\mathbb{R}$ can be extended to an element of $\mathrm{Aff}(\Delta)$.

(iv′) Every continuous function from $\partial_e(\Delta)$ to $\mathbb{R}$ can be extended to an element of $\mathrm{Aff}(\Delta)$.

(v) Whenever F is a face of Δ, then $\bar{F}$ is also a face.

(vi) Δ is a Bauer simplex.

(b) Prove that the following are equivalent:

(vii) Whenever E, F are closed faces of Δ with $co(E \cup F) = \Delta$, then $E = \Delta$ or $F = \Delta$.

(viii) Any two nonempty facially open subsets of $\partial_e(\Delta)$ have nonempty intersection.

(ix) $\mathrm{Aff}(\Delta)$ is an antilattice, i.e. if $f, g \in \mathrm{Aff}(\Delta)$, then $\{f, g\}$ has an infimum if and only if $f \leq g$ or $g \leq f$.

A Choquet simplex satisfying conditions (vii)-(ix) is called a *prime simplex*. Prime simplexes are the "opposite extreme" to Bauer simplexes. See [Alf71].

XX.9.8.5. ([Bau61]; cf. [Phe66, 1.4], [Alf71, I.2.4]) Let K be a nonempty compact convex set in a locally convex topological vector space.

(a) If $x \in K$, show that x is an extreme point of K if and only if δ_x is the only Borel probability measure on K representing x.

(b) Use (a) and XX.9.5.6. to give an alternate proof of Milman's partial converse XX.9.2.5..

XX.9.8.6. If K is a compact convex set in a locally convex topological vector space, say a Choquet simplex Δ *covers* K if there is a continuous affine map $\phi : \Delta \to K$ mapping $\partial_e(\Delta)$ homeomorphically to $\partial_e(K)$. The map ϕ is a *covering*.

(a) Show that if $\partial_e(K)$ is closed, there is a covering of K by the Bauer simplex $\Delta_{\partial_e(K)}$, and this covering of K is the unique covering of K by a Choquet simplex up to isomorphism over K (in the obvious sense).

(b) If $\partial_e(K)$ is not closed, is there always a covering of K by a Choquet simplex?

(c) If $\partial_e(K)$ is not closed, a covering of K by a Choquet simplex need not be unique. Let K be a compact convex set with a sequence (e_n) of extreme points, such that the convex hull of $\{e_1, e_2, e_3, e_4\}$ is a square with these points as corners in cyclic order, and the sequence (e_n) converges to the midpoint of the square (such a K exists in $\mathbb{R}^4$, but probably not in $\mathbb{R}^3$). The Choquet simplex Δ_{13} constructed as in XX.9.8.2.(a) with extreme points converging to $a = \frac{1}{2}(e_1 + e_3)$ covers K, as does the simplex Δ_{24} with extreme points converging to $b = \frac{1}{2}(e_2 + e_4)$, and though Δ_{13} and Δ_{24} are isomorphic, they are not isomorphic over K. There are many other Choquet simplexes covering K: if T is the tetrahedron (3-simplex) with extreme points $\{\boldsymbol{e}_1, \ldots, \boldsymbol{e}_4\}$ and Y is a nonempty closed subset of the line segment between $\boldsymbol{a} = \frac{1}{2}(\boldsymbol{e}_1 + \boldsymbol{e}_3)$ and $\boldsymbol{b} = \frac{1}{2}(\boldsymbol{e}_2 + \boldsymbol{e}_4)$ in T, there is a Choquet simplex covering K with a sequence of extreme points whose set of limit points is Y. There are $2^{\aleph_0}$ isomorphism classes of such simplexes.

XX.9.8.7. Let K be a convex set in a topological vector space X. A point p of K is an *exposed point* of K if there is a closed hyperplane H such that $H \cap K = \{p\}$, i.e. if there is a continuous linear functional ϕ on X with $\phi(x) < \phi(p)$ for all $x \in K \setminus \{p\}$.

(a) Show that every exposed point is an extreme point.

(b) [Alf71, II.5.21] Show that every extreme point of a metrizable Choquet simplex is an exposed point.

(c) Let K be the union in $\mathbb{R}^2$ of the closed unit disk and the square

$$\{(x, y) : -1 \leq x \leq 1, -2 \leq y \leq 0\} .$$

Then K is compact and convex. Show that $(1, 0)$ and $(-1, 0)$ are extreme points of K but not exposed points. Find all extreme points and exposed points of K.

There are other related notions: strongly exposed points, dentable points, etc. These notions are tied in with the structure theory of Banach spaces.

XX.9.8.8. Let K be a compact convex set in a locally convex topological vector space.

(a) Prove the following theorem (cf. [Alf71,], [Goo86a,]):

THEOREM. The following are equivalent:

(i) K is a Choquet simplex.

(ii) $(\mathrm{Aff}(K)^*, \leq)$ is a lattice.

(iii) $(\mathrm{Aff}(K), \leq)$ has the Riesz Interpolation Property ().

(iv) $(\mathrm{Aff}(K), \ll)$ has the Riesz Interpolation Property.

(v) Whenever $x_1, \dots, x_n, y_1, \dots, y_m \in K$, $\alpha_1, \dots, \alpha_n, \beta_1, \dots, \beta_m \in (0,1)$, $\sum_{j=1}^n \alpha_j = \sum_{k=1}^m \beta_k = 1$, and

$$\sum_{j=1}^n \alpha_j x_j = \sum_{k=1}^m \beta_k y_k$$

there are $z_{jk} \in K$ for $1 \le j \le n$, $1 \le k \le m$ and $\gamma_{jk} \in [0,1]$ such that $\sum_{k=1}^m \gamma_{jk} = \alpha_j$, $\sum_{j=1}^n \gamma_{ij} = \beta_k$, and

$$x_j = \sum_{k=1}^m \alpha_j^{-1} \gamma_{jk} z_{jk} \text{ and } y_k = \sum_{j=1}^n \beta_k^{-1} \gamma_{jk} z_{jk}$$

for all j, k (the (z_{jk}) and (γ_{jk}) are called a *Riesz decomposition* of $\sum_j \alpha_j x_j$ and $\sum_k \beta_k y_k$.) We then have

$$\sum_{j=1}^n \alpha_j x_j = \sum_{k=1}^m \beta_k y_k = \sum_{j=1}^n \sum_{k=1}^m \gamma_{jk} z_{jk} \ .$$

(b) Prove the following theorem (cf. [Alf71,], [Goo86a,]):

THEOREM. The following are equivalent:

(i) K is a Bauer simplex.

(ii) $(\mathrm{Aff}(K), \le)$ is a lattice.

(iii) $(\mathrm{Aff}(K), \le, 1)$ is isometrically linearly isomorphic to $(C(X), \le, 1)$ for some compact Hausdorff space X.

(iv) If $X = \partial_e K$, then X is closed in K and the restriction from K to X is an isometric linear isomorphism from $\mathrm{Aff}(K)$ onto $C(X)$.

In (iii) and (iv), K is isomorphic to Δ_X.

XX.9.8.9. Let $(K_i, \phi_{j,i})$ be an inverse system where each K_i is a compact convex set in a locally convex topological vector space and the connecting maps $\phi_{j,i}$ are continuous and affine (not necessarily surjective). Let K be the inverse limit, and $\phi_i : K \to K_i$ the induced map for each i.

(a) Show that K has a natural structure as a compact convex set in a locally convex topological vector space, making the ϕ_i continuous and affine. [If K_i is in a LCS space V_i, construct K as a subset of $\prod_i V_i$ as in ().]

(b) For each i let ψ_i be the induced map from $\mathrm{Aff}(K_i)$ to $\mathrm{Aff}(K)$ given by $\psi_i(f) = f \circ \phi_i$. Show that $\cup_i \psi_i(\mathrm{Aff}(K_i))$ is uniformly dense in $\mathrm{Aff}(K)$. [Use XIII.14.5.19..]

(c) Use the equivalence of (i) and (iv) in XX.9.8.8.(a) to conclude that if each K_i is a Choquet simplex, then K is also a Choquet simplex. Use the equivalence of (i) and (v) in XX.9.8.8.(a) to give an alternate proof.

(d) As a special case, if (K_n) is a decreasing sequence of Choquet simplexes, then $\cap_n K_n$ is also a Choquet simplex.

(e) [Goo86a,] Conversely, show that every Choquet simplex is an inverse limit of a system of finite-dimensional simplexes with surjective affine connecting maps. (In particular, an inverse limit of Bauer simplexes is not necessarily a Bauer simplex.)

XX.10. The Stone-Weierstrass Theorem

The Stone-Weierstrass Theorem is one of the important theorems of functional analysis, giving a useful criterion for uniformly approximating general continuous functions by "nice" functions.

XX.10.1. The Weierstrass Approximation Theorem

The original version proved by Weierstrass in 1885 was:

XX.10.1.1. Theorem. Let I be a closed bounded interval in $\mathbb{R}$. Then every continuous function from I to $\mathbb{R}$ can be uniformly approximated arbitrarily closely on I by a polynomial.

Bernstein's Proof

In 1912 Sergei Bernstein gave a better proof of the Weierstrass Approximation Theorem in which he gave an explicit sequence of polynomials converging uniformly to a given continuous function on an interval:

XX.10.1.2. Theorem. If f is a continuous real-valued function on $[0,1]$, define, for $0 \leq x \leq 1$,

$$B_n(f)(x) = \sum_{k=0}^{n} \binom{n}{k} f\left(\frac{k}{n}\right) x^k (1-x)^{n-k}$$

(This is the n'th *Bernstein polynomial* of f.) Then $(B_n(f))$ converges uniformly to f on $[0,1]$.

Other intervals can be handled via an affine transformation.

XX.10.1.3. Bernstein, a probabilist, was apparently motivated by the following probabilistic argument (cf. [**?**]), which suggests that $B_n(f)$ should at least converge to f pointwise.

Fix f and $x \in [0,1]$. We repeatedly toss a coin with probability x of heads. Suppose we toss the coin a large number n of times, and receive a payoff of $f(r)$ dollars, where r is the fraction of tosses which are heads. In the long run (as $n \to \infty$), r will approach x with probability 1, so the payoff will approach $f(x)$ since f is continuous.

If we toss the coin n times, we will get exactly k heads with probability

$$\binom{n}{k} x^k (1-x)^{n-k}$$

so the expected payoff is

$$\sum_{k=0}^{n} \binom{n}{k} f\left(\frac{k}{n}\right) x^k (1-x)^{n-k} = B_n(f)(x) \ .$$

A direct proof of Bernstein's result can be found in [**?**] or almost any book on numerical analysis or approximation theory; a probability version of the proof can be found in [**?**]. In fact, books on numerical analysis prove the following sharpened form:

XX.10.1.4. THEOREM. Let f be a bounded real-valued function on $[0,1]$, and $B_n(f)$ the n'th Bernstein polynomial of f (XX.10.1.2.). Then

$$|f(x) - B_n(f)(x)| \leq \frac{3}{2}\,\omega\left(f, \frac{1}{\sqrt{n}}\right)$$

for all $x \in [0,1]$, where $\omega(f,\cdot)$ is the modulus of continuity () of f on $[0,1]$.

Since $\lim_{\delta\to 0}\omega(f,\delta) = 0$ if f is continuous, XX.10.1.2. is a corollary of XX.10.1.4..

Korovkin's Theorem

We give a proof of XX.10.1.2., and hence XX.10.1.1., based on a result of independent interest due to KOROVKIN [Kor53]:

XX.10.1.5. THEOREM. Let $I = [a,b]$ be a closed bounded interval, and (L_n) a sequence of positive linear operators from $C_{\mathbb{R}}(I)$ to $C_{\mathbb{R}}(I)$ (i.e. if $f \geq 0$ then $L_n f \geq 0$ for all n). Let $p_0(x) = 1$, $p_1(x) = x$, and $p_2(x) = x^2$. If $L_n p_k \to p_k$ uniformly for $k = 0,1,2$, then $L_n f \to f$ uniformly for all $f \in C_{\mathbb{R}}(I)$.

PROOF: (cf. [Bri98]) For each $t \in I$, set $g_t(x) = (x-t)^2 = t^2 p_0(x) - 2tp_1(x) + p_2(x)$. Then

$$[L_n g_t](x) = t^2[L_n p_0](x) - 2t[L_n p_1](x) + [L_n p_2](x)$$

for all n, t, x. Since $g_t \geq 0$, we have

$$0 \leq [L_n g_t](t) = t^2([L_n p_0](t) - 1) + 2t([L_n p_1](t) - t) + ([L_n p_2](t) - t^2)$$

$$\leq t^2\|L_n p_0 - p_0\| + |2t|\|L_n p_1 - p_1\| + \|L_n p_2 - p_2\|$$

and thus, since t^2 and $|2t|$ are bounded on I, for any $\eta > 0$ there is an N such that $\|L_n g_t\| < \eta$ for all $n \geq N$ and all $t \in I$.

Now fix $f \in C_{\mathbb{R}}(I)$ and $\epsilon > 0$. Since f is uniformly continuous on I, there is a $\delta > 0$ such that $|f(x) - f(y)| < \epsilon$ whenever $x, y \in I$ and $|x - y| < \delta$. Fix $t \in I$. If $x \in I$, $|x - t| \geq \delta$, we have

$$|f(t) - f(x)| \leq 2\|f\| \leq 2\|f\|\frac{(x-t)^2}{\delta^2} = \frac{2}{\delta^2}\|f\| g_t(x)$$

so for any $x \in I$ we have

$$|f(t) - f(x)| \leq \frac{2}{\delta^2}\|f\| g_t(x) + \epsilon\ .$$

Thus

$$-\epsilon p_0 - \frac{2}{\delta^2}\|f\| g_t \leq f(t)p_0 - f \leq \epsilon p_0 + \frac{2}{\delta^2}\|f\| g_t$$

and hence

$$-\epsilon L_n p_0 - \frac{2}{\delta^2}\|f\| L_n g_t \leq f(t) L_n p_0 - L_n f \leq \epsilon L_n p_0 + \frac{2}{\delta^2}\|f\| L_n g_t$$

$$|f(t)[L_n p_0](t) - [L_n f](t)| \leq \epsilon\|L_n p_0\| + \frac{2}{\delta^2}\|f\|[L_n g_t](t)\ .$$

Thus

$$|f(t) - [L_n f](t)| \le |f(t) - f(t)[L_n p_0](t)| + |f(t)[L_n p_0](t) - [L_n f](t)|$$
$$\le |f(t)||1 - [L_n p_0](t)| + \epsilon \|L_n p_0\| + \frac{2}{\delta^2}\|f\|[L_n g_t](t)$$
$$\le \|f\|\|p_0 - L_n p_0\| + \epsilon(\|p_0\| + \|p_0 - L_n p_0\|) + \frac{2}{\delta^2}\|f\|[L_n g_t](t) \ .$$

so if $\eta > 0$ and n is large enough,

$$|f(t) - [L_n f](t)| \le \|f\|\|p_0 - L_n p_0\| + \epsilon(\|p_0\| + \|p_0 - L_n p_0\|) + \frac{2\eta}{\delta^2}\|f\| \ .$$

The right side is independent of t and can be made less than 2ϵ by choosing η small enough and then n large enough. Since $\epsilon > 0$ is arbitrary, we have $L_n f \to f$ uniformly on I. 👍

XX.10.1.6. To prove XX.10.1.2., and hence XX.10.1.1., it thus suffices to show that each B_n is a positive operator (obvious) and that $B_n p_k \to p_k$ uniformly for $k = 0, 1, 2$, which is a simple calculation.

XX.10.2. The Stone-Weierstrass Theorem

In 1937 Marshall Stone formulated and proved a general version of Weierstrass's Theorem, which is now known as the Stone-Weierstrass Theorem. There are several commonly stated versions of the theorem, all of which are simple consequences of the following general version. Stone also proved a lattice version (XX.10.2.14.).

XX.10.2.1. Theorem. [Stone-Weierstrass] Let X be a compact Hausdorff space, and $C_{\mathbb{R}}(X)$ the algebra of real-valued continuous functions on X. Let A be a subalgebra of $C_{\mathbb{R}}(X)$ which is uniformly closed () and separates points (i.e. if $x, y \in X$ with $x \neq y$ there is an $f \in A$ with $f(x) \neq f(y)$). Then either $A = C_{\mathbb{R}}(X)$ or there is a $p \in X$ such that A consists of all $f \in C_{\mathbb{R}}(X)$ with $f(p) = 0$.

Here is the most commonly stated version of the Stone-Weierstrass Theorem (to prove it, consider the uniform closure of A, which is also an algebra):

XX.10.2.2. Corollary. Let X be a compact Hausdorff space, and A a subalgebra of $C_{\mathbb{R}}(X)$ which separates points and contains the constant functions. Then A is dense in $C_{\mathbb{R}}(X)$ for the uniform norm.

Weierstrass's Theorem is an immediate corollary of this, applied to $X = I$ and A the algebra of polynomials.

There is also a complex version:

XX.10.2.3. Theorem. [Complex Stone-Weierstrass] Let X be a compact Hausdorff space, and $C(X)$ the algebra of complex-valued continuous functions on X. Let A be a (complex) subalgebra of $C(X)$ which is closed under complex conjugation, uniformly closed, and separates points. Then either $A = C(X)$ or there is a $p \in X$ such that A consists of all $f \in C(X)$ with $f(p) = 0$.

A complex version of XX.10.2.2. follows immediately:

XX.10.2.4. Corollary. Let X be a compact Hausdorff space, and A a subalgebra of $C(X)$ which separates points, contains the constant functions, and is closed under complex conjugation. Then A is dense in $C(X)$ for the uniform norm.

To prove XX.10.2.3. from XX.10.2.1., note that if A is closed under complex conjugation and $f \in A$, then the real and imaginary parts $Re(f) = (f + \bar{f})/2$ and $Im(f) = (f - \bar{f})/2i$ are also in A (the converse is also true). The real-valued functions in A thus satisfy the hypotheses of XX.10.2.1..

XX.10.2.5. The hypothesis that A be closed under complex conjugation, or something similar, is necessary; see Exercise XX.10.3.10..

XX.10.2.6. Here is an important observation for the proof of XX.10.2.1.. If A is an algebra of real-valued functions on a space X, $f \in A$, and p is a polynomial with real coefficients and no constant term, then $p \circ f \in A$: if $p(t) = a_1 t + a_2 t^2 + \cdots + a_n t^n$, then $p \circ f = a_1 f + a_2 f^2 + \cdots + a_n f^n \in A$. If A contains the constant functions, the same is true if p is a polynomial with constant term. If (p_n) is a sequence of polynomials (without constant term) which converge uniformly on the range of f to a function g, then $p_n \circ f \to g \circ f$ uniformly on X, so if A is uniformly closed, $g \circ f \in A$. Here is an important application:

XX.10.2.7. Lemma. Let A be a uniformly closed algebra of real-valued bounded functions on a set X. If $f \in A$, then $|f| \in A$.

Since $|f| = g \circ f$, where $g(t) = |t|$, this follows from the next lemma:

XX.10.2.8. Lemma. For any $m \in \mathbb{N}$ there is a sequence of polynomials without constant term converging uniformly to $g(t) = |t|$ on $[-m, m]$.

Proof: This can be quickly deduced from XX.10.1.1., but we give a simple direct argument. First consider the interval $[-1, 1]$. By V.12.5.9., the Taylor polynomials $q_n(t)$ around 0 converge uniformly to $h(t) = (1 + t)^{1/2}$ on $[-1, 1]$. Set $r_n(t) = q_n(t^2 - 1)$; then r_n is a polynomial, and $r_n(t)$ converges uniformly to $h(t^2 - 1) = g(t)$ on $[-1, 1]$ (since $t^2 - 1$ maps $[-1, 1]$ into $[-1, 1]$). It is unclear whether r_n has a nonzero constant term; but if c_n is the constant term of r_n, then $c_n = r_n(0) \to g(0) = 0$, so if $p_n(t) = r_n(t) - c_n$, then p_n is a polynomial without constant term, and $p_n \to g$ uniformly on $[-1, 1]$.

For $[-m, m]$, set $\phi_n(t) = m p_n(t/m)$. Then ϕ_n is a polynomial without constant term, and $\phi_n \to g$ uniformly on $[-m, m]$. 👍

XX.10.2.9. Lemma. Let A be a uniformly closed algebra of real-valued bounded functions on a set X. If $f, g \in A$, then $f \vee g = \max(f, g)$ and $f \wedge g = \min(f, g)$ are in A.

Proof: $f \vee g = \frac{1}{2}(f + g + |f - g|)$ and $f \wedge g = \frac{1}{2}(f + g - |f - g|)$. 👍

By induction, if $f_1, \ldots, f_n \in A$, then $f_1 \vee \cdots \vee f_n$ and $f_1 \wedge \cdots \wedge f_n$ are in A.

XX.10.2.10. LEMMA. Let A be an algebra of real-valued functions on X which separates the points of X, and $x, y \in X$. If there are $f, g \in A$ with $f(x) \neq 0$ and $g(y) \neq 0$, then for any $a, b \in \mathbb{R}$ there is an $h \in A$ with $h(x) = a$ and $h(y) = b$.

PROOF: If $\phi = f^2 + g^2$, then $\phi(x) > 0$ and $\phi(y) > 0$. If $\phi(x) = \phi(y)$, let ψ be a function in A with $\psi(x) \neq \psi(y)$. Then for some (almost any) $r \in \mathbb{R}$ the function $\theta = \phi + r\psi$ has $c = \theta(x)$ and $d = \theta(y)$ distinct nonzero numbers. It is easy to find a quadratic polynomial p with no constant term such that $p(c) = a$ and $p(d) = b$ by solving two linear equations for the coefficients. Then $h = p \circ \theta$ is the desired element of A. 👍

We are thus in the situation where the following definition applies (for a more general version, see ()):

XX.10.2.11. DEFINITION. Let X be a compact Hausdorff space. A subspace L of $C_{\mathbb{R}}(X)$ is a *lattice* if $f \wedge g \in L$ for all $f, g \in L$.

A lattice L in $C_{\mathbb{R}}(X)$ has the *strong separation property* if, whenever $x, y \in X$, $x \neq y$, and $a, b \in \mathbb{R}$, there is an $f \in L$ with $f(x) = a$ and $f(y) = b$.

Since $f \vee g = -[(-f) \wedge (-g)]$, if L is a lattice and $f, g \in L$, then $f \vee g \in L$.

XX.10.2.12. A uniformly closed subalgebra A of $C_{\mathbb{R}}(X)$ is a lattice by XX.10.2.9., and, if A separates points and there is no point of X at which all the functions in A vanish, A has the strong separation property by XX.10.2.10.. Note also:

XX.10.2.13. PROPOSITION. Let X be a compact Hausdorff space, and L a lattice in $C_{\mathbb{R}}(X)$. If L separates points and the constant functions are in L, then L has the strong separation property.

PROOF: Let $x, y \in A$, $x \neq y$, and $a \leq b \in \mathbb{R}$. There is an $f \in L$ with $f(x) \neq f(y)$. Replacing f by $-f$ if necessary, we may assume $f(x) < f(y)$, and multiplying f by a scalar we may assume $f(y) - f(x) \geq b - a$. Adding a constant to f, we may assume $f(x) = a$, and thus $f(y) \geq b$. If $g = f \wedge (b1)$, then $g \in L$, $g(x) = a$, and $g(y) = b$. The case $a \geq b$ is obtained by interchanging x and y. 👍

We then have the lattice version of XX.10.2.2.:

XX.10.2.14. THEOREM. [STONE] Let X be a compact Hausdorff space, and L a lattice in $C_{\mathbb{R}}(X)$ with the strong separation property. Then L is uniformly dense in $C_{\mathbb{R}}(X)$.

PROOF: Let $f \in C_{\mathbb{R}}(X)$. Fix $\epsilon > 0$. Let $x \in X$. Let $\mathcal{U}$ be the set of all open sets U in X with the property that there is a $g \in L$ with $g(x) = f(x)$ and $|f(y) - g(y)| < \epsilon$ for all $y \in U$. Since there is a $g \in L$ with $g(x) = f(x)$, there is an open neighborhood of x in $\mathcal{U}$ by continuity. And if $z \neq x$, there is a $g \in L$ with $g(x) = f(x)$ and $g(z) = f(z)$, so there is an open neighborhood of z in $\mathcal{U}$ by continuity. Thus $\mathcal{U}$ is an open cover of X. Let $\{U_1, \ldots, U_n\}$ be a finite subcover, and g_k a function in L with $g_k(x) = f(x)$ and $|f(y) - g_k(y)| < \epsilon$ for all $y \in U_k$. Set $g_x = g_1 \wedge \cdots \wedge g_n \in L$. Then $g_x(x) = f(x)$ and $g_x(y) < f(y) + \epsilon$ for all $y \in X$.

Thus for every $x \in X$ there is an $h \in L$ with $h(x) = f(x)$ and $h(y) < f(y) + \epsilon$ for all $y \in X$. Let $\mathcal{V}$ be the collection of all open sets V in X for which there is an $h \in L$ with $h(y) < f(y) + \epsilon$ for all $y \in X$ and $|f(y) - h(y)| < \epsilon$ for all $y \in V$. By continuity every point of X has an open neighborhood in $\mathcal{V}$, so $\mathcal{V}$ is an open cover of X. Let $\{V_1, \ldots, V_m\}$ be a finite subcover, and $h_1, \ldots, h_m$ corresponding functions in L. If $h = h_1 \vee \cdots \vee h_m \in L$, then $|f(x) - h(x)| < \epsilon$ for all $x \in X$. 👍

XX.10.2.15. Corollary. Let X be a compact Hausdorff space, and L a lattice in $C_{\mathbb{R}}(X)$ which separates points and contains the constant functions. Then L is uniformly dense in $C_{\mathbb{R}}(X)$.

XX.10.2.16. The usual proof of XX.10.2.14. uses the AC. I am indebted to T. Tao for pointing out this version of the argument which does not use any choice (https://mathoverflow.net/questions/445361/stone-weierstrass-theorem-without-ac); this modification of the usual proof is similar to the modifications in the proof of XIII.11.4.1.–XIII.11.4.2. to eliminate use of the AC. I have been unable to find this argument in the literature, or even a clear statement that the Stone-Weierstrass Theorem does not depend on the AC.

XX.10.2.17. Examples. (i) Let X be a compact Hausdorff space, and $p \in X$. If L is the set of all functions in $C_{\mathbb{R}}(X)$ vanishing at p, then L is a closed subalgebra of $C_{\mathbb{R}}(X)$, hence a lattice, and separates points, but does not have the strong separation property (and is not dense in $C_{\mathbb{R}}(X)$).

(ii) A lattice which separates points does not necessarily have the strong separation property, even if there is no point where all the elements of L vanish. Let $X = \{a, b\}$ be a two-point space with the discrete topology, so that $C_{\mathbb{R}}(X) \cong \mathbb{R}^2$, and let $L = \{f : f(b) = 2f(a)\}$ (i.e. $L = \{(x, 2x) : x \in \mathbb{R}\} \subseteq \mathbb{R}^2\}$). Then L is a lattice in $C_{\mathbb{R}}(X)$ which separates points, but does not have the strong separation property. (L does not contain the constant functions and is not dense in $C_{\mathbb{R}}(X)$.)

(iii) For L to be a lattice in $C_{\mathbb{R}}(X)$ by our definition, it is not enough that L be a lattice in the induced ordering from $C_{\mathbb{R}}(X)$. Let $X = \{a, b, c\}$ be a three-point space with the discrete topology, so that $C_{\mathbb{R}}(X) \cong \mathbb{R}^3$. Let $L = \left\{f : f(c) = \frac{1}{2}(f(a) + f(b))\right\}$ (i.e. $L = \left\{\left(x, y, \frac{1}{2}(x + y)\right) : x, y \in \mathbb{R}\right\} \subseteq \mathbb{R}^3$). Then L is a subspace of $C_{\mathbb{R}}(X)$ containing the constants which has the strong separation property, and L is a lattice in the induced ordering. But if $f = \left(1, 0, \frac{1}{2}\right)$ and $g = \left(0, 1, \frac{1}{2}\right)$, the supremum of f and g in L is $(1, 1, 1)$, which is not the supremum $\left(1, 1, \frac{1}{2}\right)$ in $C_{\mathbb{R}}(X)$. And L is not dense in $C_{\mathbb{R}}(X)$.

XX.10.2.18. We now prove XX.10.2.1.. Suppose first that for every $x \in X$ there is a $g \in A$ with $g(x) \neq 0$. Then the hypotheses of XX.10.2.14. hold (XX.10.2.12.), so A is uniformly dense in $C_{\mathbb{R}}(X)$, and since A is uniformly closed, $A = C_{\mathbb{R}}(X)$.

Now suppose there is a $p \in X$ such that $g(p) = 0$ for all $g \in A$. (There cannot be more than one such p since A separates points.) Let B be the set of all functions of the form $f = g + c$, where $g \in A$ and c is a constant. Note that for such an f, $c = f(p)$. It is clear that B is an algebra of functions. Suppose (f_n) is a sequence in B, and $f_n \to f$ uniformly. Write $f_n = g_n + c_n$, with $g_n \in A$ and $c_n = f_n(p)$ a constant. Then $c_n \to c = f(p)$, and hence $g_n \to g = f - c$ uniformly. Thus $g \in A$ since A is uniformly closed, and $f = g + c \in B$. Thus B is uniformly closed. By the first part of the proof, $B = C_{\mathbb{R}}(X)$. Now

suppose $f \in C_{\mathbb{R}}(X)$ with $f(p) = 0$. Then $f \in B$, so $f = g + c$ for some $g \in A$ and constant c. But $0 = f(p) = g(p) + c = 0 + c = c$, so $f = g \in A$.

This completes the proof of XX.10.2.1.. 

XX.10.3. Exercises

XX.10.3.1. Prove the following corollary of XX.10.2.1.:

THEOREM. Let X be a locally compact Hausdorff space. Let A be a uniformly closed subalgebra of $C^{\circ}_{\mathbb{R}}(X)$ which separates points of X, such that there is no point of X at which all the functions in A vanish. Then $A = C^{\circ}_{\mathbb{R}}(X)$.

[Regard A as a subalgebra of $C_{\mathbb{R}}(X^{\dagger})$.]

XX.10.3.2. Let X be a locally compact, σ-compact Hausdorff space. Let A be an algebra of real-valued continuous functions on X which separate points of X, such that there is no point of X at which all the functions in A vanish. Show that if f is any real-valued continuous function on X, then there is a sequence (f_n) of functions in A converging u.c. to f on X.

XX.10.3.3. **General Weierstrass Approximation Theorem**. Let X be a compact subset of $\mathbb{R}^n$ for some n.

(a) Show that any continuous function from X to $\mathbb{R}$ can be uniformly approximated arbitrarily closely by a polynomial in the coordinates (in $\mathbb{R}^n$).

(b) Show that any continuous function from X to $\mathbb{R}^m$ for any m can be uniformly approximated arbitrarily closely by a function whose m coordinate functions are all polynomials in the coordinates (in $\mathbb{R}^n$).

XX.10.3.4. Let X be a compact subset of $\mathbb{C}$. Let A be the subalgebra of $C(X)$ consisting of all functions of the form $g(z) = p(z, \bar{z})$, where p is a polynomial of two variables with complex coefficients. Then A separates points of X and contains the constant functions. Show that A is closed under complex conjugation and hence is dense in $C(X)$ by XX.10.2.4..

XX.10.3.5. (a) Let X and Y be compact Hausdorff spaces. Show that every real-valued continuous function on $X \times Y$ can be uniformly approximated arbitrarily closely by (finite) sums of functions of the form $f \otimes g$, where $f \in C_{\mathbb{R}}(X)$, $g \in C_{\mathbb{R}}(Y)$, and

$$(f \otimes g)(x, y) = f(x)g(y) \ .$$

(b) Prove a similar result for complex-valued continuous functions. In fact, every complex-valued continuous function on $X \times Y$ is a uniform limit of finite sums of functions of the form $\lambda(f \otimes g)$, where λ is 1 or i and f and g are real-valued continuous functions on X and Y respectively.

(c) Use (a) to give an alternate proof of Fubini's Theorem for continuous functions (IX.3.4.7.):

THEOREM. Let $R = [a, b] \times [c, d]$ be a rectangle in $\mathbb{R}^2$, and $h : R \to \mathbb{R}$ a continuous function. Then

$$\iint_R h \, dA = \int_a^b \int_c^d h(x, y) \, dy \, dx = \int_c^d \int_a^b h(x, y) \, dx \, dy \ .$$

[First prove the theorem if $h = f \otimes g$, and take uniform limits.] Generalize to Radon measures on general compact Hausdorff spaces.

XX.10.3.6. Let $a, b \in \mathbb{R}$, $a < b$. Let $C_{sing}([a,b])$ be the set of all continuous functions $f : [a,b] \to \mathbb{R}$ such that f is differentiable a.e. and $f' = 0$ a.e. on $[a,b]$.

(a) Show that $C_{sing}([a,b])$ is a subalgebra of $C_{\mathbb{R}}([a,b])$ containing the constant functions.

(b) By scaling the Cantor function, show that $C_{sing}([a,b])$ separates points of $[a,b]$.

(c) Conclude that $C_{sing}([a,b])$ is uniformly dense in $C_{\mathbb{R}}([a,b])$.

There is an explicit proof of this result not using the Stone-Weierstrass Theorem; cf. XIX.5.8.6..

XX.10.3.7. Let f be a continuous function on an interval $[a,b]$, and suppose that all the *moments*

$$\int_a^b f(x)x^n \, dx$$

($n \in \mathbb{N}_0$) of f are zero. Prove that f is identically zero on $[a,b]$. [It suffices to show that

$$\int_a^b [f(x)]^2 \, dx = 0 \ .$$

Show that

$$\int_a^b f(x)p(x) \, dx = 0$$

for any polynomial p, and apply the Weierstrass Approximation Theorem.]

XX.10.3.8. Here is an "integral" version of Weierstrass's Theorem.

(a) If f is a polynomial with integer coefficients, regarded as an element of $C([0,1])$, then of course $f(0)$ and $f(1)$ are integers. The rest of the problem will show that if f is an element of $C([0,1])$ such that $f(0)$ and $f(1)$ are integers, then f is a uniform limit on $[0,1]$ of polynomials with integer coefficients.

(b) Let $g(x) = x + x(1-2x)(1-x) = 2x - 3x^2 + 2x^3$. Show that g is a strictly increasing function from $[0,1]$ onto $[0,1]$. The function g has fixed points 0, 1/2, and 1; if $0 < x < 1/2$, then $x < g(x) < 1/2$; if $1/2 < x < 1$, then $1/2 < g(x) < x$.

(c) Show that the iterates (g_i) of g converge pointwise on $(0,1)$ to the constant function $1/2$, and that the convergence is uniform on compact subsets (i.e. on subintervals of the form $[\epsilon, 1-\epsilon]$ for $\epsilon > 0$). Such iterates are strictly increasing.

(d) Show by induction on n that if k is any integer, $1 \le k \le 2^n - 1$, and $\epsilon > 0$, then there are integer linear combinations (ϕ_m) of powers of the g_i and $1 - g_i$ such that $0 \le \phi_m \le 1$ on $[0,1]$ and such that (ϕ_m) converges uniformly to the constant function $\frac{k}{2^n}$ on $[\epsilon, 1-\epsilon]$.

(e) If p is a polynomial with integer coefficients and $p(0) = p(1) = 0$, and $\lambda \in \mathbb{R}$, show that there is a sequence of polynomials with integer coefficients converging uniformly to λp on $[-1,1]$.

(f) If f is a continuous function on $[0,1]$ such that $f(0)$ and $f(1)$ are integers, then there is a linear polynomial q with integer coefficients with $q(x) = f(x)$ for $x = 0, 1$. Apply the Stone-Weierstrass Theorem and (e) to conclude that $f - q$, and hence f, can be approximated uniformly on $[0,1]$ by polynomials with integer coefficients.

XX.10.3.9. This problem is an extension of Exercise XX.10.3.8..

(a) Let f be a polynomial with integer coefficients, regarded as an element of $C([-1,1])$. Show that $f(-1)$, $f(0)$, and $f(1)$ are integers, and that $f(-1) \equiv f(1) \bmod 2$ (i.e. both are even or both odd). The rest of the problem will show that if f is an element of $C([-1,1])$ such that $f(-1)$, $f(0)$, and $f(1)$ are integers, and $f(-1) \equiv f(1) \bmod 2$, then f is a uniform limit on $[-1,1]$ of polynomials with integer coefficients.

(b) If p is a polynomial with integer coefficients and $p(-1) = p(0) = p(1) = 0$, and $\lambda \in \mathbb{R}$, show that there is a sequence of polynomials with integer coefficients converging uniformly to λp on $[-1,1]$. [Consider functions of the form $\psi(x) = \phi(1-x^2)$, where ϕ is one of the ϕ_m from 1(d).]

(c) If f is a continuous function on $[-1,1]$ such that $f(-1)$, $f(0)$, and $f(1)$ are integers and $f(-1) \equiv f(1) \bmod 2$, then there is a quadratic polynomial q with integer coefficients with $q(x) = f(x)$ for $x = -1, 0, 1$. Apply the Stone-Weierstrass Theorem and (b) to conclude that $f - q$, and hence f, can be approximated uniformly on $[-1,1]$ by polynomials with integer coefficients.

XX.10.3.10. (a) Let $\mathbb{T}$ be the unit circle in $\mathbb{C}$. Each polynomial with complex coefficients can be regarded as a continuous function from $\mathbb{T}$ to $\mathbb{C}$, and this set of polynomials forms a subalgebra P of $C(\mathbb{T})$. P contains the constant functions and separates points of $\mathbb{T}$. But P is not closed under complex conjugation (in fact, if p and $\bar{p}$ are both in P, then p is a constant function).

(b) Regard $\mathbb{T}$ alternatively as $[0, 2\pi]$ with the endpoints identified, and $C(\mathbb{T})$ as the algebra of continuous functions $f : [0, 2\pi] \to \mathbb{C}$ with $f(2\pi) = f(0)$. P then becomes an algebra of "trigonometric polynomials" on $[0, 2\pi]$ (but not all trigonometric polynomials), functions of the form

$$f(t) = \sum_{k=0}^{n} c_k e^{ikt}$$

for some $n \in \mathbb{N}$ (depending on f) and $\{c_k\}$ in $\mathbb{C}$.

(c) If $f \in P$, then $\int_0^{2\pi} f(t)e^{it}\,dt = 0$. The same holds if f is in the uniform closure $\bar{P}$ of P in $C(\mathbb{T})$.

(d) For $z \in \mathbb{T}$, let $f(z) = \bar{z}$. Alternatively, if $t \in [0, 2\pi]$, let $f(t) = e^{-it}$. Then $f \in C(\mathbb{T})$, and $\int_0^{2\pi} f(t)e^{it}\,dt = 2\pi$. Thus f is not in $\bar{P}$.

(e) Let $\mathbb{D}$ be the open unit disk in $\mathbb{C}$. Each $f \in P$ defines an analytic function on $\mathbb{D}$. If (f_n) is a sequence in P converging uniformly on $\mathbb{T}$ to a function $f \in \bar{P}$, then, by the Maximum Modulus Theorem, (f_n) also converges uniformly on $\bar{\mathbb{D}}$ to a function which is continuous on $\bar{\mathbb{D}}$ and analytic on $\mathbb{D}$. Conversely, if f is continuous on $\bar{\mathbb{D}}$ and analytic on $\mathbb{D}$, the Taylor polynomials (partial sums of the Taylor series) for f around 0 converge uniformly to f on $\bar{\mathbb{D}}$ (and, in particular, on $\mathbb{T}$), so f is in $\bar{P}$. Thus $\bar{P}$ consists precisely of the complex-valued continuous functions on $\mathbb{T}$ which extend to a function continuous on $\bar{\mathbb{D}}$ and analytic on $\mathbb{D}$.

(f) $\bar{P}$ also consists precisely of the functions in $C(\mathbb{T})$ whose negative Fourier coefficients vanish ().

(g) A *trigonometric polynomial* on $[0, 2\pi]$ is a function of the form

$$f(t) = \sum_{k=-n}^{n} c_k e^{ikt}$$

for some $n \in \mathbb{N}$ (depending on f) and $\{c_k\}$ in $\mathbb{C}$. Then $f \in C(\mathbb{T})$. A trigonometric polynomial can also be written

$$f(t) = \sum_{k=0}^{n} a_k \cos kt + i \sum_{k=1}^{n} b_k \sin kt$$

for $n \in \mathbb{N}$ and $a_k, b_k \in \mathbb{C}$. Show that the trigonometric polynomials are dense in $C(\mathbb{T})$.

See books on function algebras, e.g. [Bro69], for a thorough study of more sophisticated examples of this type.

XX.10.3.11. Let X be a compact Hausdorff space, and let P be a set of nonnegative real-valued continuous functions on X with the following properties:

(i) $f + g \in P$ for all $f, g \in P$.

(ii) $\alpha f \in P$ for all $f \in P$, $\alpha > 0$.

(iii) Either

(1) $f \wedge g \in P$ for all $f, g \in P$

or

(2) $f \vee g \in P$ for all $f, g \in P$

Let $L = P - P = \{f - g : f, g \in P\}$.

(a) Show that L is a lattice in $C_{\mathbb{R}}(X)$. [Use

$$(f_1 - g_1) \wedge (f_2 - g_2) = [(f_1 + g_2) \wedge (f_2 + g_1)] - (g_1 + g_2)$$

$$(f_1 - g_1) \vee (f_2 - g_2) = [(f_1 + g_2) \vee (f_2 + g_1)] - (g_1 + g_2)$$

and $f \vee g = -[(-f) \wedge (-g)]$.]

(b) Conclude from XX.10.2.15. that if P separates points and contains a nonzero constant function, then L is uniformly dense in $C_{\mathbb{R}}(X)$.

Examples of sets P satisfying the hypotheses are the set of nonnegative continuous convex functions on an interval $[a, b]$ and the set of nonnegative continuous concave functions on $[a, b]$. Thus every continuous function on $[a, b]$ can be uniformly approximated arbitrarily closely by the sum of a continuous convex function and a continuous concave function (difference of two continuous convex functions).

XX.10.3.12. Use the Stone-Weierstrass Theorem to give another proof of the Tietze Extension Theorem () for compact Hausdorff spaces: let X be a compact Hausdorff space, and Z a closed subset of X. Let A be the subalgebra of $C_{\mathbb{R}}(Z)$ consisting of the restrictions to Z of continuous functions from X to $\mathbb{R}$.

(a) Use Urysohn's Lemma to show that A is uniformly closed in $C_{\mathbb{R}}(Z)$. (This is a bit tricky.)

(b) Conclude from the Stone-Weierstrass Theorem that $A = C_{\mathbb{R}}(Z)$, i.e. that every continuous function from Z to $\mathbb{R}$ extends to X.

This proof is not easier than the proof in (), and the result is less general, but it is a different approach. A simpler argument for (a) can be given using C*-algebra theory (XX.16.2.3.).

XX.10.3.13. Prove the following converse to XX.10.2.2. (there is an analogous converse to XX.10.2.4.). If X is completely regular, let $BC_{\mathbb{R}}(X)$ be the algebra of bounded real-valued continuous functions on X. $BC_{\mathbb{R}}(X)$ is a commutative real Banach algebra under the supremum norm, isometrically isomorphic to $C_{\mathbb{R}}(\beta X)$ ().

THEOREM. Let X be a completely regular topological space. If every unital subalgebra of $BC_{\mathbb{R}}(X)$ which separates points of X is (uniformly) dense in $BC_{\mathbb{R}}(X)$, then X is compact.

[If X is not compact, choose $p \in X$ and $q \in \beta X \setminus X$, and let A be the subalgebra of $BC_{\mathbb{R}}(X) \cong C_{\mathbb{R}}(\beta X)$ of functions f with $f(p) = f(q)$; then A contains the constants and separates points of X. $A \cong C_{\mathbb{R}}(Y)$, where Y is the quotient of βX obtained by identifying p and q.]

XX.10.3.14. A $\mathcal{C}^\infty$ Weierstrass Approximation Theorem. Let f be a $\mathcal{C}^\infty$ function on the interval $I = [a, b]$.

(a) Let $n \in \mathbb{N}$ and $\epsilon > 0$. Show that there is a polynomial p such that

$$|f^{(k)}(x) - p^{(k)}(x)| < \epsilon$$

for all k, $0 \leq k \leq n$, and all $x \in I$. [Set $c = \max(1, b-a)$. Let q_n be a polynomial with $|f^{(n)}(x) - q_n(x)| < \frac{\epsilon}{c^n}$ for all $x \in I$. Successively set

$$q_{k-1}(x) = f^{(k-1)}(a) + \int_a^x q_k(t)\, dt$$

for $k = n, n-1, \ldots, 1$, and set $p = q_0$.]

(b) Show that there is a sequence (p_n) of polynomials such that $p_n^{(k)} \to f^{(k)}$ uniformly on I for each $k \in \mathbb{N} \cup \{0\}$.

(c) Conclude that the polynomials are dense in $\mathcal{C}^\infty(I)$ for its natural topology ().

(d) Show similarly that if $r \in \mathbb{N}$, then the polynomials are dense in $\mathcal{C}^r(I)$ for its natural topology ().

(e) If I is a closed box in $\mathbb{R}^n$, similarly prove that polynomials in the coordinates are dense in $\mathcal{C}^\infty(I)$ and $C^r(I)$ for their natural topologies.

(f) Formulate and prove a version of the Stone-Weierstrass Theorem giving necessary and sufficient conditions for a subalgebra of $\mathcal{C}^r(I)$ or $\mathcal{C}^\infty(I)$ to be dense for the natural topology.

XX.11. Hilbert Spaces

A Hilbert space is a vector space over $\mathbb{R}$ or $\mathbb{C}$ with an inner product or "dot product" which is complete with respect to the norm induced by the inner product. A Hilbert space can be thought of as a special kind of Banach space which has an intrinsic Euclidean geometry; in fact, every finite-dimensional subspace of a Hilbert space is a Euclidean space.

Hilbert spaces are the nicest kinds of topological vector spaces, essentially Euclidean spaces which are allowed to be infinite-dimensional. They share many pleasant properties with Euclidean spaces. In fact, they are so nice they are not themselves very interesting mathematically: there is up to isometric isomorphism exactly one of each dimension, finite or infinite. Like vector spaces, they are mainly important not in and of themselves, but as the setting for operators, which are highly nontrivial and very important.

Hilbert spaces can be either real or complex. The theories of real and complex Hilbert spaces are essentially identical and can be done in parallel. When we get to operators, however, the theories diverge somewhat, and for technical reasons (e.g. the Fundamental Theorem of Algebra) operator theory works better on complex Hilbert spaces. Thus in applications and more advanced work on operators, complex Hilbert spaces are used almost exclusively. Adhering to custom, we will take the default meaning of the term "Hilbert space" to be "complex Hilbert space."

XX.11.1. Inner Products

Although a unified treatment can be given (XX.11.1.10.), it is clearer to separately define inner products in real and complex vector spaces.

Real Inner Products

XX.11.1.1. DEFINITION. Let $\mathcal{V}$ be a vector space over $\mathbb{R}$. A *bilinear form* on $\mathcal{V}$ is a function

$$\langle \cdot, \cdot \rangle : \mathcal{V} \times \mathcal{V} \to \mathbb{R}$$

(i.e. a function which assigns to each ordered pair of vectors a scalar) which is linear in each entry when the other entry is fixed, i.e.

(i) $\langle x_1 + x_2, y \rangle = \langle x_1, y \rangle + \langle x_2, y \rangle$ for all $x_1, x_2, y \in \mathcal{V}$.

(i′) $\langle x, y_1 + y_2 \rangle = \langle x, y_1 \rangle + \langle x, y_2 \rangle$ for all $x, y_1, y_2 \in \mathcal{V}$.

(ii) $\langle \alpha x, y \rangle = \alpha \langle x, y \rangle$ for all $x, y \in \mathcal{V}$, $\alpha \in \mathbb{R}$.

(ii′) $\langle x, \alpha y \rangle = \alpha \langle x, y \rangle$ for all $x, y \in \mathcal{V}$, $\alpha \in \mathbb{R}$.

A bilinear form is *symmetric* if

(iii) $\langle y, x \rangle = \langle x, y \rangle$ for all $x, y \in \mathcal{V}$.

A symmetric bilinear form is *positive* (or *positive semidefinite*) if

(iv) $\langle x, x \rangle \geq 0$ for all $x \in \mathcal{V}$.

A positive symmetric bilinear form is *definite* (or *positive definite*) if

(v) $\langle x, x \rangle = 0$ for $x \in \mathcal{V}$ if and only if $x = 0$.

A positive symmetric bilinear form is called a *real pre-inner product.*

A positive definite symmetric bilinear form is called a *real inner product.*

XX.11.1.2. REMARKS. (i) Note that the inner product of two vectors is a *scalar*. Thus an inner product is not really a "multiplication" on the vector space, although it has some flavor of a product.

(ii) In a symmetric form, properties (i′) and (ii′) follow automatically from (i) and (ii) respectively. Since most forms we consider are symmetric (or hermitian in the complex case), we will rarely have to separately consider (i′) and (ii′).

XX.11.1.3. **Notation.** The notation $\langle x, y\rangle$ is probably the most common notation for an inner product. Other common notations are (x, y), $\langle x|y\rangle$, and $(x|y)$. Additional notations are also occasionally used.

XX.11.1.4. EXAMPLES. (i) On $\mathbb{R}^n$, the usual dot product is a real inner product: if $\boldsymbol{x} = (x_1, \ldots, x_n)$ and $\boldsymbol{y} = (y_1, \ldots, y_n)$, then

$$\langle \boldsymbol{x}, \boldsymbol{y}\rangle = \boldsymbol{x} \cdot \boldsymbol{y} = x_1y_1 + \cdots + x_ny_n = \sum_{k=1}^{n} x_ky_k \ .$$

This is the *standard inner product* on $\mathbb{R}^n$.

(ii) On $C_{\mathbb{R}}([a, b])$, the real vector space of continuous real-valued functions on $[a, b]$, define

$$\langle f, g\rangle = \int_a^b f(t)g(t)\,dt \ .$$

then $\langle \cdot, \cdot\rangle$ is a real inner product on $C_{\mathbb{R}}([a, b])$.

These two examples obviously have considerable similarity, and can be adapted to a wide range of settings. In fact, these are the "generic" examples; every inner product looks essentially like them (XX.11.5.21.).

(iii) Write elements of $\mathbb{R}^n$ as column vectors. If A is an $n \times n$ matrix over $\mathbb{R}$, for $\boldsymbol{x}, \boldsymbol{y} \in \mathbb{R}^n$ define

$$(\boldsymbol{x}, \boldsymbol{y}) = \langle A\boldsymbol{x}, \boldsymbol{y}\rangle = \boldsymbol{y}^t A\boldsymbol{x}$$

where $\langle \cdot, \cdot\rangle$ is the standard inner product. Then $(\cdot, \cdot)$ is a bilinear form on $\mathbb{R}^n$. We have

$$(\boldsymbol{y}, \boldsymbol{x}) = \boldsymbol{x}^t A\boldsymbol{y} = [\boldsymbol{y}^t A^t\boldsymbol{x}]^t = \boldsymbol{y}^t A^t\boldsymbol{x} = \langle A^t\boldsymbol{x}, \boldsymbol{y}\rangle$$

since transpose is the identity on $\mathbb{R}$; thus $(\cdot, \cdot)$ is symmetric if and only if A is symmetric (i.e. $A^t = A$). The form is a pre-inner product if and only if A is positive (), or equivalently if $A = A^t$ and all eigenvalues of A are nonnegative; it is an inner product if and only if A is positive definite, i.e. positive and invertible (i.e. $A = A^t$ and all eigenvalues of A are strictly positive).

We can recover A: if A_{jk} is the (j, k) entry of A, then $A_{jk} = (\boldsymbol{e}_k, \boldsymbol{e}_j)$, where $\boldsymbol{e}_i$ is the i'th standard basis vector. Conversely, if $[\cdot, \cdot]$ is any bilinear form on $\mathbb{R}^n$, set $B_{jk} = [\boldsymbol{e}_k, \boldsymbol{e}_j]$; then a simple calculation shows that

$$[\boldsymbol{x}, \boldsymbol{y}] = \langle B\boldsymbol{x}, \boldsymbol{y}\rangle$$

for any $\boldsymbol{x}, \boldsymbol{y} \in \mathbb{R}^n$, where $B = (B_{jk})$, so every bilinear form on $\mathbb{R}^n$ is of this type. The matrix B is called the *matrix of the bilinear form* with respect to the standard basis of $\mathbb{R}^n$.

Complex Inner Products

XX.11.1.5. The definitions in XX.11.1.1. make sense if $\mathbb{R}$ is merely replaced by $\mathbb{C}$. However, they are not very interesting. In fact, bilinearity is essentially incompatible with positivity: if $\alpha \in \mathbb{C}$ with $\alpha \notin \mathbb{R}$, and $x \in \mathcal{V}$, if $\langle \cdot, \cdot \rangle$ is bilinear we have

$$\langle \alpha x, \alpha x \rangle = \alpha^2 \langle x, x \rangle$$

and since α^2 is not a nonnegative real number, $\langle x, x \rangle$ and $\langle \alpha x, \alpha x \rangle$ cannot both be nonnegative unless they are zero.

Fortunately, there is a fairly simple way around the difficulty, based on the fact that if $\alpha \in \mathbb{C}$, then $\alpha \bar{\alpha} \geq 0$. We replace bilinearity by "sesquilinearity" (*sesqui-* is a Latin prefix meaning "one and a half"):

XX.11.1.6. DEFINITION. Let $\mathcal{V}$ be a vector space over $\mathbb{C}$. A *sesquilinear form* on $\mathcal{V}$ is a function

$$\langle \cdot, \cdot \rangle : \mathcal{V} \times \mathcal{V} \to \mathbb{C}$$

(i.e. a function which assigns to each ordered pair of vectors a scalar) which is linear in the first entry when the second entry is fixed and conjugate-linear in the second entry when the first entry is fixed, i.e.

(i) $\langle x_1 + x_2, y \rangle = \langle x_1, y \rangle + \langle x_2, y \rangle$ for all $x_1, x_2, y \in \mathcal{V}$.

(i′) $\langle x, y_1 + y_2 \rangle = \langle x, y_1 \rangle + \langle x, y_2 \rangle$ for all $x, y_1, y_2 \in \mathcal{V}$.

(ii) $\langle \alpha x, y \rangle = \alpha \langle x, y \rangle$ for all $x, y \in \mathcal{V}$, $\alpha \in \mathbb{C}$.

(ii′) $\langle x, \alpha y \rangle = \bar{\alpha} \langle x, y \rangle$ for all $x, y \in \mathcal{V}$, $\alpha \in \mathbb{C}$.

A sesquilinear form is *hermitian* if

(iii) $\langle y, x \rangle = \overline{\langle x, y \rangle}$ for all $x, y \in \mathcal{V}$.

A hermitian sesquilinear form is *positive* (or *positive semidefinite*) if

(iv) $\langle x, x \rangle \geq 0$ for all $x \in \mathcal{V}$.

A positive hermitian sesquilinear form is *definite* (or *positive definite*) if

(v) $\langle x, x \rangle = 0$ for $x \in \mathcal{V}$ if and only if $x = 0$.

A positive hermitian sesquilinear form is called a *pre-inner product.*

A positive definite hermitian sesquilinear form is called a *(complex) inner product.*

XX.11.1.7. **Notation:** We have made the convention that sesquilinear forms and inner products are linear in the first variable and conjugate-linear in the second, the usual convention in mathematics. For obscure reasons, the opposite convention is common in mathematical physics, so readers should be aware of the convention used in any reference. The difference will have no practical effect, and a trivial notational change (reversing order in the inner product) will convert to the opposite convention.

XX.11.1.8. EXAMPLES. (i) On $\mathbb{C}^n$, if $\boldsymbol{x} = (x_1, \ldots, x_n)$ and $\boldsymbol{y} = (y_1, \ldots, y_n)$, define

$$\langle \boldsymbol{x}, \boldsymbol{y} \rangle = x_1\overline{y_1} + \cdots + x_n\overline{y_n} = \sum_{k=1}^{n} x_k\overline{y_k} \ .$$

This is an inner product, called the *standard inner product* on $\mathbb{C}^n$.

(ii) On $C([a,b])$, the complex vector space of continuous complex-valued functions on $[a,b]$, define

$$\langle f, g \rangle = \int_a^b f(t)\overline{g(t)}\, dt \ .$$

then $\langle \cdot, \cdot \rangle$ is an inner product on $C([a,b])$.

These two examples obviously have considerable similarity, and can be adapted to a wide range of settings. In fact, these are the "generic" examples; every inner product looks essentially like them (XX.11.5.21.).

(iii) Write elements of $\mathbb{C}^n$ as column vectors. If A is an $n \times n$ matrix over $\mathbb{C}$, for $\boldsymbol{x}, \boldsymbol{y} \in \mathbb{C}^n$ define

$$(\boldsymbol{x}, \boldsymbol{y}) = \langle A\boldsymbol{x}, \boldsymbol{y} \rangle = \boldsymbol{y}^* A \boldsymbol{x}$$

where $\langle \cdot, \cdot \rangle$ is the standard inner product and, for a matrix B,

$$B^* = \overline{B^t}$$

is the complex conjugate of the transpose. Then $(\cdot, \cdot)$ is a sesquilinear form on $\mathbb{C}^n$. We have

$$(\boldsymbol{y}, \boldsymbol{x}) = \boldsymbol{x}^* A \boldsymbol{y} = [\boldsymbol{y}^* A^* \boldsymbol{x}]^* = \overline{\boldsymbol{y}^* A^* \boldsymbol{x}} = \overline{\langle A^* \boldsymbol{x}, \boldsymbol{y} \rangle}$$

and thus $(\cdot, \cdot)$ is hermitian if and only if A is hermitian (i.e. $A^* = A$). The form is a pre-inner product if and only if A is positive (), or equivalently if $A = A^*$ and all eigenvalues of A are nonnegative; it is an inner product if and only if A is positive definite, i.e. positive and invertible (i.e. $A = A^*$ and all eigenvalues of A are strictly positive).

We can recover A: if A_{jk} is the (j,k) entry of A, then $A_{jk} = (\boldsymbol{e}_k, \boldsymbol{e}_j)$, where $\boldsymbol{e}_i$ is the i'th standard basis vector. Conversely, if $[\cdot, \cdot]$ is any sesquilinear form on $\mathbb{C}^n$, set $B_{jk} = [\boldsymbol{e}_k, \boldsymbol{e}_j]$; then a simple calculation shows that

$$[\boldsymbol{x}, \boldsymbol{y}] = \langle B\boldsymbol{x}, \boldsymbol{y} \rangle$$

for any $\boldsymbol{x}, \boldsymbol{y} \in \mathbb{C}^n$, where $B = (B_{jk})$, so every sesquilinear form on $\mathbb{C}^n$ is of this type. The matrix B is called the *matrix of the sesquilinear form* with respect to the standard basis of $\mathbb{C}^n$.

XX.11.1.9. If $\mathcal{V}$ is a complex vector space, then $\mathcal{V}$ can be regarded as a real vector space by restricting scalar multiplication. However, if $\langle \cdot, \cdot \rangle$ is a (complex) inner product on $\mathcal{V}$, it does not become a real inner product by simply restricting scalar multiplication (for one thing, it is complex-valued, not real-valued). But there is a simple conversion: if we define

$$(x, y) = Re(\langle x, y \rangle)$$

then it is easily checked that $(\cdot, \cdot)$ is a real inner product on $\mathcal{V}$ satisfying $(x,x) = \langle x, x \rangle$ for all $x \in \mathcal{V}$.

A Unified Treatment

A unified treatment of real and complex inner products can be given by making the convention that "complex conjugation" $\alpha \mapsto \bar{\alpha}$ is the identity map on $\mathbb{R}$. With this convention, we may meld the two definitions:

XX.11.1.10. DEFINITION. Let $\mathbb{F}$ be $\mathbb{R}$ or $\mathbb{C}$, and $\mathcal{V}$ a vector space over $\mathbb{F}$. A *pre-inner product* on $\mathcal{V}$ is a function

$$\langle \cdot, \cdot \rangle : \mathcal{V} \times \mathcal{V} \to \mathbb{F}$$

satisfying

(i) $\langle x_1 + x_2, y \rangle = \langle x_1, y \rangle + \langle x_2, y \rangle$ for all $x_1, x_2, y \in \mathcal{V}$.

(ii) $\langle \alpha x, y \rangle = \alpha \langle x, y \rangle$ for all $x, y \in \mathcal{V}$, $\alpha \in \mathbb{F}$.

(iii) $\langle y, x \rangle = \overline{\langle x, y \rangle}$ for all $x, y \in \mathcal{V}$.

(iv) $\langle x, x \rangle \geq 0$ for all $x \in \mathcal{V}$.

The pre-inner product is an *inner product* if it additionally satisfies

(v) $\langle x, x \rangle = 0$ for $x \in \mathcal{V}$ if and only if $x = 0$.

It is automatic that such a pre-inner product also satisfies

(i′) $\langle x, y_1 + y_2 \rangle = \langle x, y_1 \rangle + \langle x, y_2 \rangle$ for all $x, y_1, y_2 \in \mathcal{V}$.

(ii′) $\langle x, \alpha y \rangle = \bar{\alpha} \langle x, y \rangle$ for all $x, y \in \mathcal{V}$, $\alpha \in \mathbb{F}$.

XX.11.1.11. DEFINITION. A *(real or complex) inner product space* is a pair $(\mathcal{V}, \langle \cdot, \cdot \rangle)$, where $\mathcal{V}$ is a vector space over $\mathbb{R}$ or $\mathbb{C}$ and $\langle \cdot, \cdot \rangle$ is an inner product on $\mathcal{V}$.

An inner product space is a vector space $\mathcal{V}$ with specified inner product on $\mathcal{V}$. As usual, we will sometimes abuse language by saying "Let $\mathcal{V}$ be an inner product space." There will then implicitly be a specified inner product on $\mathcal{V}$. (By convention, we will take "inner product space" to mean "complex inner product space" unless otherwise qualified.)

XX.11.2. The CBS Inequality and the Norm

An inner product on a real or complex vector space defines a "norm"

$$\|x\| = \sqrt{\langle x, x \rangle}$$

but to prove that this is truly a norm, specifically to prove the triangle inequality, requires a preliminary inequality which is itself extremely important.

XX.11.2.1. THEOREM. [CBS INEQUALITY] Let $\langle \cdot, \cdot \rangle$ be a pre-inner product on a real or complex vector space $\mathcal{V}$. Then

$$|\langle x, y \rangle|^2 \leq \langle x, x \rangle \langle y, y \rangle$$

for all $x, y \in \mathcal{V}$. If the pre-inner product is an inner product, we have equality if and only if $\{x, y\}$ is linearly dependent.

PROOF: Fix $x, y \in \mathcal{V}$. Suppose first that $\langle y, y \rangle \neq 0$ and set

$$\alpha = -\frac{\langle x, y \rangle}{\langle y, y \rangle} \ .$$

We then have

$$\begin{aligned} 0 \leq \langle x + \alpha y, x + \alpha y \rangle &= \langle x, x \rangle + \alpha \langle y, x \rangle + \bar{\alpha} \langle x, y \rangle + \alpha \bar{\alpha} \langle y, y \rangle \\ &= \langle x, x \rangle - \frac{\langle x, y \rangle}{\langle y, y \rangle} \langle y, x \rangle - \frac{\langle y, x \rangle}{\langle y, y \rangle} \langle x, y \rangle + \frac{\langle x, y \rangle \langle y, x \rangle}{\langle y, y \rangle^2} \langle y, y \rangle \\ &= \langle x, x \rangle - \frac{|\langle x, y \rangle|^2}{\langle y, y \rangle} \end{aligned}$$

and putting the second term on the left and multiplying by $\langle y, y \rangle$ gives the inequality.

Now suppose $\langle y, y \rangle = 0$. If the pre-inner product is an inner product, then $y = 0$, so $\langle x, y \rangle = 0$ by (real) linearity in the second variable and there is nothing to prove. For the general case, set $\beta = -n\langle x, y \rangle$ for $n \in \mathbb{N}$. Then

$$\begin{aligned} 0 \leq \langle x + \beta y, x + \beta y \rangle &= \langle x, x \rangle + \beta \langle y, x \rangle + \bar{\beta} \langle x, y \rangle + \beta \bar{\beta} \langle y, y \rangle \\ &= \langle x, x \rangle + \beta \langle y, x \rangle + \bar{\beta} \langle x, y \rangle = \langle x, x \rangle - 2n |\langle x, y \rangle|^2 \ . \end{aligned}$$

This must be true for all $n \in \mathbb{N}$, so $\langle x, y \rangle = 0$.

If x or y is zero, we clearly have equality. Suppose x and y are nonzero and we have equality, and the pre-inner product is an inner product. Then there are suitable scalar multiples z and w of x and y respectively with

$$\langle z, z \rangle = \langle w, w \rangle = \langle z, w \rangle = 1 \ .$$

We then have

$$\langle z - w, z - w \rangle = \langle z, z \rangle - 2\langle z, w \rangle + \langle w, w \rangle = 0$$

so $z = w$, i.e. x and y are scalar multiples of each other. 👍

XX.11.2.2. The name "CBS inequality" is not the one most commonly used, but is the most appropriate. The names CAUCHY, BUNYAKOVSKII, and SCHWARZ are associated with the inequality, and it is commonly called by various subsets of these names (most commonly the "Cauchy-Schwarz inequality.") Here is a summary of the history:

(i) The first version of the CBS inequality to appear in print was for the standard inner product in $\mathbb{R}^n$, by CAUCHY in [Cau21] in 1821. See Exercise XX.11.11.1. for CAUCHY'S proof.

(ii) In 1859, V. BUNYAKOVSKII stated and indicated a proof of the inequality for the inner product of XX.11.1.4.(ii) [Bun59]. This paper, although written in French and not Russian (BUNYAKOVSKII was actually

Ukrainian and studied in Paris), was published in Russia and was apparently little noticed in Western Europe. See Exercise XX.11.11.3. for BUNYAKOVSKII'S statement and argument.

(iii) In 1885, H. SCHWARZ published an important and influential paper on minimal surfaces [Sch88] in which he proved, as a relatively minor technical result, a slightly more general integral version of the inequality. He was apparently unaware of BUNYAKOVSKII'S paper. Because SCHWARZ'S paper was widely read and studied, the inequality became known and was often called the "Schwarz inequality." SCHWARZ did make a substantive contribution: although he only stated the result for integrals, he gave a simple and elegant proof which works verbatim for any real inner product. See Exercise XX.11.11.4. for SCHWARZ'S proof.

(iv) It is unclear who first stated the inequality for complex inner products, or who first discovered the proof given above. The arguments of CAUCHY, BUNYAKOVSKII, and SCHWARZ do not work directly for complex inner products, although the complex case can be easily derived from the real case; see Exercise XX.11.11.5..

The website http://www-stat.wharton.upenn.edu/~steele/Publications/Books/CSMC/CSMC_index.html for the book [Ste04] contains more information and links to electronic copies of the papers by BUNYAKOVSKII and SCHWARZ. The book itself has a thorough study of the CBS inequality and many related inequalities.

The Norm

XX.11.2.3. If $(\mathcal{V}, \langle\cdot,\cdot\rangle)$ is an inner product space over $\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$, for $x \in \mathcal{V}$ define

$$\|x\| = \sqrt{\langle x, x\rangle} \ .$$

Whenever we refer to a norm on an inner product space, we mean this induced norm unless otherwise specified.

With this notation, the CBS inequality can be rephrased:

$$|\langle x, y\rangle| \leq \|x\|\|y\|$$

for $x, y \in \mathcal{V}$. A useful consequence is:

XX.11.2.4. PROPOSITION. Let $(\mathcal{V}, \langle\cdot,\cdot\rangle)$ be an inner product space, and $x \in \mathcal{V}$. Then

$$\|x\| = \max_{\|y\|=1} |\langle x, y\rangle| = \sup_{\|y\|=1} |\langle x, y\rangle| \ .$$

In particular, if $\langle x, y\rangle = 0$ for all y with $\|y\| = 1$, then $x = 0$.

PROOF: We have $\|x\| \geq |\langle x, y\rangle|$ for $\|y\| = 1$ by the CBS inequality, and equality is obtained for $y = \frac{x}{\|x\|}$ if $x \neq 0$ and for any y if $x = 0$. 👍

XX.11.2.5. PROPOSITION. $\|\cdot\|$ is a norm on $\mathcal{V}$.

PROOF: It is clear that $\|x\| \geq 0$ for all x and $\|x\| = 0$ if and only if $x = 0$. We have

$$\|\alpha x\| = \sqrt{\langle \alpha x, \alpha x\rangle} = \sqrt{\alpha\bar{\alpha}\langle x, x\rangle} = |\alpha|\sqrt{\langle x, x\rangle} = |\alpha|\|x\|$$

for $x \in \mathcal{V}$, $\alpha \in \mathbb{F}$ since $|\alpha| = \sqrt{\alpha\bar{\alpha}}$. For the triangle inequality,

$$\|x+y\|^2 = \langle x+y, x+y\rangle = \langle x,x\rangle + \langle x,y\rangle + \langle y,x\rangle + \langle y,y\rangle \leq \|x\|^2 + 2\|x\|\|y\| + \|y\|^2 = (\|x\| + \|y\|)^2$$

for $x, y \in \mathcal{V}$. 👍

The Parallelogram Law and Polarization Identity

The norm on an inner product space satisfies the following geometric property:

XX.11.2.6. Proposition. [Parallelogram Law] Let $(\mathcal{V}, \langle\cdot,\cdot\rangle)$ be an inner product space (real or complex), and $x, y \in \mathcal{V}$. Then

$$\|x+y\|^2 + \|x-y\|^2 = 2(\|x\|^2 + \|y\|^2) \ .$$

Proof:

$$\|x+y\|^2 + \|x-y\|^2 = \langle x+y, x+y\rangle + \langle x-y, x-y\rangle$$
$$= \langle x,x\rangle + \langle x,y\rangle + \langle y,x\rangle + \langle y,y\rangle + \langle x,x\rangle - \langle x,y\rangle - \langle y,x\rangle + \langle y,y\rangle$$
$$= 2\langle x,x\rangle + 2\langle y,y\rangle = 2(\|x\|^2 + \|y\|^2) \ .$$

👍

XX.11.2.7. "Most" norms on vector spaces do not satisfy the Parallelogram Law and therefore do not come from inner products. For example, on $\mathbb{R}^2$, the norm $\|\cdot\|_2$ comes from the standard inner product; but neither $\|\cdot\|_1$ or $\|\cdot\|_\infty$ come from an inner product: since $\|\boldsymbol{e}_1\|_1 = \|\boldsymbol{e}_2\|_1 = 1$ but $\|\boldsymbol{e}_1 + \boldsymbol{e}_2\|_1 = \|\boldsymbol{e}_1 - \boldsymbol{e}_2\|_1 = 2$, the Parallelogram Law is not satisfied for $\|\cdot\|_1$, and similarly for $\|\cdot\|_\infty$.

In fact, we have a converse to XX.11.2.6., sometimes called the *Fréchet-von Neumann-Jordan Theorem*:

XX.11.2.8. Proposition. [Polarization Identity] (i) Let $\mathcal{V}$ be a real vector space, and $\|\cdot\|$ a norm on $\mathcal{V}$. Then $\|\cdot\|$ is induced from a (real) inner product if and only if it satisfies the Parallelogram Law, and the inner product giving the norm is unique and satisfies

$$\langle x,y\rangle = \frac{1}{4}\left(\|x+y\|^2 - \|x-y\|^2\right)$$

for $x, y \in \mathcal{V}$.

(ii) Let $\mathcal{V}$ be a complex vector space, and $\|\cdot\|$ a norm on $\mathcal{V}$. Then $\|\cdot\|$ is induced from an inner product if and only if it satisfies the Parallelogram Law, and the inner product giving the norm is unique and satisfies

$$\langle x,y\rangle = \frac{1}{4}\left(\|x+y\|^2 - \|x-y\|^2 + i\|x+iy\|^2 - i\|x-iy\|^2\right)$$

for $x, y \in \mathcal{V}$.

PROOF: We write the proof of (ii); the proof of (i) is nearly identical but easier. If the norm comes from an inner product, then a straightforward argument similar to the proof of XX.11.2.6. (Exercise XX.11.11.9.) shows that the inner product satisfies the Polarization Identity and is thus unique. Conversely, if the "inner product" defined by the Polarization Identity is a true inner product, then for $x \in \mathcal{V}$

$$\langle x, x\rangle = \frac{1}{4}\left(\|2x\|^2 - \|0\|^2 + i\|(1+i)x\|^2 - i\|(1-i)x\|^2\right) = \|x\|^2$$

since $|1+i| = |1-i|$; so the norm it defines is the given one, which therefore satisfies the Parallelogram Law. Thus it suffices to show that if the norm satisfies the Parallelogram Law, the Polarization Identity defines an inner product on $\mathcal{V}$.

So suppose the norm satisfies the Parallelogram Law, and define $\langle\cdot,\cdot\rangle$ by the Polarization Identity. A simple straightforward calculation (not using the Parallelogram Law) shows that $\langle y, x\rangle = \overline{\langle x, y\rangle}$ and $\langle x, iy\rangle = -i\langle x, y\rangle$ for any $x, y \in \mathcal{V}$, and hence $\langle ix, y\rangle = i\langle x, y\rangle$ for $x, y \in \mathcal{V}$. Next, for $x, y, z \in \mathcal{V}$,

$$\|x + y + 2z\|^2 + \|x - y\|^2 = \|(x+z) + (y+z)\|^2 + \|(x+z) - (y+z)\|^2 = 2(\|x+z\|^2 + \|y+z\|^2)$$

by the Parallelogram Law, and similarly

$$\|x + y - 2z\|^2 + \|x - y\|^2 = 2(\|x-z\|^2 + \|y-z\|^2)$$

$$\|x + y + 2iz\|^2 + \|x - y\|^2 = 2(\|x+iz\|^2 + \|y+iz\|^2)$$

$$\|x + y - 2iz\|^2 + \|x - y\|^2 = 2(\|x-iz\|^2 + \|y-iz\|^2)$$

so we have

$$4\langle x+y, 2z\rangle = \|x+y+2z\|^2 - \|x+y-2z\|^2 + i\|x+y+2iz\|^2 - i\|x+y-2iz\|^2$$

$$= 2\|x+z\|^2+2\|y+z\|^2-2\|x-z\|^2-2\|y-z\|^2+2i\|x+iz\|^2+2i\|y+iz\|^2-2i\|x-iz\|^2-2i\|y-iz\|^2 = 8(\langle x, z\rangle+\langle y, z\rangle)$$

$$\langle x+y, 2z\rangle = 2(\langle x, z\rangle + \langle y, z\rangle)$$

and in the special case $y = 0$,

$$\langle x, 2z\rangle = 2\langle x, z\rangle$$

and therefore, for general x, y, z,

$$\langle x+y, z\rangle = \frac{1}{2}\langle x+y, 2z\rangle = \langle x, z\rangle + \langle y, z\rangle$$

and $\langle\cdot,\cdot\rangle$ is additive in each variable. We have also

$$\langle 2x, y\rangle = 2\langle x, y\rangle$$

for any x, y and we get by iteration that

$$\langle \alpha x, y\rangle = \alpha\langle x, y\rangle$$

for all $x, y \in \mathcal{V}$ and every dyadic rational number α. Since

$$\langle \alpha x, y\rangle = \frac{1}{4}\left(\|\alpha x + y\|^2 - \|\alpha x - y\|^2 + i\|\alpha x + iy\|^2 - i\|\alpha x - iy\|^2\right)$$

is clearly a continuous function of α for fixed x, y, we have

$$\langle \alpha x, y\rangle = \alpha\langle x, y\rangle$$

for all $\alpha \in \mathbb{R}$. Since it is also true for $\alpha = i$, it holds for all $\alpha \in \mathbb{C}$ and $\langle\cdot,\cdot\rangle$ is an inner product. 👍

Thus the norm and inner product completely determine each other. One way of phrasing this is:

XX.11.2.9. Corollary. Let $(\mathcal{V}, \langle\cdot,\cdot\rangle)$ and $(\mathcal{W}, (\cdot,\cdot))$ be inner product spaces over the same field, and $T : \mathcal{V} \to \mathcal{W}$ a linear transformation. Then T is an isometry (i.e. $\|Tx\| = \|x\|$ for all $x \in \mathcal{V}$) if and only if T preserves inner products (i.e. $(Tx, Ty) = \langle x, y\rangle$ for all $x, y \in \mathcal{V}$).

Continuity of the Inner Product

XX.11.2.10. The induced norm on an inner product space $(\mathcal{V}, \langle\cdot,\cdot\rangle)$ defines a topology on $\mathcal{V}$, called the *induced topology* on $\mathcal{V}$. We will always implicitly use this topology on $\mathcal{V}$ unless otherwise specified.

The next result is also an immediate consequence of the CBS inequality:

XX.11.2.11. Proposition. Let $(\mathcal{V}, \langle\cdot,\cdot\rangle)$ be an inner product space. Then the inner product is *jointly continuous*: if (x_n) and (y_n) are sequences in $\mathcal{V}$, $x, y \in \mathcal{V}$, and $x_n \to x$, $y_n \to y$, then

$$\langle x_n, y_n\rangle \to \langle x, y\rangle \ .$$

In particular, the inner product is *separately continuous*:

$$\langle x_n, y\rangle \to \langle x, y\rangle \text{ and } \langle x, y_n\rangle \to \langle x, y\rangle \ .$$

Proof: We have

$$\begin{aligned} |\langle x_n, y_n\rangle - \langle x, y\rangle| &\le |\langle x_n, y_n\rangle - \langle x_n, y\rangle| + |\langle x_n, y\rangle - \langle x, y\rangle| \\ = |\langle x_n, y_n - y\rangle| + |\langle x_n - x, y\rangle| &\le \|x_n\|\|y_n - y\| + \|x_n - x\|\|y\| \ . \end{aligned}$$

Since (x_n) converges, it is bounded; hence both terms go to 0 as $n \to \infty$. 👍

XX.11.3. Completeness and Hilbert Spaces

XX.11.3.1. Definition. A *(complex) Hilbert space* is a complex inner product space which is complete with respect to the induced norm. A *real Hilbert space* is a real inner product space which is complete with respect to the induced norm. In light of XX.11.2.8., we can also say, by slight abuse of terminology, that a Hilbert space is a Banach space whose norm satisfies the Parallelogram Law.

In this section, the term "Hilbert space" will denote either a real or complex Hilbert space. But in the rest of this volume, the term "Hilbert space," unless qualified with "real," will denote a *complex* Hilbert space. The letter $\mathcal{H}$ will generally be used to denote a Hilbert space.

Note that specification of an inner product (or, equivalently, a norm satisfying the Parallelogram Law) is part of the definition of a Hilbert space. But we will frequently employ the usual abuse of terminology by saying "Let $\mathcal{H}$ be a Hilbert space."

XX.11.3.2. EXAMPLES. (i) $\mathbb{C}^n$ is a Hilbert space (with respect to the standard inner product) for any n. $\mathbb{R}^n$ is a real Hilbert space.

(ii) $C([a,b])$ is not a Hilbert space with respect to the inner product of XX.11.1.8.(ii) since it is not complete (Exercise XX.11.11.10.).

(iii) The sequence space ℓ^2 of square-summable sequences of complex numbers is a Hilbert space with respect to the inner product

$$\langle \boldsymbol{x}, \boldsymbol{y} \rangle = \sum_{k=1}^{\infty} x_k \overline{y_k}$$

where $\boldsymbol{x} = (x_1, x_2, \dots)$, $\boldsymbol{y} = (y_1, y_2, \dots)$ ().

(iv) More generally, $L^2(X, \mathcal{A}, \mu)$, the space of square-integrable functions on a measure space $(X, \mathcal{A}, \mu)$ (or, more precisely, of equivalence classes of square-integrable functions, with functions agreeing almost everywhere identified), with inner product

$$\langle f, g \rangle = \int_X f \overline{g} \, d\mu$$

is a Hilbert space (). If S is a set, let μ be counting measure on S, and denote $L^2(S, \mu)$ by $\ell^2(S)$. Then $\ell^2 = \ell^2(\mathbb{N})$.

XX.11.3.3. The definition and basic properties of ℓ^2 were given in 1906 by D. HILBERT, who was the first to describe something approaching the modern notion of a "Hilbert space," and developed by E. SCHMIDT, F. RIESZ, and others in immediately succeeding years. The name "Hilbert space" (apparently referring to what we today call ℓ^2) is generally attributed to SCHMIDT, but according to [Jah03, p. 385] was first used in 1908 by A. SCHÖNFLIES. The definition of an abstract Hilbert space was, however, not given until 1928 by J. VON NEUMANN [vN30].

Completion of an Inner Product Space

Just as with metric spaces () and normed vector spaces (), every inner product space can be completed to a Hilbert space:

XX.11.3.4. THEOREM. Let $(\mathcal{V}, \langle \cdot, \cdot \rangle)$ be a (real or complex) inner product space. Then $\mathcal{V}$ can be isometrically embedded, in a unique way up to isometric isomorphism, as a dense subspace of a (real or complex) Hilbert space, called the *completion* of $\mathcal{V}$.

PROOF: This theorem can be proved directly in the same way as () and (); see Exercise XX.11.11.12.. But there is a much easier argument using XX.11.2.8.: if $\mathcal{H}$ is the completion of $\mathcal{V}$ with respect to the induced norm, then the norm on $\mathcal{H}$ satisfies the Parallelogram Law on a dense subspace, hence by continuity on the whole space. Thus it comes from an inner product which must extend the inner product on $\mathcal{V}$ by Polarization. 👍

XX.11.3.5. As usual, there is often a concrete realization of the completion of an inner product space: if it can be identified with a subspace of a Hilbert space, the closure of this subspace is the completion.

Pre-Hilbert Spaces

XX.11.3.6. DEFINITION. A *pre-Hilbert space* is a complex vector space with a pre-inner product.

Real pre-Hilbert spaces can be defined accordingly, but we will stick to the complex case.

Any (complex) inner product space is a pre-Hilbert space. But there are other natural ones. Here is an example of a very common kind:

XX.11.3.7. EXAMPLE. Let $\mathcal{PC}([a,b])$ be the set of piecewise-continuous complex-valued functions on $[a,b]$. Define a sesquilinear form on $\mathcal{PC}([a,b])$ by

$$\langle f,g\rangle = \int_a^b f(t)\overline{g(t)}\,dt\ .$$

This is a pre-inner product, but not an inner product: if f is zero except at finitely many points, then $\langle f,f\rangle = 0$, but f is not the zero element of $\mathcal{PC}([a,b])$.

XX.11.3.8. PROPOSITION. Let $(\mathcal{V},\langle\cdot,\cdot\rangle)$ be a pre-Hilbert space. Then

(i) If

$$\mathcal{N} = \{x\in\mathcal{V} : \langle x,x\rangle = 0\}$$

then $\mathcal{N}$ is a closed subspace of $\mathcal{V}$.

(ii) The pre-inner product on $\mathcal{V}$ induces an inner product on $\mathcal{V}/\mathcal{N}$ by

$$\langle [x],[y]\rangle = \langle x,y\rangle$$

for $x,y\in\mathcal{V}$.

PROOF: This is more or less a special case of (), and is proved in a similar way. 👍

XX.11.3.9. EXAMPLE. Let $\mathcal{PC}([a,b])$ be as in XX.11.3.7.. Then $\mathcal{N}$ consists of all functions which are zero except at finitely many points. If f is piecewise-continuous, the equivalence class $[f]$ of f consists precisely of all (necessarily piecewise-continuous) functions which agree with f except at finitely many points. Let $PC([a,b])$ be the set of equivalence classes of piecewise-continuous functions. Then the pre-inner product of XX.11.3.7. gives a well-defined inner product on $PC([a,b])$. We often think of the elements of $PC([a,b])$ as functions on $[a,b]$, but they are technically equivalence classes of functions; but the distinction can often be overlooked without essential difficulty. We can naturally identify $C([a,b])$ with a (dense) subspace of $PC([a,b])$.

XX.11.3.10. DEFINITION. Let $(\mathcal{V},\langle\cdot,\cdot\rangle)$ be a pre-Hilbert space. The *completion* of $\mathcal{V}$ is the Hilbert space obtained by completing $\mathcal{V}/\mathcal{N}$.

XX.11.4. Best Approximation

Hilbert spaces have a nice property not shared by general Banach spaces which is important in applications. If A is a nonempty closed convex set in a Hilbert space $\mathcal{H}$ (e.g. a closed subspace), and $x \in \mathcal{H}$, then there is a unique vector $y \in A$ which is closest to x. This theorem was proved by Beppo Levi in 1906 [?].

We use the notation $\rho(x, y) = \|x - y\|$, and

$$\rho(x, A) = \inf_{y \in A} \rho(x, y) = \inf_{y \in A} \|x - y\| \ .$$

XX.11.4.1. Theorem. Let $\mathcal{H}$ be a Hilbert space and A a nonempty closed convex subset of $\mathcal{H}$. For any $x \in \mathcal{H}$, there is a unique $y \in A$ such that

$$\|x - y\| = \rho(x, y) = \rho(x, A) = \inf_{z \in A} \|x - z\| = \min_{z \in A} \|x - z\| \ .$$

We need a lemma which is an immediate consequence of the Parallelogram Law:

XX.11.4.2. Lemma. Let A be a nonempty convex set in an inner product space $\mathcal{V}$, $x \in \mathcal{V}$, and $\epsilon > 0$. If $y, z \in A$ with $\|x - y\|^2 < \rho(x, A)^2 + \epsilon$ and $\|x - z\|^2 < \rho(x, A)^2 + \epsilon$, then $\|y - z\|^2 < 4\epsilon$.

Proof: Set $w = \frac{1}{2}(y + z)$. Then $w \in A$ since A is convex, so $\|x - w\| \geq \rho(x, A)$. We have

$$x - w + \frac{1}{2}(y - z) = x - z$$

$$x - w - \frac{1}{2}(y - z) = x - y$$

so by the Parallelogram Law

$$\|x - z\|^2 + \|x - y\|^2 = \left\|x - w + \frac{1}{2}(y - z)\right\|^2 + \left\|x - w - \frac{1}{2}(y - z)\right\|^2 = 2\left(\|x - w\|^2 + \left\|\frac{1}{2}(y - z)\right\|^2\right)$$

$$\|y - z\|^2 = 2\|x - z\|^2 + 2\|x - y\|^2 - 4\|x - w\|^2 < 2\rho(x, A)^2 + 2\epsilon + 2\rho(x, A)^2 + 2\epsilon - 4\rho(x, A)^2 = 4\epsilon \ .$$

We now prove Theorem XX.11.4.1..

Proof: Let (y_n) be a sequence in A with $\|x - y_n\| \to \rho(x, A)$. Then Lemma XX.11.4.2. implies that (y_n) is a Cauchy sequence in $\mathcal{H}$. Let $y = \lim y_n$. Then $y \in A$ since A is closed, and

$$\|x - y\| = \lim_{n \to \infty} \|x - y_n\| = \rho(x, A) \ .$$

If $z \in A$ with $\|x - z\| = \rho(x, A)$, then the hypotheses of Lemma XX.11.4.2. are satisfied for every $\epsilon > 0$, and we conclude $y = z$. 

XX.11.4.3. Lemma XX.11.4.2. really says that an inner product space is uniformly convex (XX.11.11.15.). The argument above shows that the closest approximation theorem holds in any uniformly convex Banach space.

XX.11.4.4. Examples. (i) The closest approximation result does not hold in general Banach spaces. In $(\mathbb{R}^2, \|\cdot\|_\infty)$, if A is the closed unit ball and $x = (2, 0)$, then there is a closest vector in A to x (there must be since A is compact), but it is not unique; in fact, any vector $(1, y)$ with $|y| \leq 1$ is a closest approximation to x in A.

(ii) The proof of XX.11.4.1. uses completeness. The result fails in general in an inner product space which is not complete. For example, let $\mathcal{V} = C([0, 1])$ with the standard inner product, and let

$$A = \left\{ f \in C([0,1]) : \int_0^{1/2} f(t)\,dt - \int_{1/2}^1 f(t)\,dt = 1 \right\} .$$

Then it is easily checked that A is a closed convex set in $\mathcal{V}$. But there is no closest vector to 0 (vector of minimum norm) in A: $\rho(0, A) = 1$, but there is no f in A of norm 1. (In the completion, the unique closest vector in $\bar{A}$ to 0 is the function which is 1 on $\left[0, \frac{1}{2}\right)$ and -1 on $\left(\frac{1}{2}, 1\right]$.)

XX.11.5. Orthogonality

Hilbert spaces have a geometric structure similar to that of Euclidean space. The most important geometric notion is *orthogonality*:

XX.11.5.1. Definition. Let $(\mathcal{V}, \langle\cdot,\cdot\rangle)$ be an inner product space over $\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$. If $x, y \in \mathcal{V}$, then x and y are *orthogonal* (with respect to $\langle\cdot,\cdot\rangle$), written $x \perp y$, if $\langle x, y\rangle = 0$.

XX.11.5.2. The geometric term *perpendicular* is sometimes used as a synonym for *orthogonal*. But in functional analysis we prefer to use *orthogonal*, especially for complex inner product spaces. Note that in a complex inner product space, "perpendicular" and "orthogonal" do not quite have the same meaning: for example, in the one-dimensional (complex) Hilbert space $\mathbb{C}^1$ with standard inner product, the vectors 1 and i are "perpendicular" but not orthogonal.

We have $0 \perp y$ for every y. Conversely, we have a useful rephrasing of the simple result XX.11.2.4.:

XX.11.5.3. Proposition. Let $(\mathcal{V}, \langle\cdot,\cdot\rangle)$ be an inner product space, and $x \in \mathcal{V}$. Then $x \perp y$ for all $y \in \mathcal{V}$ if and only if $x = 0$.

Orthogonal Complement

XX.11.5.4. Definition. Let $(\mathcal{V}, \langle\cdot,\cdot\rangle)$ be an inner product space, and $S \subseteq \mathcal{V}$. The *orthogonal complement* of S (in $\mathcal{V}$) is

$$S^\perp = \{x \in \mathcal{V} : \langle x, y\rangle = 0 \text{ for all } y \in S\}.$$

$S^\perp$ is a closed subspace of $\mathcal{V}$ (whether or not S is a subspace; in fact, $S^\perp = (span(S))^\perp$).

The next norm relation is fundamental.

XX.11.5.5. Proposition. [Pythagorean Theorem] Let $\mathcal{V}$ be an inner product space, and $x, y \in \mathcal{V}$ with $x \perp y$. Then

$$\|x+y\|^2 = \|x\|^2 + \|y\|^2 \ .$$

Proof: Expand $\langle x+y, x+y\rangle$. 👍

The converse is true in a real inner product space, but not a complex one (take 1 and i in $\mathbb{C}^1$). But there is a partial converse:

XX.11.5.6. Proposition. Let $\mathcal{V}$ be an inner product space over $\mathbb{F}$, and $x, y \in \mathcal{V}$. The following are equivalent:

(i) $x \perp y$.

(ii) $\|x+\alpha y\|^2 = \|x\|^2 + |\alpha|^2\|y\|^2$ for all $\alpha \in \mathbb{F}$.

(iii) $\|x+\alpha y\| \geq \|x\|$ for all $\alpha \in \mathbb{F}$.

Proof: (i) $\Rightarrow$ (ii) is XX.11.5.5., and (ii) $\Rightarrow$ (iii) is trivial. For (iii) $\Rightarrow$ (i), we may assume $y \neq 0$. Set

$$\alpha = -\frac{\langle x, y\rangle}{\langle y, y\rangle}$$

and then a calculation as in the proof of XX.11.2.1. shows that

$$\|x+\alpha y\|^2 = \|x\|^2 - \frac{|\langle x, y\rangle|}{\|y\|^2}$$

which is only $\geq \|x\|^2$ if $\langle x, y\rangle = 0$. 👍

If $\mathcal{H}$ is a Hilbert space, $\mathcal{Y}$ is a closed subspace of $\mathcal{H}$, and $x \in \mathcal{H}$, then there is a closest vector $y \in \mathcal{Y}$ to X. It turns out that $z = x - y \in \mathcal{Y}^\perp$:

XX.11.5.7. Proposition. Let $\mathcal{H}$ be a Hilbert space, and $\mathcal{Y}$ a closed subspace of $\mathcal{H}$. Then every $x \in \mathcal{H}$ can be uniquely written as $y + z$, where $y \in \mathcal{Y}$ and $z \in \mathcal{Y}^\perp$. The y is the closest vector in $\mathcal{Y}$ to x.

Proof: By XX.11.4.1. there is a (unique) closest vector $y \in \mathcal{Y}$ to x. Set $z = x - y$. Let $w \in \mathcal{Y}$. Then, for any $\alpha \in \mathbb{C}$,

$$\|z + \alpha w\| = \|x - (y - \alpha w)\| \geq \|x - y\| = \|z\|$$

since $y - \alpha w \in \mathcal{Y}$. Thus $z \perp w$ by XX.11.5.6.. If also $x = y' + z'$ with $y' \in \mathcal{Y}$, $z' \in \mathcal{Y}^\perp$, we have $y + z - y' - z' = 0$, so

$$y - y' = z' - z \in \mathcal{Y} \cap \mathcal{Y}^\perp = \{0\}$$

and $y = y'$, $z = z'$. 👍

XX.11.5.8. Example. Completeness is essential in XX.11.5.7.. As a slight variation of Example XX.11.4.4., let

$$\mathcal{Y} = \left\{ f \in C([0,1]) : \int_0^{1/2} f(t)\,dt - \int_{1/2}^1 f(t)\,dt = 0 \right\} .$$

Then $\mathcal{Y}$ is a closed subspace of $C([0,1])$ (with respect to the norm induced by the standard inner product). But if f is the constant function 1, there is no decomposition $f = g + h$ with $g \in \mathcal{Y}$ and $h \in \mathcal{Y}^\perp$. In fact, $\mathcal{Y}^\perp = \{0\}$ in $C([0,1])$ even though $\mathcal{Y}$ is a proper subspace of $C([0,1])$.

XX.11.5.9. If $\mathcal{V}$ is an inner product space and $S \subseteq \mathcal{V}$, then $S^{\perp\perp} = (S^\perp)^\perp$ is a closed subspace of $\mathcal{V}$ containing S. If $\mathcal{V}$ is complete, then $S^{\perp\perp}$ is the *smallest* closed subspace containing S:

XX.11.5.10. Proposition. Let $\mathcal{H}$ be a Hilbert space and $S \subseteq \mathcal{H}$. Then $S^{\perp\perp}$ is the closed linear span of S.

Proof: Let $\mathcal{Y}$ be the closed linear span of S, i.e. the closure of $span(S)$. Then $\mathcal{Y} \subseteq S^{\perp\perp}$, and $\mathcal{Y}^\perp = S^\perp$. If $x \in S^{\perp\perp}$, then $x = y + z$ with $y \in \mathcal{Y}$ and $z \in \mathcal{Y}^\perp$. But since $x, y \in S^{\perp\perp}$, $z = x - y \in S^{\perp\perp} = \mathcal{Y}^{\perp\perp}$. Thus

$$z \in \mathcal{Y}^\perp \cap \mathcal{Y}^{\perp\perp} = \{0\}$$

so $x = y \in \mathcal{Y}$, i.e. $\mathcal{Y} = S^{\perp\perp}$. 👍

XX.11.5.11. Corollary. Let $\mathcal{H}$ be a Hilbert space and $\mathcal{Y}$ a closed subspace. Then $\mathcal{Y} = \mathcal{Y}^{\perp\perp}$. In particular, $\mathcal{Y} = \mathcal{H}$ if and only if $\mathcal{Y}^\perp = \{0\}$, so if $S \subseteq \mathcal{H}$, then the closed linear span of S is $\mathcal{H}$ if and only if $S^\perp = \{0\}$.

This result can fail if the space is not complete (Example XX.11.5.8.).

Orthonormal Sets

XX.11.5.12. Definition. A set $\{e_j : j \in J\}$ of vectors in an inner product space is *orthonormal* if $\langle e_j, e_k \rangle = \delta_{jk}$ for all $j, k \in J$, i.e. it is a mutually orthogonal set of unit vectors.

Of course, any subset of an orthonormal set is orthonormal. A set is orthonormal if and only if every finite subset (in fact, every two-element subset) is orthonormal.

XX.11.5.13. Proposition. An orthonormal set in an inner product space is linearly independent.

Proof: Suppose $S = \{e_j : j \in J\}$ is an orthonormal set, and suppose

$$\alpha_1 e_{j_1} + \cdots + \alpha_n e_{j_n} = 0$$

for some $j_1, \ldots, j_n$ and scalars $\alpha_1, \ldots, \alpha_n$. Then for $1 \leq m \leq n$

$$0 = \langle \alpha_1 e_{j_1} + \cdots + \alpha_n e_{j_n}, e_{j_m} \rangle = \sum_{r=1}^{n} \alpha_r \langle e_{j_r}, e_{j_m} \rangle = \alpha_m$$

so S is linearly independent. 👍

Orthonormal sets are very nice to work with. If S is an orthonormal set, then it is easy to see how to explicitly write any vector in $span(S)$ as a convex combination of the vectors in S:

XX.11.5.14. PROPOSITION. Let $S = \{e_1, \ldots, e_n\}$ be a finite orthonormal set in an inner product space, and $x \in span(S)$. Then the unique representation of x as a linear combination of $\{e_1, \ldots, e_n\}$ is

$$x = \sum_{k=1}^{n} \langle x, e_k \rangle e_k \ .$$

We also have

$$\|x\|^2 = \sum_{k=1}^{n} |\langle x, e_k \rangle|^2 \ .$$

PROOF: Suppose

$$x = \sum_{k=1}^{n} \alpha_k e_k$$

is the unique expression of x as a linear combination of S, then, for each j,

$$\langle x, e_j \rangle = \sum_{k=1}^{n} \alpha_k \langle e_k, e_j \rangle = \alpha_j \ .$$

👍

The number $\langle x, e_j \rangle$ is often called the *Fourier coefficient* of x with respect to e_j (cf. ()).

This finite result has an important generalization to infinite orthonormal sets:

XX.11.5.15. THEOREM. Let $S = \{e_j : j \in J\}$ be an orthonormal set in an inner product space $\mathcal{V}$, and $\mathcal{Y}$ the closed linear span of S in $\mathcal{V}$. Then, for any $y \in \mathcal{Y}$:

(i) The sum

$$\sum_{j \in J} \langle y, e_j \rangle e_j$$

converges unconditionally to y in $\mathcal{V}$, i.e. the net of finite subsums converges to y.

(ii) The unordered sum

$$\sum_{j \in J} |\langle y, e_j \rangle|^2$$

converges (absolutely) to $\|y\|^2$, i.e. the net of finite subsums converges to $\|y\|^2$.

PROOF: Let $F = \{e_{j_1}, \ldots, e_{j_n}\}$ be a finite subset of S, and set

$$y_F = \sum_{k=1}^{n} \langle y, e_{j_k} \rangle e_{j_k}$$

and $z_F = y - y_F$. We have that $y_F \in span(F)$, and that

$$\langle z_F, e_{j_m} \rangle = \langle y, e_{j_m} \rangle - \langle y_F, e_{j_m} \rangle = 0$$

for $1 \leq m \leq n$; thus $z_F \in (span(F))^{\perp}$. So we have

$$\|y\|^2 = \|y_F\|^2 + \|z_F\|^2 \geq \|y_F\|^2 = \sum_{k=1}^{n} |\langle y, e_{j_k} \rangle|^2 \ .$$

Thus the sum in (ii) converges, and is $\leq \|y\|^2$.

On the other hand, if $\epsilon > 0$ there is an $x \in span(S)$ with $\|x - y\| < \epsilon$. We have $x \in span(E)$ for some finite subset E of S. If $F = \{e_{j_1}, \ldots, e_{j_n}\}$ is a finite subset of of S containing E, then

$$\|y - y_F\| \leq \|y - x\|$$

since y_F is the closest vector in $span(F)$ to y. Thus

$$\left\| y - \sum_{k=1}^{n} \langle y, e_{j_k} \rangle e_{j_k} \right\| < \epsilon$$

and the finite subsums in (i) converge to y. Also,

$$\sum_{k=1}^{n} |\langle y, e_{j_k} \rangle|^2 = \|y_F\|^2 \geq (\|y\| - \|y - y_F\|)^2 \geq (\|y\| - \epsilon)^2$$

which can be made arbitrarily close to $\|y\|^2$ by choosing ϵ sufficiently small. Thus the sum in (ii) converges to $\|y\|^2$. 👍

XX.11.5.16. COROLLARY. Let $\mathcal{H}$ be a Hilbert space, $S = \{e_j : j \in J\}$ an orthonormal set in $\mathcal{H}$, and $x \in \mathcal{H}$. Then

$$\sum_{j \in J} |\langle x, e_j \rangle|^2 \leq \|x\|^2$$

(*Bessel's inequality*). In particular, $\langle x, e_j \rangle \neq 0$ for only countably many j. We have

$$\sum_{j \in J} |\langle x, e_j \rangle|^2 = \|x\|^2$$

(*Parseval's relation*) if and only if x is in the closed linear span of S.

PROOF: Let $\mathcal{Y}$ be the closed linear span of S, and write $x = y + z$ with $y \in \mathcal{Y}$, $z \in \mathcal{Y}^{\perp}$. Then

$$\|x\|^2 = \|y\|^2 + \|z\|^2 \geq \|y\|^2 = \sum_{j \in J} |\langle y, e_j \rangle|^2 = \sum_{j \in J} |\langle x, e_j \rangle|^2$$

with equality if and only if $z = 0$. 👍

Orthonormal Bases

The next result is a combination of parts of XX.11.5.11. and XX.11.5.15.:

XX.11.5.17. COROLLARY. Let $\mathcal{H}$ be a Hilbert space, and $S = \{e_j : j \in J\}$ an orthonormal set in $\mathcal{H}$. The following are equivalent:

(i) S is a maximal orthonormal set (not contained in any strictly larger orthonormal set).

(ii) $S^\perp = \{0\}$.

(iii) The closed linear span of S is $\mathcal{H}$.

(iv) For every $x \in \mathcal{H}$, there is a unique unordered sum

$$\sum_{j\in J} \alpha_j e_j$$

which converges to x. We necessarily have that the unordered sum

$$\sum_{j\in J} |\alpha_j|^2$$

converges to $\|x\|^2$, and $\alpha_j = \langle x, e_j\rangle$.

PROOF: For the equivalence of (i) and (ii), note that if S' is an orthonormal set containing S, then $S'\backslash S \subseteq S^\perp$. Conversely, if $S^\perp \neq \{0\}$, let x be a unit vector in $S^\perp$; then $S \cup \{x\}$ is an orthonormal set strictly larger than S.

For the uniqueness in (iv), suppose the unordered sum $\sum_j \alpha_j e_j$ converges to x. Then, by linearity and continuity of the inner product, we have, for each k,

$$\langle x, e_k\rangle = \lim_{F\subseteq S} \sum_{j\in F} \langle \alpha_j e_j, e_k\rangle = \alpha_k$$

where the limit is over the net of finite subsets F of S. 👍

XX.11.5.18. DEFINITION. If $\mathcal{H}$ is a Hilbert space, an *orthonormal basis* for $\mathcal{H}$ is an orthonormal set S in $\mathcal{H}$ satisfying the equivalent conditions of XX.11.5.17..

XX.11.5.19. An orthonormal basis is linearly independent (XX.11.5.13.). If $\mathcal{H}$ is finite-dimensional, then an orthonormal basis for $\mathcal{H}$ is finite, hence a Hamel basis. But an orthonormal basis for an infinite-dimensional Hilbert space is not a Hamel basis. For example, if $\{e_{j_1}, e_{j_2}, \dots\}$ is a sequence of distinct elements of an orthonormal basis for $\mathcal{H}$, then the series

$$\sum_{n=1}^{\infty} \frac{1}{n} e_{j_n}$$

converges in $\mathcal{H}$ to a vector which cannot be written as a finite linear combination of the e_j by the uniqueness in XX.11.5.17.. A countable orthonormal basis for a Hilbert space is an unconditional Schauder basis ().

XX.11.5.20. As with Hamel bases in vector spaces (), there is nothing remotely unique about orthonormal bases for Hilbert spaces. For example, any two perpendicular unit vectors in $\mathbb{R}^2$ form an orthonormal basis for $\mathbb{R}^2$ or $\mathbb{C}^2$ (with respect to the usual inner product). $\mathbb{C}^2$ has many other orthonormal bases not contained in the subset $\mathbb{R}^2$.

If $\mathcal{H}$ is a complex Hilbert space, whether an orthonormal set is an orthonormal basis depends whether $\mathcal{H}$ is regarded as a complex Hilbert space or as a real Hilbert space with inner product $(\cdot,\cdot) = Re\langle\cdot,\cdot\rangle$. If B is an orthonormal basis for $\mathcal{H}$ as a complex Hilbert space, it is an orthonormal set, but not an orthonormal basis, for $\mathcal{H}$ as a real Hilbert space; the set

$$B \cup iB = \{e, ie : e \in B\}$$

is an orthonormal basis for $\mathcal{H}$ as a real Hilbert space.

We have a companion result slightly generalizing XX.11.5.17., which is an immediate corollary of XX.11.5.17., the continuity of the inner product, and the CBS inequality:

XX.11.5.21. Corollary. Let $\mathcal{H}$ be a Hilbert space, and $\{e_j : j \in J\}$ an orthonormal basis for $\mathcal{H}$. Let $x, y \in \mathcal{H}$. Write

$$x = \sum_{j\in J} \alpha_j e_j \ , \quad y = \sum_{j\in J} \beta_j e_j$$

as in XX.11.5.17.. Then the unordered sum

$$\sum_{j\in J} \alpha_j \overline{\beta_j}$$

converges absolutely to $\langle x, y\rangle$.

The next theorem is the main theoretical result about orthonormal bases:

XX.11.5.22. Theorem. Let $\mathcal{H}$ be a Hilbert space. Then

(i) $\mathcal{H}$ has an orthonormal basis.

(ii) Every orthonormal set in $\mathcal{H}$ is contained in an orthonormal basis.

(iii) Any two orthonormal bases for $\mathcal{H}$ have the same cardinality.

Proof: The proof of (i) is a prototype Zorn's Lemma argument (using the characterization of an orthonormal basis as a maximal orthonormal set), similar to the proof in III.11.2.32. (but easier), using XX.11.5.11., and is left to the reader. Part (ii) can be proved in a similar way: if S is an orthonormal set in $\mathcal{H}$, consider only orthonormal sets containing S. Alternately, let $\mathcal{Y}$ be the closed linear span of S. Then $\mathcal{Y}^\perp$ is a closed subspace of $\mathcal{H}$ and thus itself a Hilbert space, so has an orthonormal basis B'. Then $B = S \cup B'$ is an orthonormal basis for $\mathcal{H}$ containing S.

To prove (iii), first note that if $\mathcal{H}$ has a finite orthonormal basis B with n elements, then B is a Hamel basis for $\mathcal{H}$ and thus $\mathcal{H}$ is an n-dimensional vector space. Thus any other orthonormal basis for $\mathcal{H}$ also has exactly n elements. Now assume that one (hence every) orthonormal basis for $\mathcal{H}$ is infinite. Let $\{e_j : j \in J\}$ be an orthonormal basis for $\mathcal{H}$ of cardinality λ, and $\{f_k : k \in K\}$ another orthonormal basis for $\mathcal{H}$ of cardinality κ. Then each e_j is in the closed linear span of countably many f_k (). Every f_k occurs in one of

these, since otherwise $e_j \in \{f_k\}^\perp$ for all j. Thus K is a union of λ countable sets, so $\kappa \leq \aleph_0 \cdot \lambda$. Similarly, $\lambda \leq \aleph_0 \cdot \kappa$. Since λ and κ are infinite, $\lambda = \kappa$ (II.9.9.4.). 👍

Note that the AC is needed for this proof; in fact, (i) and (ii) may be equivalent to the AC. (The full AC is not needed for (iii), but some weaker form is (II.9.9.4.).)

XX.11.5.23. DEFINITION. Let $\mathcal{H}$ be a Hilbert space over $\mathbb{F}$ ($\mathbb{R}$ or $\mathbb{C}$). The *orthogonal dimension* (or *Hilbert dimension*) of $\mathcal{H}$ (over $\mathbb{F}$) is the cardinality of some (hence every) orthonormal basis for $\mathcal{H}$.

XX.11.5.24. The orthogonal dimension of $\mathcal{H}$ is finite if and only if $\mathcal{H}$ is a finite-dimensional vector space, in which case the orthogonal dimension is the same as the vector space dimension. The two dimensions do not coincide for infinite-dimensional Hilbert spaces in general (). We usually only consider the orthogonal dimension for a Hilbert space $\mathcal{H}$; it is often just called the *dimension* of $\mathcal{H}$ and denoted $dim(\mathcal{H})$.

The orthogonal dimension of a finite-dimensional complex Hilbert space changes (is multiplied by 2) if it is regarded as a real Hilbert space with inner product $(\cdot,\cdot) = Re\langle\cdot,\cdot\rangle$. The orthogonal dimension of an infinite-dimensional complex Hilbert space does not change if it is regarded as a real Hilbert space (since $2\kappa = \kappa$ for any infinite cardinal κ).

The orthogonal dimension classifies Hilbert spaces up to isometric isomorphism; thus the orthogonal dimension is the *only* isomorphism invariant for Hilbert spaces:

XX.11.5.25. THEOREM. Let $\mathcal{H}$ and $\mathcal{H}'$ be Hilbert spaces over $\mathbb{F}$. Then $\mathcal{H}$ and $\mathcal{H}'$ are isometrically isomorphic (over $\mathbb{F}$) if and only if they have the same orthogonal dimension. More precisely, if $B = \{e_j : j \in J\}$ is an orthonormal basis for $\mathcal{H}$ and $B' = \{f_j : j \in J\}$ is an orthonormal basis for $\mathcal{H}'$, the map $e_j \mapsto f_j$ extends to a unique isometric isomorphism $T : \mathcal{H} \to \mathcal{H}'$.

PROOF: It is obvious from the uniqueness of orthogonal dimension that Hilbert spaces of different orthogonal dimensions cannot be isometrically isomorphic. So we need only prove the last statement. The map $T_0 : span(B) \to span(B')$ defined by

$$T_0\left(\sum_{j\in F} \alpha_j e_j\right) = \sum_{j\in F} \alpha_j f_j$$

(where F is an arbitrary finite subset of J) is a well-defined linear map since B is linearly independent. T_0 is an isometry by XX.11.5.14.. Thus T_0 extends uniquely to an isometric linear isomorphism T from $\mathcal{H}$ onto $\mathcal{H}'$. The extension satisfies

$$T\left(\sum_{j\in J} \alpha_j e_j\right) = \sum_{j\in J} \alpha_j f_j$$

by continuity (cf. XX.11.5.17.). 👍

Although the AC is not used in this proof, this theorem depends on the AC since we must know that $\mathcal{H}$ and $\mathcal{H}'$ have orthonormal bases. But if they are particular Hilbert spaces for which we know the existence of orthonormal bases of the same cardinality without using the AC (e.g. XX.11.5.29.), then the isomorphism also does not depend on the AC.

XX.11.5.26. For each cardinal κ, there is a Hilbert space whose orthogonal dimension is κ, namely $\ell^2(X)$ for a set X of cardinality κ (indicator functions of singleton subsets of X form an orthonormal basis of cardinality κ). Thus (assuming AC) there is a precise classification of Hilbert spaces up to isometric isomorphism: there is exactly one for each cardinal. (There is, of course, a separate classification for real Hilbert spaces and complex Hilbert spaces.) This classification is analogous to, but not exactly the same as, the classification up to isomorphism of vector spaces over a fixed field by their dimension.

Separable Hilbert spaces

XX.11.5.27. PROPOSITION. Let $\mathcal{H}$ be a Hilbert space. Then $\mathcal{H}$ is separable if and only if its orthogonal dimension is countable.

PROOF: If $\mathcal{H}$ has a countable orthonormal basis, then it is the closed linear span of a countable set and thus separable (). Conversely, any orthonormal basis for a Hilbert space is discrete in the relative topology (the distance between any two orthogonal unit vectors is $\sqrt{2}$), and a separable metric space cannot have an uncountable discrete subset. 👍

This proof depends on the existence of orthonormal bases and thus on the AC. But we will give a constructive proof that every separable Hilbert space has a (countable) orthonormal basis without using even the countable AC; thus this result does not depend on any form of Choice.

XX.11.5.28. Suppose $\mathcal{H}$ is a separable Hilbert space. Fix a countable dense (or just total) set in $\mathcal{H}$ and arrange it into a sequence (x_n). We will describe an explicit inductive procedure to manufacture an orthonormal basis out of the x_n, called the *Gram-Schmidt orthogonalization procedure*.

To avoid annoying notational problems, we will first go through the sequence (x_n) to discard any x_n which is a linear combination of the previous ones. Reindexing, we may thus assume the x_n are linearly independent.

In particular, $x_1 \neq 0$. Set $e_1 = \frac{x_1}{\|x_1\|}$. Then e_1 is a unit vector spanning the same one-dimensional subspace as x_1.

Now set $y_2 = x_2 - \langle x_2, e_1\rangle e_1$. Then $y_2 \neq 0$ since $\{x_1, x_2\}$ is linearly independent and hence $\{e_1, x_2\}$ is linearly independent, and

$$\langle y_2, e_1\rangle = \langle x_2, e_1\rangle - \langle x_2, e_1\rangle\langle e_1, e_1\rangle = 0$$

So $y_2 \perp e_1$. Set $e_2 = \frac{y_2}{\|y_2\|}$. Then e_2 is a unit vector orthogonal to e_1, and $span(\{e_1, e_2\}) = span(\{x_1, x_2\})$.

Continue in this manner, i.e.

$$y_3 = x_3 - \langle x_3, e_1\rangle e_1 - \langle x_3, e_2\rangle e_2$$

is a nonzero vector orthogonal to e_1 and e_2 (it is just the component of x_3 in the orthogonal complement of $span(\{x_1, x_2\})$ in $span(\{x_1, x_2, x_3\})$), and if $e_3 = \frac{y_3}{\|y_3\|}$, then $\{e_1, e_2, e_3\}$ is an orthonormal set with the same span as $\{x_1, x_2, x_3\}$. In this way we generate an orthonormal sequence (e_n), with

$$span(\{e_1, \ldots, e_n\}) = span(\{x_1, \ldots, x_n\})$$

for all n. Since the sequence (x_n) is total in $\mathcal{H}$, so is the sequence (e_n), i.e. $\{e_n : n \in \mathbb{N}\}$ is an orthonormal basis for $\mathcal{H}$.

The result is important enough that we state it as a theorem:

XX.11.5.29. THEOREM. [GRAM-SCHMIDT] Let $\mathcal{H}$ be a separable Hilbert space, and S a countable total subset of $\mathcal{H}$. Then there is a countable orthonormal basis B for $\mathcal{H}$ with $span(B) = span(S)$. The orthonormal basis B is constructed from S by an explicit algorithm.

XX.11.5.30. Several things to note about this process:

(i) The orthonormal basis obtained depends not only on the x_n, but on the order in which they are taken. Even in a two-dimensional Hilbert space the orthonormal basis is quite different in general if the order of the original vectors is changed. The reader unfamiliar with the Gram-Schmidt procedure should try some two- and three-dimensional examples to understand the process.

(ii) Nowhere in the procedure did we use that $\mathcal{H}$ is complete. Thus the process works equally well in any separable inner product space, i.e. any dense subspace of a separable Hilbert space. The conclusion is that every dense subspace of a separable Hilbert space $\mathcal{H}$ contains an orthonormal basis for $\mathcal{H}$. This is useful when $\mathcal{H}$ contains a dense subspace of nice concrete elements; cf. XX.11.5.33..

(iii) No form of Choice is used in the Gram-Schmidt process.

We thus obtain the following result without any form of AC:

XX.11.5.31. COROLLARY. Two separable Hilbert spaces over $\mathbb{F}$ are isometrically isomorphic (over $\mathbb{F}$) if and only if they have the same orthogonal dimension (over $\mathbb{F}$), which is in $\mathbb{N}_0 \cup \{\aleph_0\}$. Any separable infinite-dimensional Hilbert space (over $\mathbb{F}$) is isometrically isomorphic (over $\mathbb{F}$) to ℓ^2; hence any two separable infinite-dimensional Hilbert spaces (over $\mathbb{F}$) are isometrically isomorphic (over $\mathbb{F}$).

XX.11.5.32. Topologists generally use the term "Hilbert space" to denote the unique separable infinite-dimensional Hilbert space (i.e. ℓ^2), regarded either as a metric space or as a topological space (where it is homeomorphic to $\mathbb{R}^{\mathbb{N}}$ with the product topology (), although there is no linear homeomorphism). Thus to a topologist there is only one "Hilbert space" (up to isometry), but to an analyst there are many.

XX.11.5.33. EXAMPLE. [LEGENDRE POLYNOMIALS] Let $\mathcal{H} = L^2([-1,1])$ (we can take this simply to be the completion of $C([-1,1])$, $PC([-1,1])$, or $R([-1,1])$; cf. (), and we can work over either $\mathbb{R}$ or $\mathbb{C}$). The algebra $\mathcal{P}$ of polynomials is uniformly dense in $C([-1,1])$ by the Stone-Weierstrass Theorem (); since the uniform topology is stronger than the topology defined by the standard inner product

$$\langle f, g\rangle = \int_{-1}^{1} f(t)\overline{g(t)}\, dt$$

we have that $\mathcal{P}$ is dense in $L^2([-1,1])$. Thus, if we take $f_n(t) = t^n$, then the sequence (f_n) $(n \geq 0)$ is total in $L^2([-1,1])$.

We make an orthonormal basis for $L^2([-1,1])$ by the Gram-Schmidt procedure. Since $\|f_0\| = \sqrt{2}$, e_0 is the constant function $\frac{1}{\sqrt{2}}$. We have that

$$g_1 := f_1 - \langle f_1, e_0\rangle e_0 = t - \frac{1}{\sqrt{2}} \int_{-1}^{1} \frac{t}{\sqrt{2}}\, dt = f_1$$

(actually $f_1 \perp e_0$, so e_1 is just a unit vector in the direction of f_1). Since

$$\|g_1\| = \|f_1\| = \left[\int_{-1}^{1} |t|^2 \, dt\right]^{1/2} = \sqrt{\frac{2}{3}}$$

we have that $e_1(t) = \sqrt{\frac{3}{2}}t$.

Continuing in this manner, we obtain

$$e_n(t) = \sqrt{\frac{2n+1}{2}} p_n(t)$$

where

$$p_n(t) = \frac{1}{2^n n!} \frac{d^n}{dt^n}[(t^2-1)^n]$$

is the *n'th Legendre polynomial* (this expression is called *Rodrigues's formula*). The constants are chosen so that $p_n(1) = 1$ for all n. The polynomial p_n is the solution to the *Legendre differential equation*

$$(1-t^2)y'' - 2ty' + n(n+1)y = 0$$

with $y(1) = 1$. See e.g. [**?**, 3.7] for details, and for more examples of orthonormal bases of function spaces constructed by the Gram-Schmidt procedure.

Note that, as expected, we obtain an orthonormal basis for $L^2([-1,1])$ consisting of polynomials.

XX.11.5.34. The statement (XX.11.5.30.(ii)) that a dense subspace of a Hilbert space $\mathcal{H}$ contains an orthonormal basis for $\mathcal{H}$ can be false if $\mathcal{H}$ is nonseparable. In fact, a Hilbert space of orthogonal dimension $2^{\aleph_0}$ has a dense subspace which does not contain any uncountable orthonormal set [Dix53].

A Crinkled Curve

"There's a lot of room in Hilbert space."

Traditional

XX.11.5.35. In an infinite-dimensional Hilbert space, even a separable one, there are continuous arcs which are "crinkled" in a way impossible in a finite-dimensional Euclidean space: curves which make a right-angled turn at every point. Such a curve cannot be differentiable anywhere in any reasonable sense.

XX.11.5.36. Example. In $L^2([0,1])$ (we can avoid involving measure theory by working in the dense subspace $PC([0,1])$, cf. XX.11.3.9.), for $0 \le t \le 1$ let $f_t = \chi_{[0,t]}$, the indicator function of the subinterval $[0,t]$. It is easy to check that $t \mapsto f_t$ is a one-to-one continuous function from $[0,1]$ into $L^2([0,1])$. If $0 \le a < b < c \le 1$, then the chord $f_b - f_a$ from f_a to f_b is orthogonal to the chord $f_c - f_b$ from f_b to f_c. Thus any two consecutive chords (or indeed any two nonoverlapping chords) are orthogonal! In fact, the entire arcs from 0 to b and from b to 1 lie in orthogonal affine subspaces, i.e. the curve makes a right-angled turn at b.

See XX.11.11.13. for another sense in which "There's a lot of room in Hilbert space."

XX.11.6. Projections

The theory of subspaces and orthogonal complements in a Hilbert space has a nice alternate description in terms of orthogonal projection operators (projections).

XX.11.6.1. Definition. Let $\mathcal{H}$ be a Hilbert space, and $\mathcal{Y}$ a closed subspace. For any vector $x \in \mathcal{H}$, write $x = y + z$ with $y \in \mathcal{Y}$ and $z \in \mathcal{Y}^\perp$, and define $P_\mathcal{Y}(x)$ to be y. Then $\mathcal{P}_\mathcal{Y}$ is a function from $\mathcal{H}$ to $\mathcal{H}$, with range $\mathcal{Y}$. $P_\mathcal{Y}$ is called the *orthogonal projection operator*, or just *projection*, of $\mathcal{H}$ onto $\mathcal{Y}$.

Note that $P_\mathcal{Y}(x)$ is well defined by the uniqueness of the decomposition $x = y + z$ (XX.11.5.7.). We have $P_{\{0\}} = 0$ and $P_\mathcal{H} = I$.

XX.11.6.2. Proposition. Let $\mathcal{H}$ be a Hilbert space, and $\mathcal{Y}$ a closed subspace. Then $P_\mathcal{Y}$ is a bounded linear operator on $\mathcal{H}$ with operator norm $\|P_\mathcal{Y}\| = 1$ (unless $\mathcal{Y} = \{0\}$), and $\mathcal{N}(P_\mathcal{Y}) = \mathcal{Y}^\perp$.

Proof: If $x_1, x_2 \in \mathcal{H}$, and $x_1 = y_1 + z_1$, $x_2 = y_2 + z_2$ with $y_j \in \mathcal{Y}$, $z_j \in \mathcal{Y}^\perp$, then

$$x_1 + x_2 = (y_1 + y_2) + (z_1 + z_2)$$

must be the unique decomposition for $x_1 + x_2$, and thus

$$P_\mathcal{Y}(x_1 + x_2) = y_1 + y_2 = P_\mathcal{Y}(x_1) + P_\mathcal{Y}(x_2) \ .$$

Similarly, if $x \in \mathcal{H}$ and $\alpha \in \mathbb{F}$, and $x = y + z$ is the decomposition of x, then $\alpha x = \alpha y + \alpha z$ is the decomposition of αx, and thus

$$P_\mathcal{Y}(\alpha x) = \alpha y = \alpha P_\mathcal{Y}(x) \ .$$

Thus $P_\mathcal{Y}$ is a linear operator. If $x \in \mathcal{H}$, $x = y + z$, then by XX.11.5.5.

$$\|P_\mathcal{Y}(x)\|^2 = \|y\|^2 \leq \|y\|^2 + \|z\|^2 = \|x\|^2$$

so $P_\mathcal{Y}$ is a bounded operator and $\|P_\mathcal{Y}\| \leq 1$. But if $\mathcal{Y} \neq \{0\}$, and y is a nonzero vector in $\mathcal{Y}$, then $P_\mathcal{Y}(y) = y$, so $\|P_\mathcal{Y}\| = 1$.

It is obvious that $P_\mathcal{Y}(x) = 0$ if and only if $x \in \mathcal{Y}^\perp$. 👍

XX.11.6.3. Orthogonal projection operators are the simplest kinds of non-scalar bounded operators on a Hilbert space. They are the "building blocks" for general self-adjoint operators via the Spectral Theorem ().

XX.11.6.4. Proposition. Let $\mathcal{H}$ be a Hilbert space, and $\mathcal{Y}$ a closed subspace. Then $P_\mathcal{Y}$ is an idempotent operator on $\mathcal{H}$, i.e. $P_\mathcal{Y}^2 = P_\mathcal{Y}$. Every idempotent bounded operator P on $\mathcal{H}$ with $\|P\| \leq 1$ is an orthogonal projection operator, i.e. $P = P_\mathcal{X}$ for some closed subspace $\mathcal{X}$ of $\mathcal{H}$.

Proof: If $x \in \mathcal{H}$, $x = y + z$, then

$$P_\mathcal{Y}^2(x) = P_\mathcal{Y}(P_\mathcal{Y}(x)) = P_\mathcal{Y}(y) = y = P_\mathcal{Y}(x) \ .$$

Conversely, if $P^2 = P$, let $\mathcal{X}$ be the range of P. If $x \in \mathcal{X}$, then $x = P(v)$ for some $v \in \mathcal{H}$, so $P(x) = P^2(v) = P(v) = x$. If $w = v - x$, we then have $w \in \mathcal{N}(P)$ and $v = x + w$; thus, if v is any vector in $\mathcal{H}$, we can write $v = P(v) + w$ with $w \in \mathcal{N}(P)$. If $x \in \mathcal{X}$ and $w \in \mathcal{N}(P)$, then, for any $\alpha \in \mathbb{F}$,

$$\|x\| = \|P(x + \alpha w)\| \leq \|x + \alpha w\|$$

if $\|P\| \leq 1$; thus $x \perp w$ by XX.11.5.6., i.e. $\mathcal{N}(P) \subseteq \mathcal{X}^\perp$. But if $v \in \mathcal{X}^\perp$, we can write $v = P(v) + w$ with $w \in \mathcal{N}(P)$. Since $P(v) \in \mathcal{X}$ and $w \in \mathcal{X}^\perp$, we must have $v = w$ by XX.11.5.7., i.e. $v \in \mathcal{N}(P)$, $\mathcal{N}(P) = \mathcal{X}^\perp$. Since $\mathcal{X} = \{x \in \mathcal{H} : P(x) = x\}$ and P is bounded, if $x_n \in \mathcal{X}$ and $x_n \to x$, then $x_n = P(x_n) \to P(x)$, so $x = P(x)$, $x \in \mathcal{X}$, and $\mathcal{X}$ is closed (this can be seen more easily by noting that $\mathcal{X}$ is the null space of the bounded operator $I - P$). Thus, if $v \in \mathcal{H}$, and $v = x + w$ for $x \in \mathcal{X}$, $w \in \mathcal{X}^\perp$, we have $P(v) = x = P_{\mathcal{X}}(v)$. 👍

Thus the projections have a simple algebraic characterization: they are exactly the idempotent bounded operators on $\mathcal{H}$ of norm ≤ 1.

Here are some other elementary properties of projections:

XX.11.6.5. PROPOSITION. Let $\mathcal{H}$ be a Hilbert space, and $\mathcal{Y}$ a closed subspace. Then $P_{\mathcal{Y}^\perp} = I - P_{\mathcal{Y}}$.

XX.11.6.6. The projection $I - P$ is often written $P^\perp$. Thus $P_{\mathcal{Y}^\perp} = P_{\mathcal{Y}}^\perp$. We say two projections P and Q are *orthogonal*, written $P \perp Q$, if $PQ = 0$. We have $P_{\mathcal{X}} \perp P_{\mathcal{Y}}$ if and only if $\mathcal{Y} \subseteq \mathcal{X}^\perp$. Also, if $P \perp Q$, then $P + Q$ is a projection (and conversely). We have $P \perp P^\perp$ for any P.

XX.11.6.7. PROPOSITION. Let $\mathcal{X}$ and $\mathcal{Y}$ be closed subspaces of $\mathcal{H}$. The following are equivalent:

(i) $\mathcal{X} \subseteq \mathcal{Y}$.

(ii) $P_{\mathcal{X}} P_{\mathcal{Y}} = P_{\mathcal{Y}} P_{\mathcal{X}} = P_{\mathcal{X}}$.

(iii) $P_{\mathcal{Y}} - P_{\mathcal{X}}$ is a projection (it is $P_{\mathcal{Y} \cap \mathcal{X}^\perp}$).

XX.11.6.8. This result suggests that we can put a reasonable partial order on the projections on $\mathcal{H}$ by setting $P \leq Q$ if $PQ = QP = P$. Thus $P_{\mathcal{X}} \leq P_{\mathcal{Y}}$ if and only if $\mathcal{X} \subseteq \mathcal{Y}$, i.e. $P \leq Q$ if and only if $\mathcal{R}(P) \subseteq \mathcal{R}(Q)$. There is a "largest" projection I and a "smallest" projection 0 under this partial order. Any collection $\{P_j\}$ of projections has an infimum $P = \bigwedge_j P_j$ and a supremum $Q = \bigvee_j P_j$: if $P_j = P_{\mathcal{X}_j}$, then $P = P_{\mathcal{X}}$, where $\mathcal{X} = \cap_j \mathcal{X}_j$, and $Q = P_{\mathcal{Y}}$, where $\mathcal{Y}$ is the closed linear span of $\cup_j \mathcal{X}_j$. In particular, if P and Q are projections, with $P = P_{\mathcal{X}}$ and $Q = P_{\mathcal{Y}}$, then $P \wedge Q$ is $P_{\mathcal{X} \cap \mathcal{Y}}$ and $P \vee Q$ is $P_{\{\mathcal{X} + \mathcal{Y}\}^-}$. Thus the projections on $\mathcal{H}$ form a complete lattice ().

Using the complement $P \mapsto P^\perp = I - P$, the projections on $\mathcal{H}$ form a complete Boolean algebra.

XX.11.6.9. **Caution:** Two projections P and Q do not commute (i.e. $PQ \neq QP$) in general: for example, consider projections from $\mathbb{R}^2$ onto two one-dimensional subspaces which are distinct but not orthogonal. $P_{\mathcal{X}}$ and $P_{\mathcal{Y}}$ commute if and only if the subspaces $\mathcal{X}$ and $\mathcal{Y}$ are "nicely situated" with respect to each other. If $PQ = QP$, we have $P \wedge Q = PQ$ and $P \vee Q = P + Q - PQ$. In general, there are no simple algebraic formulas for $P \wedge Q$ or $P \vee Q$. If $P \perp Q$, i.e. if $PQ = 0$, then also $QP = 0$ and $P \wedge Q = 0$, $P \vee Q = P + Q$.

XX.11.7. Dual Spaces and Weak Topology

Bounded linear functionals on a Hilbert space are easy to describe:

XX.11.7.1. THEOREM. [RIESZ-FRÉCHET] Let $\mathcal{H}$ be a Hilbert space, and ϕ a bounded linear functional on $\mathcal{H}$. Then there is a (unique) vector $\xi \in \mathcal{H}$ with $\phi(\eta) = \langle \eta, \xi \rangle$ for all $\eta \in \mathcal{H}$; and $\|\xi\| = \|\phi\|$.

PROOF: We may assume $\|\phi\| = 1$. $\mathcal{N}(\phi)$ is a closed subspace of $\mathcal{H}$ of codimension one. Thus there is a unique unit vector $\xi \in \mathcal{N}(\phi)^\perp$ with $\phi(\xi) > 0$. Set $t = \phi(\xi)$. Then $t \leq 1$. If $\eta \in \mathcal{H}$, then

$$\eta = \langle \eta, \xi \rangle \xi + \zeta$$

for some $\zeta \in \mathcal{N}(\phi)$, and thus $\phi(\eta) = \langle \eta, \xi \rangle t$. Let $\epsilon > 0$. There is a unit vector $\eta \in \mathcal{H}$ with $|\phi(\eta)| > 1 - \epsilon$. Then, by the CBS inequality,

$$t \geq |\langle \eta, \xi \rangle| t = |\phi(\eta)| > 1 - \epsilon \ .$$

Since $\epsilon > 0$ is arbitrary, $t = 1$. If $\phi(\eta) = \langle \eta, \xi_1 \rangle$ for all η, then $\langle \eta, \xi - \xi_1 \rangle = 0$ for all η, and thus $\xi_1 = \xi$. 👍

So the dual space $\mathcal{H}^*$ of $\mathcal{H}$ may be identified with $\mathcal{H}$ (the identification is conjugate-linear), and the weak (= weak-*) topology is given by the inner product: $\xi_i \to \xi$ weakly if $\langle \xi_i, \eta \rangle \to \langle \xi, \eta \rangle$ for all η. In particular, a Hilbert space is a reflexive Banach space and the unit ball is therefore weakly compact. A useful way of stating this is:

XX.11.7.2. COROLLARY. Let $\mathcal{H}$ be a Hilbert space. If (ξ_i) is a bounded weak Cauchy net in $\mathcal{H}$ (i.e. $(\langle \xi_i, \eta \rangle)$ is Cauchy for all $\eta \in \mathcal{H}$), then there is a (unique) vector $\xi \in \mathcal{H}$ such that $\xi_i \to \xi$ weakly, i.e. $\langle \xi_i, \eta \rangle \to \langle \xi, \eta \rangle$ for all $\eta \in \mathcal{H}$.

The weak topology is, of course, distinct from the norm topology (strictly weaker) if $\mathcal{H}$ is infinite-dimensional: for example, an orthonormal sequence of vectors converges weakly to 0. The next proposition gives a connection.

XX.11.7.3. PROPOSITION. Let $\mathcal{H}$ be a Hilbert space, $\xi_i, \xi \in \mathcal{H}$, with $\xi_i \to \xi$ weakly. Then $\|\xi\| \leq \liminf \|\xi_i\|$, and $\xi_i \to \xi$ in norm if and only if $\|\xi_i\| \to \|\xi\|$.

PROOF: $\|\xi\|^2 = \lim \langle \xi_i, \xi \rangle \leq \|\xi\| \liminf \|\xi_i\|$ by the CBS inequality.

$$\|\xi_i - \xi\|^2 = \langle \xi_i, \xi_i \rangle - \langle \xi_i, \xi \rangle - \langle \xi, \xi_i \rangle + \langle \xi, \xi \rangle$$

which goes to zero if and only if $\|\xi_i\| \to \|\xi\|$. 👍

XX.11.7.4. If $\mathcal{H}$ is infinite-dimensional, then the weak topology on $\mathcal{H}$ is not first countable, and a weakly convergent net need not be (norm-)bounded. It is an easy consequence of Uniform Boundedness (XX.8.4.1.) that a weakly convergent sequence is bounded. For example, if $\{\xi_n\}$ is an orthonormal sequence in $\mathcal{H}$, then 0 is in the weak closure of $\{\sqrt{n}\xi_n\}$, but no subsequence converges weakly to 0 (cf. [Hal82, Problem 28], [**?**]). If $\mathcal{H}$ is separable, then the restriction of the weak topology to the unit ball of $\mathcal{H}$, and hence to any bounded set, is metrizable [Hal82, Problem 24].

XX.11.8. Direct Sums and Amplifications

There are two standard constructions on Hilbert spaces which are used repeatedly, direct sum and tensor product. Tensor products are discussed in XX.11.9..

XX.11.8.1. If $\{\mathcal{H}_i : i \in \Omega\}$ is a set of Hilbert spaces, we can form the Hilbert space direct sum, denoted $\bigoplus_\Omega \mathcal{H}_i$, as the set of "sequences" (indexed by Ω) $(\cdots \xi_i \cdots)$, where $\xi_i \in \mathcal{H}_i$ and $\sum_i \|\xi_i\|^2 < \infty$ (so $\xi_i \neq 0$ for only countably many i). The inner product is given by

$$\langle(\cdots \xi_i \cdots), (\cdots \eta_i \cdots)\rangle = \sum_i \langle \xi_i, \eta_i \rangle.$$

This is the completion of the algebraic direct sum with respect to this inner product. If all $\mathcal{H}_i$ are the same $\mathcal{H}$, the direct sum is called the *amplification* of $\mathcal{H}$ by $card(\Omega)$. The amplification of $\mathcal{H}$ by n (the direct sum of n copies of $\mathcal{H}$) is denoted by $\mathcal{H}^n$; the direct sum of countably many copies of $\mathcal{H}$ is denoted $\mathcal{H}^\infty$ (or sometimes $l^2(\mathcal{H})$).

Unless otherwise qualified, a "direct sum" of Hilbert spaces will always mean the Hilbert space direct sum.

XX.11.9. Tensor Products of Inner Product Spaces

We can form the (algebraic) tensor product of any (finite) collection of vector spaces over a field $\mathbb{F}$ (). If $\mathbb{F}$ is $\mathbb{R}$ or $\mathbb{C}$ and each of the vector spaces has a specified inner product, there is a canonical way to form an inner product on the tensor product.

XX.11.9.1. **Notation:** In functional analysis, it is customary to use the symbol $\odot$ instead of $\otimes$ for the algebraic tensor product of Hilbert spaces. The reason is that the algebraic tensor product of infinite-dimensional Hilbert spaces is not complete with respect to the induced inner product (it is if the spaces are finite-dimensional). But it can be completed to form a Hilbert space which is called the Hilbert space tensor product; the symbol $\otimes$ is used for the Hilbert space tensor product. We will use $\odot$ for the algebraic tensor product in this section, so our notation will be inconsistent with ().

XX.11.9.2. Definition. Let $(\mathcal{V}_k, \langle\cdot,\cdot\rangle_k)$ $(1 \leq k \leq n)$ be a finite collection of inner product spaces over $\mathbb{F}$ ($\mathbb{R}$ or $\mathbb{C}$). On the algebraic tensor product $\mathcal{V} = \mathcal{V}_1 \odot \cdots \odot \mathcal{V}_n$ over $\mathbb{F}$ define an $\mathbb{F}$-valued function on elementary tensors by

$$\langle \xi_1 \otimes \cdots \otimes \xi_n, \eta_1 \otimes \cdots \otimes \eta_n \rangle = \langle \xi_1, \eta_1 \rangle_1 \cdot \langle \xi_2, \eta_2 \rangle_2 \cdots \langle \xi_n, \eta_n \rangle_n$$

and extend to all of $\mathcal{V}$ by linearity.

XX.11.9.3. PROPOSITION. The function $\langle \cdot, \cdot \rangle$ is well defined on $\mathcal{V}$ and is an inner product.

XX.11.9.4. DEFINITION. If $\mathcal{H}_1$, $\mathcal{H}_2$ are Hilbert spaces, the Hilbert space tensor product $\mathcal{H}_1 \otimes \mathcal{H}_2$ is the completion of $\mathcal{H}_1 \odot \mathcal{H}_2$. Tensor products of finitely many Hilbert spaces are defined similarly. (Infinite tensor products are trickier and will be discussed in **??**.)

There is a nice way to view the tensor product of two (or more) Hilbert spaces:

XX.11.9.5. PROPOSITION. If $\mathcal{H}$ and $\mathcal{H}'$ are Hilbert spaces and $\{\eta_j : j \in \Omega\}$ is an orthonormal basis for $\mathcal{H}'$, then there is an isometric isomorphism from $\mathcal{H} \otimes \mathcal{H}'$ to the amplification (XX.11.8.1.) of $\mathcal{H}$ by $card(\Omega)$, given by $\sum_i \xi_i \otimes \eta_i \mapsto (\cdots \xi_i \cdots)$. In particular, $\mathcal{H}^n$ is naturally isomorphic to $\mathcal{H} \otimes \mathbb{C}^n$ and $\mathcal{H}^\infty \cong \mathcal{H} \otimes l^2$.

XX.11.9.6. If $\{\xi_j : j \in \Omega\}$ and $\{\eta_k : k \in \Lambda\}$ are orthonormal bases for $\mathcal{H}$ and $\mathcal{H}'$ respectively, then

$$\{\xi_j \otimes \eta_k : (j,k) \in \Omega \times \Lambda\}$$

is an orthonormal basis for $\mathcal{H} \otimes \mathcal{H}'$, and similarly for general finite tensor products. If $\mathcal{H}$ or $\mathcal{H}'$ is finite-dimensional, there is no distinction between $\mathcal{H} \odot \mathcal{H}'$ and $\mathcal{H} \otimes \mathcal{H}'$ since $\mathcal{H} \odot \mathcal{H}'$ is already complete. If both are finite-dimensional, $dim(\mathcal{H}) = n$ and $dim(\mathcal{H}') = m$, then $dim(\mathcal{H} \otimes \mathcal{H}') = nm$.

XX.11.9.7. The usual commutative and associative isomorphisms $\mathcal{H}_1 \otimes \mathcal{H}_2 \cong \mathcal{H}_2 \otimes \mathcal{H}_1$ and $(\mathcal{H}_1 \otimes \mathcal{H}_2) \otimes \mathcal{H}_3 \cong \mathcal{H}_1 \otimes (\mathcal{H}_2 \otimes \mathcal{H}_3) \cong \mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \mathcal{H}_3$, etc., are all isometric.

XX.11.9.8. EXAMPLE. If $(\mathcal{X}, \mu)$ is a measure space and $\mathcal{H}$ is a separable Hilbert space, then the Hilbert space $L^2(X,\mu) \otimes \mathcal{H}$ is naturally isomorphic to $L^2(X, \mu, \mathcal{H})$, the set of weakly measurable functions $f : X \to \mathcal{H}$ (i.e. $x \mapsto \langle f(x), \eta \rangle$ is a complex-valued measurable function for all $\eta \in \mathcal{H}$) such that $\int_X \|f(x)\|^2 \, d\mu(x) < \infty$, with inner product

$$\langle f, g \rangle = \int_X \langle f(x), g(x) \rangle \, d\mu(x).$$

The isomorphism sends $f \otimes \eta$ to $(x \mapsto f(x)\eta)$.

XX.11.10. Real Hilbert Spaces

One can also consider *real inner product spaces*, real vector spaces with a (bilinear, real-valued) inner product $(\cdot, \cdot)$ satisfying the properties of **??** for $\alpha \in \mathbb{R}$. A *real Hilbert space* is a complete real inner product space. A real Hilbert space $\mathcal{H}_\mathbb{R}$ can be complexified to $\mathbb{C} \otimes_\mathbb{R} \mathcal{H}_\mathbb{R}$; conversely, a (complex) Hilbert space can be regarded as a real Hilbert space by restricting scalar multiplication and using the real inner product $(\xi, \eta) = Re\langle \xi, \eta \rangle$. (Note, however, that these two processes are not quite inverse to each other.) All of the results of this section, and many (but by no means all) results about operators, hold verbatim or have obvious exact analogs in the case of real Hilbert spaces.

Throughout this volume, the term "Hilbert space," unless qualified with "real," will always denote a *complex* Hilbert space; and "linear" will mean "complex-linear."

XX.11.11. Exercises

XX.11.11.1. Prove the CBS inequality for $\mathbb{R}^n$ as follows. Let $\boldsymbol{x} = (x_1, \ldots, x_n)$ and $\boldsymbol{y} = (y_1, \ldots, y_n)$.

(a) Show that

$$\left(\sum_{k=1}^{n} x_k y_k\right)^2 + \sum_{j<k} (x_j y_k - x_k y_j)^2 = \left(\sum_{k=1}^{n} x_k^2\right)\left(\sum_{k=1}^{n} y_k^2\right) .$$

(b) Use that all the terms in the second sum are nonnegative to deduce the CBS inequality.

(c) Equality holds in the CBS inequality if and only if all terms in the second sum are zero. Show that this implies that $\{\boldsymbol{x}, \boldsymbol{y}\}$ is linearly dependent.

This was CAUCHY'S proof of the CBS inequality from [Cau21].

XX.11.11.2. Give another proof of the CBS inequality for $\mathbb{R}^n$ as follows.

(a) Show that for $x, y \in \mathbb{R}$, $|xy| \leq \frac{1}{2}(x^2 + y^2)$, with equality if and only if $y = \pm x$. [Use that $(x+y)^2$ and $(x-y)^2$ are nonnegative.]

(b) Show that it suffices to prove the CBS inequality for $\boldsymbol{x}, \boldsymbol{y}$ of norm 1.

(c) if $\boldsymbol{x} = (x_1, \ldots, x_n)$ and $\boldsymbol{y} = (y_1, \ldots, y_n)$ have norm 1, then

$$\left|\sum_{k=1}^{n} x_k y_k\right| \leq \sum_{k=1}^{n} |x_k y_k| \leq \frac{1}{2}\left(\sum_{k=1}^{n} x_k^2 + \sum_{k=1}^{n} y_k^2\right) = 1$$

with equality if and only if $\boldsymbol{y} = \pm \boldsymbol{x}$.

XX.11.11.3. Let f and g be real-valued continuous functions on $[a, b]$. Use Riemann sums for $\int_a^b f(t)g(t)\,dt$, $\int_a^b [f(t)]^2\,dt$, and $\int_a^b [g(t)]^2\,dt$, and the CBS inequality for $\mathbb{R}^n$, to prove

$$\left(\int_a^b f(t)g(t)\,dt\right)^2 \leq \left(\int_a^b [f(t)]^2\,dt\right)\left(\int_a^b [g(t)]^2\,dt\right)$$

with equality if and only if $\{f, g\}$ is linearly dependent. This was BUNYAKOVSKII'S inequality and proof from [Bun59].

XX.11.11.4. Let $(\mathcal{V}, \langle \cdot, \cdot \rangle)$ be a real pre-inner product space, and $x, y \in \mathcal{V}$.

(a) Write $\langle x + \alpha y, x + \alpha y \rangle$ as a quadratic function of α.

(b) Use the quadratic formula and the fact that $\langle x + \alpha y, x + \alpha y \rangle \geq 0$ for all α to deduce the CBS inequality.

This was essentially SCHWARZ'S proof from [Sch88] (he only explicitly considered the case where the inner product was given by a (multiple) integral as in XX.11.1.4.(ii).)

XX.11.11.5. Deduce the CBS inequality for complex pre-inner products from the inequality for real pre-inner products. [Consider the real inner product $(x, y) = Re(\langle x, y \rangle)$ and suitable scalar multiples.] This gives a simpler proof for indefinite complex inner products.

XX.11.11.6. [Ste04] Prove the CBS inequality for the standard inner product on $\mathbb{R}^n$ by induction, starting with the case $n = 2$ (it is trivial for $n = 1$).

XX.11.11.7. (a) Justify the name "Parallelogram Law" by giving a geometric interpretation in terms of the lengths of the diagonals of a parallelogram. [If $\boldsymbol{x}, \boldsymbol{y} \in \mathbb{R}^2$, consider the parallelogram with vertices $\mathbf{0}, \boldsymbol{x}, \boldsymbol{y}, \boldsymbol{x} + \boldsymbol{y}$.] See VI.3.1.22.. Show that the Pythagorean Theorem is the special case of the Parallelogram Law for a rhombus. [Given a right triangle, assemble four copies into a rhombus.]

(b) Show that the Parallelogram Law is equivalent to the statement that

$$\|x + y\|^2 - \|x - y\|^2 = 2(\|x + y\|^2 - \|x\|^2 - \|y\|^2)$$

for all x, y.

(c) Show that in an inner product space,

$$\langle x, y\rangle = \frac{1}{2}[(\|x + y\|^2 - \|x\|^2 - \|y\|^2) + i(\|x + iy\|^2 - \|x\|^2 - \|y\|^2)]$$

for all x, y. Give a similar formula for real inner products.

XX.11.11.8. Let $\mathcal{V}$ be a normed vector space over $\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$. Show that the norm on $\mathcal{V}$ comes from an inner product if and only if every two-dimensional subspace of $\mathcal{V}$ is isometrically isomorphic to $\mathbb{F}^2$ with the induced norm from the standard inner product.

XX.11.11.9. Suppose $(\mathcal{V}, \langle\cdot,\cdot\rangle)$ is an inner product space. Expand the right side of the Polarization Identity (XX.11.2.8.) to show that the identity is satisfied.

XX.11.11.10. (a) In $C([0, 1])$, let f_n $(n \geq 2)$ be defined by

$$f_n(t) = \begin{cases} 0 & \text{if} \quad 0 \leq t \leq \frac{1}{2} \\ \text{linear} & \text{if} \quad \frac{1}{2} \leq t \leq \frac{1}{2} + \frac{1}{n} \\ 1 & \text{if} \quad \frac{1}{2} \leq t \leq 1 \end{cases} .$$

Show that (f_n) is a uniformly bounded sequence in $C([0, 1])$ which is a Cauchy sequence with respect to the norm induced by the inner product, but which does not converge in $C([0, 1])$ in the induced norm. (Note that we have referred here to the uniform norm $\|\cdot\|_\infty$ () as well as the norm induced by the inner product; in this problem and succeeding problems we discuss Cauchy sequences and convergence only with respect to the norm induced by the inner product. The sequence (f_n) is bounded but not Cauchy in the uniform norm.)

(b) It is slightly harder to show that $PC([0, 1])$ (XX.11.3.9.) is not complete. Let g_n $(n \geq 2)$ be defined by

$$g_n(t) = \begin{cases} 0 & \text{if} \quad 0 \leq t \leq \frac{1}{n} \\ \sin\left(\frac{\pi}{t}\right) & \text{if} \quad \frac{1}{n} < t \leq 1 \end{cases} .$$

Show that (g_n) defines a uniformly bounded Cauchy sequence in $C([0, 1])$ which does not converge in $PC([0, 1])$.

(c) It is easier to give an example of a nonconvergent Cauchy sequence which is not uniformly bounded. Let

$$h_n(t) = \min\left(n, \frac{1}{\sqrt[3]{t}}\right)$$

for $0 \leq t \leq 1$. Then (h_n) is a Cauchy sequence in $C([0, 1])$ which does not converge even in $PC([0, 1])$.

XX.11.11.11. Let $\mathcal{R}([a,b])$ be the set of complex-valued Riemann-integrable functions on $[a,b]$.

(a) Show that the formula

$$\langle f,g\rangle = \int_a^b f(t)\overline{g(t)}\,dt$$

(where the integral is a Riemann integral) defines a pre-inner product on $\mathcal{R}([a,b])$.

(b) Explicitly describe the space $\mathcal{N}$.

(c) Let $R([a,b]) = \mathcal{R}([a,b])/\mathcal{N}$. Show that $PC([a,b])$ can be naturally identified with a dense subspace of $R([a,b])$.

(d) The Cauchy sequence (h_n) of XX.11.11.10.(c) does not converge in $R([0,1])$.

(e) Find a uniformly bounded Cauchy sequence in $R([a,b])$ that does not converge. [A Cantor set of positive measure () is helpful.]

(f) Try to describe the completion of $R([a,b])$ (which will also be the completion of $C([a,b])$ and $PC([a,b])$ since these are dense in $R([a,b])$). The example in (d) shows that we must at least add all nonnegative improperly Riemann square-integrable functions on $[a,b]$, but (e) shows that even linear combinations of these do not give enough. The answer involves Lebesgue measure and integration (); this example gives good motivation for development of the Lebesgue theory.

XX.11.11.12. Let $(\mathcal{V},\langle\cdot,\cdot\rangle)$ be a (real or complex) inner product space. Let $\mathcal{H}$ be the set of equivalence classes of Cauchy sequences in $\mathcal{V}$ as in the proof of (). Show that

$$\langle[(x_n)],[(y_n)]\rangle = \lim_{n\to\infty}\langle x_n,y_n\rangle$$

gives a well-defined inner product on $\mathcal{H}$ inducing the norm defined in ().

XX.11.11.13. Let $\mathcal{H}$ be an infinite-dimensional Hilbert space (real or complex).

(a) Show that for every $r>0$, an open ball of radius $3r$ in $\mathcal{H}$ contains infinitely many pairwise disjoint open balls of radius r. If $\mathcal{H}$ is nonseparable, an open ball of radius $3r$ contains uncountably many pairwise disjoint open balls of radius r. [Consider open balls centered at points of an orthonormal basis.] This is one justification for the statement "There's a lot of room in Hilbert space."

(b) Use (a) to show that there is no translation-invariant Borel measure on $\mathcal{H}$ for which open balls have finite positive measure.

(c) Show that an open ball of radius $2r$ in a Hilbert space (finite- or infinite-dimensional, real or complex) cannot contain more than two disjoint open balls of radius r. [If there are three such balls, consider the two-dimensional real affine subspace spanned by the centers.]

(d) In (a), 3 may be replaced by $1+\sqrt{2}\approx 2.414$ and in (c), 2 may be replaced by any number less than $1+\frac{2}{\sqrt{3}}\approx 2.1547$. (These numbers are surprisingly close together.) In fact, for any $n\in\mathbb{N}$, an open ball of radius $1+\sqrt{2\left(1-\frac{1}{n}\right)}$ is the smallest open ball containing n pairwise disjoint open balls of radius 1 in any Hilbert space of (real) dimension $n-1$ or greater; cf. https://mathoverflow.net/questions/369444/balls-in-hilbert-space (the unit balls are centered at the vertices of a regular $(n-1)$-simplex, and the large ball at the centroid). The question of the smallest open ball in a Hilbert space of (real) dimension $d<n-1$ containing n pairwise disjoint open balls of radius 1 appears to be much harder; it is essentially the optimal sphere-packing problem for fixed d and $n\gg d$ (XIII.19.4.11.).

XX.11.11.14. Let $\{\mathcal{X}_i : i \in I\}$ be an indexed collection of Banach spaces. Define the *ℓ^2-direct sum* $\bigoplus_{\ell^2} \mathcal{X}_i$ to be the subset of $\prod_{i\in I} \mathcal{X}_i$ consisting of all elements $(\cdots x_i \cdots)$ for which $\sum_{i\in I} \|x_i\|^2 < \infty$. (Note that $\bigoplus_{\ell^2} \mathcal{X}_i = \prod_{i\in I} \mathcal{X}_i$ if I is finite.)

(a) Let $\mathcal{X} = \bigoplus_{\ell^2} \mathcal{X}_i$. Show that $\mathcal{X}$ is a vector subspace of $\prod_{i\in I} \mathcal{X}_i$ and that $\|\cdot\|$ defined on $\mathcal{X}$ by

$$\|(\cdots x_i \cdots)\| = \left[\sum_{i\in I} \|x_i\|^2\right]^{1/2}$$

is a norm on $\mathcal{X}$.

(b) Show that $(\mathcal{X}, \|\cdot\|)$ is complete, i.e. a Banach space.

(c) Show that if each $\mathcal{X}_i$ is a Hilbert space (i.e. the norm satisfies the Parallelogram Law), then $\mathcal{X}$ is also a Hilbert space.

XX.11.11.15. Uniformly Convex Banach Spaces. Let $\mathcal{X}$ be a Banach space. $\mathcal{X}$ is *strictly convex* if, whenever $x, y \in \mathcal{X}$, $x \neq y$, $\|x\| = \|y\| = 1$, we have $\left\|\frac{1}{2}(x+y)\right\| < 1$. $\mathcal{X}$ is *uniformly convex* if for every $\epsilon > 0$ there is a $\delta > 0$ such that, whenever $x, y \in X$, $\|x\| = \|y\| = 1$, $\|x-y\| > \epsilon$, we have $\left\|\frac{1}{2}(x+y)\right\| < 1-\delta$. Note that a uniformly convex Banach space is strictly convex.

(a) Show that $\mathcal{X}$ is strictly convex if and only if every element of $\mathcal{X}$ of norm 1 is an extreme point of the closed unit ball of $\mathcal{X}$ ().

(b) Show that any (closed) subspace of a strictly [resp. uniformly] convex Banach space is strictly [resp. uniformly] convex.

(c) Use the Parallelogram Law to show that any Hilbert space is uniformly convex (cf. XX.11.4.2.).

(d) Prove *Clarkson's Inequality* [**?**]: if $z, w \in \mathbb{C}$, $p \in [2, \infty)$, $q = \frac{p}{p-1}$ (XX.15.1.1.), then

$$|z+w|^p + |z-w|^p \leq 2(|z|^q + |w|^q)^{p/q}$$

$$|z+w|^q + |z-w|^q \geq 2(|z|^p + |w|^p)^{q/p}$$

(the case $p = 2$ is just the Parallelogram Law).

(e) Show that $(\mathbb{R}^n, \|\cdot\|_p)$ is uniformly convex for $1 < p < \infty$, but that $(\mathbb{R}^n, \|\cdot\|_1)$ and $(\mathbb{R}^n, \|\cdot\|_\infty)$ are not strictly convex. What about ℓ^p or $L^p(X, \mathcal{A}, \mu)$ for a measure space $(X, \mathcal{A}, \mu)$?

(f) Show that a strictly convex finite-dimensional Banach space is uniformly convex.

(g) Show that any ℓ^2-direct sum (XX.11.11.14.) of strictly convex Banach spaces is strictly convex.

(h) Show that $\bigoplus_{\ell^2}(\mathbb{R}^2, \|\cdot\|_p)$ for $p \in \mathbb{N}$, $p \geq 2$, is strictly convex but not uniformly convex. Thus (g) is not true if "strictly" is replaced by "uniformly." (But it is if the index set is finite.)

(i) Formulate and prove a precise statement to the effect that $\bigoplus_{\ell^2} \mathcal{X}_i$ is uniformly convex if and only if the $\mathcal{X}_i$ are "uniformly uniformly convex." Deduce the last statement of (h).

(j) Adapt the proof of XX.11.4.1. to show that every uniformly convex Banach space has the best approximation property.

It is known that a uniformly convex Banach space is always reflexive (Milman-Pettis Theorem). A strictly convex Banach space need not be reflexive; in fact, every separable Banach space has an equivalent strictly convex norm (cf. https://math.stackexchange.com/questions/488790/is-there-a-non-reflexive-banach-space-whi rq=1).

XX.11.11.16. Let $\mathcal{H}$ be a Hilbert space (real or complex).

(a) Show that the norm topology and weak topology coincide on the unit sphere of $\mathcal{H}$. [Use XX.11.7.3..]

(b) Show that this fails in most Banach spaces, even Banach spaces isomorphic to a Hilbert space. [If $\mathcal{H}$ is a Hilbert space, consider $\mathbb{F} \oplus \mathcal{H}$ with max norm $\|(\lambda, x)\| = \max(|\lambda|, \|x\|)$, and recall that an orthonormal sequence in $\mathcal{H}$ converges to 0 weakly.] Is it true in a uniformly convex Banach space?

XX.11.12. Sesquilinear Forms and Operators

XX.11.12.1. If $\mathcal{X}$ is a normed complex vector space, $\mathcal{H}$ a Hilbert space, and $T : \mathcal{X} \to \mathcal{H}$ a bounded operator, set

$$B(x, y) = \langle Tx, y\rangle \ .$$

Then it is easily checked that B is a sesquilinear form on $\mathcal{X} \times \mathcal{H}$, which is *bounded*, i.e. there is a K such that

$$|B(x, y)| \leq K\|x\|\|y\|$$

for all $x \in \mathcal{X}$, $y \in \mathcal{H}$. The smallest such K, the *norm* $\|B\|$ of B, is equal to $\|T\|$.

The following converse establishes a one-one correspondence between bounded operators and bounded sesquilinear forms. We state it for complex spaces; there is an essentially identical analogous version for real spaces, replacing "sesquilinear" with "bilinear."

XX.11.12.2. Proposition. Let $\mathcal{X}$ be a normed vector space, $\mathcal{H}$ a Hilbert space, and B a bounded sesquilinear form on $\mathcal{X} \times \mathcal{H}$. Then there is a unique bounded operator $T : \mathcal{X} \to \mathcal{H}$ such that

$$B(x, y) = \langle Tx, y\rangle$$

for all $x \in \mathcal{X}$, $y \in \mathcal{H}$. $\|T\| = \|B\|$.

Proof: Fix $x \in \mathcal{X}$. Define $\phi : \mathcal{H} \to \mathbb{C}$ by $\phi(y) = B(x, y)$. Then ϕ is a conjugate-linear functional on $\mathcal{H}$, and ϕ is bounded ($\|\phi\| \leq \|B\|\|x\|$). Thus by XX.11.7.1. there is a unique $z \in \mathcal{H}$ with

$$\phi(y) = B(x, y) = \langle z, y\rangle \ .$$

Set $Tx = z$. In this way a function $T : \mathcal{X} \to \mathcal{H}$ is defined. It is an easy consequence of the linearity of B in the first variable that T is linear. If $x \in \mathcal{X}$, we have

$$\|Tx\| = \sup_{\|y\|=1} |\langle Tx, y\rangle| = \sup_{\|y\|=1} |B(x, y)| \leq \|B\|\|x\|$$

and thus T is bounded and $\|T\| \leq \|B\|$. By taking the supremum over all x with $\|x\| = 1$, we obtain $\|T\| = \|B\|$. 👍

XX.11.12.3. There is thus a one-one correspondence between bounded operators and bounded sesquilinear forms. Each point of view has its advantages. Some early authors such as Hilbert used the form approach exclusively instead of working with operators, but some parts of the theory become almost impossibly difficult and cumbersome (e.g. composition of operators) from this point of view. I. Fredholm and F. Riesz emphasized the operator point of view, which is superior for most purposes.

The following special case of XX.11.12.2. is especially useful in the theory of partial differential equations:

XX.11.12.4. PROPOSITION. Let $\mathcal{H}$ be a Hilbert space, and B a bounded sesquilinear form on $\mathcal{H} \times \mathcal{H}$ for which there is an $\epsilon > 0$ such that

$$|B(x,x)| \geq \epsilon \|x\|^2$$

for all $x \in \mathcal{H}$. Then there is a unique $T \in \mathcal{B}(\mathcal{H})$ with

$$B(x,y) = \langle Tx, y \rangle$$

for all $x, y \in \mathcal{H}$. T is invertible and $\|T\| = \|B\|$. Thus there is a unique $S \in \mathcal{B}(\mathcal{H})$, namely $S = T^{-1}$, such that

$$B(Sx,y) = \langle x, y \rangle$$

for all $x, y \in \mathcal{H}$. S is invertible and $\|S\| \leq \frac{1}{\epsilon}$.

There is an analogous result for real Hilbert spaces, with "sesquilinear" replaced by "bilinear."

XX.11.12.5. COROLLARY. Let $\mathcal{H}$ be a Hilbert space, and B a bounded sesquilinear form on $\mathcal{H} \times \mathcal{H}$ for which there is an $\epsilon > 0$ such that

$$|B(x,x)| \geq \epsilon \|x\|^2$$

for all $x \in \mathcal{H}$. If ϕ is any bounded linear functional on $\mathcal{H}$, then there is a unique $z \in \mathcal{H}$ such that $\phi(x) = B(x,z)$ for all $x \in \mathcal{H}$.

PROOF: Let T and $S = T^{-1}$ be as in XX.11.12.4. (so $(S^*)^{-1} = T^*$). There is a unique $y \in \mathcal{H}$ with $\phi(x) = \langle x, y \rangle$ for all $x \in \mathcal{H}$. Then $z = S^*y$ is such a z:

$$B(x,z) = \langle Tx, z \rangle = \langle x, T^*z \rangle = \langle x, y \rangle = \phi(x)$$

for all x. Conversely, if z is such a vector, then $\phi(x) = \langle x, T^*z \rangle$ for all x, so $T^*z = y$, $z = S^*y$. 👍

XX.11.12.6. For the proof of XX.11.12.4., everything follows immediately from XX.11.12.2. except invertibility of T, which is a consequence of the next elementary result, and uniqueness of S, which is immediate [if S' is another such operator, then for each $x \in \mathcal{H}$ we have $B(Sx,y) = B(S'x,y)$ and hence $B((S-S')x,y) = 0$ for all $y \in \mathcal{H}$, and in particular for $y = (S-S')x$, so

$$0 = |B((S-S')x,(S-S')x)| \geq \epsilon \|(S-S')x\|^2$$

and $(S-S')x = 0$.]

XX.11.12.7. PROPOSITION. Let $\mathcal{H}$ be a Hilbert space, and $T \in \mathcal{B}(\mathcal{H})$ with the property that there is an $\epsilon > 0$ such that $\langle Tx, x \rangle \geq \epsilon \|x\|^2$ for all $x \in \mathcal{H}$. Then T is invertible. $\|T^{-1}\| \leq \frac{1}{\epsilon}$.

PROOF: By the CBS inequality, $\|Tx\| \geq \epsilon \|x\|$ for all $x \in \mathcal{H}$, i.e. T is bounded below. Thus T is one-to-one with closed range (). If $x \perp \mathcal{R}(T)$, then $\langle Tx, x \rangle = 0$, so $x = 0$, and $\mathcal{R}(T)$ is dense in $\mathcal{H}$. Thus $\mathcal{R}(T) = \mathcal{H}$. We have, for any $x \in \mathcal{H}$, $\|x\| = \|T(T^{-1}x)\| \geq \epsilon \|T^{-1}x\|$. 👍

XX.11.12.8. In many references, Proposition XX.11.12.4., or sometimes XX.11.12.5., is called the "Lax-Milgram Theorem" (or sometimes "the famous Lax-Milgram Theorem") since it appeared in [LM54]. Although it is useful, it does not seem to merit named status, let alone fame, since

(1) It is such an easy and obvious consequence of XX.11.7.1. (although the proofs in [LM54] and in some other references such as [Yos80] are unnecessarily complicated).

(2) The more general result XX.11.12.2. was well known to Hilbert, Riesz, and other early workers in Hilbert space, long before Lax and Milgram came along.

Not everything published by prominent mathematicians deserves hagiography.

XX.12. Banach Algebras and Spectral Theory

Most of the advanced study of operators is connected with the spectrum, which is a generalization of the set of eigenvalues. While the most immediate applications of spectral theory are to operators, the theory itself is done most efficiently in the more general context of Banach algebras, and spectral theory has numerous applications beyond the case of operators. We will thus first set up the theory of Banach algebras and develop spectral theory there.

XX.12.1. Banach Algebras

A Banach algebra is a Banach space which has a multiplication with nice compatibility properties:

XX.12.1.1. Definition. Let $\mathbb{F}$ be $\mathbb{R}$ or $\mathbb{C}$. A *normed algebra* over $\mathbb{F}$ is an algebra () A over $\mathbb{F}$ with a norm satisfying

$$\|xy\| \leq \|x\|\|y\|$$

for all $x, y \in A$ (*submultiplicative norm*). If A is a normed algebra which is a Banach space (i.e. is complete), A is a *Banach algebra*.

We thus have real Banach algebras and complex Banach algebras. For technical reasons, we will usually consider complex Banach algebras, especially for spectral theory; thus we will make the convention that the term "Banach algebra" without the qualification "real" will denote a *complex* Banach algebra.

There are a great many important Banach algebras with varied properties. For example:

XX.12.1.2. Examples. (i) Let $\mathcal{X}$ be a Banach space (over $\mathbb{F}$). Then $\mathcal{B}(\mathcal{X})$, with the usual operations and operator norm (), is a Banach algebra (over $\mathbb{F}$).

(ii) Let X be a compact Hausdorff space, and let $C(X)$ be the set of complex-valued continuous functions on X. Give $C(X)$ the usual operations of pointwise addition, pointwise multiplication, and pointwise scalar multiplication, and the supremum norm (). Then $C(X)$ is a (complex) Banach algebra. Similarly, $C_{\mathbb{R}}(X)$ is a real Banach algebra. More generally, if X is locally compact, the set $C_0(X)$ of complex-valued continuous functions vanishing at infinity () is a Banach algebra with the same operations and norm.

(iii) As a special case of (i), $M_n(\mathbb{F}) = \mathcal{B}(\mathbb{F}^n)$ becomes a Banach algebra when given the operator norm from any norm on $\mathbb{F}^n$. Thus there are many norms on $M_n(\mathbb{F})$ making it into a Banach algebra. As a special case, or as a special case of (ii) with X a one-point space, $\mathbb{F}$ is a Banach algebra over $\mathbb{F}$ with norm $\|\alpha\| = |\alpha|$.

(iv) If $\mathcal{X}$ is any Banach space, define $xy = 0$ for all $x, y \in \mathcal{X}$. Then $\mathcal{X}$ is a Banach algebra. (This example is not very interesting, to be sure.)

These examples only scratch the surface of the possibilities, even the interesting possibilities.

Joint Continuity of Multiplication

In a Banach space (or just normed vector space), addition and scalar multiplication are jointly continuous. In a normed algebra, multiplication is also jointly continuous:

XX.12.1.3. PROPOSITION. Let A be a normed algebra. If $x_n, y_n, x, y \in A$ and $x_n \to x$, $y_n \to y$, then $x_n y_n \to xy$.

PROOF: By the usual argument,

$$\|x_n y_n - xy\| = \|x_n y_n - x_n y + x_n y - xy\| \leq \|x_n y_n - x_n y\| + \|x_n y - xy\| \leq \|x_n\|\|y_n - y\| + \|y\|\|x_n - x\| \ .$$

Since (x_n) converges, it is bounded (). 👍

Completion of a Normed Algebra

XX.12.1.4. Similarly, if A is a normed algebra, then its completion () has a natural multiplication making it a Banach algebra. For if (x_n) and (y_n) are Cauchy sequences in A, then, for any n and m,

$$\|x_n y_n - x_m y_m\| = \|x_n y_n - x_n y_m + x_n y_m - x_m y_m\| \leq \|x_n y_n - x_n y_m\| + \|x_n y_m - x_m y_m\| \leq \|x_n\|\|y_n - y_m\| + \|y_m\|\|x_n - x_m\| \ .$$

Since Cauchy sequences are bounded (), it follows that $(x_n y_n)$ is a Cauchy sequence.

Unital Banach Algebras and Unitization

XX.12.1.5. Examples XX.12.1.2.(ii) and (iv) show that a Banach algebra need not have a multiplicative identity. A Banach algebra with a multiplicative identity is a *unital Banach algebra*. The multiplicative identity, if it exists, is generally denoted 1. We usually assume $\|1\| = 1$; while this is not necessarily true in general, the norm can be replaced by an equivalent Banach algebra norm with this property (Exercise XX.12.6.1.).

If a Banach algebra is not unital, a unit can be added in a systematic way:

XX.12.1.6. PROPOSITION. Let A be a nonunital Banach algebra over $\mathbb{F}$. Let $A^\dagger = A \oplus \mathbb{F}$. Define addition and scalar multiplication coordinatewise, and multiplication and a norm by

$$(x, \lambda) \cdot (y, \mu) = (xy + \lambda y + \mu x, \lambda\mu)$$

$$\|(x, \lambda)\| = \|x\| + |\lambda| \ .$$

Then $A^\dagger$ is a unital Banach algebra containing a copy of A as an ideal () of codimension 1, called the *unitization* of A.

The rule for multiplication can be remembered by thinking of (x, λ) as $x + \lambda 1$. (The multiplicative identity is $(0, 1)$.)

PROOF: Checking the algebraic rules for an algebra is routine but tedious, and is left to the reader. It is clear that $\|\cdot\|$ is a norm on $A^\dagger$. For submultiplicativity, if $x, y \in A$, $\lambda, \mu \in \mathbb{F}$,

$$\|(x, \lambda)(y, \mu)\| = \|xy + \lambda y + \mu x\| + |\lambda\mu| \leq \|xy\| + \|\lambda y\| + \|\mu x\| + |\lambda\mu|$$

$$\leq \|x\|\|y\| + |\lambda|\|y\| + |\mu|\|x\| + |\lambda\mu| = (\|x\| + |\lambda|)(\|y\| + |\mu|) \ .$$

The map $x \mapsto (x, 0)$ identifies A with a subalgebra (ideal) of $A^\dagger$. To see that $A^\dagger$ is complete, if (a_n, λ_n) is a Cauchy sequence in $A^\dagger$, then (a_n) is a Cauchy sequence in A and (λ_n) a Cauchy sequence in $\mathbb{F}$. These converge to some a and λ, and $(a_n, \lambda_n) \to (a, \lambda)$. 👍

XX.12.1.7. Many aspects of Banach algebra theory are technically simpler for unital Banach algebras; XX.12.1.6. allows the nonunital case to be largely reduced to the unital case. We do not want to just restrict to unital Banach algebras, however, since many naturally occurring Banach algebras are nonunital. Many, but not all, nonunital Banach algebras have an approximate unit () which can be used as a substitute.

XX.12.2. Invertibility, Ideals, and Quotients

One of the remarkable and appealing aspects of the theory of Banach algebras is the intricate interplay between the topology and the algebraic structure. One of the most basic, and most important, examples of this is the use of power series in Banach algebras to construct inverses (and, later, other elements).

XX.12.2.8. Recall that an element x in a unital algebra A is *invertible* if there is a $y \in A$ with $xy = yx = 1$. **Caution:** Since a Banach algebra is not necessarily commutative, for x to be invertible it is not generally enough that there is a y with $yx = 1$ (such an x is *left invertible*), or that there is a z with $xz = 1$ (such an x is *right invertible*); cf. (). However, as in any unital ring, if x is both left and right invertible, the left and right inverses coincide and x is invertible (and conversely): if $yx = xz = 1$, then

$$y = y(xz) = (yx)z = z \ .$$

XX.12.2.9. THEOREM. Let A be a unital Banach algebra, and $x \in A$. If the power series

$$\sum_{k=0}^{\infty} x^k$$

(where $x^0 = 1$ by convention) converges in A, the sum is a multiplicative inverse for $1 - x$. If $\|x\| < 1$, then the power series converges to a multiplicative inverse for $1 - x$, and

$$\|(1-x)^{-1}\| \leq \frac{1}{1 - \|x\|} \ .$$

PROOF: Suppose the series converges, and let y be the sum. If

$$s_n = \sum_{k=0}^{n} x^k$$

is the partial sum to n, so that $s_n \to y$, we have by a simple calculation that

$$s_n(1-x) = (1-x)s_n = 1 - x^{n+1} \ .$$

The left side converges to $y(1-x) = (1-x)y$, and the right side to 1 since $x^{n+1} \to 0$. For the second statement, since $\|x^k\| \leq \|x\|^k$ for every k by submultiplicativity, we have that

$$\sum_{k=1}^{\infty} \|x^k\|$$

converges by comparison to the geometric series with ratio $\|x\|$, and hence $\sum_{k=0}^{\infty} x^k$ converges (). By the triangle inequality,

$$\left\| \sum_{k=0}^{\infty} x^k \right\| \leq \sum_{k=0}^{\infty} \|x^k\| \leq \sum_{k=0}^{\infty} \|x\|^k = \frac{1}{1-\|x\|} \ .$$

XX.12.2.10. Corollary. Let A be a unital Banach algebra, and $u \in A$. If $\|u-1\| < 1$, then u is invertible in A, and

$$\|u^{-1}\| \leq \frac{1}{1-\|u-1\|} \ .$$

Proof: Apply the theorem with $x = 1-u$.

XX.12.2.11. Corollary. Let A be a unital Banach algebra, and $u, v \in A$. If u is invertible in A and

$$\|u-v\| < \frac{1}{\|u^{-1}\|}$$

then v is also invertible in A, and

$$\|v^{-1}\| \leq \frac{\|u^{-1}\|}{1-\|u^{-1}\|\|u-v\|} \ .$$

Thus the open ball around u of radius $\frac{1}{\|u^{-1}\|}$ consists entirely of invertible elements. In particular, the set of invertible elements in A is an open set.

Proof: If $\|u-v\| < \frac{1}{\|u^{-1}\|}$, then

$$\|1-u^{-1}v\| = \|u^{-1}(u-v)\| \leq \|u^{-1}\|\|u-v\| < 1$$

so $u^{-1}v$ is invertible and v is left invertible. Similarly, $\|1-vu^{-1}\| < 1$ so v is right invertible. We have

$$\|v^{-1}u\| = \|(u^{-1}v)^{-1}\| \leq \frac{1}{1-\|u^{-1}v-1\|}$$

so

$$\|v^{-1}\| = \|(v^{-1}u)u^{-1}\| \leq \|v^{-1}u\|\|u^{-1}\| \leq \frac{\|u^{-1}\|}{1-\|u^{-1}v-1\|} = \frac{\|u^{-1}\|}{1-\|u^{-1}(v-u)\|} \leq \frac{\|u^{-1}\|}{1-\|u^{-1}\|\|v-u\|} \ .$$

XX.12.2.12. Note that the bound

$$\|v^{-1}\| \leq \frac{\|u^{-1}\|}{1 - \|u^{-1}v - 1\|}$$

in the proof is generally better than the bound in the statement of the result; but the bound in the statement is usually easier to compute.

Continuity of Inversion

XX.12.2.13. If A is a unital algebra, write A^{-1} for the set of invertible elements of A. Note that A^{-1} is a group () under multiplication, since a product of invertible elements is invertible.

XX.12.2.14. Corollary. Let A be a unital Banach algebra. Then the map $x \mapsto x^{-1}$ is a continuous function from A^{-1} to A^{-1}.

Proof: By the sequential criterion, it suffices to show that if (u_n) is a sequence in A^{-1} converging to $u \in A^{-1}$, then $u_n^{-1} \to u^{-1}$. There is an N such that

$$\|u_n - u\| < \frac{1}{2\|u^{-1}\|}$$

for all $n \geq N$. Thus, for $n \geq N$, we have

$$\|u_n^{-1}\| \leq \frac{\|u^{-1}\|}{1 - \|u^{-1}\|\|u_n - u\|} < 2\|u^{-1}\| \ .$$

So, for $n \geq N$,

$$\|u_n^{-1} - u^{-1}\| = \|u_n^{-1}(u - u_n)u^{-1}\| \leq \|u_n^{-1}\|\|u_n - u\|\|u^{-1}\| < 2\|u^{-1}\|^2\|u_n - u\|$$

which goes to 0 as $n \to \infty$. 👍

XX.12.2.15. Corollary. If A is a unital Banach algebra, then A^{-1} (with the norm topology) is a topological group () under multiplication.

XX.12.2.16. If I is an ideal in a Banach algebra A, it follows from continuity of multiplication that the closure $\bar{I}$ is also an ideal. If I is a proper ideal, it is not immediately obvious that $\bar{I}$ is a proper ideal (i.e. I could be dense in A); in fact, this can happen if A is nonunital (). But it cannot happen if A is a unital Banach algebra:

XX.12.2.17. Corollary. Let A be a unital Banach algebra, and I proper ideal of A. Then $\bar{I}$ is also a proper ideal of A.

Proof: An ideal in a unital algebra is a proper ideal if and only if it contains no invertible elements. Thus if I is a proper ideal, it is contained in the set S of noninvertible elements of A. But S is closed in A, so $\bar{I} \subseteq S$ and $\bar{I}$ is a proper ideal. 👍

XX.12.3. Spectrum

We now define the crucial notion of the spectrum of an element of a Banach algebra. For reasons partially explained in XX.12.3.5., we will consider only *complex* Banach algebras. For simplicity, we will also only develop the theory for unital Banach algebras. Thus, in this section (except (XX.12.3.2.)), all Banach algebras will be unital and complex; subalgebras will be assumed to contain the multiplicative identity. All homomorphisms will be assumed unital.

XX.12.3.1. DEFINITION. Let A be a unital Banach algebra, $x \in A$. The *spectrum* of x in A is

$$\sigma_A(x) = \{\lambda \in \mathbb{C} : x - \lambda 1 \text{ is not invertible}\} .$$

The complement of $\sigma_A(x)$ in $\mathbb{C}$ is called the *resolvent set* of x in A, denoted $\rho_A(x)$.

Thus $\sigma_A(x)$ is a subset of $\mathbb{C}$, which depends on x, and in general also on A (XX.12.3.11.). In many instances the A is understood (or, more importantly, the spectrum is independent of the choice of A, e.g. ()), and we just write $\sigma(x)$ for $\sigma_A(x)$.

XX.12.3.2. If A is a nonunital Banach algebra and $x \in A$, we can define $\sigma_A(x) = \sigma_{A^\dagger}(x)$. We then have $0 \in \sigma_A(x)$ for every $x \in A$. Although much of the theory we develop works in the nonunital case with occasional technical complications, for simplicity we will not consider spectrum in a nonunital Banach algebra from now on.

Here are the two most important examples, which together underly and motivate spectral theory:

XX.12.3.3. EXAMPLES. (i) Let $\mathcal{X}$ be a complex Banach space, and $T \in \mathcal{B}(\mathcal{X})$. Then $\sigma(T) = \sigma_{\mathcal{B}(\mathcal{X})}(T)$ is the set of $\lambda \in \mathbb{C}$ such that $T - \lambda I$ is not invertible, i.e. is either not injective or not surjective (the Bounded Inverse Theorem implies that if $T - \lambda I$ is injective and surjective, then $(T - \lambda I)^{-1} \in \mathcal{B}(\mathcal{X})$). If $T - \lambda I$ is not injective, then λ is by definition an eigenvalue of T. Thus $\sigma(T)$ can be thought of as the set of *generalized eigenvalues* of T.

If $\mathcal{X}$ is finite-dimensional, then by () $T - \lambda I$ is surjective if and only if it is injective. Thus in this case $\sigma(T)$ is exactly the set of eigenvalues of T, a finite nonempty subset of $\mathbb{C}$.

(ii) Let X be a compact Hausdorff space, and $A = C(X)$. If $f \in A$, then f is invertible in A if and only if f never takes the value 0. Thus $f - \lambda 1$ is invertible if and only if f never takes the value λ, i.e. $\sigma_A(f)$ is precisely the range of f, a nonempty compact subset of $\mathbb{C}$.

XX.12.3.4. Note that the spectrum of an element of a Banach algebra is a purely algebraic concept, and the norm plays no role in its definition. We may more generally define the spectrum of an element in any unital algebra over $\mathbb{C}$ in an identical way. (Thus, if $\mathcal{V}$ is a finite-dimensional complex vector space and $T \in \mathcal{L}(\mathcal{V})$, then $\sigma(T)$ is the set of eigenvalues of T.) However, the interplay between the topological and algebraic structure in a Banach algebra has important consequences for the *properties* of the spectrum.

XX.12.3.5. Example XX.12.3.3.(i) shows one basic reason why we restrict to complex algebras: operators on real vector spaces can fail to have (real) eigenvalues since $\mathbb{R}$ is not algebraically closed, for example a rotation in $\mathbb{R}^2$. There are deeper reasons why we restrict to complex algebras, involving applications of Complex Analysis (e.g. XX.12.3.27.).

Topological Properties of the Spectrum and Resolvent

XX.12.3.6. PROPOSITION. Let A be a unital Banach algebra, and $x \in A$. Then $\sigma_A(x)$ is closed in $\mathbb{C}$, i.e. $\rho_A(x)$ is open in $\mathbb{C}$.

PROOF: This follows immediately from the fact that A^{-1} is open in A, since $\lambda \mapsto x - \lambda 1$ is a continuous function from $\mathbb{C}$ to A. 👍

XX.12.3.7. PROPOSITION. Let A be a unital Banach algebra, and $x \in A$. If $\lambda \in \sigma_A(x)$, then $|\lambda| \leq \|x\|$. Thus $\sigma_A(x)$ is bounded in $\mathbb{C}$, hence compact.

PROOF: The case $x = 0$ is trivial ($\sigma_A(0) = \{0\}$), so suppose $x \neq 0$. Let $\alpha \in \mathbb{C}$. If $|\alpha| < \frac{1}{\|x\|}$, then the series

$$\sum_{k=0}^{\infty} (\alpha x)^k$$

converges to an inverse for $1 - \alpha x$ by XX.12.2.9.. So if $\lambda \in \mathbb{C}$, $|\lambda| > \|x\|$, we have that $1 - \frac{1}{\lambda}x$ is invertible, and hence $x - \lambda 1 = -\lambda(1 - \frac{1}{\lambda}x)$ is also invertible and $\lambda \notin \sigma_A(x)$. 👍

XX.12.3.8. We will see later (XX.12.3.27.) that $\sigma_A(x)$ is always nonempty. A more careful analysis (XX.12.3.32.) along the lines of the argument in the proof of XX.12.3.7. will give a more precise description of the size of the set $\sigma_A(x)$.

XX.12.3.9. Let A be a unital Banach algebra, and $x \in A$. Then continuity of inversion implies that the function $R : \rho_A(x) \to A^{-1}$ given by $R(\lambda) = (\lambda 1 - x)^{-1} = -(x - \lambda 1)^{-1}$ is continuous. R is called the *resolvent function* of x, with $R(\lambda)$ usually denoted $R_\lambda(x)$; it is actually far more than just continuous in λ (XX.12.3.25.). (The sign convention for $R_\lambda(x)$ is not universal.)

Dependence of Spectrum on the Algebra

XX.12.3.10. The spectrum of an element can depend on which containing Banach algebra is considered: if A is a (unital) Banach algebra and B a (unital) closed subalgebra of A, hence itself a Banach algebra, and $x \in B$, then x can be invertible in A but not in B, i.e. we can have $x^{-1} \notin B$. Obviously $\sigma_A(x) \subseteq \sigma_B(x)$, but the containment can be proper:

XX.12.3.11. EXAMPLE. Let $\mathbb{T}$ be the unit circle in $\mathbb{C}$, and $A = C(\mathbb{T})$. Let f be the "identity function" $f(z) = z$ from $\mathbb{T}$ to $\mathbb{C}$ (note that the term "identity function" can be confusing here since f is not the multiplicative identity of A). Then $\sigma_A(f)$ is the range of f (XX.12.3.3.(ii)), i.e. $\sigma_A(f) = \mathbb{T}$.

Let B be the subset of A consisting of functions which extend to functions continuous on the closed unit disk $\bar{\mathbb{D}}$ and holomorphic on $\mathbb{D}$ (B is exactly the algebra $\bar{P}$ of Exercise XX.10.3.10.). By the Maximum Modulus Theorem (), such an extension, if it exists, is unique. By the Maximum Modulus Theorem and XII.4.1.2., B is a closed unital subalgebra of A, and $f \in B$. However, if $|\lambda| \leq 1$, the unique extension g_λ of

$f - \lambda 1$ to $\bar{\mathbb{D}}$ is $g_\lambda(z) = z - \lambda$, which is not invertible in B. If $|\lambda| > 1$, then $\frac{1}{g_\lambda}$ is holomorphic on $\mathbb{C} \setminus \{\lambda\}$, hence on $\bar{\mathbb{D}}$, so $f - \lambda 1$ is invertible in B. Thus $\sigma_B(f) = \bar{\mathbb{D}}$.

However, $\sigma_B(x)$ cannot be too much larger than $\sigma_A(x)$:

XX.12.3.12. PROPOSITION. Let A be a unital Banach algebra and B a closed unital subalgebra of A, and let $x \in B$. Then $\sigma_A(x) \subseteq \sigma_B(x)$ and $\partial(\sigma_B(x)) \subseteq \partial(\sigma_A(x)) \subseteq \sigma_A(x)$, where ∂ denotes topological boundary ().

PROOF: We have already made the trivial observation that $\sigma_A(x) \subseteq \sigma_B(x)$. Suppose $\lambda \in \partial(\sigma_B(x))$. Then $\lambda \in \sigma_B(x)$ since $\sigma_B(x)$ is closed, and there is a sequence (λ_n) in $\rho_B(x)$ with $\lambda_n \to \lambda$. Since $\rho_B(x) \subseteq \rho_A(x)$, $\lambda_n \in \rho_A(x)$ for all n, so either $\lambda \in \partial(\sigma_A(x))$ (if $\lambda \in \sigma_A(x)$) or $\lambda \in \rho_A(x)$. But if $\lambda \in \rho_A(x)$ (i.e. $x - \lambda 1$ is invertible in A), then $(x - \lambda_n 1)^{-1} \to (x - \lambda 1)^{-1}$ by XX.12.3.9., and $(x - \lambda_n 1)^{-1} \in B$ for all n, so $(x - \lambda 1)^{-1} \in B$ since B is closed in A, contradicting that $\lambda \in \sigma_B(x)$. Thus $\lambda \in \partial(\sigma_A(x))$. 👍

XX.12.3.13. Thus, if A is a unital Banach algebra and B a closed unital subalgebra of A, and $x \in B$, then $\sigma_B(x)$ is the union of $\sigma_A(x)$ and possibly some bounded connected components of the complement of $\sigma_A(x)$. If $\sigma_A(x)$ does not divide $\mathbb{C}$ (i.e. if the complement is connected), then necessarily $\sigma_B(x) = \sigma_A(x)$. This is also true if $\sigma_B(x)$ has empty interior.

Spectral Mapping Properties

XX.12.3.14. If f is a polynomial with complex coefficients, and x is an element of a unital algebra A, then there is an obvious way to apply f to x to obtain an element $f(x) \in A$: if

$$f(X) = \alpha_0 + \alpha_1 X + \alpha_2 X^2 + \cdots + \alpha_n X^n$$

then

$$f(x) = \alpha_0 1 + \alpha_1 x + \alpha_2 x^2 + \cdots + \alpha_n x^n \ .$$

If f and g are polynomials with complex coefficients, and $x \in A$, then $(f + g)(x) = f(x) + g(x)$ and $(fg)(x) = f(x)g(x)$, i.e. the map $f \mapsto f(x)$ is a homomorphism () from the polynomial ring $\mathbb{C}[X]$ to A.

XX.12.3.15. PROPOSITION. [SPECTRAL MAPPING THEOREM FOR POLYNOMIALS] Let A be a unital algebra over $\mathbb{C}$, $x \in A$, and f a polynomial with complex coefficients. Then

$$\sigma_A(f(x)) = \{f(\lambda) : \lambda \in \sigma_A(x)\} \ .$$

PROOF: Let $\mu \in \mathbb{C}$. Since $\mathbb{C}$ is algebraically closed, the polynomial $f(X) - \mu$ factors into linear factors in $\mathbb{C}[X]$:

$$f(X) - \mu = (X - \lambda_1)(X - \lambda_2) \cdots (X - \lambda_n)$$

for some $\lambda_1, \ldots, \lambda_n \in \mathbb{C}$ (not necessarily distinct). We then have

$$f(x) - \mu 1 = (x - \lambda_1 1) \cdots (x - \lambda_n 1)$$

in A. Then by the next lemma $f(x) - \mu 1$ is invertible in A if and only if $x - \lambda_k 1$ is invertible in A for all k, i.e. $\mu \in \sigma_A(f(x))$ if and only if $\lambda_k \in \sigma_A(x)$ for some k. Since the numbers $\lambda_1, \ldots, \lambda_n$ are precisely the complex numbers λ such that $f(\lambda) = \mu$, the result follows. 👍

XX.12.3.16. Lemma. Let A be a unital ring (e.g. a unital algebra over a field $\mathbb{F}$), and $a_1, \ldots, a_n \in A$. If the a_k commute, then $a = a_1 a_2 \cdots a_n$ is invertible in A if and only if each a_k is invertible in A.

Proof: If the a_k are invertible, then a is invertible, and $a^{-1} = a_n^{-1} \cdots a_1^{-1}$ (this direction holds even if the a_k do not commute). Conversely, if the a_k commute and a is invertible, we have for each k

$$a_k(a_1 a_2 \cdots a_{k-1} a_{k+1} \cdots a_n a^{-1}) = 1$$

$$(a^{-1} a_1 a_2 \cdots a_{k-1} a_{k+1} \cdots a_n) a_k = 1$$

so a_k is both left and right invertible in A. 👍

Note that the conclusion can be false if the a_k do not commute ().

XX.12.3.17. Proposition. [Spectral Mapping Theorem for Inverses] Let A be a unital algebra over $\mathbb{C}$, and $x \in A$. If x is invertible in A (i.e. $0 \notin \sigma_A(x)$), then

$$\sigma_A(x^{-1}) = \left\{ \frac{1}{\lambda} : \lambda \in \sigma_A(x) \right\} .$$

Proof: Since x^{-1} is invertible, $0 \notin \sigma_A(x^{-1})$. If $\lambda \neq 0$, we have

$$x^{-1} - \frac{1}{\lambda} 1 = -\frac{1}{\lambda} x^{-1}(x - \lambda 1)$$

and x^{-1} and $x - \lambda 1$ commute, so $x^{-1} - \frac{1}{\lambda} 1$ is invertible if and only if $x - \lambda 1$ is invertible. 👍

XX.12.3.18. The two previous spectral mapping theorems are special cases of the following result. If A is a unital algebra over $\mathbb{C}$, $x \in A$, and f is a rational function in one variable with coefficients in $\mathbb{C}$ and no poles in $\sigma_A(x)$, so f defines a continuous function on $\sigma_A(x)$, write $f = \frac{p}{q}$ with p and q complex polynomials, in lowest terms, i.e. p and q have no common roots and q has no roots in $\sigma_A(x)$. Then $p(x)$ and $q(x)$ are defined in A, and $q(x)$ is invertible by XX.12.3.15.. We can then define $f(x) = p(x)q(x)^{-1} \in A$. (This is well defined since p and q are unique up to scalar multiples.) It is easily checked that $f \mapsto f(x)$ is an algebra homomorphism.

XX.12.3.19. PROPOSITION. [SPECTRAL MAPPING THEOREM FOR RATIONAL FUNCTIONS] Let A be a unital algebra over $\mathbb{C}$, $x \in A$, and f a rational function with complex coefficients and no poles in $\sigma_A(x)$. Then

$$\sigma_A(f(x)) = \{f(\lambda) : \lambda \in \sigma_A(x)\} .$$

PROOF: Let $\mu \in \mathbb{C}$. Then, for $z \in \mathbb{C}$,

$$f(z) - \mu = \frac{p(z)}{q(z)} - \mu = \frac{p(z) - \mu q(z)}{q(z)}$$

where p and q are polynomials with no common roots. Note that $q(z)$ and $p(z) - \mu q(z)$ also have no common roots. Let $\alpha_1, \ldots, \alpha_n$ be the roots of $p - \mu q$ and $\beta_1, \ldots, \beta_m$ the roots of q. We have

$$f(x) - \mu 1 = c(x - \alpha_1 1) \cdots (x - \alpha_n 1)(x - \beta_1 1)^{-1} \cdots (x - \beta_m 1)^{-1}$$

where c is a nonzero constant. Since the last m factors are invertible and the factors commute, $f(x) - \mu 1$ is invertible if and only if none of the α_k are in $\sigma_A(x)$. But the α_k are precisely the $z \in \mathbb{C}$ for which $p(z) - \mu q(z) = 0$, which are precisely the z for which $f(z) = \mu$ (since none of the β_k are roots of $p - \mu q$). 👍

Here is a cute fact related in spirit:

XX.12.3.20. PROPOSITION. Let A be a unital algebra over $\mathbb{C}$, $x, y \in A$. Then

$$\sigma_A(xy) \cup \{0\} = \sigma_A(yx) \cup \{0\} .$$

PROOF: Suppose $\lambda \neq 0$ and $xy - \lambda 1$ is invertible (i.e. $\lambda \notin \sigma_A(xy)$). Then, if $r = (xy - \lambda 1)^{-1}$, we have

$$(xy - \lambda 1)r = r(xy - \lambda 1) = 1$$

$$xyr = rxy = 1 - \lambda r$$

So we have

$$-\frac{1}{\lambda}(1 - yrx)(yx - \lambda 1) = -\frac{1}{\lambda}[yx - yrxyx + \lambda yrx - \lambda 1] = -\frac{1}{\lambda}[yx - y(1 - \lambda r)x + \lambda yrx - \lambda 1] = 1$$

and similarly $-\frac{1}{\lambda}(yx - \lambda 1)(1 - yrx) = 1$, so $yx - \lambda 1$ is invertible and $\lambda \notin \sigma_A(yx)$. The x and y can be interchanged in the argument. 👍

XX.12.3.21. So, while $0 \in \sigma_A(xy)$ (i.e. xy not invertible) does not imply $0 \in \sigma_A(yx)$ (i.e. yx not invertible), the rest of the two spectra are identical. If A is a Banach algebra and xy is invertible but yx is not invertible, then 0 is an isolated point of the spectrum of yx (since $\sigma_A(xy) = \sigma_A(yx) \setminus \{0\}$ is closed in $\mathbb{C}$).

Holomorphic Properties of the Resolvent

Recall (XX.12.3.9.) that if x is an element of a unital Banach algebra A, the resolvent function of x is defined to be

$$R_\lambda(x) = (\lambda 1 - x)^{-1}$$

for $\lambda \in \rho_A(x) \subseteq \mathbb{C}$. In what follows, we keep A and x fixed, and just write R_λ for $R_\lambda(x)$.

XX.12.3.22. PROPOSITION.

$$\lim_{|\lambda|\to\infty} R_\lambda = 0 \ .$$

PROOF: Note that since $\sigma_A(x)$ is bounded (XX.12.3.7.), R_λ is defined for $|\lambda|$ sufficiently large, so the limit potentially exists. If $|\lambda|$ is large, we have

$$R_\lambda = (\lambda 1 - x)^{-1} = \alpha(1 - \alpha x)^{-1}$$

where $\alpha = \frac{1}{\lambda}$. We have

$$\lim_{\alpha\to 0}(1 - \alpha x) = 1$$

and by XX.12.2.10. and XX.12.2.14. we also have

$$\lim_{\alpha\to 0}(1 - \alpha x)^{-1} = 1 \ .$$

Thus

$$\lim_{\alpha\to 0} \alpha(1 - \alpha x)^{-1} = 0 \ .$$

XX.12.3.23. PROPOSITION. Let $\lambda, \mu \in \rho_A(x)$. Then

$$R_\mu = (1 - y)^{-1} R_\lambda$$

where $y = (\lambda - \mu)R_\lambda$.

PROOF: We have

$$\mu 1 - x = (\lambda 1 - x) - (\lambda - \mu) = (\lambda 1 - x)(1 - y)$$

so the formula follows by taking inverses. 

Putting this together with XX.12.2.9., we obtain:

XX.12.3.24. COROLLARY. Let $\lambda_0 \in \rho_A(x)$, and $\lambda \in \mathbb{C}$. If the series

$$\sum_{k=0}^{\infty}(\lambda_0 - \lambda)^k R_{\lambda_0}^{k+1}$$

converges in A, then $\lambda \in \rho_A(x)$ and the sum is R_λ. In particular, if $|\lambda - \lambda_0| < \frac{1}{\|R_{\lambda_0}\|}$, $\lambda \in \rho_A(x)$ and the series converges to R_λ.

PROOF: Apply XX.12.3.23. with (λ, μ) replaced by (λ_0, λ), and apply XX.12.2.9. to $y = (\lambda_0 - \lambda)R_{\lambda_0}$. 👍

XX.12.3.25. Thus R_λ is locally representable as a power series, and thus is an "analytic function" of λ. There is a theory of Banach-space-valued analytic functions () which applies. However, we will need only the following weaker form which reduces consideration to complex-valued functions:

XX.12.3.26. COROLLARY. Let $\phi \in A^*$, and define $f_\phi(\lambda) = \phi(R_\lambda)$ for $\lambda \in \rho_A(x)$. Then f_ϕ is a holomorphic (analytic) complex-valued function on $\rho_A(x)$.

PROOF: Fix $\lambda_0 \in \rho_A(x)$. If $|\lambda - \lambda_0| < \frac{1}{\|R_{\lambda_0}\|}$, then the infinite series

$$\sum_{k=0}^{\infty}\phi(R_{\lambda_0}^{k+1})(\lambda_0 - \lambda)^k = \sum_{k=0}^{\infty}(-1)^k\phi(R_{\lambda_0}^{k+1})(\lambda - \lambda_0)^k$$

converges to $f_\phi(\lambda)$ by XX.12.3.24. and continuity of ϕ. Thus f_ϕ is locally representable by a convergent power series. 👍

The Spectrum is Nonempty!

The first major consequence is:

XX.12.3.27. THEOREM. Let A be a unital Banach algebra, and $x \in A$. Then $\sigma_A(x)$ is nonempty.

PROOF: Suppose $\sigma_A(x) = \emptyset$, so $\rho_A(x) = \mathbb{C}$. Let $\phi \in A^*$. Then f_ϕ is an entire function (). We have

$$\lim_{|\lambda|\to\infty} f_\phi(\lambda) = 0$$

by XX.12.3.22. and continuity of ϕ. Thus f_ϕ is bounded, hence constant by Liouville's Theorem (XII.3.3.10.). Since the limit at infinity is 0, f_ϕ is identically 0, i.e. $\phi(R_\lambda) = 0$ for all $\lambda \in \mathbb{C}$ and all $\phi \in A^*$. By () this implies that $R_\lambda = 0$ for all λ, a contradiction. 👍

A simple corollary is:

XX.12.3.28. Corollary. [Gelfand-Mazur Theorem] The only (complex) Banach division algebra is $\mathbb{C}$.

Proof: Recall that A is a division algebra if every nonzero element is invertible. If $x \in A$, there is a $\lambda \in \sigma_A(x)$. For this λ, $x - \lambda 1$ is not invertible; hence $x - \lambda 1 = 0$, $x = \lambda 1$. Thus every element of A is a scalar multiple of 1. 👍

Spectral Radius

Let x be an element of a unital Banach algebra A. Since $\sigma_A(x)$ is a nonempty compact subset of the plane, it makes sense to make the following definition:

XX.12.3.29. Definition. The *spectral radius* of x is

$$r_\sigma(x) = \sup_{\lambda \in \sigma_A(x)} |\lambda| = \max_{\lambda \in \sigma_A(x)} |\lambda| \ .$$

XX.12.3.30. The notation $r_\sigma(x)$ does not reflect the choice of the Banach algebra A containing x, on which the spectral radius potentially depends. But it is an immediate consequence of XX.12.3.12. that if B is a unital Banach subalgebra of A and $x \in B$, then the same spectral radius for x is obtained whether $\sigma_A(x)$ or $\sigma_B(x)$ is used in the definition, so $r_\sigma(x)$ in fact does not depend on which Banach algebra containing x is used. We could indeed just use the *smallest* Banach subalgebra of A containing x, i.e. the closed linear span of $\{x^n : n \geq 0\}$.

XX.12.3.31. Note also that the spectral radius of x depends only on the *algebraic* structure of A and not on the norm. However, we needed to know that A was a Banach algebra with respect to *some* norm in order to conclude that $\sigma_A(x)$ is nonempty and bounded so that the spectral radius is well defined.

There is nonetheless a tight relationship between the spectral radius and norm:

XX.12.3.32. Theorem. Let A be a Banach algebra and $x \in A$. Then

$$r_\sigma(x) = \lim_{n \to \infty} \|x^n\|^{1/n} = \inf_n \|x^n\|^{1/n} \ .$$

The theorem will be proved in several steps.

XX.12.3.33. Part of the content of the theorem is that

$$\lim_{n \to \infty} \|x^n\|^{1/n}$$

exists and equals

$$\inf_n \|x^n\|^{1/n} \ .$$

This can be proved directly using IV.1.12.5., setting $\alpha_n = \|x^n\|$, since $\|x^{n+m}\| = \|x^n x^m\| \leq \|x^n\|\|x^m\|$ for any $n, m \in \mathbb{N}$ by submultiplicativity. It will not be necessary for us to prove this since it will follow automatically from our other arguments. The sequence $(\|x^n\|^{1/n})$ is not necessarily nonincreasing ().

The first observation for the proof of XX.12.3.32. is that $r_\sigma(x) \leq \|x\|$ by XX.12.3.7.. We can do better by noting the following consequence of the Spectral Mapping Theorem for polynomials (XX.12.3.15.):

XX.12.3.34. Proposition. Let x be an element of a unital Banach algebra A, and f a polynomial with complex coefficients. Then

$$r_\sigma(f(x)) = \max_{\lambda \in \sigma_A(x)} |f(\lambda)| \ .$$

In particular, $r_\sigma(x^n) = [r_\sigma(x)]^n$ for any $n \in \mathbb{N}$.

XX.12.3.35. Corollary. Let x be an element of a unital Banach algebra A. Then

$$r_\sigma(x) \leq \inf_n \|x^n\|^{1/n} \ .$$

Proof: By XX.12.3.34. and XX.12.3.7. we have, for any n,

$$[r_\sigma(x)]^n = r_\sigma(x^n) \leq \|x^n\| \ .$$

XX.12.3.36. So to finish the proof of Theorem XX.12.3.32., it suffices to show that

$$r_\sigma(x) \geq \limsup_{n \to \infty} \|x^n\|^{1/n} \ .$$

This will take some work using Complex Analysis. Our argument follows [Ped89]; roughly speaking, it is based on XII.4.4.6..

XX.12.3.37. Fix $\phi \in A^*$ and let $f_\phi(\lambda) = \phi(R_\lambda)$. Then f_ϕ is analytic on $\rho_A(x)$, and in particular on $\Omega = \{\lambda \in \mathbb{C} : |\lambda| > r_\sigma(x)\}$. We have that

$$f_\phi(\lambda) = \frac{1}{\lambda}\phi\left(\left[1 - \frac{1}{\lambda}x\right]^{-1}\right) = \frac{1}{\lambda}\phi\left(\sum_{k=0}^{\infty}\left[\frac{1}{\lambda}x\right]^k\right) = \frac{1}{\lambda}\sum_{k=0}^{\infty}\phi\left(\left[\frac{1}{\lambda}x\right]^k\right) = \sum_{k=0}^{\infty}\lambda^{-k-1}\phi(x^k)$$

for $|\lambda| > \|x\|$; thus this is the Laurent series for f_ϕ on Ω and converges to f_ϕ u.c. on Ω (XII.4.4.12.).

XX.12.3.38. Now fix $s > r_\sigma(x)$. For any $n \in \mathbb{N}$, the series

$$\sum_{k=0}^{\infty} \lambda^{n-k} \phi(x^k)$$

converges uniformly to $g_n(\lambda) = \lambda^{n+1} f_\phi(\lambda)$ on the circle γ of radius s around 0, so we can compute the integral of g_n around γ by integrating term-by-term:

$$\int_0^{2\pi} s^{n+1} e^{i(n+1)\theta} \phi(se^{i\theta})\, d\theta = \sum_{k=0}^{\infty} \left[\int_0^{2\pi} s^{n-k} e^{i(n-k)\theta} \phi(x^k)\, d\theta \right] = \int_0^{2\pi} \phi(x^n)\, d\theta = 2\pi\phi(x^n)$$

since the integrals for $k \neq n$ are zero. Thus we obtain that

$$|\phi(x^n)| \leq s^{n+1} M(s) \|\phi\|$$

where $M(s) = \max_{|\lambda|=s} \|R_\lambda\|$. Since $\phi \in A^*$ is arbitrary, by the Hahn-Banach Theorem () we conclude that

$$\|x^n\| \leq s^{n+1} M(s)$$

$$\|x^n\|^{1/n} \leq s^{\frac{n+1}{n}} M(s)^{1/n}$$

for every n. Taking lim sup as $n \to \infty$, we obtain

$$\limsup_{n\to\infty} \|x^n\|^{1/n} \leq s \ .$$

This holds for all $s > r_\sigma(x)$, so we conclude

$$\limsup_{n\to\infty} \|x^n\|^{1/n} \leq r_\sigma(x) \ .$$

This completes the proof of Theorem XX.12.3.32.. 

XX.12.4. Holomorphic Functional Calculus

XX.12.4.1. If $f(t) = \alpha_1 t + \cdots + \alpha_n t^n$ is a polynomial with complex coefficients, without constant term (i.e. $f(0) = 0$), and x is an element of an algebra A over $\mathbb{C}$, then there is an obvious way to apply f to x to obtain an element $f(x) = \alpha_1 x + \cdots + \alpha_n x^n \in A$. If A is a Banach algebra, there is a very important way of extending this procedure to holomorphic functions, called *functional calculus*.

XX.12.4.2. If X is a compact subset of $\mathbb{C}$, denote by $H(X)$ the algebra of functions holomorphic in a neighborhood of X and vanishing at 0 if $0 \in X$, with functions identified if they agree on a neighborhood of X. Functional calculus gives a homomorphism from $H(\sigma_A(x))$ to the Banach subalgebra of A generated by x extending the map for polynomials. The image of f is denoted $f(x)$. The element $f(x)$ can be defined using the Cauchy Integral Formula, but in some cases (e.g. if f is entire) it is also given by a power series. If A is unital, functional calculus is also defined for holomorphic functions not vanishing at zero. Functional calculus has the following properties, which (along with the elementary definition for polynomials) determine it uniquely:

XX.12.4.3. PROPOSITION. Let A be a Banach algebra and $x \in A$. Then

(i) For any $f \in H(\sigma_A(x))$, $\sigma_A(f(x)) = \{f(\lambda) : \lambda \in \sigma_A(x)\}$.

(ii) If $f \in H(\sigma_A(x))$ and $g \in H(f(\sigma_A(x))) = H(\sigma_A(f(x)))$, so $g \circ f \in H(\sigma_A(x))$, then $(g \circ f)(x) = g(f(x))$.

(iii) If $f_n, f \in H(\sigma_A(x))$ and $f_n \to f$ uniformly on a neighborhood of $\sigma_A(x)$, then $f_n(x) \to f(x)$.

(iv) If B is a Banach algebra and $\phi : A \to B$ a continuous (bounded) homomorphism, then $\phi(f(x)) = f(\phi(x))$ for any $f \in H(\sigma_A(x))$.

PROOF: (i): Suppose A is unital. Let f be analytic on $\mathcal{U}$ containing $\sigma_A(x)$. If $\lambda \in \sigma_A(x)$, then $f(z) - f(\lambda) = (z - \lambda)g(z)$ with g analytic on $\mathcal{U}$; then $f(x) - f(\lambda)1 = (x - \lambda 1)g(x)$, and since $x - \lambda 1$ and $g(x)$ commute and $x - \lambda 1$ is not invertible, $f(\lambda) \in \sigma_A(f(x))$. Conversely, if $\mu \notin \{f(\lambda) : \lambda \in \sigma_A(x)\}$, then $h(z) = (f(z) - \mu)^{-1}$ is analytic on $\{z \in \mathcal{U} : f(z) \neq \mu\}$, which contains $\sigma_A(x)$, and $h(x) = (f(x) - \mu 1)^{-1}$.
(ii)-(iv) are straightforward. 👍

XX.12.4.4. An especially important case of functional calculus uses the exponential function $f(z) = e^z$. If x is any element of a unital Banach algebra A, then $f(x)$ is defined and denoted e^x. The element e^x is given by the power series $\sum_{n=0}^{\infty} \frac{x^n}{n!}$. For any x, e^x is invertible, with inverse e^{-x}; $e^{x+y} = e^x e^y$ if x and y commute. If A is a Banach *-algebra, then $(e^x)^* = e^{(x^*)}$. Conversely, if $\sigma_A(x)$ is contained in a simply connected open set not containing 0, let $f(z)$ be a branch of the logarithm holomorphic in a neighborhood of $\sigma_A(x)$; then $y = f(x)$ satisfies $e^y = x$. In particular, if $\|1 - x\| < 1$, then there is a $y \in A$ with $\|y\| < \pi/2$ with $e^y = x$ (use the principal branch of log).

XX.12.4.5. If A is a unital Banach algebra, write A^{-1} (also often written $\mathrm{GL}_1(A)$) for the (open) set of invertible elements in A, and A_o^{-1} (or $\mathrm{GL}_1(A)_o$) for the connected component of the identity in A^{-1}. Then

$$exp(A) = \{e^y : y \in A\} \subseteq A^{-1}$$

is path-connected, and by the above the subgroup of A^{-1} generated algebraically by $exp(A)$ is a connected open subgroup, hence equal to A_o^{-1}. In particular, A_o^{-1} is an open subgroup of A^{-1}, and every element of A_o^{-1} is a finite product of exponentials.

If A and B are unital Banach algebras and ϕ is a bounded homomorphism from A onto B, and $y \in B^{-1}$, then there is not necessarily an $x \in A^{-1}$ with $\phi(x) = y$:

XX.12.4.6. EXAMPLE. Let $\mathbb{D}$ be the closed unit disk in $\mathbb{C}$, and $\mathbb{T}$ its boundary. There is a *-homomorphism $\phi : C(\mathbb{D}) \to C(\mathbb{T})$ given by restriction. But if $g \in C(\mathbb{T})$ with $g(z) = z$, then $g \in C(\mathbb{T})^{-1}$, but there is no $f \in C(\mathbb{D})^{-1}$ with $\phi(f) = g$.

The image in the Calkin algebra of a Fredholm operator of nonzero index is another example.
However:

XX.12.4.7. PROPOSITION. If $\phi : A \to B$ is a surjective bounded homomorphism of unital Banach algebras, then $\phi(A_o^{-1}) = B_o^{-1}$.

This can be proved either by an application of the Open Mapping Theorem or by noting that if $x \in A$, then $\phi(e^x) = e^{\phi(x)}$.

Homomorphisms

We have a generalization of XX.12.3.10.:

XX.12.4.8. PROPOSITION. Let A and B be unital Banach algebras, and $\phi : A \to B$ a unital homomorphism. If $x \in A$, then $\sigma_B(\phi(x)) \subseteq \sigma_A(x)$.

PROOF: If $y \in A$ is invertible in A, then $\phi(y)$ is invertible in B $[\phi(y)^{-1} = \phi(y^{-1})]$. 👍

XX.12.5. Spectral Theory for Bounded Operators

In this section, we examine the spectrum and its properties for bounded operators on Banach spaces, concentrating almost exclusively on the case of operators on Hilbert spaces.

We will essentially follow the first comprehensive development and exposition of this theory, given by F. Riesz [?] in 1913, abstracted to Banach spaces and Hilbert spaces (which did not exist in 1913!) and with some modern technical simplifications.

XX.12.5.1. If $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$ ($\mathcal{X}, \mathcal{Y}$ Banach spaces) is invertible in the algebraic sense, i.e. T is one-to-one and onto, then T^{-1} is automatically bounded by the Open Mapping Theorem. So there are two ways a bounded operator T can fail to be invertible:

T is not bounded below (recall that T is *bounded below* if $\exists \epsilon > 0$ such that $\|Tx\| \geq \epsilon \|x\|$ for all $x \in \mathcal{X}$)

$\mathcal{R}(T)$ is not dense.

These possibilities are not mutually exclusive. For example, if T is a normal operator on a Hilbert space, then $\mathcal{N}(T) = \mathcal{R}(T)^{\perp}$ (), so if $\mathcal{R}(T)$ is not dense, then T is not one-to-one and hence not bounded below. Thus a normal operator on a Hilbert space is invertible if and only if it is bounded below.

XX.12.5.2. Proposition. Let T be a bounded operator on a Hilbert space $\mathcal{H}$. Then T is invertible if and only if both T and T^* are bounded below.

Proof: If T is invertible, then for any x we have $\|x\| = \|T^{-1}(Tx)\| \leq \|T^{-1}\|\|Tx\|$, so T is bounded below. Since T^* is also invertible, T^* is bounded below too.

Conversely, suppose T and T^* are bounded below. In particular, T^* is one-to-one, so $\mathcal{N}(T^*) = \mathcal{R}(T)^{\perp} = \{0\}$, and thus $\mathcal{R}(T)$ is dense in $\mathcal{H}$. If $y \in \mathcal{H}$, then there is a sequence (y_n) in $\mathcal{R}(T)$ with $y_n \to y$. For each n there is an $x_n \in \mathcal{H}$ (unique, since T is one-to-one) with $y_n = Tx_n$. Fix $\epsilon > 0$ such that $\|Tx\| \geq \epsilon \|x\|$ for all $x \in \mathcal{H}$. Then, for any n and m,

$$\|x_n - x_m\| \leq \epsilon^{-1} \|Tx_n - Tx_m\| = \epsilon^{-1} \|y_n - y_m\|$$

and since (y_n) is a Cauchy sequence, so is (x_n). Let $x_n \to x$. We then have $Tx_n \to Tx$ since T is continuous (bounded), so $y = Tx$ and T is surjective. T^{-1} is automatically bounded by the Bounded Inverse Theorem. ☝

Recall the following definition from XX.12.3.1., rewritten in the context of operators and expanded:

XX.12.5.3. Definition. Let $\mathcal{X}$ be a normed vector space, $T \in \mathcal{B}(\mathcal{X})$. The *spectrum* of T is

$$\sigma(T) = \{\lambda \in \mathbb{C} : T - \lambda I \text{ is not invertible}\}$$

The *point spectrum* of T is

$$\sigma_p(T) = \{\lambda \in \mathbb{C} : T - \lambda I \text{ is not one-to-one}\}$$

(thus $\sigma_p(T)$ is exactly the set of eigenvalues of T). The *continuous spectrum* $\sigma_c(T)$ of T is the set of $\lambda \in \mathbb{C}$ such that $T - \lambda I$ is one-to-one with dense range, but not bounded below. The *residual spectrum* $\sigma_r(T)$ is the set of $\lambda \in \mathbb{C}$ such that $T - \lambda I$ is one-to-one but does not have dense range.

Note that $\sigma(T)$ is the disjoint union of $\sigma_p(T)$, $\sigma_c(T)$, and $\sigma_r(T)$. One or more of these sets can be empty (XX.12.5.8.). But we have the fundamental fact from XX.12.3.6., XX.12.3.27., and XX.12.3.32.:

XX.12.5.4. THEOREM. Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{B}(\mathcal{X})$. Then

(i) $\sigma(T)$ is a nonempty compact subset of $\mathbb{C}$.

(ii) $r_\sigma(T) = \max_{\lambda\in\sigma(T)} |\lambda| = \lim_{n\to\infty} \|T^n\|^{1/n} = \inf_n \|T^n\|^{1/n}$.

XX.12.5.5. The spectrum of T can be thought of as the set of "generalized eigenvalues" of T (note that every actual eigenvalue of T is in the spectrum). The first definition (not the same as the one here – essentially the reciprocal) and name "spectrum" were given by HILBERT; the modern definition is due to F. RIESZ.

XX.12.5.6. PROPOSITION. Let $\mathcal{H}$ be a Hilbert space, and $T \in \mathcal{B}(\mathcal{H})$. Then $\sigma(T^*) = \{\bar\lambda : \lambda \in \sigma(T)\}$.

PROOF: This follows immediately from the fact that if $S \in \mathcal{B}(\mathcal{H})$, then S is invertible if and only if S^* is invertible, and $(T + \lambda I)^* = T^* + \bar\lambda I$. 👍

The relation between $\sigma_p(T)$, $\sigma_c(T)$, $\sigma_r(T)$ and $\sigma_p(T^*)$, $\sigma_c(T^*)$, $\sigma_r(T^*)$ is slightly more complicated:

XX.12.5.7. PROPOSITION. Let $\mathcal{H}$ be a Hilbert space, and $T \in \mathcal{B}(\mathcal{H})$. If $\lambda \in \mathbb{C}$, then

(i) If $\lambda \in \sigma_p(T)$, then $\bar\lambda \in \sigma_p(T^*) \cup \sigma_r(T^*)$.

(ii) If $\lambda \in \sigma_r(T)$, then $\bar\lambda \in \sigma_p(T^*)$.

(iii) $\lambda \in \sigma_p(T) \cup \sigma_r(T)$ if and only if $\bar\lambda \in \sigma_p(T^*) \cup \sigma_r(T^*)$.

(iv) $\lambda \in \sigma_c(T)$ if and only if $\bar\lambda \in \sigma_c(T^*)$.

PROOF: Parts (i) and (ii) follow immediately from the relation $\mathcal{N}(S) = \mathcal{R}(S^*)^\perp$; (iii) follows trivially from (i) and (ii), and (iv) follows from (iii) and XX.12.5.6. by process of elimination. 👍

XX.12.5.8. EXAMPLES. (i) If $\mathcal{X}$ is finite-dimensional, then $\sigma(T) = \sigma_p(T)$ is the set of eigenvalues of T.
(ii) If T is a normal operator on a Hilbert space, then $\mathcal{N}(T) = \mathcal{R}(T)^\perp$ (), so if $\mathcal{R}(T)$ is not dense, then T is not one-to-one and hence not bounded below. Thus a normal operator on a Hilbert space is invertible if and only if it is bounded below, and $\sigma_r(T) = \emptyset$.
(iii) Let (α_n) be a bounded sequence in $\mathbb{C}$. Define $T : \ell^2 \to \ell^2$ by

$$T(\xi_1, \xi_2, \dots) = (\alpha_1\xi_1, \alpha_2\xi_2, \dots) \ .$$

Then $T \in \mathcal{B}(\ell^2)$, $\|T\| = \sup_n |\alpha_n|$. We have $\sigma_p(T) = \{\alpha_n : n \in \mathbb{N}\}$, $\sigma_r(T) = \emptyset$ since T is normal, and $\sigma(T)$ is the closure of $\sigma_p(T)$, so if $\sigma_p(T)$ is not closed we have $\sigma_c(T) = \sigma(T) \setminus \sigma_p(T) \neq \emptyset$.

(iv) Let T be the *unilateral shift* on ℓ^2:

$$T(\xi_1, \xi_2, \dots) = (0, \xi_1, \xi_2, \dots) .$$

Then T is an isometry, hence $\|T\| = 1$. T is one-to-one, but $\mathcal{R}(T)$ is not dense in ℓ^2; thus $0 \in \sigma_r(T)$. It is easy to see that $\sigma_p(T) = \emptyset$. By XX.12.5.6., XX.12.5.7., and (v) below, $\sigma(T)$ is the closed unit disk $\bar{\mathbb{D}}$ in $\mathbb{C}$, $\sigma_r(T)$ is the open unit disk, and $\sigma_c(T)$ is the unit circle.

(v) Let T^* be the adjoint of the unilateral shift of (iv). Then T^* is the *left shift*:

$$T^*(\xi_1, \xi_2, \dots) = (\xi_2, \xi_3, \dots) .$$

If $\lambda \in \mathbb{C}$, $|\lambda| < 1$, then the vector $x_\lambda = (1, \lambda, \lambda^2, \dots)$ is in ℓ^2 and $T^*(x_\lambda) = \lambda x_\lambda$; thus $\lambda \in \sigma_p(T^*)$. It is easy to see that no complex number of absolute value 1 can be an eigenvalue of T^*, so $\sigma_p(T^*)$ is the open unit disk $\mathbb{D}$. Thus $\sigma(T^*)$ contains $\bar{\mathbb{D}}$ since it is closed. But $\|T^*\| = 1$, so $r_\sigma(T^*) \le 1$ and $\sigma(T^*) \subseteq \bar{\mathbb{D}}$. Thus $\sigma(T^*) = \bar{\mathbb{D}}$. By XX.12.5.6., XX.12.5.7., and (iv), $\sigma_c(T^*)$ is the unit circle and $\sigma_r(T^*) = \emptyset$.

Numerical Range

XX.12.5.9. The *numerical range* of an operator T on a Hilbert space $\mathcal{H}$ is

$$W(T) = \{\langle Tx, x\rangle : \|x\| = 1\}.$$

Set

$$w(T) = \sup\{|\lambda| : \lambda \in W(T)\}.$$

It is obvious that $W(T^*) = \{\bar{\lambda} : \lambda \in W(T)\}$, so $w(T^*) = w(T)$; if $T = T^*$, then $W(T) \subseteq \mathbb{R}$. (Conversely, if $W(T) \subseteq \mathbb{R}$, then $T = T^*$: for $\xi, \eta \in \mathcal{H}$, expand $\langle T(\xi + \eta), \xi + \eta\rangle \in \mathbb{R}$ and $\langle T(\xi + i\eta), \xi + i\eta\rangle \in \mathbb{R}$.)

XX.12.5.10. Proposition. If $T \in \mathcal{B}(\mathcal{H})$, then $\sigma(T) \subseteq \overline{W(T)}$ and $r_\sigma(T) \le w(T) \le \|T\|$.

Proof: To see that $\sigma(T) \subseteq \overline{W(T)}$, note that if $\lambda \in \sigma(T)$, then by XX.12.5.2. either $T - \lambda I$ or $(T - \lambda I)^*$ is not bounded below, so there is a sequence (x_n) of unit vectors such that either $(T - \lambda I)x_n \to 0$ or $(T - \lambda I)^* x_n \to 0$. In either case, we obtain that $\langle (T - \lambda I)x_n, x_n\rangle \to 0$ by the CBS inequality. The inequality $r_\sigma(T) \le w(T)$ follows immediately, and $w(T) \le \|T\|$ is immediate from the CBS inequality. ☝

XX.12.5.11. Examples. (i) Note that $r_\sigma(T) = w(T) = \|T\|$ does not hold for general operators: for example, let T be the (nilpotent) operator on $\mathbb{C}^2$ given by the matrix $\begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}$. Then $\sigma(T) = \{0\}$, so $r_\sigma(T) = 0$; but $\|T\| = 1$. It can be shown by an easy calculation that $W(T) = \{\lambda : |\lambda| \le 1/2\}$, so $w(T) = 1/2$.

(ii) If $\mathcal{H}$ is finite-dimensional and $T \in \mathcal{B}(\mathcal{H})$, then $W(T)$ is closed since the unit sphere in $\mathcal{H}$ is compact, and thus $\sigma(T) \subseteq W(T)$. But if $\mathcal{H}$ is infinite-dimensional, neither statement is true in general. Let $T \in \mathcal{B}(\ell^2)$ be defined by

$$T(\xi_1, \xi_2, \dots) = (\xi_1, \xi_2/2, \dots, \xi_n/n, \dots) .$$

Then $\sigma(T) = \{0\} \cup \{\frac{1}{n} : n \in \mathbb{N}\}$. But $\langle Tx, x\rangle \ne 0$ if $x \ne 0$, so $0 \notin W(T)$. It is not hard to compute that $W(T) = (0, 1]$.

XX.12.5.12. The expression $\langle Tx, x\rangle$ is not linear in x, and anyway the set of unit vectors is not convex. However, perhaps remarkably, the numerical range $W(T)$ *is* always convex (Hausdorff-Toeplitz Theorem). See XX.12.6.2. for a proof. It is also true that $w(T)$ is a norm on $\mathcal{B}(\mathcal{H})$ for a Hilbert space $\mathcal{H}$ (XX.12.6.3.).

Self-Adjoint and Positive Operators

XX.12.5.13. Definition. A (necessarily self-adjoint; cf. XX.12.6.4.) bounded operator T on a Hilbert space $\mathcal{H}$ is *positive* if $\langle Tx, x\rangle \geq 0$ for all $x \in \mathcal{H}$ (i.e. $W(T) \subseteq [0, +\infty)$). Write $T \geq 0$ if T is positive, and write $\mathcal{B}(\mathcal{H})_+$ for the set of positive operators on $\mathcal{H}$.

XX.12.5.14. If $T \in \mathcal{B}(\mathcal{H})$, then $T^*T \geq 0$ (this is also true if T is conjugate-linear); if $T = T^*$, then $\lambda I - T \geq 0$ for $\lambda \geq \|T\|$. Sums and nonnegative scalar multiples of positive operators are positive.

If S, T are self-adjoint operators, write $S \leq T$ if $T - S \geq 0$, i.e. if $\langle Sx, x\rangle \leq \langle Tx, x\rangle$ for all x. If $T = T^*$, we have $-w(T)I \leq T \leq w(T)I$, and in particular $-\|T\|I \leq T \leq \|T\|I$.

XX.12.5.15. Let S be a positive operator, and let m and M be the inf and sup of $W(S)$ respectively. The form $(x, y) = \langle Sx, y\rangle$ is positive semidefinite, and thus satisfies the CBS inequality, yielding, for all x, y,

$$|\langle Sx, y\rangle|^2 \leq \langle Sx, x\rangle\langle Sy, y\rangle \leq \langle Sx, x\rangle M\|y\|^2 \leq M^2\|x\|^2\|y\|^2.$$

Setting $y = Sx$ and dividing through by $\|Sx\|^2$, we obtain, for all x,

$$\langle S^2x, x\rangle = \langle Sx, Sx\rangle = \|Sx\|^2 \leq M\langle Sx, x\rangle \leq M^2\|x\|^2.$$

Since $0 \leq M \leq \|S\|$, we conclude:

XX.12.5.16. Proposition. Let S be a positive operator, and let m and M be the inf and sup of $W(S)$ respectively. Then

(i) $\|S\| = M$ and $S^2 \leq MS$.

(ii) If S is bounded below, then $m > 0$.

[For (ii), if $\|Sx\| \geq \epsilon\|x\|$ for all x, then $M > 0$, and for $\|x\| = 1$ we have

$$\epsilon^2 = \epsilon^2\|x\|^2 \leq \langle Sx, Sx\rangle \leq M\langle Sx, x\rangle$$

so $m \geq \frac{\epsilon^2}{M}$. In fact, $\epsilon = m$ works and this is the largest possible ϵ.]

XX.12.5.17. Proposition. If T is a self-adjoint operator on a Hilbert space H, and m and M are the inf and sup of $W(T)$ respectively, then $\sigma(T) \subseteq [m, M] \subseteq \mathbb{R}$ and $m, M \in \sigma(T)$. Thus $r_\sigma(T) = w(T)$.

Proof: $\sigma(T) \subseteq [m, M]$ by XX.12.5.10.. Note that $mI \leq T \leq MI$. Applying XX.12.5.16.(ii) to $T - mI$ and $MI - T$, we obtain $m, M \in \sigma(T)$. 👍

XX.12.5.18. PROPOSITION. Let T be a self-adjoint element of $\mathcal{B}(\mathcal{H})$. Then $r_\sigma(T) = \|T\| (= w(T))$.

PROOF: By scaling, we may assume $r_\sigma(T) = w(T) = 1$, so $-I \leq T \leq I$. Set $S = (T+I)/2$; then $0 \leq S \leq I$. By XX.12.5.16., $S^2 \leq S$, so $I - T^2 = 4(S - S^2) \geq 0$, $0 \leq T^2 \leq I$, $\|T^2\| = \|T\|^2 \leq 1$ by () and XX.12.5.16.. 👍

XX.12.5.19. In particular, if $T \geq 0$, then $\sigma(T) \subseteq [0, \|T\|]$ and $\|T\| \in \sigma(T)$.

XX.12.5.20. The result of XX.12.5.18. also follows easily from the spectral radius formula, since if T is self-adjoint we have $\|T^2\| = \|T\|^2$ (), so by iteration $\|T^{2^n}\| = \|T\|^{2^n}$ and thus

$$r_\sigma(T) = \lim_{m\to\infty} \|T^m\|^{1/m} = \lim_{n\to\infty} \|T^{2^n}\|^{1/2^n} = \|T\| \ .$$

However, the proof in XX.12.5.18. is more elementary, not requiring ().

We can by a similar argument extend XX.12.5.18.:

XX.12.5.21. PROPOSITION. Let $\mathcal{H}$ be a Hilbert space, and $T \in \mathcal{B}(\mathcal{H})$. If T is normal, then $r_\sigma(T) = w(T) = \|T\|$.

PROOF: We have $\|T\|^2 = \|T^*T\|$ (), and for each n, $\|T^n\|^2 = \|(T^n)^*T^n\| = \|(T^*T)^n\|$ since T is normal. But T^*T is self-adjoint, so $\|(T^*T)^{2^n}\| = \|T^*T\|^{2^n} = \|T\|^{2^{n+1}}$. Thus we have

$$r_\sigma(T) = \lim_{n\to\infty} \|T^{2^n}\|^{1/2^n} = \lim_{n\to\infty} [\|(T^*T)^{2^n}\|^{1/2}]^{1/2^n} = \lim_{n\to\infty} \|(T^*T)^{2^n}\|^{1/2^{n+1}} = \|T\| \ .$$

👍

XX.12.5.22. PROPOSITION. Let T be a positive operator on a Hilbert space $\mathcal{H}$, and $x, y \in \mathcal{H}$. Then $\langle T(x+y), x+y\rangle \leq [\langle Tx, x\rangle^{1/2} + \langle Ty, y\rangle^{1/2}]^2$.

PROOF: We have $\langle T(x+y), x+y\rangle = \langle Tx, x\rangle + 2Re\langle Tx, y\rangle + \langle Ty, y\rangle$, and by the CBS inequality $Re\langle Tx, y\rangle \leq [\langle Tx, x\rangle\langle Ty, y\rangle]^{1/2}$. 👍

XX.12.5.23. COROLLARY. Let T be a positive operator on $\mathcal{H}$, and $\{x_i\}$ a total set of vectors in $\mathcal{H}$. If $\langle Tx_i, x_i\rangle = 0$ for all i, then $T = 0$.

XX.12.5.24. If X is a compact subset of $\mathbb{C}$ not containing 0, and $k \in \mathbb{N}$, there is in general no bound on the norm of T^{-1} as T ranges over all operators with $\|T\| \leq k$ and $\sigma(T) \subseteq X$. For example, let $S_n \in \mathcal{B}(l^2)$ be the truncated shift:

$$S_n(\alpha_1, \alpha_2, \dots) = (0, \alpha_1, \alpha_2, \dots, \alpha_n, 0, 0, \dots)$$

and let $T_n = I - S_n$. $\|S_n\| = 1$, so $\|T_n\| \leq 2$ for all n. Since S_n is nilpotent, $\sigma(S_n) = \{0\}$, so $\sigma(T_n) = \{1\}$ for all n. T_n is invertible, with $T_n^{-1} = I + S_n + S_n^2 + \cdots + S_n^n$, and $\|T_n^{-1}\xi_1\| = \sqrt{n+1}$, so $\|T_n^{-1}\| \geq \sqrt{n+1}$.

If T is restricted to normal operators, then there is a bound: if T is an invertible normal operator, then $\|T^{-1}\| = d^{-1}$, where d is the distance from 0 to $\sigma(T)$. This follows immediately from II.1.6.3 and the elementary fact that $\sigma(T^{-1}) = \{\lambda^{-1} : \lambda \in \sigma(T)\}$ (cf. II.1.5.2(i)).

XX.12.6. Exercises

XX.12.6.1. (a) If A is a unital normed algebra, show that $\|1\| \geq 1$. [$1 = 1 \cdot 1$.]

(b) Give an example of a Banach algebra norm $\|\cdot\|$ on $M_2(\mathbb{C})$ for which $\|I\| > 1$. [Try $\|[a_{ij}]\| = \sum_{i,j} |a_{ij}|$. There are many other possibilities.]

(c) Let A be a unital Banach algebra with norm $\|\cdot\|$. For $x \in A$, define

$$|||a||| = \sup_{\|x\|=1} \|ax\|$$

(i.e. define $L_a \in \mathcal{B}(A)$ by $L_a(x) = ax$, and set $|||a||| = \|L_a\|_{op}$). Show that $|||\cdot|||$ is a Banach algebra norm on A equivalent to $\|\cdot\|$, and that $|||1||| = 1$.

(d) [Kat04, VIII.1.4] Show, more generally, that if A is a Banach space with norm $\|\cdot\|$ which is a unital algebra under a multiplication which is separately continuous, then the norm $|||\cdot|||$ defined in (c) is a Banach algebra norm on A equivalent to $\|\cdot\|$, with $|||1||| = 1$, and in particular multiplication is jointly continuous. [First observe that $|||a||| \geq \frac{\|a\|}{\|1\|}$ for any a. Then show the map $a \mapsto L_a$ from A to $\mathcal{B}(A)$ has closed graph. Conclude that $(A, |||\cdot|||)$ is complete and (using the Closed Graph Theorem) that $|||\cdot|||$ is equivalent to $\|\cdot\|$.]

(e) What if A is nonunital? See XX.16.1.2. for a nonunital version.

XX.12.6.2. This problem gives a proof of the Hausdorff-Toeplitz Theorem:

THEOREM. Let $\mathcal{V}$ be a (complex) inner product space, and $T \in \mathcal{L}(\mathcal{V})$ (not necessarily bounded). Then $W(T)$ is a convex subset of $\mathbb{C}$.

(a) Show that $W(\alpha T + \beta I) = \{\alpha\lambda + \beta : \lambda \in W(T)\}$ for $\alpha, \beta \in \mathbb{C}$, and $\langle Tx, x\rangle = \langle T(\lambda x), \lambda x\rangle$ for $|\lambda| = 1$.

(b) If α and β are complex numbers, show that there is a $\lambda \in \mathbb{C}$, $|\lambda| = 1$, with $\lambda\alpha + \bar{\lambda}\beta$ a nonnegative real number. [Consider $\pm\frac{\bar{\alpha}-\beta}{|\bar{\alpha}-\beta|}$ if $\beta \neq \bar{\alpha}$.] Conclude that if $x, y \in \mathcal{V}$, there is a $\lambda \in \mathbb{C}$, $|\lambda| = 1$, such that $\langle T(\lambda x), y\rangle + \langle Ty, \lambda x\rangle$ is a nonnegative real number.

(c) Conclude from (a) and (b) that to show that $W(T)$ is convex for all T, it suffices to show that if $\langle Tx, x\rangle = 0$ and $\langle Ty, y\rangle = 1$ for $x, y \in \mathcal{V}$, $\|x\| = \|y\| = 1$, $\langle Tx, y\rangle + \langle Ty, x\rangle \geq 0$, then for any $\lambda \in [0, 1]$ there is a $z \in \mathcal{V}$, $\|z\| = 1$, with $\langle Tz, z\rangle = \lambda$.

(d) Let $x, y \in \mathcal{V}$ be as in (c). Show that if $0 \leq \alpha \leq 1$, then $(1-\alpha)x + \alpha y \neq 0$.

(e) For $0 \leq \alpha \leq 1$, set

$$z_\alpha = \frac{(1-\alpha)x + \alpha y}{\|(1-\alpha)x + \alpha y\|}$$

and $f(\alpha) = \langle Tz_\alpha, z_\alpha\rangle$. Show that f is a real-valued continuous function on $[0, 1]$.

(f) Since $f(0) = 0$ and $f(1) = 1$, f takes all values in $[0, 1]$ by the Intermediate Value Theorem.

XX.12.6.3. (a) Let $\mathcal{V}$ be a (complex) inner product space, and $T \in \mathcal{L}(\mathcal{V})$ (not assumed bounded). If $w(T) = 0$, i.e. if $\langle Tx, x\rangle = 0$ for all $x \in \mathcal{V}$, show that $T = 0$. [If $x, y \in \mathcal{V}$, expand $\langle T(x+y), x+y\rangle$ and $T(x+iy), x+iy\rangle$ and conclude that $\langle Tx, y\rangle = 0$.]

(b) Show that the result in (a) is not necessarily true in a real inner product space. [Consider a 90° rotation in $\mathbb{R}^2$.]

(c) Let $\mathcal{H}$ be a Hilbert space. If $S, T \in \mathcal{B}(\mathcal{H})$, show that $w(S+T) \leq w(S) + w(T)$. Thus w is a norm on $\mathcal{B}(\mathcal{H})$. Is it equivalent to the operator norm? Is $\mathcal{B}(\mathcal{H})$ complete with respect to the norm w?

XX.12.6.4. Let $\mathcal{V}$ be a (complex) inner product space, and $T \in \mathcal{L}(\mathcal{V})$ (not necessarily bounded). Suppose $W(T) \subseteq \mathbb{R}$, i.e. $\langle Tx, x\rangle \in \mathbb{R}$ for all $x \in \mathcal{V}$. Show that $\langle Tx, y\rangle = \langle x, Ty\rangle$ for all $x, y \in \mathcal{V}$. [As in XX.12.6.3., expand $\langle T(x+y), x+y\rangle$ and $\langle T(x+iy), x+iy\rangle$.]

XX.12.6.5. [] (a) Let T be the operator on $\mathbb{C}^2$ with triangular matrix

$$\begin{bmatrix} a_1 & b \\ 0 & a_2 \end{bmatrix}.$$

Note that a_1 and a_2 are the eigenvalues of T. Show that $W(T)$ is the ellipse with foci at a_1 and a_2 and minor axis $|b|$. (If $a_1 = a_2$, this ellipse is a circle with radius $|b|/2$, and if $b = 0$, so T is normal, $W(T)$ is just the line segment between a_1 and a_2.) XX.12.5.11. is a special case.

(b) Show that every operator T on $\mathbb{C}^2$ is unitarily equivalent to one with a triangular matrix of this form (with $b \geq 0$), and thus $W(T)$ is an ellipse. (Things are not nearly so simple even for $\mathbb{C}^3$.)

XX.12.6.6. (a) Let $T \in \mathcal{B}(\mathbb{R}^2)$ have matrix

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

with respect to the standard basis. Show that

$$\|T\| = \|A\| = \sqrt{\frac{a^2+b^2+c^2+d^2+\sqrt{a^4+6a^2b^2-2a^2c^2-2a^2d^2+8abcd+b^4-2b^2c^2-2b^2d^2+c^4+6c^2d^2+d^4}}{2}}.$$

[Use that $\|A\|$ is the square root of the largest eigenvalue of A^tA.]

(b) Find a similar formula if $T \in \mathcal{B}(\mathbb{C}^2)$, i.e. $a, b, c, d \in \mathbb{C}$.

(c) (For masochists only, or for someone adept at using computer algebra programs) Find a similar formula for 3×3 and 4×4 matrices.

(d) Show that if $n \geq 5$, there is no algebraic formula for the norm of an $n \times n$ matrix A in terms of the entries of A. Specifically, show that the norm of the matrix

$$\begin{bmatrix} 2 & 1 & 0 & 0 & 0 \\ 1 & 3 & 1 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 \end{bmatrix}$$

which in this case is just the largest eigenvalue, approximately 3.917, cannot be written in terms of radicals and rational numbers, i.e. its characteristic polynomial is not solvable by radicals over $\mathbb{Q}$ (D. Zare; cf. https://mathoverflow.net/questions/268453/is-there-an-algebraic-formula-for-the-eigenvalues-of-a-symmetric-n
For larger n just add rows and columns of 0's.

The formula in (a) is not for serious use; it is only to indicate that even in the 2×2 case, the norm of a matrix or linear transformation does not have a simple algebraic formula.

XX.12.6.7. Prove the following nonlinear version of XX.12.2.9.:

THEOREM. Let $\mathcal{X}$ be a Banach space, and $f : \mathcal{X} \to \mathcal{X}$ a strict contraction (a Lipschitz function with Lipschitz constant < 1). Let $\iota : \mathcal{X} \to \mathcal{X}$ be the identity function. Then $g = \iota - f$ is a homeomorphism from $\mathcal{X}$ onto $\mathcal{X}$.

[Reduce to the case $f(0) = 0$ (). Set $f^0 = \iota$ and $f^k = f \circ f \circ \cdots \circ f$ (k times) for $k > 0$, and $h_n = \sum_{k=0}^{n} f^k$. Show that (h_n) converges pointwise on X, and uniformly on bounded sets, to an inverse for g.]

XX.13. Fredholm Operators and Fredholm Index

Fredholm operators are a very important class of "almost invertible" operators. To each Fredholm operator there is associated an integer "index" which roughly speaking measures the extent to which the operator fails to be invertible (or, more precisely, to have a "small" invertible perturbation). Arguably the most important fact about Fredholm operators is that a compact perturbation of a Fredholm operator is also Fredholm, with the same index; in particular, any compact perturbation of an invertible operator is Fredholm, with index 0.

The name "Fredholm operator" is in honor of Swedish mathematician I. Fredholm. It is argued in [Lax02] that there is "no historical justification for this," and that the notions of Fredholm operator and Fredholm index should be attributed to Fritz Noether (son of Max Noether and brother of Emmy Noether). However, Fredholm, who worked around the turn of the 20th century, before Banach spaces were defined, developed some of the crucial basic properties of such operators in his work on integral equations (nicely described in [Lax02]), although he did indeed only consider operators of index 0. The names "Fredholm operator" and "Fredholm index" are also well established so we will use them instead of the names "Noether operator" and "Noether index" used in [Lax02].

The theory of Fredholm operators and Fredholm index is not only important for applications, but (in retrospect) was a pioneering example of bringing algebraic topology into the theory of operator algebras. In fact, it was one of the first examples of the process called "noncommutative topology," which underlies much of the modern theory of operator algebras. See the introduction to [Con94] for an excellent survey of noncommutative topology and geometry.

XX.13.1. Banach Space Preliminaries

The first elementary result uses the quotient norm: if $\mathcal{Y}$ is a closed subspace of a normed vector space $\mathcal{X}$, the *quotient norm* on $\mathcal{X}/\mathcal{Y}$ is the norm $\|x+\mathcal{Y}\| = \inf\{\|x-y\| : y \in \mathcal{Y}\} = \inf\{\|z\| : z+\mathcal{Y} = x+\mathcal{Y}\}$.

XX.13.1.1. Proposition. Let $\mathcal{Y}$ be a proper closed subspace of a normed vector space $\mathcal{X}$, and $\epsilon > 0$. Then there is a $x \in \mathcal{X}$ with $\|x\| \leq 1+\epsilon$ and $\|x-y\| \geq 1$ for all $y \in \mathcal{Y}$.

Proof: Let x be a suitable preimage of a unit vector in $\mathcal{X}/\mathcal{Y}$. 👍

Next we obtain a useful fact which is a simple consequence of the Hahn-Banach Theorem:

XX.13.1.2. Proposition. Let $\mathcal{X}$ be a normed vector space, and $\mathcal{Y}$ a finite-dimensional subspace (which is automatically closed.) Then $\mathcal{Y}$ has a closed complementary subspace $\mathcal{Z}$ (i.e. $\mathcal{Y}+\mathcal{Z} = \mathcal{X}$ and $\mathcal{Y} \cap \mathcal{Z} = \{0\}$.) If $\mathcal{R}$ is a closed subspace of $\mathcal{X}$ with $\mathcal{Y} \cap \mathcal{R} = \{0\}$, then $\mathcal{Z}$ may be chosen to contain $\mathcal{R}$.

Proof: Let $\{x_1, \ldots, x_n\}$ be a basis for $\mathcal{Y}$, and define linear functionals ϕ_i $(1 \leq i \leq n)$ on $\mathcal{Y}$ by $\phi_i(\sum_{j=1}^n \alpha_j x_j) = \alpha_i$ (i.e. $\phi_i(x_j) = \delta_{ij}$.) Then each ϕ_i is bounded since $\mathcal{Y}$ is finite-dimensional. If $\mathcal{W}$ is the subspace of $\mathcal{X}$ spanned by $\mathcal{Y}$ and $\mathcal{R}$, then $\mathcal{W}$ is closed (the image of $\mathcal{W}$ in $\mathcal{X}/\mathcal{R}$ is the same as the image of $\mathcal{Y}$, hence is finite-dimensional and therefore closed), so $\mathcal{W} \cong \mathcal{Y} \oplus \mathcal{R}$. Extend ϕ_i to $\mathcal{W}$ by setting it equal to 0 on $\mathcal{R}$. Then extend ϕ_i to a bounded linear functional ψ_i on $\mathcal{X}$ by the Hahn-Banach Theorem. Define $P \in \mathcal{B}(\mathcal{X})$ by $Py = \sum_{i=1}^n \psi_i(y)x_i$. Then $\mathcal{R}(P) = \mathcal{Y}$, and $P|_{\mathcal{Y}}$ is the identity (P is a projection onto $\mathcal{Y}$.) Then $\mathcal{Z} = \mathcal{N}(P)$ is a closed subspace of $\mathcal{X}$ complementary to $\mathcal{Y}$, containing $\mathcal{R}$. 👍

We recall the definitions of some standard terms from operator theory which will be used in this section.

XX.13.1.3. DEFINITION. Let $\mathcal{X}$ and $\mathcal{Y}$ be normed vector spaces, and $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$. Then T is *bounded below* if there is an $\epsilon > 0$ such that $\|Tx\| \geq \epsilon \|x\|$ for all $x \in \mathcal{X}$.

An operator which is bounded below is one-to-one, and its range is closed if $\mathcal{X}$ is a Banach space.

XX.13.1.4. DEFINITION. An operator $T \in \mathcal{B}(\mathcal{X})$ has *finite ascent* n if the chain $\mathcal{N}(T) \subseteq \mathcal{N}(T^2) \subseteq \cdots$ stabilizes at n, i.e. $\mathcal{N}(T^n) = \mathcal{N}(T^{n+1}) = \cdots$.

T has *finite descent* m if the chain $\mathcal{R}(T) \supseteq \mathcal{R}(T^2) \supseteq \cdots$ stabilizes at m.

XX.13.1.5. Note that if $\mathcal{N}(T^n) = \mathcal{N}(T^{n+1})$, then $\mathcal{N}(T^n) = \mathcal{N}(T^{n+m})$ for all m: if $x \in \mathcal{N}(T^{r+1}) \backslash \mathcal{N}(T^r)$ for some $r > n$, then $T^{r-n}x \in \mathcal{N}(T^{n+1}) \setminus \mathcal{N}(T^n)$. Similarly, if $\mathcal{R}(T^n) = \mathcal{R}(T^{n+1})$, then $\mathcal{R}(T^n) = \mathcal{R}(T^{n+m})$ for all m.

XX.13.1.6. It is fairly exceptional for an operator to have finite ascent or descent, but note that an injective operator has finite ascent 1, and a surjective operator finite descent 1. Every operator on a finite-dimensional space has finite ascent and descent. A normal operator () on a Hilbert space has finite ascent 1, but not necessarily finite descent, even if it is compact (Exercise XX.13.6.1.).

XX.13.1.7. DEFINITION. If $T : \mathcal{X} \to \mathcal{Y}$ is a bounded operator, the *adjoint* of T is the operator $T^* : \mathcal{Y}^* \to \mathcal{X}^*$ defined by $T^*(\phi) = \phi \circ T$. ($\mathcal{X}^*$ is the usual Banach space dual of $\mathcal{X}$, the space of bounded linear functionals on $\mathcal{X}$.)

XX.13.1.8. $T^* \in \mathcal{B}(\mathcal{Y}^*, \mathcal{X}^*)$ and $\|T^*\| = \|T\|$ by the Hahn-Banach Theorem. If $\mathcal{X}$ and $\mathcal{Y}$ are Hilbert spaces, then $\mathcal{X}^*$ and $\mathcal{Y}^*$ can be identified with $\mathcal{X}$ and $\mathcal{Y}$ in the standard way, and then T^* agrees with the usual adjoint operator defined by the inner product: $\langle Tx, y\rangle = \langle x, T^*y\rangle$ for $x \in \mathcal{X}$, $y \in \mathcal{Y}$.

XX.13.1.9. PROPOSITION. If $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$ is finite-rank, then T^* is finite-rank.

PROOF: T factors through $\mathcal{R}(T)$, so T^* factors through $\mathcal{R}(T)^*$, which is finite-dimensional. 👍

XX.13.2. Compact Operators

XX.13.2.1. DEFINITION. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces. An operator $T : \mathcal{X} \to \mathcal{Y}$ is *compact* if T sends bounded subsets of $\mathcal{X}$ to precompact subsets of $\mathcal{Y}$.

XX.13.2.2. In other words, if B is a bounded subset of $\mathcal{X}$, then $\overline{T(B)}$ is a compact subset of $\mathcal{Y}$. Equivalently, whenever (x_n) is a bounded sequence of vectors in $\mathcal{X}$, then (Tx_n) has a convergent subsequence. T is compact if and only if $T(\mathcal{B}_\mathcal{X})$ is totally bounded. Since a compact metric space is separable, if $T : \mathcal{X} \to \mathcal{Y}$ is compact, $\overline{\mathcal{R}(T)}$ is a separable subspace of $\mathcal{Y}$.

XX.13.2.3. In many references, particularly older ones, compact operators are called *completely continuous operators.*

XX.13.2.4. It is obvious that a compact operator is bounded, and the composition (in either order) of a compact operator with a bounded operator is compact. It is easily seen using the total boundedness criterion that a (norm-)limit of compact operators is compact. The set of compact operators from $\mathcal{X}$ to $\mathcal{Y}$, denoted $\mathcal{K}(\mathcal{X},\mathcal{Y})$, is a closed subspace of $\mathcal{B}(\mathcal{X},\mathcal{Y})$; $\mathcal{K}(\mathcal{X}) = \mathcal{K}(\mathcal{X},\mathcal{X})$ is a closed two-sided ideal in $\mathcal{B}(\mathcal{X})$. Every finite-rank bounded operator is compact; for many, but not all, Banach spaces, every compact operator is a limit of finite-rank operators (see the discussion below.)

XX.13.2.5. It is easily seen that a bounded operator is weakly continuous (cf. [?].) So if $\mathcal{X}$ is a Hilbert space (or, more generally, a reflexive Banach space), $\mathcal{B}_\mathcal{X}$ is weakly compact, so if $T \in \mathcal{B}(\mathcal{X},\mathcal{Y})$, $T(\mathcal{B}_\mathcal{X})$ is weakly compact and thus (norm-)closed. In particular, if $T \in \mathcal{K}(\mathcal{X},\mathcal{Y})$, then $T(\mathcal{B}_\mathcal{X})$ is already closed and therefore compact.

XX.13.2.6. PROPOSITION. If $T \in \mathcal{K}(\mathcal{X},\mathcal{Y})$, then $T^* \in \mathcal{K}(\mathcal{Y}^*,\mathcal{X}^*)$.

PROOF: Let $\epsilon > 0$. Since $T(\mathcal{B}_\mathcal{X})$ is totally bounded, there are $x_1,\cdots,x_n \in \mathcal{B}_\mathcal{X}$ such that, for each $x \in \mathcal{B}_\mathcal{X}$, there is an i with $\|Tx - Tx_i\| < \epsilon/3$. Give $\mathbb{F}^n$ the infinity norm, i.e. $\|(\alpha_1,\ldots,\alpha_n)\| = \max|\alpha_i|$, and define $S : \mathcal{Y}^* \to \mathbb{F}^n$ by $S\phi = (\phi(Tx_1),\ldots,\phi(Tx_n))$. S is finite-rank and bounded and hence compact, so $S(\mathcal{B}_{\mathcal{Y}^*})$ is totally bounded; let $\phi_1,\cdots,\phi_m \in \mathcal{B}_{\mathcal{Y}^*}$ be such that, for every $\phi \in \mathcal{B}_{\mathcal{Y}^*}$, there is a j such that $\|S\phi - S\phi_j\| < \epsilon/3$. If $\phi \in \mathcal{B}_{\mathcal{Y}^*}$, choose a corresponding ϕ_j; then, for any $x \in \mathcal{B}_\mathcal{X}$, with corresponding x_i,

$$|T^*\phi(x) - T^*\phi_j(x)| = |\phi(Tx) - \phi_j(Tx)|$$
$$\leq |\phi(Tx) - \phi(Tx_i)| + |\phi(Tx_i) - \phi_j(Tx_i)| + |\phi_j(Tx_i) - \phi_j(Tx)|$$
$$\leq \|Tx - Tx_i\| + \|S\phi - S\phi_j\| + \|Tx_i - Tx\| < \epsilon/3 + \epsilon/3 + \epsilon/3 = \epsilon\ .$$

Thus $\|T^*\phi - T^*\phi_j\| \leq \epsilon$, so $T^*(\mathcal{B}_{\mathcal{Y}^*})$ is totally bounded. 👍

While the proof of XX.13.2.6. is not difficult, there is an alternate approach (of comparable difficulty) on a Hilbert space which is worth noting:

XX.13.2.7. THEOREM. If $\mathcal{Y}$ is a Hilbert space, then $\mathcal{K}(\mathcal{X},\mathcal{Y})$ is the closure of the finite-rank bounded operators from $\mathcal{X}$ to $\mathcal{Y}$.

PROOF: We again use a total boundedness argument. Let $T \in \mathcal{K}(\mathcal{X},\mathcal{Y})$, and $\epsilon > 0$. Choose $x_1,\cdots,x_n \in \mathcal{B}_\mathcal{X}$ such that, for any $x \in \mathcal{B}_\mathcal{X}$, there is an i with $\|Tx - Tx_i\| < \epsilon/2$. Let $P \in \mathcal{B}(\mathcal{Y})$ be the orthogonal projection onto the subspace spanned by $\{Tx_1,\cdots,Tx_n\}$. Then P is finite-rank, $PTx_i = Tx_i$ for all i, and $\|P\| = 1$. If $x \in \mathcal{B}_\mathcal{X}$, and a corresponding x_i is chosen, then

$$\|PTx - Tx\| \leq \|PTx - PTx_i\| + \|Tx_i - Tx\| < \epsilon/2 + \epsilon/2 = \epsilon\ .$$

Thus $\|PT - T\| \leq \epsilon$, and PT has finite rank. 👍

XX.13.2.8. If $T \in \mathcal{K}(\mathcal{X},\mathcal{Y})$ and $\mathcal{Y}$ is a Hilbert space, an alternate proof of XX.13.2.6. is then obtained by taking (T_n) of finite rank and $T_n \to T$; then $T_n^* \to T^*$, and T_n^* is finite-rank by XX.13.1.9.. Similarly, if $T \in \mathcal{K}(\mathcal{X},\mathcal{Y})$ and $\mathcal{X}$ is a Hilbert space, apply XX.13.2.7. to $T^* \in \mathcal{K}(\mathcal{Y}^*,\mathcal{X})$ (using XX.13.2.6.) to conclude that $\mathcal{K}(\mathcal{X},\mathcal{Y})$ is also the closure of the finite-rank bounded operators from $\mathcal{X}$ to $\mathcal{Y}$ (there is also a simple direct proof.)

XX.13.2.9. DEFINITION. A Banach space $\mathcal{X}$ has the *approximation property* if every compact operator on $\mathcal{X}$ is a (norm-)limit of finite-rank (bounded) operators on $\mathcal{X}$.

XX.13.2.10. XX.13.2.7. shows that Hilbert spaces have the approximation property. All standard Banach spaces have the approximation property. P. ENFLO [Enf73] constructed the first example of a Banach space without the approximation property; see [Jam82] for a discussion of this and related matters, and [Gow95] for more recent developments.

Strictly Singular Operators

There is a slightly larger class of operators which to some extent behave like compact operators:

XX.13.2.11. DEFINITION. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces, with $\mathcal{X}$ infinite-dimensional. An operator $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$ is *strictly singular* if T is not bounded below on any infinite-dimensional subspace of $\mathcal{X}$.

XX.13.2.12. It follows from () that every compact operator is strictly singular. Every strictly singular operator on a Hilbert space, or many standard Banach spaces, is compact; but there are operators on some Banach spaces which are strictly singular but not compact (XX.13.6.2.).

XX.13.3. Fredholm Operators

XX.13.3.1. DEFINITION. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces and $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$. T is a *Fredholm operator* if $\mathcal{N}(T)$ is finite-dimensional and $\mathcal{R}(T)$ has finite codimension. The *index* of T is $dim\ \mathcal{N}(T) - codim\ \mathcal{R}(T)$. Denote the set of Fredholm operators from $\mathcal{X}$ to $\mathcal{Y}$ by $\mathcal{F}(\mathcal{X}, \mathcal{Y})$, and write $\mathcal{F}(\mathcal{X})$ for $\mathcal{F}(\mathcal{X}, \mathcal{X})$.

XX.13.3.2. EXAMPLES.

(i) If $\mathcal{X}$ and $\mathcal{Y}$ are finite-dimensional, then every operator from $\mathcal{X}$ to $\mathcal{Y}$ is Fredholm with index $dim\ \mathcal{X} - dim\ \mathcal{Y}$.

(ii) If T is invertible, then T is Fredholm with index 0.

(iii) Let S be the unilateral shift on the Hilbert space l^2 of square-summable sequences, defined by $S(\alpha_1, \alpha_2, \dots) = (0, \alpha_1, \alpha_2, \dots)$. Then S is Fredholm with index -1. S^n is Fredholm with index $-n$, and $(S^*)^n$ is Fredholm with index n.

XX.13.3.3. Definition XX.13.3.1. is not the most common one, which in addition requires $\mathcal{R}(T)$ to be closed. However, the two definitions are equivalent, since a Fredholm operator in the sense of XX.13.3.1. always has closed range. Although strictly speaking we will not need this fact for our development of the theory, we give a proof for completeness (and to show that we are not redefining the notion of Fredholm operator), and also because the argument gives some important structural properties of Fredholm operators.

XX.13.3.4. PROPOSITION. Let $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$. Then $\mathcal{R}(T)$ is closed.

PROOF: Let $\mathcal{W}$ be a complementary subspace for $\mathcal{R}(T)$ in $\mathcal{Y}$; then $\mathcal{W}$ is finite-dimensional and hence closed. Let $\mathcal{Z}$ be a closed subspace of $\mathcal{X}$ complementary to $\mathcal{N}(T)$ (XX.13.1.2.). Then $\mathcal{R}(T|_{\mathcal{Z}}) = \mathcal{R}(T)$. Define a bounded operator S from the Banach space $\mathcal{W} \oplus \mathcal{Z}$ to $\mathcal{Y}$ by $S(w, z) = w + Tz$. Then S is a bijection, hence a homeomorphism by the Open Mapping Theorem, and $S(\{0\} \oplus \mathcal{Z}) = \mathcal{R}(T)$. 👍

A corollary of the proof gives a simple picture of a Fredholm operator:

XX.13.3.5. COROLLARY. Let $\mathcal{X}$, $\mathcal{Y}$ be Banach spaces, and $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$. Then there are closed subspaces $\mathcal{Z}$, $\mathcal{W}$ of $\mathcal{X}$ and $\mathcal{Y}$ complementary to $\mathcal{N}(T)$ and $\mathcal{R}(T)$, respectively, such that $\mathcal{X} \cong \mathcal{N}(T) \oplus \mathcal{Z}$, $\mathcal{Y} \cong \mathcal{W} \oplus \mathcal{R}(T)$, and $T \cong 0 \oplus U$, where U is a linear isomorphism from $\mathcal{Z}$ onto $\mathcal{R}(T)$ (i.e. U is bounded below.)

XX.13.3.6. COROLLARY. Let $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$. Then there is an $S \in \mathcal{F}(\mathcal{Y}, \mathcal{X})$, with $index(S) = -index(T)$, such that $ST = I_{\mathcal{X}} - P$ and $TS = I_{\mathcal{Y}} - Q$, where P and Q are finite-rank bounded idempotent operators.

PROOF: Under the above identifications, S may be taken as $0 \oplus U^{-1} : \mathcal{W} \oplus \mathcal{R}(T) \to \mathcal{N}(T) \oplus \mathcal{Z}$. 👍

XX.13.3.7. The operator S is a *quasi-inverse* for T: $T = TST$. (If S is as defined in the proof, T is also a quasi-inverse for S.)

We obtain another characterization of Fredholm operators from XX.13.3.5.:

XX.13.3.8. COROLLARY. Let $\mathcal{X}$, $\mathcal{Y}$ be Banach spaces, and $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$. Then $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$ if and only if there is a closed subspace $\mathcal{Z}$ of $\mathcal{X}$, of finite codimension, with $T(\mathcal{Z})$ of finite codimension in $\mathcal{Y}$, such that T is bounded below on $\mathcal{Z}$. If there is such a $\mathcal{Z}$, then $index(T) = codim(\mathcal{Z}) - codim(T(\mathcal{Z}))$.

XX.13.3.9. COROLLARY. Let $\mathcal{X}$, $\mathcal{Y}$ be Banach spaces, and $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$. Then there is an $\epsilon > 0$ such that $T + S \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$ and $index(T + S) = index(T)$ for all $S \in \mathcal{B}(X, Y)$, $\|S\| < \epsilon$.

PROOF: Let $\mathcal{Z}$ be a closed subspace of finite codimension in $\mathcal{X}$ such that T is bounded below on $\mathcal{Z}$. Then, if $\|S\|$ is sufficiently small, $T + S$ is bounded below on $\mathcal{Z}$ and $(T + S)(\mathcal{Z})$ is a small enough perturbation of $T(\mathcal{Z})$ to have the same codimension (). 👍

Another important consequence of XX.13.3.5. is:

XX.13.3.10. Corollary. Let $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$. Then $T^* \in \mathcal{F}(\mathcal{Y}^*, \mathcal{X}^*)$, $dim(\mathcal{N}(T^*)) = codim(\mathcal{R}(T))$, $codim(\mathcal{R}(T^*)) = dim(\mathcal{N}(T))$, and $index(T^*) = -index(T)$.

Proof: If $T = 0 \oplus U : \mathcal{N}(T) \oplus \mathcal{Z} \to \mathcal{W} \oplus \mathcal{R}(T)$, then $T^* = 0 \oplus U^* : \mathcal{W}^* \oplus \mathcal{R}(T)^* \to \mathcal{N}(T)^* \oplus \mathcal{Z}^*$, and U^* is invertible; thus $\mathcal{N}(T^*) = \mathcal{W}^* \oplus \{0\}$ and $\mathcal{R}(T^*) = \{0\} \oplus \mathcal{Z}^*$. We have $\mathcal{W}^* \cong \mathcal{W}$ and $\mathcal{N}(T)^* \cong \mathcal{N}(T)$ since they are finite-dimensional. 👍

XX.13.3.11. Actually, if $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$, then $\mathcal{N}(T^*) = \mathcal{R}(T)^\perp = \{\phi \in \mathcal{Y}^* : \phi|_{\mathcal{R}(T)} = 0\} \cong (\mathcal{Y}/\overline{\mathcal{R}(T)})^*$. Thus $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$ is Fredholm if and only if $\mathcal{R}(T)$ is closed and $\mathcal{N}(T)$ and $\mathcal{N}(T^*)$ are finite-dimensional, and $index(T) = dim\ \mathcal{N}(T) - dim\ \mathcal{N}(T^*)$.

It is useful not to require that the range of a Fredholm operator be closed as part of the definition. The next proof is an example.

XX.13.3.12. Proposition. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces, $T \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$, $S \in \mathcal{B}(\mathcal{Y}, \mathcal{X})$. If ST and TS are Fredholm, then S and T are Fredholm.

Proof: We show T is Fredholm. $\mathcal{N}(T) \subseteq \mathcal{N}(ST)$, which is finite-dimensional, and $\mathcal{R}(T) \supseteq \mathcal{R}(TS)$, which has finite codimension. 👍

Conversely:

XX.13.3.13. Theorem. Let $\mathcal{X}, \mathcal{Y}, \mathcal{Z}$ be Banach spaces, and $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$ and $S \in \mathcal{F}(\mathcal{Y}, \mathcal{Z})$. Then $ST \in \mathcal{F}(\mathcal{X}, \mathcal{Z})$ and $index(ST) = index(S) + index(T)$.

Proof: Let $\mathcal{U}$ be a closed subspace of $\mathcal{X}$ complementary to $\mathcal{N}(T)$ on which T is bounded below. Then $U = T|_{\mathcal{U}}$ is an isomorphism from $\mathcal{U}$ onto $\mathcal{R}(T)$. Set $\mathcal{Y}_2 = \mathcal{R}(T) \cap \mathcal{N}(S)$ and $\mathcal{X}_2 = U^{-1}(\mathcal{Y}_2)$. Then $\mathcal{X}_2$ is a finite-dimensional subspace of $\mathcal{U}$. Let $\mathcal{X}_1$ be a closed subspace of $\mathcal{U}$ complementary to $\mathcal{X}_2$, and let $\mathcal{Y}_1 = U(\mathcal{X}_1) = T(\mathcal{X}_1)$. Then $\mathcal{Y}_1$ is a closed subspace of $\mathcal{Y}$ with zero intersection with $\mathcal{N}(S)$, and $\mathcal{Y}_1$ and $\mathcal{Y}_2$ span $\mathcal{R}(T)$, and since $\mathcal{Y}_2$ is finite-dimensional and $\mathcal{R}(T)$ has finite codimension in $\mathcal{Y}$, $\mathcal{Y}_1$ has finite codimension in $\mathcal{Y}$. Let $\mathcal{V}$ be a closed subspace of $\mathcal{Y}$ containing $\mathcal{Y}_1$ which is complementary to $\mathcal{N}(S)$ (XX.13.1.2.), and $\mathcal{Y}_3$ a subspace of $\mathcal{V}$ complementary to $\mathcal{Y}_1$. Then $\mathcal{Y}_3$ is finite-dimensional, and we have

$$\mathcal{Y} \cong \mathcal{Y}_1 \oplus \mathcal{Y}_2 \oplus \mathcal{Y}_3 \oplus \mathcal{Y}_4$$

where $\mathcal{Y}_4$ is a subspace of $\mathcal{N}(S)$ complementary to $\mathcal{Y}_2$. Then $\mathcal{Y}_2, \mathcal{Y}_3, \mathcal{Y}_4$ are finite-dimensional, $\mathcal{Y}_2$ and $\mathcal{Y}_4$ span $\mathcal{N}(S)$, and $\mathcal{Y}_1$ and $\mathcal{Y}_2$ span $\mathcal{R}(T)$. Then S is bounded below on $\mathcal{V}$ (cf. the proof of XX.13.3.4.), and $V = S|_{\mathcal{V}}$ maps $\mathcal{V}$ isomorphically onto $\mathcal{R}(S)$. Also, $UV = ST|_{\mathcal{X}_1}$ maps $\mathcal{X}_1$ isomorphically onto $\mathcal{Z}_1 = V(\mathcal{Y}_1) = S(Y_1)$. Since $\mathcal{Y}_1$ has finite codimension in $\mathcal{Y}$ and $\mathcal{R}(S)$ has finite codimension in $\mathcal{Z}$, $\mathcal{Z}_1$ has finite codimension in $\mathcal{Z}$ and ST is Fredholm.

We have

$$\mathcal{X} \cong \mathcal{X}_1 \oplus \mathcal{X}_2 \oplus \mathcal{X}_3$$

$$\mathcal{Z} \cong \mathcal{Z}_1 \oplus \mathcal{Z}_2 \oplus \mathcal{Z}_3$$

where $\mathcal{X}_3 = \mathcal{N}(T)$, $\mathcal{Z}_3 = V(\mathcal{Y}_3) = S(\mathcal{Y}_3)$, and $\mathcal{Z}_2$ is a subspace of $\mathcal{Z}$ complementary to $\mathcal{R}(S)$. Set $a_k = dim(\mathcal{X}_k)$, $b_k = dim(\mathcal{Y}_k)$, and $c_k = dim(\mathcal{Z}_k)$. We then have

$$index(T) = a_3 - (b_3 + b_4)$$

$$index(S) = (b_2 + b_4) - c_2$$

$$index(ST) = (a_2 + a_3) - (c_2 + c_3) \ .$$

But $b_2 = a_2$ and $c_3 = b_3$ since U and V are isomorphisms, so we have

$$index(ST) = b_2 + a_3 - b_3 - c_2 = index(S) + index(T) \ .$$

XX.13.4. Fredholm Operators of Index 0 and the Fredholm Alternative

We first note an immediate consequence of XX.13.3.5.:

XX.13.4.1. PROPOSITION. Let $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$ have index 0. Then there are $V, F \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$ with V invertible and F finite-rank, with $T = V + F$.

The converse is also true (XX.13.5.12.).

PROOF: Under the identifications $\mathcal{X} \cong \mathcal{N}(T) \oplus \mathcal{Z}$, $\mathcal{Y} \cong \mathcal{W} \oplus \mathcal{R}(T)$, $T \cong 0 \oplus U$, we have that $dim(\mathcal{N}(T)) = dim(\mathcal{W}) < \infty$, so there is a (necessarily bounded) linear isomorphism $S : \mathcal{N}(T) \to \mathcal{W}$. Set $V = S \oplus U$, $F = -S \oplus 0$. 

The next observation is called the *Fredholm Alternative*. The last statement follows from XX.13.3.10..

XX.13.4.2. PROPOSITION. Let $T \in \mathcal{F}(\mathcal{X}, \mathcal{Y})$ have index 0. Then T is injective if and only if T is surjective. So either the equation $Tx = y$ has a unique solution for each $y \in \mathcal{Y}$, or the homogeneous equation $Tx = 0$ has a nontrivial (but finite-dimensional) space of solutions.

Furthermore, the equation $T^*\phi = \psi$ has a unique solution for each ψ if and only if $Tx = y$ has a unique solution for each y, and the solution set of $T^*\phi = 0$ has the same (finite) dimension as the solution set of $Tx = 0$.

XX.13.4.3. The result is sometimes paraphrased: "If the solution to $Tx = y$ is unique, then it exists."

XX.13.5. Relation between Compact and Fredholm Operators

The next theorem is the main result of this section.

XX.13.5.1. THEOREM. Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then $I + T$ is Fredholm, of index 0.

The proof that $I + T$ is Fredholm consists of the next three lemmas.

XX.13.5.2. LEMMA. Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then $\mathcal{N}(I+T)$ is finite-dimensional.

PROOF: $T = -I$ on $\mathcal{N}(I+T)$, and thus the unit ball of $\mathcal{N}(I+T)$ is compact. 👍

XX.13.5.3. LEMMA. Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then $\mathcal{R}(I+T)$ is closed.

PROOF: Let $\mathcal{Z}$ be a closed subspace of $\mathcal{X}$ complementary to $\mathcal{N}(I+T)$ (XX.13.1.2.). It suffices to show that $I+T$ is bounded below on $\mathcal{Z}$; then $\mathcal{R}(I+T) = \mathcal{R}((I+T)|_{\mathcal{Z}})$ is closed. Suppose (x_n) is a sequence of unit vectors in $\mathcal{Z}$ with $\|(I+T)x_n\| \to 0$. Passing to a subsequence we may assume that $Tx_n \to y$ for some y, since T is compact. But $(I+T)x_n \to 0$, so $x_n \to -y$, and thus $\|y\| = 1$ and $Ty = -y$, i.e. $(I+T)y = 0$, $y \in \mathcal{N}(I+T)$. But $y \in \mathcal{Z}$ since $-x_n \to y$ and $\mathcal{Z}$ is closed; hence $y \in \mathcal{Z} \cap \mathcal{N}(I+T) = \{0\}$, a contradiction. 👍

XX.13.5.4. LEMMA. Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then $\mathcal{R}(I+T)$ has finite codimension.

PROOF: Consider the Banach space $\mathcal{Y} = \mathcal{X}/\mathcal{R}(I+T)$. We show that $\mathcal{Y}$ is finite-dimensional by showing that the dual space $\mathcal{Y}^*$ is finite-dimensional. $\mathcal{Y}^*$ can be identified with the subspace of $\mathcal{X}^*$ consisting of functionals vanishing on $\mathcal{R}(I+T)$. But $\mathcal{Y}^*$ is precisely $\mathcal{N}((I+T)^*) = \mathcal{N}(I+T^*)$. $T^* \in \mathcal{K}(\mathcal{X}^*)$ by XX.13.2.6., so $\mathcal{N}(I+T^*)$ is finite-dimensional by XX.13.5.2.. 👍

It remains to be shown that $index(I+T) = 0$. Our proof is partly based in spirit on [RSN90, §70] (repeated without attribution in the rather dreadful paper [Ram01]). We first obtain another important property of $I+T$ which is a simple (but nonobvious) consequence of the compactness of T.

XX.13.5.5. PROPOSITION. Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then $I+T$ has finite ascent and finite descent.

PROOF: If $I+T$ does not have finite ascent, by XX.13.1.1. choose for each n a vector $x_n \in \mathcal{N}((I+T)^n)$ with $\|x_n\| \le 2$ and $\|x_n - y\| \ge 1$ for all $y \in \mathcal{N}((I+T)^{n-1})$. Then, for $m < n$,

$$\|Tx_m - Tx_n\| = \|x_n - (I+T)x_n + (I+T)x_m - x_m\| \ge 1$$

since $x_m - (I+T)x_m + (I+T)x_n \in \mathcal{N}((I+T)^{n-1})$. Thus (Tx_n) has no convergent subsequence, contradicting compactness of T.

The proof that $I+T$ has finite descent is virtually identical. 👍

XX.13.5.6. LEMMA. If $\mathcal{X}$ is a Banach space and $T \in \mathcal{K}(\mathcal{X})$, then $index(I+T) = 0$.

PROOF: Let n be the maximum of the ascent and descent of $I+T$, so $\mathcal{N}((I+T)^n) = \mathcal{N}((I+T)^{n+k})$ and $\mathcal{R}((I+T)^n) = \mathcal{R}((I+T)^{n+k})$ for all k. Note that $(I+T)^n = I+S$ for $S \in \mathcal{K}(\mathcal{X})$, so $(I+T)^n$ is Fredholm and hence $\mathcal{R} = \mathcal{R}((I+T)^n)$ is closed and $\mathcal{N} = \mathcal{N}((I+T)^n)$ is finite-dimensional. Then $\mathcal{N} \cap \mathcal{R} = \{0\}$, for if $0 \neq y = (I+T)^n x \in \mathcal{N} \cap \mathcal{R}$, then $x \in \mathcal{N}((I+T)^{2n}) \setminus \mathcal{N}((I+T)^n)$, a contradiction. Thus $(I+T)^n$ maps $\mathcal{R}$ isomorphically onto $\mathcal{R}$ (since $\mathcal{R} = \mathcal{R}((I+T)^{2n})$.) If $\mathcal{Z}$ is a closed subspace of $\mathcal{X}$ containing $\mathcal{R}$ which is complementary to $\mathcal{N}$, then $(I+T)^n$ also maps $\mathcal{Z}$ isomorphically onto $\mathcal{R}$, and it follows that $\mathcal{Z} = \mathcal{R}$, i.e. $\mathcal{N}$ and $\mathcal{R}$ are complementary subspaces of $\mathcal{X}$. Since both $\mathcal{N}$ and $\mathcal{R}$ are invariant under $I+T$ and $(I+T)|_{\mathcal{R}}$ is an isomorphism, $index(I+T) = index((I+T)|_{\mathcal{N}})$. But $\mathcal{N}$ is finite-dimensional, so $index((I+T)|_{\mathcal{N}}) = 0$. 👍

This completes the proof of XX.13.5.1.. 💪

The proof of XX.13.5.6. actually shows that $I+T$ has a simple form:

XX.13.5.7. COROLLARY. Let $\mathcal{X}$ be a Banach space, $T \in \mathcal{K}(\mathcal{X})$. Then there are complementary closed subspaces $\mathcal{N}$ and $\mathcal{R}$ of $\mathcal{X}$, each invariant under T (and hence under $I+T$), with $\mathcal{N}$ finite-dimensional, such that $(I+T)|_{\mathcal{R}}$ is invertible and $(I+T)|_{\mathcal{N}}$ is nilpotent.

It is well known (and useful) that every operator on a finite-dimensional space has this property.

The next theorem [Atk53] gives a useful alternate characterization of Fredholm operators.

XX.13.5.8. THEOREM. [ATKINSON'S THEOREM] Let $\mathcal{X}$ be an infinite-dimensional Banach space and $\pi : \mathcal{B}(\mathcal{X}) \to \mathcal{Q}(\mathcal{X})$ the quotient map onto the Calkin algebra $\mathcal{Q}(\mathcal{X}) = \mathcal{B}(\mathcal{X})/\mathcal{K}(\mathcal{X})$ of $\mathcal{X}$. Then $T \in \mathcal{B}(\mathcal{X})$ is Fredholm if and only if $\pi(T)$ is invertible in $\mathcal{Q}(\mathcal{X})$.

PROOF: If T is Fredholm, let S be a quasi-inverse for T as in XX.13.3.6.; then $\pi(S)$ is an inverse for $\pi(T)$.

Conversely, suppose $\pi(T)$ is invertible in $\mathcal{Q}(\mathcal{X})$, and let $S \in \mathcal{B}(\mathcal{X})$ such that $\pi(S) = \pi(T)^{-1}$. Then $ST = I+K$, $TS = I+L$ for $K, L \in \mathcal{K}(\mathcal{X})$. $I+K$ and $I+L$ are Fredholm by XX.13.5.1., so S and T are Fredholm by XX.13.3.12.. 👍

XX.13.5.9. COROLLARY.

(i) If $\mathcal{X}$ is a Banach space, $S, T \in \mathcal{F}(\mathcal{X})$, and $K \in \mathcal{K}(\mathcal{X})$, then ST and $T+K$ are Fredholm.

(ii) The set $\mathcal{F}(\mathcal{X})$ of Fredholm operators on $\mathcal{X}$ is open in $\mathcal{B}(\mathcal{X})$.

Part (ii) is an immediate consequence of XX.13.3.9., or follows directly from (). It also follows from XX.13.3.9. that *index* is locally constant on $\mathcal{F}(\mathcal{X})$, hence constant on connected components. In particular, we obtain:

XX.13.5.10. Corollary. Let $\mathcal{X}$ be a Banach space, and $T \in \mathcal{F}(\mathcal{X})$. Then $index(T) = index(T+K)$ for any $K \in \mathcal{K}(\mathcal{X})$.

Proof: T and $T+K$ are connected in $\mathcal{F}(\mathcal{X})$ by the path $T+tK$, $0 \le t \le 1$. 👍

XX.13.5.11. The *index* map from the connected components of $\mathcal{F}(\mathcal{X})$ to $\mathbb{Z}$ is thus well defined, but it is not either injective or surjective in general: it can fail to be injective since the invertible elements of $\mathcal{B}(\mathcal{X})$ are not necessarily connected [**?**], and we can even have $index(T) = 0$ for every $T \in \mathcal{F}(\mathcal{X})$ (e.g. for the examples of [**?**]; cf. [**?**].) If $\mathcal{H}$ is a Hilbert space, the *index* map is a bijection from the connected components of $\mathcal{F}(\mathcal{H})$ onto $\mathbb{Z}$.

XX.13.5.12. Theorem. Let $T \in \mathcal{F}(\mathcal{X})$. Then the following are equivalent:

(i) $index(T) = 0$.

(ii) There are $U, K \in \mathcal{B}(\mathcal{X})$ with U invertible, K compact, and $T = U + K$.

(iii) There are $V, F \in \mathcal{B}(\mathcal{X})$ with V invertible, F finite-rank, and $T = V + F$.

Proof: (i) ⇒ (iii) is XX.13.4.1. and (iii) ⇒ (ii) is trivial. For (ii) ⇒ (i), if $T = U+K$, then $U^{-1}T = I+U^{-1}K$ is Fredholm with index 0 by XX.13.5.1.. It is obvious that if S is Fredholm and W is invertible, then WS is Fredholm and $index(WS) = index(S)$; thus $T = U(U^{-1}T)$ is Fredholm and $index(T) = 0$. 👍

The argument of [RSN90, §70] gives a direct proof of (iii) ⇒ (i).

XX.13.5.13. Note that if $\mathcal{X}$ has the approximation property, then there is a simple proof of (ii) ⇒ (iii): if $T = U + K$ with U invertible and K compact, approximate K closely enough by a finite rank F that $V = U + (K - F)$ is invertible (using the fact that the set of invertible elements of $\mathcal{B}(\mathcal{X})$ is open); then $T = V + F$.

Finally, we state the Fredholm Alternative in its usual form:

XX.13.5.14. Corollary. [Fredholm Alternative] If $\mathcal{X}$ is a Banach space and $T \in \mathcal{K}(\mathcal{X})$, then $I + T$ is injective if and only if it is surjective. So either the equation $(I+T)x = y$ has a unique solution for every y, or the homogeneous equation $(I+T)x = 0$ has a nontrivial (but finite-dimensional) space of solutions.

Furthermore, the equation $(I+T^*)\phi = \psi$ has a unique solution for each ψ if and only if $(I+T)x = y$ has a unique solution for each y, and the solution set of $(I+T^*)\phi = 0$ has the same (finite) dimension as the solution set of $(I+T)x = 0$.

XX.13.5.15. Note also that if $T \in \mathcal{K}(\mathcal{X})$, then XX.13.5.1. and its consequences, notably XX.13.5.14., are valid not only for $I + T$ but also for $T - \lambda I = -\lambda(I + (-\lambda^{-1}T))$ for any $\lambda \neq 0$. This is useful in describing the eigenvalues of T. The results of Fredholm theory, especially XX.13.5.5., are used to prove that the spectrum of a compact operator on an infinite-dimensional Banach space consists of 0 and at most countably many isolated nonzero eigenvalues of finite multiplicity.

XX.13.5.16. The results of this section can be extended: if T is Fredholm and S is strictly singular, then $T+S$ is Fredholm and $index(T+S) = index(T)$ (cf. ()). Thus the Fredholm Alternative holds more generally for strictly singular operators.

XX.13.6. Exercises

XX.13.6.1. (a) Use the Spectral Theorem () to show that every normal operator on a Hilbert space has finite ascent 1.

(b) Consider the multiplication operator on ℓ^2 given by

$$T(x_1, x_2, \dots) = \left(x_1, \frac{x_2}{2}, \dots, \frac{x_n}{n}, \dots\right) .$$

Show that T is self-adjoint, hence normal, and compact, but does not have finite descent.

The difference between ascent and descent (at least in this case) is that the null space of an operator is closed but the range is not necessarily closed. In fact, if T is a normal operator on a Hilbert space, then the closure of the range of T^n is the same as the closure of $\mathcal{R}(T)$ for all n (it is the orthogonal complement of $\mathcal{N}(T) = \mathcal{N}(T^n)$).

(c) Define $S : \ell^2 \to \ell^2$ by

$$S(x_1, x_2, \dots) = \left(\frac{x_2}{2}, \dots, \frac{x_n}{n}, \dots\right) .$$

Then S is a (nonnormal) compact operator which does not have finite ascent or descent.

XX.13.6.2. (a) Show that every strictly singular operator on a Hilbert space is compact.

(b) Show that the inclusion map from ℓ^1 to ℓ^2 is not compact. [Consider the standard basis.]

(c) Show that the inclusion map from ℓ^1 to ℓ^2 is strictly singular. [Use that the weak topology on ℓ^1 has the same convergent sequences as as the norm topology ().]

(d) Let $\mathcal{X} = \ell^1 \oplus \ell^2$. Define $T \in \mathcal{B}(\mathcal{X})$ by $T(x, y) = (0, x)$. Show that T is strictly singular but not compact.

(e) Show that if $p < q$, the inclusion of ℓ^p into ℓ^q is strictly singular but not compact. So if $1 < p < q < \infty$, there is an operator on the reflexive (even uniformly convex, if the 2-norm is used on the direct sum) Banach space $\ell^p \oplus \ell^q$ which is strictly singular but not compact.

XX.13.6.3. Let $\mathcal{X}$ be a Banach space. Show that the set of strictly singular operators on $\mathcal{X}$ is a closed two-sided ideal in $\mathcal{B}(\mathcal{X})$.

XX.13.6.4. Let X be a Banach space, and S a strictly singular operator on $\mathcal{X}$. Modify the proofs for compact operators to show the following:

(a) If $T \in \mathcal{F}(\mathcal{X})$, then $T+S \in \mathcal{F}(\mathcal{X})$ and $index(T+S) = index(T)$. In particular, if T is invertible, then $T+S$ is a Fredholm operator of index 0.

(b) $\sigma(S)$ consists of 0 and at most countably many nonzero numbers, each an eigenvalue of finite multiplicity, with no nonzero accumulation point.

XX.14. The Spectral Theorem

The Spectral Theorem, in its various forms, gives a precise description of the structure of self-adjoint and, more generally, normal operators on a Hilbert space. It roughly says that such an operator is, up to unitary equivalence, a "multiplication operator with multiplicity" with a simple explicit description. The name "Spectral Theorem" comes from the fact that the description is expressed in terms of the spectrum of the operator.

XX.14.1. The Finite-Dimensional Spectral Theorem

We first discuss the Spectral Theorem on a finite-dimensional Hilbert space. As might be expected, this situation is pure Linear Algebra with no essential use of functional analysis.

XX.14.1.1. Theorem. [Finite-Dimensional Spectral Theorem] Let $\mathcal{H}$ be a finite-dimensional Hilbert space, and T a normal operator on $\mathcal{H}$. Then there is an orthonormal basis for $\mathcal{H}$ consisting of eigenvectors of T.

XX.14.1.2. Corollary. Let $A \in \mathbb{M}_n = M_n(\mathbb{C})$ be a normal matrix. Then A is unitarily equivalent to a diagonal matrix.

XX.14.1.3. The converse is true too: if $A \in \mathbb{M}_n$ is unitarily equivalent to a diagonal matrix, then A is normal.

We now give the proof of Theorem XX.14.1.1..

Proof: The proof of XX.14.1.1. is a simple complete induction (infinite regress), based on () and the elementary facts that if T is normal, then so is $T - \lambda I$ for any $\lambda \in \mathbb{C}$ and that any operator on a finite-dimensional complex vector space has at least one eigenvalue ().

Suppose the result holds for Hilbert spaces of dimension $< n$, and that $\mathcal{H}$ is n-dimensional. Let λ be an eigenvalue of T, and $\mathcal{E}_\lambda$ the corresponding eigenspace, i.e.

$$\mathcal{E}_\lambda = \{x \in \mathcal{H} : Tx = \lambda x\} \ .$$

Then $\mathcal{E}_\lambda = \mathcal{N}(T - \lambda I)$ is a nontrivial subspace of $\mathcal{H}$, so $\mathcal{E}_\lambda^\perp = \mathcal{R}(T - \lambda I)$ () is a subspace of $\mathcal{H}$ of dimension $< n$ (recall that every subspace of $\mathcal{H}$ is closed). If $x \in \mathcal{E}_\lambda^\perp$, then $x = (T - \lambda I)y$ for some y, and hence

$$Tx = T(T - \lambda I)y = (T - \lambda I)(Ty) \in \mathcal{R}(T - \lambda I) = \mathcal{E}_\lambda^\perp \ .$$

So T maps $\mathcal{E}_\lambda^\perp$ into itself, and so $S = T|_{\mathcal{E}_\lambda^\perp}$ is an operator on $\mathcal{E}_\lambda^\perp$. It is easily checked that the adjoint of S is $T^*|_{\mathcal{E}_\lambda^\perp}$, since $\mathcal{E}_\lambda = \mathcal{N}((T - \lambda I)^*)$ and $\mathcal{E}_\lambda^\perp = \mathcal{R}((T - \lambda I)^*)$ because $T - \lambda I$ is normal, and therefore $\mathcal{E}_\lambda$ and $\mathcal{E}_\lambda^\perp$ are invariant under T^* by the same argument as for T. Thus S is normal, so by the inductive assumption there is an orthonormal basis for $\mathcal{E}_\lambda^\perp$ consisting of eigenvectors of S, and putting this basis together with any orthonormal basis of $\mathcal{E}_\lambda$ gives an orthonormal basis for $\mathcal{H}$ consisting of eigenvectors of T. 👍

XX.14.1.4. The orthonormal basis in XX.14.1.1. is not unique. However, the decomposition of $\mathcal{H}$ into eigenspaces of T is unique, and is a more natural way to phrase the Spectral Theorem:

XX.14.1.5. Corollary. Let $\mathcal{H}$ be a finite-dimensional Hilbert space, and T a normal operator on $\mathcal{H}$. Let $\lambda_1, \ldots, \lambda_m$ be the distinct eigenvalues of T, and $\mathcal{E}_{\lambda_1}, \ldots, \mathcal{E}_{\lambda_m}$ the corresponding eigenspaces. Then

(i) $\mathcal{E}_{\lambda_j} \perp \mathcal{E}_{\lambda_k}$ for $j \neq k$.

(ii) The subspaces $\{\mathcal{E}_{\lambda_1}, \ldots, \mathcal{E}_{\lambda_m}\}$ span $\mathcal{H}$.

Thus $\mathcal{H} \cong \mathcal{E}_{\lambda_1} \oplus \cdots \oplus \mathcal{E}_{\lambda_m}$.

There is an alternate phrasing in terms of projection operators. For each k, let E_k be the orthogonal projection of $\mathcal{H}$ onto $\mathcal{E}_{\lambda_k}$. Then:

XX.14.1.6. Corollary. Let $\mathcal{H}$ be a finite-dimensional Hilbert space, and T a normal operator on $\mathcal{H}$. Let $\lambda_1, \ldots, \lambda_m$ be the distinct eigenvalues of T. Then there are unique projections $E_1, \ldots, E_m \in \mathcal{B}(\mathcal{H})$ such that

(i) $E_j \perp E_k$ for $j \neq k$.

(ii) $E_1 + \cdots + E_m = I$.

(iii) $E_k T = T E_k = E_k T E_k = \lambda_k E_k$ for each k.

(iv) $\lambda_1 E_1 + \cdots + \lambda_m E_m = T$.

Furthermore, the E_k are nonzero. The expression in (iv) is called the *spectral resolution* of T.

XX.14.1.7. This representation can be extended. If f is a polynomial with complex coefficients, and $f(T)$ is defined in the standard way (), then an easy calculation shows that

$$f(T) = f(\lambda_1)E_1 + \cdots + f(\lambda_m)E_m$$

where $E_1, \ldots, E_m$ are as in XX.14.1.6.. Since $f(T)$ is also normal, and the eigenvalues of $f(T)$ are $f(\lambda_1), \ldots, f(\lambda_m)$, then this expression is almost the spectral resolution of $f(T)$, except that the $f(\lambda_k)$ need not be distinct and if not some terms in this sum could be combined.

XX.14.1.8. In particular, if f_k is a polynomial with $f_k(\lambda_k) = 1$ and $f_k(\lambda_j) = 0$ for $j \neq k$ (cf. V.11.1.3.), then $f_k(T) = E_k$. Thus the E_k are expressible as polynomials in T.

XX.14.1.9. Conversely, an operator on a finite-dimensional $\mathcal{H}$ with an orthonormal basis of eigenvectors is unitarily equivalent to a diagonal operator, hence normal. A nonnormal operator on $\mathbb{C}^n$ may or may not have n linearly independent eigenvectors (), and even if it does they cannot be orthonormal.

XX.15. L^p-Spaces

In this section, we define and prove the basic properties of the L^p-spaces of a measure space. These are very important examples of Banach spaces, especially L^2-spaces, which are Hilbert spaces.

XX.15.1. Conjugate Exponents

This subsection simply sets up some simple notation and terminology which will prove very useful.

XX.15.1.1. DEFINITION. Let p be a real number greater than 1. The number $q = \frac{p}{p-1}$ is called the *conjugate exponent* to p. The pair (p, q) is a *conjugate pair of exponents*.

If $p > 1$, then $q > 1$ also. This definition is symmetric in p and q, as is immediate from the next proposition, which gives several equivalent versions of the defining equality. The proof is a simple exercise in high-school algebra.

XX.15.1.2. PROPOSITION. Let $p, q > 1$. The following are equivalent:

(i) q is the conjugate exponent to p, i.e. $q = \frac{p}{p-1}$.

(ii) p is the conjugate exponent to q, i.e. $p = \frac{q}{q-1}$.

(iii) $\frac{1}{p} + \frac{1}{q} = 1$.

(iv) $pq - q = p$.

(v) $p - \frac{p}{q} = 1$.

(vi) $\frac{p}{q} = p - 1$.

(vii) $(p-1)(q-1) = 1$.

Note that if $1 < p < 2$, then $q > 2$, and if $p = 2$ then $q = 2$ (i.e. 2 is "self-conjugate"). As p increases, q decreases; as $p \to 1$, $q \to \infty$ (and vice versa). We extend the definition of a conjugate pair to include the pairs $(1, \infty)$ and $(\infty, 1)$, i.e. the conjugate exponent to 1 is ∞ and vice versa. These pairs behave somewhat differently than the pairs for $1 < p < \infty$, however, and some results do not apply to them.

XX.15.2. $\mathcal{L}^p$-Spaces, Norms, and Inequalities

XX.15.2.1. DEFINITION. Let $(X, \mathcal{A}, \mu)$ be a measure space and $0 < p < \infty$. If f is an $\mathcal{A}$-measurable function from X to $\mathbb{C}$, set

$$J_p(f) = \int_X |f|^p \, d\mu \in [0, \infty]$$

$$\|f\|_p = [J_p(f)]^{1/p} = \left[\int_X |f|^p \, d\mu\right]^{1/p}$$

(where $\infty^{1/p} = \infty$).

We let $\mathcal{L}^p_{\mathbb{C}}(X,\mathcal{A},\mu)$ (or $\mathcal{L}^p_{\mathbb{C}}(\mu)$ if X and $\mathcal{A}$ are understood) be the set of measurable functions from X to $\mathbb{C}$ such that $J_p(f) < \infty$. $\mathcal{L}^p_{\mathbb{R}}(X,\mathcal{A},\mu)$ is defined similarly. We let $\mathcal{L}^p(X,\mathcal{A},\mu)$ stand for either $\mathcal{L}^p_{\mathbb{C}}(X,\mathcal{A},\mu)$ or $\mathcal{L}^p_{\mathbb{R}}(X,\mathcal{A},\mu)$ when the base field is unimportant (it must of course always be specified and kept in mind).

The space $\mathcal{L}^p(\mu)$ is really only interesting if μ is σ-finite or at least semifinite, since it is rather degenerate otherwise (XX.15.5.7., Exercise XX.15.9.4.–XX.15.9.5.). However, the definition and basic properties need no assumptions about the measure space.

The next proposition records some obvious properties of the $\mathcal{L}^p$-spaces.

XX.15.2.2. PROPOSITION. Let $(X,\mathcal{A},\mu)$ be a measure space and $0 < p < \infty$. Then

(i) $\mathcal{L}^p_{\mathbb{R}}(X,\mathcal{A},\mu) \subseteq \mathcal{L}^p_{\mathbb{C}}(X,\mathcal{A},\mu)$.

(ii) If $f \in \mathcal{L}^p(X,\mathcal{A},\mu)$, g is $\mathcal{A}$-measurable, and $|g| \le |f|$ a.e., then $g \in \mathcal{L}^p(X,\mathcal{A},\mu)$. In particular, if g is $\mathcal{A}$-measurable, then $g \in \mathcal{L}^p(X,\mathcal{A},\mu)$ if and only if $|g| \in \mathcal{L}^p(X,\mathcal{A},\mu)$.

(iii) If $r > 0$ and $f \in \mathcal{L}^p(X,\mathcal{A},\mu)$, then $|f|^{p/r} \in \mathcal{L}^r(X,\mathcal{A},\mu)$ and $\||f|^{p/r}\|_r = \|f\|_p^{p/r}$. In particular, if $p > 1$ and q is the conjugate exponent to p, and $f \in \mathcal{L}^p(X,\mathcal{A},\mu)$, then $|f|^{p-1} \in \mathcal{L}^q(X,\mathcal{A},\mu)$ and $\||f|^{p-1}\|_q = \|f\|_p^{p-1}$ (XX.15.1.2.(vi)).

(iv) If $f : X \to \mathbb{C}$ is $\mathcal{A}$-measurable, then $f \in \mathcal{L}^p_{\mathbb{C}}(X,\mathcal{A},\mu)$ if and only if the real and imaginary parts of f are in $\mathcal{L}^p_{\mathbb{R}}(X,\mathcal{A},\mu)$.

We will eventually show that $\|\cdot\|_p$ is a seminorm on $\mathcal{L}^p(\mu)$ if $p \ge 1$. The triangle inequality (which only holds for $p \ge 1$) will take some work. We first get a weak form of the triangle inequality which will be enough to show that $\mathcal{L}^p(\mu)$ is a vector space, even for $0 < p < 1$:

XX.15.2.3. PROPOSITION. Let $(X,\mathcal{A},\mu)$ be a measure space, $0 < p < \infty$, and $f,g \in \mathcal{L}^p_{\mathbb{C}}(X,\mathcal{A},\mu)$, $\alpha \in \mathbb{C}$. Then

$$J_p(f+g) \le 2^p[J_p(f) + J_p(g)]$$
$$J_p(\alpha f) = |\alpha|^p J_p(f)\ .$$

In particular, $f+g$ and αf are in $\mathcal{L}^p_{\mathbb{C}}(X,\mathcal{A},\mu)$, and $\mathcal{L}^p_{\mathbb{C}}(X,\mathcal{A},\mu)$ is a complex vector space (hence $\mathcal{L}^p_{\mathbb{R}}(X,\mathcal{A},\mu)$ is a real vector space).

PROOF: The statement for αf is obvious. For the first statement, we have

$$\begin{aligned} J_p(f+g) &= \int_X |f+g|^p\,d\mu \le \int_X (|f|+|g|)^p\,d\mu \le \int_X (2\max(|f|,|g|))^p\,d\mu \\ &= 2^p \int (\max(|f|^p,|g|^p)\,d\mu \le 2^p \int_X (|f|^p + |g|^p)\,d\mu \\ &= 2^p \left[\int_X |f|^p\,d\mu + \int_X |g|^p\,d\mu\right] = 2^p[J_p(f) + J_p(g)]\ . \end{aligned}$$

In order to prove the triangle inequality for $\|\cdot\|_p$ $(1 < p < \infty)$, we need to establish some inequalities: Young's Inequality for products, Hölder's Inequality, and finally Minkowski's Inequality. We begin with Young's Inequality for products after observing a simple preliminary lemma:

XX.15.2.4. LEMMA. Let $x, y \in (0, \infty)$ and $0 \leq t \leq 1$. Then

$$t \log x + (1-t) \log y \leq \log(tx + (1-t)y) \ .$$

We have equality if and only if $x = y$ or $t = 0$ or 1.

The proof is essentially just the observation that the graph of $\log x$ is (strictly) concave downward.

XX.15.2.5. PROPOSITION. [YOUNG'S INEQUALITY FOR PRODUCTS] Let $\alpha, \beta \in [0, \infty)$ and (p, q) a conjugate pair of exponents with $1 < p < \infty$. Then

$$\alpha\beta \leq \frac{1}{p}\alpha^p + \frac{1}{q}\beta^q$$

with equality if and only if $\alpha^p = \beta^q$.

PROOF: If α or β is 0, the result is trivial. Otherwise, we have

$$\log(\alpha\beta) = \log\alpha + \log\beta = \frac{1}{p}\log(\alpha^p) + \frac{1}{q}\log(\beta^q) \leq \log\left(\frac{1}{p}\alpha^p + \frac{1}{q}\beta^q\right)$$

where the inequality comes from Lemma XX.15.2.4. with $x = \alpha^p$, $y = \beta^q$, $t = \frac{1}{p}$. Since the log function is strictly increasing, the result follows. 👍

See Exercise XX.15.9.1. for an equivalent statement and another proof of Young's Inequality for products, and Exercise XX.15.9.2. for a more general version. There is another inequality due to YOUNG for convolutions ().

We now obtain Hölder's Inequality, which is a generalization of the CBS Inequality (XX.11.2.1.). This inequality will not only be used in this section, but will be important in other applications.

XX.15.2.6. PROPOSITION. [HÖLDER'S INEQUALITY] Let $(X, \mathcal{A}, \mu)$ be a measure space, (p, q) a conjugate pair with $1 < p < \infty$, $f \in \mathcal{L}^p(\mu)$, and $g \in \mathcal{L}^q(\mu)$. Then $fg \in \mathcal{L}^1(\mu)$ and

$$\int_X |fg| \, d\mu \leq \|f\|_p \|g\|_q \ .$$

We have equality if and only if $|g|^q = \alpha|f|^p$ a.e. for some $\alpha > 0$, or if $f = 0$ a.e. or $g = 0$ a.e.

PROOF: If $f = 0$ a.e. or $g = 0$ a.e. both sides are 0, so equality holds. Otherwise, let $F = \frac{1}{\|f\|_p} f$, $G = \frac{1}{\|g\|_q} g$. Then $\|F\|_p = \|G\|_q = 1$, and we have, using Young's Inequality for products,

$$\frac{1}{\|f\|_p \|g\|_q} \int_X |fg| \, d\mu = \int_X |FG| \, d\mu \leq \frac{1}{p}\int_X |F|^p \, d\mu + \frac{1}{q}\int_X |G|^q \, d\mu = \frac{1}{p} + \frac{1}{q} = 1 \ .$$

We have equality if and only if $|F|^p = |G|^q$ a.e. Note that multiplying f or g by a nonzero scalar does not change $|F|$ and $|G|$. 👍

We can now prove the triangle inequality for $\| \cdot \|_p$ for $1 \leq p < \infty$. This inequality is usually called *Minkowski's Inequality* (see XX.15.9.11. for a more general version).

XX.15.2.7. THEOREM. [MINKOWSKI'S INEQUALITY] Let $(X, \mathcal{A}, \mu)$ be a measure space, and $1 \leq p < \infty$. If $f, g \in \mathcal{L}^p(X, \mathcal{A}, \mu)$, then $f + g \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ and

$$\|f + g\|_p \leq \|f\|_p + \|g\|_p \ .$$

PROOF: The case $p = 1$ is essentially just the usual triangle inequality for numbers, and is left to the reader. So we assume $p > 1$.

We have already noted that $f + g \in \mathcal{L}^p(\mu)$ (XX.15.2.3.). Let q be the conjugate exponent to p. Then by XX.15.2.2.(iii), $|f + g|^{p-1} \in \mathcal{L}^q(\mu)$ and

$$\||f + g|^{p-1}\|_q = \|f + g\|_p^{p/q} = \|f + g\|_p^{p-1} \ .$$

Next note that

$$|f + g|^p = |f + g||f + g|^{p-1} \leq (|f| + |g|)|f + g|^{p-1} = |f||f + g|^{p-1} + |g||f + g|^{p-1} \ .$$

Thus, by Hölder's Inequality,

$$\|f + g\|_p^p = \int_X |f + g|^p \, d\mu \leq \int_X |f||f + g|^{p-1} \, d\mu + \int_X |g||f + g|^{p-1} \, d\mu$$

$$\leq \|f\|_p \||f + g|^{p-1}\|_q + \|g\|_p \||f + g|^{p-1}\|_q = (\|f\|_p + \|g\|_p)\|f + g\|_p^{p-1} \ .$$

If $\|f + g\|_p = 0$, the result is trivial; otherwise, divide by $\|f + g\|_p^{p-1}$. 👍

XX.15.2.8. COROLLARY. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $1 \leq p < \infty$. Then $\| \cdot \|_p$ is a seminorm on $\mathcal{L}^p(X, \mathcal{A}, \mu)$.

PROOF: It is obvious that $\|f\|_p \in [0, \infty)$ if $f \in \mathcal{L}^p(\mu)$, and it follows from XX.15.2.3. that if $f \in \mathcal{L}^p(\mu)$ and α is a scalar, then $\|\alpha f\|_p = |\alpha| \|f\|_p$ (these statements are also true if $0 < p < 1$). Minkowski's Inequality gives the triangle inequality (for $1 \leq p < \infty$). 👍

This seminorm is usually not a norm: $\|f\|_p = 0$ if (and only if) $f = 0$ a.e. We will remedy this in the next section.

The function $\| \cdot \|_p$ does not satisfy the triangle inequality for $0 < p < 1$ in general:

XX.15.2.9. EXAMPLE. Let $X = \{a, b\}$ be a two-point space, and μ counting measure on $(X, \mathcal{P}(X))$. Let $f(a) = 1$, $f(b) = 0$, $g(a) = 0$, $g(b) = 1$. For any p, $0 < p < \infty$, we have $\|f\|_p = \|g\|_p = 1$, $\|f + g\|_p = 2^{1/p}$. So if $p < 1$, $\|f + g\|_p > 2$ and $\| \cdot \|_p$ does not satisfy the triangle inequality.

XX.15.3. L^p-Spaces

Definition as a quotient, completeness, density of simple functions, density of continuous functions for Borel measures

Let $(X, \mathcal{A}, \mu)$ be a measure space. Since $\|\cdot\|_p$ is usually only a seminorm and not a norm on $\mathcal{L}^p(X, \mathcal{A}, \mu)$, by the usual process () we reduce to the quotient by the subspace of vectors of seminorm 0, which in this case is the set of functions which are 0 a.e. This reduction effectively means that we identify functions which are equal a.e.

XX.15.3.1. Definition. Let $0 \le p < \infty$. $L^p(X, \mathcal{A}, \mu)$ (denoted just $L^p(\mu)$ when X and $\mathcal{A}$ are understood) is the quotient of $\mathcal{L}^p(X, \mathcal{A}, \mu)$ by the subspace

$$\{f \in \mathcal{L}^p(X, \mathcal{A}, \mu) : \|f\|_p = 0\} = \{f : f \text{ measurable}, f = 0 \text{ a.e.}\} .$$

(As with $\mathcal{L}^p$, L^p can stand for either $L^p_{\mathbb{R}}$ or $L^p_{\mathbb{C}}$; the base field should always be specified in a specific context.)

If $f \in \mathcal{L}^p(\mu)$, we denote by $[f]$ the image of f in $L^p(\mu)$:

$$[f] = \{g \in \mathcal{L}^p(\mu) : f = g \text{ a.e.}\} .$$

As in (), the seminorm $\|\cdot\|_p$ on $\mathcal{L}^p(\mu)$ drops to a norm on $L^p(\mu)$, also denoted $\|\cdot\|_p$, by $\|[f]\|_p = \|f\|_p$.

Many authors are rather sloppy in distinguishing between $\mathcal{L}^p(\mu)$ and $L^p(\mu)$, and functional analysts tend to be rather casual about the difference; we will eventually follow this convention of thinking of elements of $L^p(\mu)$ as functions rather than equivalence classes of functions, but in this section we will make a careful distinction in establishing the basic properties of these spaces (which can be used to carefully justify the casual convention).

The most important fact about L^p-spaces is that they are Banach spaces:

XX.15.3.2. Theorem. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $1 \le p < \infty$. If (f_k) is a Cauchy sequence in $\mathcal{L}^p(X, \mathcal{A}, \mu)$, then there is a subsequence of (f_k) converging pointwise a.e. to an $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ such that $f_k \to f$ in $\mathcal{L}^p(X, \mathcal{A}, \mu)$. In particular, $L^p(X, \mathcal{A}, \mu)$ is complete.

Proof: A Cauchy sequence with a convergent subsequence converges to the same limit (). Thus, passing to a subsequence, we may assume $\|f_{k+1} - f_k\|_p \le 2^{-k}$ for each k, and we will show that (f_k) converges pointwise a.e. to a function f, and $\|f_k - f\|_p \to 0$.

For each n, let $g_n = f_1 + \sum_{k=1}^n |f_{k+1} - f_k|$. Then (g_n) is an increasing sequence; let $g = \lim g_n = \sup g_n$. Then g is an extended nonnegative real-valued measurable function on $(X, \mathcal{A})$. For each n we have

$$\int_X g_n^p \, d\mu = \|g_n\|_p^p \le \left[\|f_1\|_p + \sum_{k=1}^n \|f_{k+1} - f_k\|_p \right]^p \le (1 + \|f_1\|_p)^p$$

and so, by the Monotone Convergence Theorem,

$$\int_X g^p \, d\mu = \sup_n \int_X g_n^p \, d\mu \le (1 + \|f_1\|_p)^p < \infty .$$

Thus, although g may technically not be in $\mathcal{L}^p(X, \mathcal{A}, \mu)$ since it may take the value $+\infty$, it is finite a.e. and equal a.e. to a function $h \in \mathcal{L}^p(X, \mathcal{A}, \mu)$. For any $x \in X$ with $g(x) < \infty$ the series $f_{k+1}(x) = f_1(x) + \sum_{k=1}^{\infty}[f_{k+1}(x) - f_k(x)]$ of scalars converges absolutely, hence converges; call the sum $f(x)$. Extend f to be 0 on the x's for which $g(x) = +\infty$. Then f is an $\mathcal{A}$-measurable function from X to $\mathbb{C}$, $f_k \to f$ pointwise a.e., and $|f| \leq |h|$ a.e., so $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$. We also have

$$|f - f_k|^p \leq |h|^p \text{ a.e.}$$

for all k, and $|h|^p \in \mathcal{L}^1(X, \mathcal{A}, \mu)$; since $|f - f_k|^p \to 0$ pointwise a.e., by the Dominated Convergence Theorem we have

$$\lim_{k\to\infty} \|f - f_k\|_p^p = \lim_{k\to\infty} \left[\int_X |f - f_k|^p \ d\mu\right] = 0 \ .$$

It is interesting to note that, although it is somewhat easier to prove that $\|\cdot\|_p$ is a seminorm (i.e. satisfies the triangle inequality) for $p = 2$ than for general p (cf. ()), and considerably easier for $p = 1$, it is no easier to prove completeness of L^p for $p = 1$ or $p = 2$ than for general p.

XX.15.3.3. An important observation from XX.15.3.2., stated a bit imprecisely, is that if $f_n \to f$ in $L^p(X, \mathcal{A}, \mu)$, then there is a subsequence of (f_n) converging pointwise a.e. to f. It is necessary to pass to subsequences in general if $p < \infty$ (Exercise XX.15.9.12.). If $f_n \to f$ in $L^p(X, \mathcal{A}, \mu)$, then $f_n \to f$ in measure ().

It is usually important to identify some dense subsets of "nice" elements in any Banach space, and this is particularly important in the L^p-spaces. For example, we will show () that in L^p-spaces arising from Borel measures on good topological spaces, the continuous functions are dense in L^p for any p. One general and very useful fact is true in any L^p-space:

XX.15.3.4. THEOREM. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $1 \leq p < \infty$. Then the (classes of) simple functions in $L^p(X, \mathcal{A}, \mu)$ are dense in $L^p(X, \mathcal{A}, \mu)$.

PROOF: By working with real and imaginary parts, it suffices to prove the result for $L^p_{\mathbb{R}}(\mu)$. If $f \in \mathcal{L}^p_{\mathbb{R}}(\mu)$, then by () there is a sequence of real-valued simple functions (s_n) converging pointwise to f, with $|s_n| \leq |f|$ for all n. Thus each $s_n \in \mathcal{L}^p_{\mathbb{R}}(\mu)$. We have $|s_n - f|^p \leq |2f|^p$ for all n, and $|2f|^p \in \mathcal{L}^1(\mu)$. Since $|s_n - f|^p \to 0$ pointwise, by the Dominated Convergence Theorem we have

$$\lim_{n\to\infty} \|s_n - f\|_p^p = \lim_{n\to\infty} \left[\int_X |s_n - f|^p \, d\mu\right] = 0 \ .$$

XX.15.4. $\mathcal{L}^\infty$- and L^∞-Spaces

XX.15.5. Comparison Between $\mathcal{L}^p$-Spaces and L^p-Spaces

Let $(X, \mathcal{A}, \mu)$ be a measure space. There is no containment between the $\mathcal{L}^p$-spaces or the L^p-spaces of $(X, \mathcal{A}, \mu)$ as p varies, except in certain special cases. There are two competing constraints which can cause a (measurable) function f to fail to be in $\mathcal{L}^p(X, \mathcal{A}, \mu)$:

(i) f can go to zero "too slowly" (or not at all) at "infinity."

(ii) f can go to infinity "too rapidly" on a small portion of X.

The first problem gets worse as p decreases, and the second problem gets worse as p increases. We will make these problems precise in this subsection, and give examples.

Consider the first constraint.

XX.15.5.1. Example. Suppose $(X, \mathcal{A}, \mu)$ contains measurable subsets of arbitrarily large finite measure (e.g. μ is σ-finite but not finite). Choose an increasing sequence (B_n) in $\mathcal{A}$ with $\mu(B_1) \geq 1$ and $\mu(B_n) + 1 \leq \mu(B_{n+1}) < \infty$ for all $n > 1$. Then, by taking successive differences, there is a sequence (A_n) of pairwise disjoint sets in $\mathcal{A}$ with $1 \leq \mu(A_n) < \infty$ for all n. Fix p, $0 < p < \infty$, and define a function $f : X \to [0, 1]$ by setting

$$f(x) = \frac{1}{[n\mu(A_n)]^{1/p}} \text{ if } x \in A_n$$

$$f(x) = 0 \text{ if } x \notin \cup_n A_n \ .$$

Then f is measurable, and we have

$$J_p(f) = \sum_{n=1}^{\infty} \frac{1}{n\mu(A_n)} \mu(A_n) = \sum_{n=1}^{\infty} \frac{1}{n} = \infty$$

so $f \notin \mathcal{L}^p(X, \mathcal{A}, \mu)$. However, if $p < r < \infty$, we have

$$J_r(f) = \sum_{n=1}^{\infty} \frac{1}{n^{r/p}\mu(A_n)^{r/p}} \mu(A_n) = \sum_{n=1}^{\infty} \frac{1}{n^{r/p}\mu(A_n)^{r/p-1}} \leq \sum_{n=1}^{\infty} \frac{1}{n^{r/p}} < \infty$$

so $f \in \cap_{r>p} \mathcal{L}^r(X, \mathcal{A}, \mu)$. (Note that f is bounded, so $f \in \mathcal{L}^\infty(X, \mathcal{A}, \mu)$ also.) In particular, $\mathcal{L}^r(X, \mathcal{A}, \mu)$ is not contained in $\mathcal{L}^p(X, \mathcal{A}, \mu)$ for $p < r \leq \infty$.

In the absence of such subsets, we have a containment:

XX.15.5.2. Proposition. Let $(X, \mathcal{A}, \mu)$ be a finite measure space, and let $0 < p \leq r \leq \infty$. Then $\mathcal{L}^r(X, \mathcal{A}, \mu)$ is contained in $\mathcal{L}^p(X, \mathcal{A}, \mu)$.

Proof: If $r = \infty$, the result holds since any bounded measurable function on a finite measure space is integrable. So assume $r < \infty$ and let $f \in \mathcal{L}^r(X, \mathcal{A}, \mu)$. Set

$$A = \{x \in X : |f(x)| \geq 1\}$$

$$B = \{x \in X : |f(x)| < 1\} \ .$$

Then $|f|^p \le |f|^r$ on A, so we have

$$J_p(f) = \int_X |f|^p \, d\mu = \int_A |f|^p \, d\mu + \int_B |f|^p \, d\mu \le \int_A |f|^r \, d\mu + \int_B |f|^p \, d\mu$$

$$\le J_r(f) + \mu(B) < \infty$$

so $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$. 👍

Now we turn to the second constraint.

XX.15.5.3. EXAMPLE. Let $(X, \mathcal{A}, \mu)$ be a measure space which contains measurable sets of arbitrarily small positive measure. Let $B_1 \in \mathcal{A}$ with $0 < \mu(B_1) \le 1$, and inductively let $B_n \in \mathcal{A}$ with $0 < \mu(B_n) \le \frac{1}{3}\mu(B_{n-1})$ for $n > 1$. Set $A_n = B_n \setminus (\cup_{k=n+1}^{\infty} B_k)$. Then the A_n are pairwise disjoint, and since

$$\mu(\cup_{k=n+1}^{\infty} B_k) \le \sum_{k=n+1}^{\infty} \mu(B_k) \le \sum_{m=1}^{\infty} 3^{-m}\mu(B_n) = \frac{\mu(B_n)}{2}$$

we have $0 < \frac{1}{2}\mu(B_n) \le \mu(A_n)$. Also, $\mu(A_n) \le \mu(B_n) \le 3^{-n+1}$.

Fix p, $0 < p < \infty$. Define a function $f : X \to [0, \infty)$ by

$$f(x) = [\mu(A_n)]^{-1/p} \text{ if } x \in A_n$$

$$f(x) = 0 \text{ if } x \notin \cup_n A_n \ .$$

Then we have

$$J_p(f) = \sum_{n=1}^{\infty} [\mu(A_n)]^{-1} \mu(A_n) = \infty$$

so $f \notin \mathcal{L}^p(X, \mathcal{A}, \mu)$. But if $0 < r < p$, we have

$$J_r(f) = \sum_{n=1}^{\infty} [\mu(A_n)]^{-r/p} \mu(A_n) = \sum_{n=1}^{\infty} [\mu(A_n)]^{1-r/p} \le \sum_{n=1}^{\infty} [3^{1-r/p}]^{-n+1} < \infty$$

so $f \in \cap_{r<p} \mathcal{L}^r(X, \mathcal{A}, \mu)$. In particular, $\mathcal{L}^r(X, \mathcal{A}, \mu)$ is not contained in $\mathcal{L}^p(X, \mathcal{A}, \mu)$ for any $r < p$. Also, f is not essentially bounded, so $f \notin \mathcal{L}^\infty(X, \mathcal{A}, \mu)$, i.e. $\mathcal{L}^p(X, \mathcal{A}, \infty)$ is not contained in $\mathcal{L}^\infty(X, \mathcal{A}, \mu)$.

We again have a containment in the absence of this situation:

XX.15.5.4. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space. Suppose there is an $\epsilon > 0$ such that, for every $A \in \mathcal{A}$, either $\mu(A) = 0$ or $\mu(A) \geq \epsilon$. Let $0 < r \leq p \leq \infty$. Then $\mathcal{L}^r(X, \mathcal{A}, \mu)$ is contained in $\mathcal{L}^p(X, \mathcal{A}, \mu)$.

PROOF: Let $f \in \mathcal{L}^r(\mu)$. We first show that f is essentially bounded. We may assume $\|f\|_r > 0$, since otherwise $f = 0$ a.e. Set $M = \frac{\|f\|_r}{\epsilon^{1/r}}$ and let $C = \{x \in X : |f(x)| > M\}$. Since

$$M^r \mu(C) = \frac{\|f\|_r^r}{\epsilon} \mu(C) < \int_C |f|^r \, d\mu \leq \int_X |f|^r \, d\mu = \|f\|_r^r$$

we have $\mu(C) < \epsilon$, so $\mu(C) = 0$, i.e. $|f| \leq M$ a.e. and $f \in \mathcal{L}^\infty(X, \mathcal{A}, \mu)$. If $p < \infty$, let $A = \{x : |f(x)| \geq 1\}$ and $B = \{x : |f(x)| < 1\}$. Then $|f|^p < |f|^r$ on B, and

$$\mu(A) \leq \int_A |f|^r \, d\mu \leq \int_X |f|^r \, d\mu = J_r(f) < \infty$$

and we have

$$J_p(f) = \int_X |f|^p \, d\mu = \int_A |f|^p \, d\mu + \int_B |f|^p \, d\mu$$

$$< \int_A |f|^p \, d\mu + \int_B |f|^r \, d\mu \leq M^p \mu(A) + J_r(f) < \infty$$

so $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$. 👍

XX.15.5.5. EXAMPLES. (a) A set with counting measure satisfies the hypotheses of XX.15.5.4. (with $\epsilon = 1$). Thus $\ell^r(X) \subseteq \ell^p(X)$ for any X if $r < p$.

(b) If $(X, \mathcal{A}, \mu)$ is a measure space containing both sets of arbitrarily large and arbitrarily small finite positive measure (e.g. $(\mathbb{R}, \mathcal{M}, \lambda)$), then there is no containment either way between $\mathcal{L}^p(X, \mathcal{A}, \mu)$ and $\mathcal{L}^r(X, \mathcal{A}, \mu)$ for $p \neq r$.

There is, however, a large subspace which is common to $\mathcal{L}^p(\mu)$ for all p. A measurable function f has *support of finite measure* if $\{x : f(x) \neq 0\}$ has finite measure. (Some authors say that such a function has *finite support*, but this term, while more efficient, is ambiguous.) We can similarly define functions with support of σ-finite measure.

If $(X, \mathcal{A}, \mu)$ is a measure space, let $\mathcal{L}^{\text{oo}}(X, \mathcal{A}, \mu)$ (distinguish between oo and ∞!) be the set of essentially bounded measurable functions with support of finite measure. The characteristic function of a set of finite measure is in $\mathcal{L}^{\text{oo}}(X, \mathcal{A}, \mu)$, hence so is any linear combination of such functions (simple functions with support of finite measure).

XX.15.5.6. PROPOSITION. $\mathcal{L}^{\text{oo}}(X, \mathcal{A}, \mu) \subseteq \mathcal{L}^p(X, \mathcal{A}, \mu)$ for $0 < p \leq \infty$, and $\mathcal{L}^{\text{oo}}(X, \mathcal{A}, \mu)$ is dense in $\mathcal{L}^p(X, \mathcal{A}, \mu)$ if $p < \infty$.

The density for $p < \infty$ is immediate from the proof of XX.15.3.4., since a simple function which is in $\mathcal{L}^p$ for some p must be in $\mathcal{L}^{\text{oo}}$ (Exercise ()).

$\mathcal{L}^{\infty\circ}(X, \mathcal{A}, \mu)$ is not dense in $\mathcal{L}^{\infty}(X, \mathcal{A}, \mu)$ unless μ is finite, in which case $\mathcal{L}^{\infty\circ}(X, \mathcal{A}, \mu) = \mathcal{L}^{\infty}(X, \mathcal{A}, \mu)$. We say a function f has *support of almost finite measure* if $\{x : |f(x)| > \epsilon\}$ has finite measure for all $\epsilon > 0$. This implies, but is not equivalent to, that f has support of σ-finite measure (consider the constant function 1 on $(\mathbb{R}, \mathcal{L}, \lambda)$). It is easily shown (Exercise ()) that the closure of $\mathcal{L}^{\infty\circ}(X, \mathcal{A}, \mu)$ in $\mathcal{L}^{\infty}(X, \mathcal{A}, \mu)$ is the set of essentially bounded functions with support of almost finite measure.

It is worth noting the next result:

XX.15.5.7. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space and $0 < p < \infty$. Then any function in $\mathcal{L}^p(X, \mathcal{A}, \mu)$ has support of almost finite measure (in particular, of σ-finite measure).

This proposition is false for $\mathcal{L}^{\infty}(X, \mathcal{A}, \mu)$ if μ is not finite.

XX.15.5.8. REMARK. For a fixed measure space $(X, \mathcal{A}, \mu)$, $L^p(X, \mathcal{A}, \mu)$ is constructed from $\mathcal{L}^p(X, \mathcal{A}, \mu)$ by dividing out by the same subspace of functions for every p. Thus if $\mathcal{L}^r(X, \mathcal{A}, \mu)$ is contained in $\mathcal{L}^p(X, \mathcal{A}, \mu)$ for some p and r, it is technically strictly correct also that $L^r(X, \mathcal{A}, \mu)$ is contained in $L^p(X, \mathcal{A}, \mu)$. The converse also holds, as is easy to check. Thus, in all the above containment results of this section, $\mathcal{L}^p$ and $\mathcal{L}^r$ can be replaced by L^p and L^r to give strictly correct containment statements.

XX.15.5.9. Now suppose $(X, \mathcal{A}, \mu)$ is a measure space and $\mathcal{B}$ is a sub-σ-algebra of $\mathcal{A}$. Set $\nu = \mu|_{\mathcal{B}}$. It is then obvious that $\mathcal{L}^p(X, \mathcal{B}, \nu)$ is a subspace of $\mathcal{L}^p(X, \mathcal{A}, \mu)$ for any p, and the p-seminorms agree.

However, it is technically not strictly correct in most cases to say that $L^p(X, \mathcal{B}, \nu)$ is a subspace of $L^p(X, \mathcal{A}, \mu)$, since the elements of these spaces are different: if $f \in \mathcal{L}^p(X, \mathcal{B}, \nu)$, the corresponding elements are

$$[f]_{\mathcal{A}} = \{g : g \ \mathcal{A}\text{-measurable}, \ g = f \text{ a.e.}\}$$

$$[f]_{\mathcal{B}} = \{g : g \ \mathcal{B}\text{-measurable}, \ g = f \text{ a.e.}\}$$

which are not the same sets in general. However, the map $[f]_{\mathcal{B}} \mapsto [f]_{\mathcal{A}}$ is a linear isometry from $L^p(X, \mathcal{B}, \nu)$ onto a (complete, hence closed) subspace of $L^p(X, \mathcal{A}, \mu)$, usually called the *inclusion map*, and by making this identification we usually, if rather casually, think of $L^p(X, \mathcal{B}, \nu)$ as a closed subspace of $L^p(X, \mathcal{A}, \mu)$ for any p.

Normally, the inclusion map sends $L^p(X, \mathcal{B}, \nu)$ onto a proper subspace of $L^p(X, \mathcal{A}, \mu)$. But there is one important case where it should be noted that the inclusion map is surjective, hence an isometric isomorphism:

XX.15.5.10. PROPOSITION. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $(X, \mathcal{M}, \bar{\mu})$ its completion. Then, for any p, the inclusion map from $L^p(X, \mathcal{A}, \mu)$ to $L^p(X, \mathcal{M}, \bar{\mu})$ is an isomorphism.

The proof is immediate from the fact that every $\mathcal{M}$-measurable function is equal a.e. to an $\mathcal{A}$-measurable function (). Note that $\mathcal{L}^p(X, \mathcal{M}, \bar{\mu})$ is considerably larger than $\mathcal{L}^p(X, \mathcal{A}, \mu)$ in general.

In particular, $L^p(\mathbb{R}, \mathcal{L}, \lambda)$ is naturally isomorphic to $L^p(\mathbb{R}, \mathcal{B}, \lambda)$ for any p.

Embeddings of Quotient Spaces

XX.15.5.11. In light of these subtleties, it is desirable to have a careful and systematic way of saying one quotient space is "embedded" in another. For another example, we would like to say that $C([0,1]) \subseteq L^p([0,1],\mathcal{L},\lambda)$ for any p, but this does not make sense; what we mean is that $C([0,1]) \subseteq \mathcal{L}^p([0,1],\mathcal{L},\lambda)$ and this embedding passes to the quotient in an obvious way. It will be especially important to have such a notion of embedding for Sobolev spaces (), where the "embeddings" are not generally obvious and sometimes rather tricky.

XX.15.5.12. Instead of working in the utmost generality, we will stick to the case of normed vector spaces made as a quotient from a vector space with a seminorm. So we will notationally use script letters to denote a vector space (over a fixed base field $\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$) with a seminorm and the same Roman letter to denote the normed quotient, for example let $\mathcal{V}$ be a vector space with seminorm $\|\cdot\|_{\mathcal{V}}$, $\mathcal{N}_{\mathcal{V}} = \{v \in \mathcal{V} : \|v\|_{\mathcal{V}} = 0\}$, $V = \mathcal{V}/\mathcal{N}_{\mathcal{V}}$. The prototype example is $\mathcal{V} = \mathcal{L}^p(X,\mathcal{A},\mu)$, $\mathcal{N}_{\mathcal{V}} = \{f \in \mathcal{V} : f = 0 \ \mu\text{-a.e.}\}$, $V = L^p(X,\mathcal{A},\mu)$. And as a special case, if $(V,\|\cdot\|_V)$ is a normed vector space, we can take $\mathcal{V} = V$, $\|\cdot\|_{\mathcal{V}} = \|\cdot\|_V$, $\mathcal{N}_{\mathcal{V}} = \{0\}$.

XX.15.5.13. Definition. Let $(\mathcal{V},\|\cdot\|_{\mathcal{V}})$ and $(\mathcal{W},\|\cdot\|_{\mathcal{W}})$ be vector spaces with seminorms, and $V = \mathcal{V}/\mathcal{N}_{\mathcal{V}}$ and $W = \mathcal{W}/\mathcal{N}_{\mathcal{W}}$ the quotient normed spaces. We say V is *embedded in* W, written $V \hookrightarrow W$, if

(i) $\mathcal{V} \subseteq \mathcal{W}$.

(ii) $\mathcal{N}_{\mathcal{V}} = \mathcal{V} \cap \mathcal{N}_{\mathcal{W}}$ (so there is an injective induced map $\iota : V \to W$).

(iii) There is a constant K such that $\|v\|_{\mathcal{W}} \leq K\|v\|_{\mathcal{V}}$ for all $v \in \mathcal{V}$ (i.e. ι is bounded [continuous]).

XX.15.5.14. As an example, $C([0,1]) \hookrightarrow L^p([0,1],\mathcal{L},\lambda)$ for $1 \leq p \leq \infty$. And if $(X,\mathcal{A},\mu)$ is a measure space, $\mathcal{B}$ is a sub-σ-algebra of $\mathcal{A}$, and $\nu = \mu|_{\mathcal{B}}$, then $L^p(X,\mathcal{B},\nu) \hookrightarrow L^p(X,\mathcal{A},\mu)$ for $1 \leq p \leq \infty$ (in both cases we may take $K = 1$). And:

XX.15.5.15. Proposition. Let $(X,\mathcal{A},\mu)$ be a finite measure space, and let $1 \leq p \leq r \leq \infty$. Then $L^r(X,,\mu) \hookrightarrow L^p(X,\mathcal{A},\mu)$.

Proof: By XX.15.5.2., $\mathcal{L}^r(X,\mathcal{A},\mu) \subseteq \mathcal{L}^p(X,\mathcal{A},\mu)$, and the null spaces coincide. We need only show that there is a K such that $\|f\|_p \leq K\|f\|_r$ for all $f \in \mathcal{L}^r(X,\mathcal{A},\mu)$. It suffices to show this for $\|f\|_r = 1$. So suppose f is such that

$$\|f\|_r = \left[\int_X |f|^r \, d\mu\right]^{1/r} = 1 = \int_X |f|^r \, d\mu \ .$$

Let $A = \{x \in X : |f(x)| \leq 1\}$, $B = X \setminus A = \{x \in X : |f(x)| > 1\}$. Then

$$\int_X |f|^p \, d\mu = \int_A |f|^p \, d\mu + \int_B |f|^p \, d\mu \leq \mu(A) + \int_B |f|^r \, d\mu$$

$$\leq \mu(X) + \int_X |f|^r \, d\mu = \mu(X) + 1$$

so $\|f\|_p \leq (\mu(X)+1)^{1/p}$. 👍

XX.15.5.16. More generally, at least in the case where both $\mathcal{V}$ and $\mathcal{W}$ are subspaces of a larger vector space (e.g. if they are both spaces of $\mathbb{F}$-valued functions on a set X), we will say that $V \hookrightarrow W$ if, writing π for the quotient map from $\mathcal{V}$ to V,

(i) $\pi(\mathcal{V} \cap \mathcal{W}) = V$.

(ii) $\mathcal{N}_{\mathcal{V}} \cap \mathcal{W} = \mathcal{V} \cap \mathcal{N}_{\mathcal{W}}$ (so there is an injective induced map $\iota : V \to W$).

(iii) There is a constant K such that $\|v\|_{\mathcal{W}} \leq K\|v\|_{\mathcal{V}}$ for all $v \in \mathcal{V} \cap \mathcal{W}$ (i.e. ι is bounded [continuous]).

This will be useful, for example, in saying that a space of equivalence classes "consists of" continuous functions, meaning that each equivalence class contains a (unique) continuous function.

XX.15.5.17. Note that if $V \hookrightarrow W$, so that V can be considered to be a subspace of W, the embedding map ι is not generally a topological embedding, i.e. the relative W-topology on V may be strictly weaker than the V-topology. In fact, $\iota(V)$ is frequently dense in W in our applications. And in many applications, ι is actually compact (). In this case, we say V is *compactly embedded* in W, written $V \hookrightarrow_c W$.

XX.15.6. L^p-spaces for Borel Measures

Density of continuous functions, separability, Egorov's Theorem

XX.15.7. The Dual of L^p-Spaces

The dual of (most) L^p-spaces can be nicely described as an L^q-space, where q is the conjugate exponent. The next result is called the *Riesz Representation Theorem*. There is another result also called the "Riesz Representation Theorem" (), so when this name is used readers should be cautioned to note which theorem is being referenced.

XX.15.7.1. Theorem. [Riesz Representation Theorem for L^p] Let $1 \leq p \leq \infty$, and let q be the conjugate exponent to p. Let $(X, \mathcal{A}, \mu)$ be a measure space.

(i) Let $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$. Then g defines a bounded linear functional ϕ_g on $L^p(X, \mathcal{A}, \mu)$ by

$$\phi_g(f) = \int_X fg \, d\mu \ .$$

We have $\|\phi_g\| \leq \|g\|_q$.

(ii) If $p > 1$ or if μ is σ-finite, then $\|\phi_g\| = \|g\|$ for all $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$. If $g, h \in \mathcal{L}^q(X, \mathcal{A}, \mu)$ and $\phi_g = \phi_h$, then $g = h$ a.e.

(iii) If $1 < p < \infty$, or if $p = 1$ and μ is σ-finite, then every bounded linear functional on $L^p(X, \mathcal{A}, \mu)$ is of the form ϕ_g for some $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$.

XX.15.7.2. Corollary. Let $1 \leq p < \infty$. Let $(X, \mathcal{A}, \mu)$ be a measure space, with μ σ-finite if $p = 1$. Then $L^p(X, \mathcal{A}, \mu)^*$ is isometrically isomorphic to $L^q(X, \mathcal{A}, \mu)$ under the correspondence $\phi_g \leftrightarrow [g]$.

XX.15.7.3. We give the proof of Theorem XX.15.7.1.. Part (i) is an almost immediate corollary of Hölder's Inequality XX.15.2.6.: since $fg \in \mathcal{L}^1(X, \mathcal{A}, \mu)$ for any $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$, the linear functional ϕ_g is well defined on $L^p(X, \mathcal{A}, \mu)$, and

$$\|\phi_g\| = \sup\{|\phi_g(f)| : f \in \mathcal{L}^p(X, \mathcal{A}, \mu\}, \|f\|_p = 1\} = \sup\left\{\left|\int_X fg\, d\mu\right| : f \in \mathcal{L}^p(X, \mathcal{A}, \mu), \|f\|_p = 1\right\}$$

$$\leq \sup\left\{\int_X |fg|\, d\mu : f \in \mathcal{L}^p(X, \mathcal{A}, \mu), \|f\|_p = 1\right\} \leq \|g\|_q \ .$$

XX.15.7.4. For (ii), we only need to show $\|\phi_g\| \geq \|g\|_q$, and we may assume $\|g\|_q \neq 0$. If $1 < p < \infty$ set

$$f(x) = \begin{cases} \frac{|g(x)|^q}{g(x)} & \text{if} \quad g(x) \neq 0 \\ 0 & \text{if} \quad g(x) = 0 \end{cases} \ .$$

Then

$$|f|^p = (|g|^{q-1})^p = |g|^q$$

so $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ and $\|f\|_p = \|g\|_q^{q/p}$; and $fg = |g|^q$, so $\phi_g(f) = \|g\|_q^q$; thus

$$\|\phi_g\| \geq \frac{\|g\|_q^q}{\|g\|_q^{q/p}} = \|g\|_q^{q-q/p} = \|g\|_q \ .$$

If $p = \infty$, so $q = 1$, let $g \in \mathcal{L}^1(X, \mathcal{A}, \mu)$. Define the *signum function* σ_g of g by

$$\sigma_g(x) = \begin{cases} \frac{g(x)}{|g(x)|} & \text{if} \quad g(x) \neq 0 \\ 0 & \text{if} \quad g(x) = 0 \end{cases}$$

Then σ_g takes only values of absolute value 1, perhaps along with 0, so $\sigma_g \in \mathcal{L}^\infty(X, \mathcal{A}'\mu)$ and $\|\sigma_g\|_\infty = 1$ (unless $g = 0$ a.e.) We have $\overline{\sigma_g} g = |g|$, so $\phi_g(\overline{\sigma_g}) = \|g\|_1 \leq \|\phi_g\|$.

XX.15.7.5. Part (ii) is trickier to prove for $p = 1$, and we need the hypothesis that μ is σ-finite. Fix $n \in \mathbb{N}$, large enough that $\|g\|_\infty > \frac{1}{n}$, and set

$$A = \left\{x \in X : \|g\|_\infty - \frac{1}{n} \leq |g(x)| \leq \|g\|_\infty\right\} \ .$$

Then $\mu(A) > 0$. Let (A_k) be an increasing sequence of sets in A with $A = \cup_k A_k$ and $0 < \mu(A_k) < \infty$. Set

$$f_k(x) = \begin{cases} \frac{|g(x)|}{g(x)} & \text{if} \quad x \in A_k \\ 0 & \text{if} \quad x \notin A_k \end{cases} \ .$$

Then $|f_k| = \chi_{A_k}$, so $f_k \in \mathcal{L}^1(X, \mathcal{A}, \mu)$ and $\|f_k\|_1 = \mu(A_k)$. We have $f_k g = |g|\chi_{A_k}$, so

$$\phi_g(f_k) = \int_X |g|\chi_{A_k}\, d\mu = \int_{A_k} |g|\, d\mu \geq \left(\|g\|_\infty - \frac{1}{n}\right)\mu(A_k) \ .$$

Thus

$$\|\phi_g\| \geq \frac{\left(\|g\|_\infty - \frac{1}{n}\right)\mu(A_k)}{\mu(A_k)} = \|g\|_\infty - \frac{1}{n} \ .$$

Since $n \in \mathbb{N}$ is arbitrarily large, $\|\phi_g\| \geq \|g\|_\infty$.
For the last statement of (ii), if $\phi_g = \phi_h$, then $0 = \phi_g - \phi_h = \phi_{g-h}$, so $0 = \|\phi_{g-h}\| = \|g - h\|_q$, $g - h = 0$ a.e.

XX.15.7.6. We now turn to (iii). We will prove this in three stages: first for μ finite, then σ-finite, and then for general μ (if $p > 1$). First assume μ is finite, and let ϕ be a bounded linear functional on $L^p(X, \mathcal{A}, \mu)$. For $A \in \mathcal{A}$ define

$$\nu(A) = \phi([\chi_A])$$

(note that $\chi_A \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ since μ is finite). Then ν is a finitely additive complex measure on $(X, \mathcal{A})$. If (A_k) is a sequence of pairwise disjoint sets in $\mathcal{A}$ with union A, set $B_n = \cup_{k=1}^n A_k$; then $(\chi_A - \chi_{B_n})^p$ decreases to 0, so by the MCT

$$\|\chi_A - \chi_{B_n}\|_p^p = \int_X (\chi_A - \chi_{B_n})^p \, d\mu \to 0$$

and thus $[\chi_{B_n}] \to [\chi_A]$ in $L^p(X, \mathcal{A}, \mu)$. Since ϕ is continuous,

$$\nu(B_n) = \sum_{k=1}^n \nu(A_k) = \sum_{k=1}^n \phi(\chi_{A_k}) = \phi\left(\sum_{k=1}^n \chi_{A_k}\right) = \phi(\chi_{B_n}) \to \phi(\chi_A) = \nu(A)$$

so ν is countably additive, i.e. a complex measure on (X, ν). Then

$$|\nu(A)| = |\phi(\chi_A)| \le \|\phi\| \|\chi_A\|_p = \|\phi\| \mu(A)^{1/p}$$

for all $A \in \mathcal{A}$.

We have $\nu \ll \mu$, so by the Radon-Nikodým Theorem there is a $g = \frac{d\nu}{d\mu} \in \mathcal{L}^1(X, \mathcal{A}, \mu)$ such that $\nu(A) = \int_A g \, d\mu$ for all $A \in \mathcal{A}$. Then $g \in \mathcal{L}^1(X, \mathcal{A}, \mu)$. If $s = \sum_{k=1}^n \alpha_k \chi_{A_k}$ is any simple function, then by linearity we have

$$\phi(s) = \sum_{k=1}^n \alpha_k \phi(\chi_{A_k}) = \sum_{k=1}^n \alpha_k \int_{A_k} g \, d\mu = \sum_{k=1}^n \int_{A_k} sg \, d\mu = \int_X sg \, d\mu \ .$$

Since $s \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ and ϕ is bounded, we have

$$\left| \int_X sg \, d\mu \right| = |\phi(s)| \le \|\phi\| \|s\|_p \ .$$

Now let $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$. Let (s_n) be an increasing sequence of simple functions converging pointwise to $|f|$. Then $h_n = (|f| - s_n)^p$ decreases to 0, so by the MCT

$$\int_X h_n \, d\mu = \int_X (|f| - s_n)^p \, d\mu \to 0$$

and thus $s_n \to |f|$ in $L^p(X, \mathcal{A}, \mu)$.

We show $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$. First consider the case $p = 1$, so $q = \infty$. Let $\alpha > \|\phi\|$, and set

$$A = \{x \in X : |g(x)| \ge \alpha\} \ .$$

Set

$$f = \begin{cases} \frac{|g(x)|}{g(x)} & \text{if} \quad x \in A \\ 0 & \text{if} \quad x \notin A \end{cases} \ .$$

Then f is bounded, hence in $\mathcal{L}^p(X, \mathcal{A}, \mu)$; $|f| = \chi_A$, so $\|f\|_p = \mu(A)$. Let (s_n) be a sequence of simple functions converging pointwise to f, with $|s_n| \leq 1$ for all n. Then $s_n g \to fg = |g|\chi_A$, and $|s_n g| \leq |g|$ for all n. Thus by the DCT

$$\int_X |g|\chi_A \, d\mu = \int_X fg \, d\mu = \lim_{n\to\infty} \int_X s_n g \, d\mu = \lim_{n\to\infty} \phi(s_n) = \phi(f)$$

so we have

$$\int_X |g|\chi_A \, d\mu \leq \|\phi\|\|f\|_1 = \|\phi\|\mu(A) \ .$$

On the other hand, $|g| > \alpha$ on A, so

$$\int_X |g|\chi_A \, d\mu = \int_A |g| \, d\mu \geq \alpha\mu(A) \ .$$

Since $\alpha\mu(A) \leq \|\phi\|\mu(A)$ and $\alpha > \|\phi\|$, we conclude $\mu(A) = 0$. This is true for every $\alpha > \|\phi\|$, so $\|g\|_\infty \leq \|\phi\|$, and in particular $g \in \mathcal{L}^\infty(X, \mathcal{A}, \mu)$.

Now suppose $p > 1$. Write $\phi = \phi_{re} + i\phi_{im}$; the corresponding g is $g_{re} + ig_{im}$, where g_{re} and g_{im} are the functions corresponding to ϕ_{re} and ϕ_{im} respectively. To show $\phi \in \mathcal{L}^q(X, \mathcal{A}, \mu)$, it suffices to show that g_{re} and g_{im} are in $\mathcal{L}^q(X, \mathcal{A}, \mu)$, i.e. we may assume g is real-valued. Then σ_g is a simple function. Let (s_n) be an increasing sequence of nonnegative simple functions converging pointwise to $|g|$. Then $r_n = \sigma_g s_n^{q-1}$ is a simple function, $|r_n| = s_n^{q-1} \leq |g|^{q-1}$, $s_n^q \leq r_n g$, and $(r_n g)$ is an increasing sequence of nonnegative functions converging to $|g|^q$. For each n we have

$$\int_X s_n^q \, d\mu \leq \int_X r_n g \, d\mu = \phi(r_n) \leq \|\phi\|\|r_n\|_p$$

$$\int_X s_n^q \, d\mu = \int_X s_n^{p(q-1)} \, d\mu = \int_X (s_n^{q-1})^p \, d\mu = \int_X |r_n|^p \, d\mu = \|r_n\|_p^p$$

$$\int_X s_n^q \, d\mu \leq \|\phi\|\|r_n\|_p = \|\phi\| \left[\int_X s_n^q \, d\mu\right]^{1/p}$$

$$\left[\int_X s_n^q \, d\mu\right]^{1-1/p} = \left[\int_X s_n^q \, d\mu\right]^{1/q} \leq \|\phi\| \ .$$

By the MCT,

$$\left[\int_X |g|^q \, d\mu\right]^{1/q} = \lim_{n\to\infty} \left[\int_X s_n^q \, d\mu\right]^{1/q} \leq \|\phi\|$$

so $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$.

To conclude the proof of (iii) in the finite case, let $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$. Let (s_n) be a sequence of simple functions converging to f, with $|s_n| \leq |f|$ for all n. Then $[s_n] \to [f]$ in $L^p(X, \mathcal{A}, \mu)$ (). Since $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$, $|fg| \in \mathcal{L}^1(X, \mathcal{A}, \mu)$ by Hölder's Inequality, and $|s_n g| \leq |fg|$ for all n. Since $s_n g \to fg$, by the DCT we have

$$\int_X fg \, d\mu = \lim_{n\to\infty} \int_X s_n g \, d\mu = \lim_{n\to\infty} \phi([s_n]) = \phi([f])$$

since ϕ is continuous. Thus $\phi = \phi_g$.

XX.15.7.7. Now assume μ is σ-finite. Let (X_n) be an increasing sequence of sets in $\mathcal{A}$ with $X = \cup_n X_n$ and $\mu(X_n) < \infty$. Let $\mu_n = \mu|_{X_n}$. By the first part of the proof, for each n there is a $g_n \in \mathcal{L}^q(X, \mathcal{A}, \mu)$ with $g_n = 0$ on $X \setminus X_n$ and $\phi(f) = \int_{X_n} f g_n \, d\mu_n = \int_X f g_n \, d\mu$ for any $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ supported on X_n. By uniqueness of g_n, we must have $g_{n+1}|_{X_n} = g_n$ a.e., so modifying the g_n on null sets we may assume $g_{n+1}|_{X_n} = g_n$ for all n. Let g be the function on X which is equal to g_n on X_n for each n. If $p = 1$, we clearly have $\|g\|_\infty = \sup_n \|g_n\|_\infty$, and since $\|g_n\|_\infty \leq \|\phi\|$ for all n, we have $\|g\|_\infty \leq \|\phi\|$, so $g \in \mathcal{L}^\infty(X, \mathcal{A}, \mu)$.

Suppose $p > 1$, so q is finite. We have that $|g_n|$ increases to $|g|$, hence $|g_n|^q$ increases to $|g|^q$, and by the MCT we have

$$\int_X |g|^q \, d\mu = \lim_{n\to\infty} \int_X |g_n|^q \, d\mu \leq \|\phi\|^q$$

so $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$.

If $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$, then $|fg| \in \mathcal{L}^1(X, \mathcal{A}, \mu)$ by Hölder's Inequality. If $f_n = f\chi_{X_n}$, then $f_n g_n = f_n g \to fg$, so by the DCT

$$\int_X fg \, d\mu = \lim_{n\to\infty} \int_X f_n g_n \, d\mu = \lim_{n\to\infty} \phi(f_n) = \phi(f)$$

by continuity of ϕ. Thus $\phi = \phi_g$.

XX.15.7.8. Finally, suppose μ is arbitrary and $p > 1$. For each $A \in \mathcal{A}$ of σ-finite measure, let $\mu_A = \mu|_A$; then there is a $g_A \in \mathcal{L}^q(X, \mathcal{A}, \mu)$, identically 0 on A^c, so that

$$\phi([f]) = \int_A f g_A \, d\mu_A = \int_X f g_A \, d\mu$$

for all $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ supported on A. If $A \subseteq B$, then $g_B|_A = g_A$ a.e. For A σ-finite, set $\rho(A) = \int_X |g_A|^q \, d\mu$. We have $\rho(A) \leq \|\phi\|^q$ for every A. Set

$$M = \sup\{\rho(A) : A \in \mathcal{A} \text{ of } \sigma\text{-finite measure}\} \, .$$

Then $M \leq \|\phi\|^q$. Let (A_n) be a sequence of σ-finite sets in $\mathcal{A}$ with $\rho(A_n) \to M$; we may assume the sets A_n are increasing since a finite or countable union of sets of σ-finite measure has σ-finite measure. Set $A = \cup_n A_n$. Then $A \in \mathcal{A}$ has σ-finite measure. If $B \in \mathcal{A}$ has σ-finite measure and $C = B \setminus A$, then $\int_C |g_C|^q \, d\mu = 0$, so $g_C = 0$ a.e. and $g_B = g_A \chi_B$ a.e. If $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$, then the support B of f is σ-finite, so

$$\phi(f) = \int_B f g_B \, d\mu = \int_X f g_A \, d\mu$$

so $\phi = \phi_{g_A}$.

This completes the proof of Theorem XX.15.7.1.. 

XX.15.7.9. Theorem XX.15.7.1.(ii) holds for $p = 1$ more generally if μ is decomposable, but (iii) can fail (XX.15.9.10.). Part (ii) can fail for $p = 1$ for a bad measure space (XX.15.9.4.). Parts (i) and (ii) hold for $p = \infty$, but (iii) rarely does, even if μ is finite (XX.15.7.12.).

XX.15.7.10. Thus, if $1 < p < \infty$, we have $L^p(X, \mathcal{A}, \mu)^{**} = L^p(X, \mathcal{A}, \mu)$ (more precisely, the natural map from $L^p(X, \mathcal{A}, \mu)$ to $L^p(X, \mathcal{A}, \mu)^{**}$ is an isometric isomorphism) for any measure space $(X, \mathcal{A}, \mu)$, i.e. $L^p(X, \mathcal{A}, \mu)$ is *reflexive* for $1 < p < \infty$. $L^1(X, \mathcal{A}, \mu)$ and $L^\infty(X, \mathcal{A}, \mu)$ are rarely reflexive (only if they are finite-dimensional!)

XX.15.7.11. XX.15.7.1.(i) can be rephrased in a symmetric form: if $(X, .\mathcal{A}, \mu)$ is a measure space, and (p, q) is a conjugate pair (allowing $(1, \infty)$ and $(\infty, 1)$), then there is a pairing $\beta : L^p(X, \mathcal{A}, \mu) \times L^q(X, \mathcal{A}, \mu) \to \mathbb{F}$ given by

$$\beta(f, g) = \int_X fg \, d\mu$$

which is a bilinear form (XX.11.1.1.), and which is bounded (XX.11.12.1.) with $\|\beta\| \leq 1$ by Hölder's Inequality. By XX.15.7.1.(ii) we have $\|\beta\| = 1$ if $1 < p, q < \infty$ or if μ is σ-finite, and in fact we always have $\|\beta\| = 1$ if L^p and L^q are nonzero (cf. XX.15.9.4.).

The Dual of L^∞

Each element of $L^1(X, \mathcal{A}, \mu)$ defines a bounded linear functional on $L^\infty(X, \mathcal{A}, \mu)$, so there is a bounded linear map $T : L^1(X, \mathcal{A}, \mu) \to L^\infty(X, \mathcal{A}, \mu)^*$ given by $T([g]) = \phi_g$. This map is isometric (XX.15.7.1.(ii)), but is rarely surjective (in fact, if and only if $L^\infty(X, \mathcal{A}, \mu)$ is finite-dimensional)..

XX.15.7.12. Examples. (i) Let c be the closed subspace of $\ell^\infty = L^\infty(\mathbb{N}, \mathcal{P}(\mathbb{N}), \gamma)$ consisting of convergent sequences. If $x = (\xi_1, \xi_2, \dots) \in c$, define

$$\psi(x) = \lim_{n \to \infty} \xi_n \ .$$

Then ψ is a bounded linear functional on c, and $\|\psi\| = 1$. By the Hahn-Banach Theorem, ψ extends to a bounded linear functional ϕ on ℓ^∞ with $\|\phi\| = 1$ (such a ϕ is called a *Banach limit* on ℓ^∞). But there cannot be a $y = (\eta_1, \eta_2, \dots) \in \ell^1$ with

$$\phi(x) = \int_{\mathbb{N}} xy \, d\gamma = \sum_{n=1}^{\infty} \xi_n \eta_n$$

for every $x = (\xi_1, \xi_2, \dots) \in \ell^\infty$: if there were such a y, for each n we would have

$$0 = \psi(\boldsymbol{e}_n) = \phi(\boldsymbol{e}_n) = \int_{\mathbb{N}} \boldsymbol{e}_n y \, d\gamma = \eta_n$$

so $y = 0$, a contradiction.

(ii) $L^\infty([0, 1], \mathcal{L}, \lambda)$ is a unital commutative C*-algebra (), thus is of the form $C(X)$ for a (rather bizarre) compact Hausdorff space X (). If $x \in X$, define a linear functional ϕ on $C(X)$ by $\phi(f) = f(x)$. This ϕ does not come from integration with an element of $\mathcal{L}^1([0, 1], \mathcal{L}, \lambda)$. In fact, $L^1([0, 1], \mathcal{L}, \lambda)$ is identified with the set of *normal* bounded linear functionals on $L^\infty([0, 1], \mathcal{L}, \lambda)$ ().

Example (i) can be put in the same context: $\ell^\infty \cong C(\beta\mathbb{N})$ (), so by the other Riesz Representation Theorem () $(\ell^\infty)^*$ can be identified with the set of complex Radon measures on $\beta\mathbb{N}$. The subspace ℓ^1 corresponds to the Radon measures supported on $\mathbb{N}$.

A Converse to Hölder's Inequality

We have the following partial converse to XX.15.2.6., giving a criterion for when a function is p'th power integrable:

XX.15.7.13. THEOREM. Let $(X, \mathcal{A}, \mu)$ be a semifinite measure space, and f a real- or complex-valued $\mathcal{A}$-measurable function. Let $1 \leq p \leq \infty$, and let q be the conjugate exponent. If $fg \in \mathcal{L}^1(X, \mathcal{A}, \mu)$ for all $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$, then $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$.

PROOF: Since both the hypothesis and conclusion are true for f if and only if they are true for $|f|$, it suffices to assume f is nonnegative.

The case $p = 1$ is trivial, with no restriction on μ: take g to be the constant function 1.

Now suppose $1 < p < \infty$. First assume μ is σ-finite. Let (s_n) be an increasing sequence of nonnegative simple functions converging pointwise to f, with the support of each s_n of finite measure. Then $f_n \in \mathcal{L}^p(X, \mathcal{A}, \mu)$, so defines a bounded linear functional ϕ_n on $L^q(X, \mathcal{A}, \mu)$ by

$$\phi_n([g]) = \int_X f_n g \, d\mu \ .$$

Fix $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$. Then, for every n,

$$|\phi_n([g])| = \left| \int_X f_n g \, d\mu \right| \leq \int_X |f_n g| \, d\mu \leq \int_X |fg| \, d\mu$$

we have that the ϕ_n are pointwise bounded. Thus by the Uniform Boundedness Theorem (), they are uniformly bounded, i.e. there is an M such that $|\phi_n([g])| \leq M\|g\|_q$ for all n and all $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$. Define a linear functional ϕ on $L^q(X, \mathcal{A}, \mu)$ by

$$\phi([g]) = \int_X fg \, d\mu \ .$$

If $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$, then $f_n g \to fg$, and $|f_n g| \leq |fg|$, so by the DCT

$$|\phi(g)| = \left| \int_X fg \, d\mu \right| = \lim_{n\to\infty} \left| \int_X f_n g \, d\mu \right| = \lim_{n\to\infty} |\phi_n(g)| \leq M\|g\|_q$$

so ϕ is bounded and $\|\phi\| \leq M$. Thus there is an $h \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ with $\phi = \phi_h$. We show that $f = h$ a.e. If $A \in \mathcal{A}$ with $\mu(A) < \infty$, set $\gamma_A = \sigma(f - h)\chi_A$. Then $\gamma_A \in \mathcal{L}^q(X, \mathcal{A}, \mu)$ and $\overline{\gamma_A}(f - h) = |f - h|\chi_A$. We have

$$0 = \int_X f\gamma_A \, d\mu - \int_X h\gamma_A \, d\mu = \int_X (f - h)\gamma_A \, d\mu = \int_A |f - h| \, d\mu$$

so $f - h = 0$ a.e. on A. Since A is arbitrary and μ is σ-finite, $f = h$ a.e. on X.

Now suppose μ is just semifinite. If the support of f is not σ-finite, then there is an m such that $B = \left\{x : f(x) \geq \frac{1}{m}\right\}$ is not σ-finite, hence has infinite measure. Since μ is semifinite, B contains measurable sets of arbitrarily large finite measure (XVII.1.4.14.); hence there is a $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$, supported on B, with $g \notin \mathcal{L}^1(X, \mathcal{A}, \mu)$ (XX.15.5.1.). Since $fg \geq \frac{1}{m}g$, fg is not integrable, a contradiction.

Thus $E = \{x : f(x) > 0\}$ has σ-finite measure. Reducing to the measure space $(E, \mathcal{A}_E, \mu|_E)$, which is σ-finite, we conclude from the first part of the proof that $f|_E \in \mathcal{L}^p(E, \mathcal{A}_E, \mu|_E)$, so $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$.

Now let $p = \infty$. Suppose f is not essentially bounded. If $f = \infty$ on a set of positive measure, then there is an $A \in \mathcal{A}$ with $0 < \mu(A) < \infty$ and $f = \infty$ on A. Then $\chi_A \in \mathcal{L}^1(X, \mathcal{A}, \mu)$, but $f\chi_A$ is not integrable, a contradiction. If f is finite a.e., then there is a sequence (A_n) of pairwise disjoint sets in $\mathcal{A}$ with $0 < \mu(A_n) < \infty$ and $|f| \geq 2^n$ on A_n. Set $g_n = \frac{1}{2^n \mu(A_n)} \chi_{A_n}$. Then

$$\sum_{n=1}^{\infty} g_n$$

converges pointwise and in $\|\cdot\|_1$ to a (nonnegative) function $g \in \mathcal{L}^1(X, \mathcal{A}, \mu)$. But

$$\int_{A_n} fg \, d\mu \geq 1$$

for all n, so fg cannot be integrable, again a contradiction. 👍

XX.15.7.14. As noted, the semifinite hypothesis is unnecessary if $p = 1$. If $1 < p < \infty$ and μ is not semifinite, the result fails: if $A \in \mathcal{A}$ with $\mu(A) = \infty$ contains no subsets of finite positive measure, then any integrable function equals 0 a.e. on A. Thus $\chi_A g = 0$ a.e., hence is integrable, for any $g \in \mathcal{L}^q(X, \mathcal{A}, \mu)$. But $\chi_A \notin \mathcal{L}^p(X, \mathcal{A}, \mu)$. The case $p = \infty$ can also fail if μ is not semifinite: let X be an infinite set, and take $\mu(A) = \infty$ for all nonempty $A \subseteq X$.

XX.15.8. Conditional Expectations on L^p-Spaces

We continue the discussion of conditional expectations from XVIII.6.5.16.. Let $(X, \mathcal{A}, \mu)$ be a probability measure space, and let $\mathcal{B}$ be a sub-σ-algebra of $\mathcal{A}$. Fix a field $\mathbb{F} = \mathbb{R}$ or $\mathbb{C}$. We will suppress the subscript $\mathbb{F}$ on $L^1_{\mathbb{F}}(X, \mathcal{A}, \mu)$, etc., but keep in mind that $\mathbb{F}$ has been specified.

XX.15.8.1. First note that $L^1(X, \mathcal{A}, \mu)$ is a Banach space under $\|\cdot\|_1$, and that $L^1(X, \mathcal{B}, \mu|_{\mathcal{B}})$ is a closed subspace. The conditional expectation map $\mathbf{E}$ is a linear transformation from $L^1(X, \mathcal{A}, \mu)$ onto the closed subspace $L^1(X, \mathcal{B}, \mu|_{\mathcal{B}})$; call this map $\mathbf{E}_1$. $L^\infty(X, \mathcal{A}, \mu)$ is a subspace of $L^1(X, \mathcal{A}, \mu)$ which is dense for the norm $\|\cdot\|_1$ (all simple functions are in L^∞), and is itself a Banach space under the different norm $\|\cdot\|_\infty$. Similarly, $L^\infty(X, \mathcal{B}, \mu|_{\mathcal{B}})$ is a $\|\cdot\|_1$-dense subspace of $L^1(X, \mathcal{B}, \mu|_{\mathcal{B}})$ which is an $\|\cdot\|_\infty$-closed subspace of $L^\infty(X, \mathcal{A}, \mu)$. $\mathbf{E}$ maps $L^\infty(X, \mathcal{A}, \mu)$ onto the closed subspace $L^\infty(X, \mathcal{B}, \mu|_{\mathcal{B}})$; call this map $\mathbf{E}_\infty$.

XX.15.8.2. The first observation is that $\mathbf{E}_\infty$ is bounded and has norm 1 (the argument that $\|\mathbf{E}_\infty\| \leq 1$ is described in XVIII.6.5.16., and equality holds since $\mathbf{E}_\infty(1) = 1$). We similarly have:

XX.15.8.3. Proposition. The map $\mathbf{E}_1 : L^1(X, \mathcal{A}, \mu) \to L^1(X, \mathcal{B}, \mu|_{\mathcal{B}})$ is bounded and has norm 1.

Proof: We use the fact that $L^\infty(X, \mathcal{B}, \mu|_{\mathcal{B}})$ is the dual of $L^1(X, \mathcal{B}, \mu|_{\mathcal{B}})$. By the Hahn-Banach Theorem, if $f \in \mathcal{L}^1(X, \mathcal{A}, \mu)$, then

$$\|\mathbf{E}_1([f])\|_1 = \sup \left\{ \left| \int_X g\mathbf{E}(f|\mathcal{B}) \, d\mu \right| : g \in \mathcal{L}^\infty(X, \mathcal{B}, \mu|_{\mathcal{B}}), \|g\|_\infty = 1 \right\} .$$

But for each such g, by XVIII.6.5.9. we have

$$\left|\int_X g\mathbf{E}(f|\mathcal{B})\,d\mu\right| = \left|\int_X fg\,d\mu\right| \leq \int_X |fg|\,d\mu \leq \int_X |f|\,d\mu = \|[f]\|_1 \ .$$

Thus $\mathbf{E}_1$ is bounded and $\|\mathbf{E}_1\| \leq 1$. Since $\mathbf{E}_1(1) = 1$, equality holds. 👍

XX.15.8.4. We can extend this argument. If $1 < p < \infty$, we have

$$L^\infty(X, \mathcal{A}, \mu) \subseteq L^p(X, \mathcal{A}, \mu) \subseteq L^1(X, \mathcal{A}, \mu)$$

since μ is finite, and similarly for $L^p(X, \mathcal{B}, \mu|_\mathcal{B})$, which is a $\|\cdot\|_p$-closed subspace of $L^p(X, \mathcal{A}, \mu)$. We have:

XX.15.8.5. THEOREM. Let $(X, \mathcal{A}, \mu)$ be a probability measure space, and $\mathcal{B}$ a sub-σ-algebra of $\mathcal{A}$. Let $\mathbf{E} : L^1(X, \mathcal{A}, \mu) \to L^1(X, \mathcal{B}, \mu|_\mathcal{B})$ be the conditional expectation map. Let $1 \leq p \leq \infty$. Then
(i) If $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$, then $\mathbf{E}(f|\mathcal{B}) \in \mathcal{L}^p(X, \mathcal{B}, \mu|_\mathcal{B})$.
(ii) If $\mathbf{E}_p : L^p(X, \mathcal{A}, \mu) \to L^p(X, \mathcal{B}, \mu|_\mathcal{B})$ is the induced map, then $\mathbf{E}_p$ is bounded and $\|\mathbf{E}_p\| = 1$.

PROOF: The result has already been proved for $p = 1$ and $p = \infty$. Suppose $1 < p < \infty$, and let q be the conjugate exponent. Let $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$. For each n, set

$$f_n(x) = \begin{cases} f(x) & \text{if} \quad |f(x)| \leq n \\ 0 & \text{if} \quad |f(x)| > n \end{cases}$$

Then $|f_n| \in \mathcal{L}^\infty(X, \mathcal{A}, \mu)$, so $E(|f_n||\mathcal{B}) \in \mathcal{L}^\infty(X, \mathcal{B}, \mu|_\mathcal{B}) \subseteq \mathcal{L}^p(X, \mathcal{B}, \mu|_\mathcal{B})$. If $g \in \mathcal{L}^q(X, \mathcal{B}, \mu|_\mathcal{B})$, then by XX.15.2.6.

$$\left|\int_X g\mathbf{E}(|f_n||\mathcal{B})\,d\mu\right| \leq \int_X |g\mathbf{E}(|f_n||\mathcal{B})|\,d\mu = \int_X |\mathbf{E}(|f_n|g|\mathcal{B})|\,d\mu \leq \int_X \mathbf{E}(|f_n g||\mathcal{B})\,d\mu$$

$$= \int_X |f_n g|\,d\mu \leq \|f_n\|_p \|g\|_q \leq \|f\|_p \|g\|_q$$

for each n. Since $L^q(X, \mathcal{B}, \mu|_\mathcal{B})$ is the dual of $L^p(X, \mathcal{B}, \mu|_\mathcal{B})$, by the Hahn-Banach Theorem we have, for each n,

$$\|\mathbf{E}(|f_n||\mathcal{B})\|_p = \sup\left\{\left|\int_X g\mathbf{E}(|f_n||\mathcal{B})\,d\mu\right| : g \in \mathcal{L}^q(X, \mathcal{B}, \mu|_\mathcal{B}), \|g\|_q = 1\right\} \leq \|f\|_p \ .$$

Alternately, to avoid using the Hahn-Banach Theorem, set $g_n(x) = \mathbf{E}(|f_n||\mathcal{B})(x)^{p-1}$. Then $\mathbf{E}(|f_n||\mathcal{B})g_n = \mathbf{E}(|f_n||\mathcal{B})^p = |g_n|^q$ so $g_n \in \mathcal{L}^q(X, \mathcal{B}, |_\mathcal{B})$ and

$$\|g_n\|_q = \|\mathbf{E}(|f_n||\mathcal{B})\|_p^{p/q} = \|\mathbf{E}(|f_n||\mathcal{B})\|_p^{p-1}$$

and therefore

$$\|\mathbf{E}(|f_n||\mathcal{B})\|_p^p = \int_X \mathbf{E}(|f_n|\mathcal{B})^p\,d\mu = \int_X g_n\mathbf{E}(|f_n|\mathcal{B})\,d\mu \leq \|f\|_p\|g_n\|_q = \|f\|_p\|\mathbf{E}(|f_n||\mathcal{B})\|_p^{p-1}$$

and we again conclude that $\|\mathbf{E}(|f_n||\mathcal{B})\|_p \le \|f\|_p$ for each n.
Since $|f_n|$ increases to $|f|$ a.e., $\mathbf{E}(|f_n||\mathcal{B})$ increases to $\mathbf{E}(|f||\mathcal{B})$ a.e., so by the MCT,

$$\int_X |\mathbf{E}(f|\mathcal{B})|^p \, d\mu \le \int_X \mathbf{E}(|f||\mathcal{B})^p \, d\mu = \lim_{n\to\infty} \int_X \mathbf{E}(|f_n||\mathcal{B})^p \, d\mu \le \|f\|_p^p$$

and thus $\mathbf{E}(f|\mathcal{B}) \in \mathcal{L}^p(X, \mathcal{B}, \mu|_{\mathcal{B}})$ and $\|\mathbf{E}(f|\mathcal{B})\|_p \le \|f\|_p$. So $\mathbf{E}_p$ is defined and bounded, and $\|\mathbf{E}_p\| \le 1$. Equality holds since $\mathbf{E}_p(1) = 1$. 👍

XX.15.8.6. Thus $L^p(X, \mathcal{B}, \mu|_{\mathcal{B}})$ is a very special subspace of $L^p(X, \mathcal{A}, \mu)$: there is a projection of norm 1 onto the subspace, which is unusual for general closed subspaces of Banach spaces (). If $p = 2$, $L^2(X, \mathcal{A}, \mu)$ is a Hilbert space, so $\mathbf{E}_2$ is necessarily the orthogonal projection onto the subspace $L^2(X, \mathcal{B}, \mu|_{\mathcal{B}})$ (this can be verified directly).

XX.15.9. Exercises

XX.15.9.1. Let $0 < r < 1$.
(a) Let $f(x) = x^r - rx$ for $x \ge 0$. Show that f is increasing on $[0, 1]$ and decreasing on $[1, \infty)$, and has a unique maximum $1 - r$ at $x = 1$.
(b) If $x \in [0, \infty)$, show that $x^r \le rx + (1 - r)$, with equality if and only if $x = 1$.
(c) If $a, b > 0$, show that $a^r b^{1-r} \le ra + (1 - r)b$, with equality if and only if $a = b$. [Apply (b) with $x = \frac{a}{b}$.]
(d) Show that the inequality in (c) is equivalent to Young's Inequality for products. [Let $r = \frac{1}{p}$, $\alpha = a^r$, $\beta = b^{1-r}$.]

XX.15.9.2. Here is the general version of Young's Inequality for products:
THEOREM. [YOUNG'S INEQUALITY FOR PRODUCTS, GENERAL VERSION] Let ϕ be a strictly increasing continuous function from $[0, \infty)$ onto $[0, \infty)$ (that is, $\phi(0) = 0$ and $\lim_{x\to+\infty} \phi(x) = +\infty$), and let ψ be the inverse function of ϕ. For $x \ge 0$, set

$$\Phi(x) = \int_0^x \phi(t) \, dt$$

$$\Psi(x) = \int_0^x \psi(t) \, dt \ .$$

If $\alpha, \beta \in [0, \infty)$, then

$$\alpha\beta \le \Phi(\alpha) + \Psi(\beta)$$

with equality if and only if $\beta = \phi(\alpha)$.

See Figure XX.1 for a geometric interpretation in terms of areas. The red area is $\Phi(\alpha)$ and the blue area is $\Psi(\beta)$, and $\alpha\beta$ is the area of the rectangle bounded by the dotted lines and the axes.

(a) Use () to show that, for $\beta \ge 0$,

$$\Psi(\beta) = \int_0^\beta \int_0^{\psi(y)} dx \, dy = \int_0^{\psi(\beta)} \int_{\phi(x)}^\beta dy \, dx \ .$$

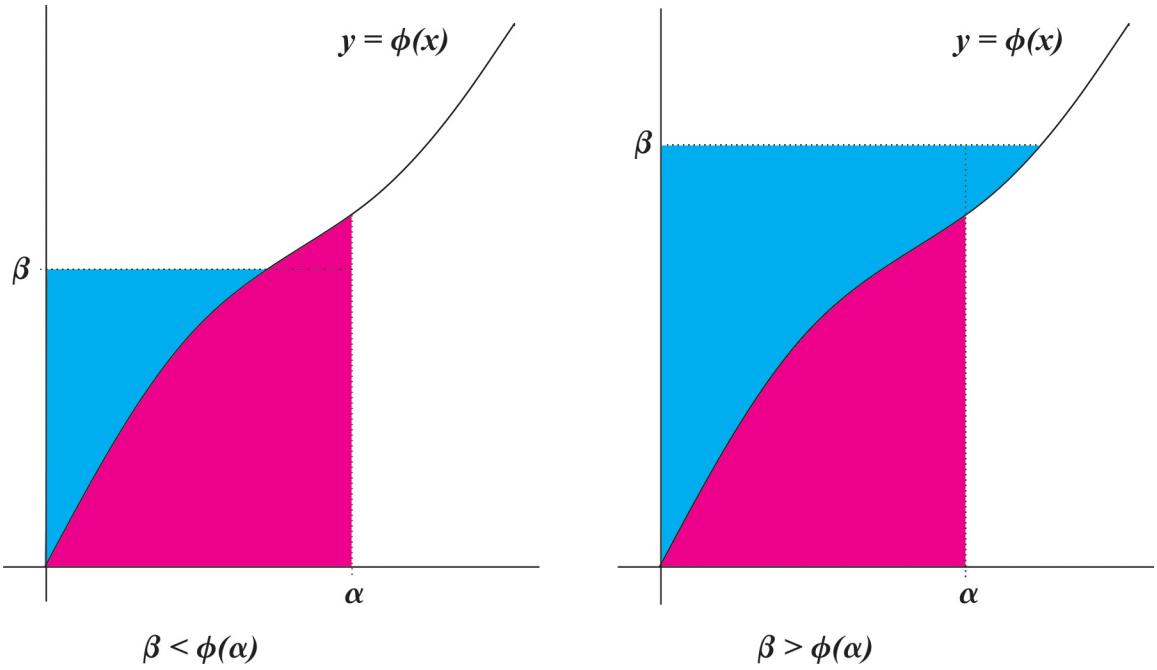

Figure XX.1: Geometric Interpretation of Young's Inequality for Products

(b) If $\beta \geq \phi(\alpha)$, then

$$\alpha\beta = \int_0^\alpha \int_0^\beta dy\,dx = \int_0^\alpha \int_0^{\phi(x)} dy\,dx + \int_0^\alpha \int_{\phi(x)}^\beta dy\,dx = \Phi(\alpha) + \int_0^\alpha \int_{\phi(x)}^\beta dy\,dx\ .$$

(c) Use (a) and (b) to prove the Theorem if $\beta \geq \phi(\alpha)$. Give a similar proof if $\beta \leq \phi(\alpha)$.
(d) Show that the Young's Inequality for products of XX.15.2.5. is the special case $\phi(x) = x^{p-1}$.

XX.15.9.3. Prove the following generalized versions of Hölder's Inequality:

THEOREM. [HÖLDER'S INEQUALITY, GENERAL VERSION] Let $(X, \mathcal{A}, \mu)$ be a measure space.
(i) Let $p, q > 1$, $r \geq 1$, with

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{r}$$

and let $f \in \mathcal{L}^p(\mu)$ and $g \in \mathcal{L}^q(\mu)$. Then $fg \in \mathcal{L}^r(\mu)$ and

$$\|fg\|_r \leq \|f\|_p \|g\|_q\ .$$

(ii) Let $p_1, \ldots, p_n > 1$, $r \geq 1$, with

$$\frac{1}{p_1} + \cdots + \frac{1}{p_n} = \frac{1}{r}$$

and let $f_k \in \mathcal{L}^{p_k}(\mu)$ for $1 \le k \le n$. Then $f_1 f_2 \cdots f_n \in \mathcal{L}^r(\mu)$ and

$$\|f_1 f_2 \cdots f_n\|_r \le \|f_1\|_{p_1} \|f_2\|_{p_2} \cdots \|f_n\|_{p_n} \ .$$

[To prove (i), note that

$$\frac{1}{p/r} + \frac{1}{q/r} = 1$$

and apply Hölder's inequality to $|f|^r$ and $|g|^r$. Prove (ii) by induction on n. For the inductive step set

$$\frac{1}{p} = \frac{1}{p_1} + \cdots + \frac{1}{p_n}$$

and $q = p_{n+1}$ to obtain $f_1 f_2 \cdots f_n \in \mathcal{L}^p$ and $\|f_1 \cdots f_{n+1}\|_r \le \|f_1 \cdots f_n\|_p \|f_{n+1}\|_{p_{n+1}}$.]

XX.15.9.4. Let $X = \{x\}$ be a one-point space, and let $\mu(\{x\}) = \infty$. Show that $\mathcal{L}^p(X, \mathcal{P}(X), \mu) = \{0\}$ for $1 \le p < \infty$, and that $\mathcal{L}^\infty(X, \mathcal{P}(X), \mu)$ is one-dimensional (the set of all scalar-valued functions). In particular, $L^\infty(X, \mathcal{P}(X), \mu)$ is larger than $L^1(X, \mathcal{P}(X), \mu)^*$.

XX.15.9.5. Let X be an uncountable set, and for $A \subseteq X$ let $\mu(A) = 0$ if A is countable and $\mu(A) = \infty$ if A is uncountable.

(a) If $1 \le p < \infty$, show that $\mathcal{L}^p(X, \mathcal{P}(X), \mu)$ is the set of functions vanishing except on a countable set, and $L^p(X, \mathcal{P}(X), \mu) = \{0\}$.

(b) Show that $\mathcal{L}^\infty(X, \mathcal{P}(X), \mu)$ is the set of all functions which are bounded on a cocountable set, and $L^\infty(X, \mathcal{P}(X), \mu)$ is infinite-dimensional and even nonseparable.

XX.15.9.6. (a) Even in a finite continuous measure space the L^p-spaces can be small simply because of the lack of sufficiently many measurable functions. Let X be an uncountable set, $\mathcal{A}$ the σ-algebra of countable-cocountable sets, and μ the measure on $(X, \mathcal{A})$ with $\mu(A) = 0$ if A is countable and $\mu(A) = 1$ if A is cocountable. A scalar-valued measurable function on A must be constant except on a countable set (). Show that $L^p(X, \mathcal{A}, \mu)$ is one-dimensional for all p, $1 \le p \le \infty$ (every measurable function is equal a.e. to a constant function).

(b) Show that the result of (a) holds true in any measure space in which every measurable set has measure either 0 or 1. Thus, if X is a set of measurable cardinality () and μ is a full $\{0,1\}$-valued measure on $(X, \mathcal{P}(X))$, then $L^p(X, \mathcal{P}(X), \mu)$ is one-dimensional for $1 \le p \le \infty$ even though there are plenty of measurable functions; every scalar-valued function is still equal a.e. to a constant function.

XX.15.9.7. (a) Show that, in the situation of Example XX.15.5.1., for any p there is an $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ which is not in $\mathcal{L}^r(X, \mathcal{A}, \mu)$ for any $r < p$. [For each n, construct a function f_n as in Example XX.15.5.1. which is in $\mathcal{L}^p(\mu)$ but not in $\mathcal{L}^{p-1/n}(\mu)$, and consider $\sum_{n=1}^\infty \frac{2^{-n}}{\|f_n\|_p} f_n$. Modify the argument slightly for $p = \infty$.]

(b) In the situation of XX.15.5.3., use a similar argument to show that if $0 < p < \infty$, there is an $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ which is not in $\mathcal{L}^r(X, \mathcal{A}, \mu)$ for any $r > p$.

(c) If $(X, \mathcal{A}, \mu)$ contains sets of both arbitrarily large and arbitrarily small finite positive measure, and $0 < s \le r \le \infty$, show that

(i) There is an f such that $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ if and only if $s \le p \le r$ (in particular, if $s = r$, there is an f such that $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ if and only if $p = r$).

(ii) If $s < r$, there is an f such that $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ if and only if $s < p \le r$.

(iii) If $s < r$, there is an f such that $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ if and only if $s \le p < r$.

(iv) If $s < r$, there is an f such that $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ if and only if $s < p < r$.

XX.15.9.8. Let $(X, \mathcal{A}, \mu)$ be a measure space, and $0 < s < p < r \le \infty$.

(a) Using the arguments of the proofs of XX.15.5.2. and XX.15.5.4., show that every $f \in \mathcal{L}^p(X, \mathcal{A}, \mu)$ can be written as $f = g + h$ with $g \in \mathcal{L}^s(X, \mathcal{A}, \mu)$, $h \in \mathcal{L}^r(X, \mathcal{A}, \mu)$, $gh = 0$, and $J_p(f) \le J_s(g) + J_r(h)$.

(b) Show that the function

$$\|f\| = \inf\{\|g\|_s + \|h\|_r : g \in \mathcal{L}^s(\mu), h \in \mathcal{L}^r(\mu), f = g + h\}$$

is a seminorm on the subspace $\mathcal{L}^s(\mu) + \mathcal{L}^r(\mu)$ of the space of $\mathcal{A}$-measurable functions, that $\|f\| = 0$ if and only if $f \in Z$, and that the quotient, which we denote $L^s(\mu) + L^r(\mu)$, is complete under the corresponding norm. Show that the inclusion map from $L^p(\mu)$ into $L^s(\mu) + L^r(\mu)$ is bounded.

(c) Show that $\mathcal{L}^s(\mu) \cap \mathcal{L}^r(\mu) \subseteq \mathcal{L}^p(\mu)$, that $\|f\| = \|f\|_s + \|f\|_r$ is a seminorm on $\mathcal{L}^s(\mu) \cap \mathcal{L}^r(\mu)$, $\|f\| = 0$ if and only if $f \in Z$, and that the quotient, which we denote $L^s(\mu) \cap L^r(\mu)$, is complete under the corresponding norm. Show that the inclusion map from $L^s(\mu) \cap L^r(\mu)$ into $L^p(\mu)$ is bounded.

XX.15.9.9. (a) Prove directly that if $p > 1$ and q is conjugate to p, the map $a \mapsto \phi_a$ is an isometric isomorphism from ℓ^q to $(\ell^p)^*$, where

$$\phi_a(x) = \sum_{k=1}^{\infty} \alpha_k \xi_k$$

for $a = (\alpha_1, \alpha_2, \dots)$ and $x = (\xi_1, \xi_2, \dots)$. [Use Hölder's inequality and the fact that $\{\boldsymbol{e}_k\}$ is a Schauder basis for ℓ^p ().]

(b) Give a similar proof that $(c_0)^* \cong \ell^1$ and that $(\ell^1)^* \cong \ell^\infty$.

This gives an alternate proof that ℓ^p is complete for $1 \le p \le \infty$.

XX.15.9.10. Show that if $(X, \mathcal{A}, \mu)$ is a decomposable measure space, show that $L^1(X, \mathcal{A}, \mu)^*$ is naturally isometrically isomorphic to $L^\infty(X, \underline{\mathcal{A}}, \underline{\mu})$, where $(X, \underline{\mathcal{A}}, \underline{\mu})$ is the saturation () of $(X, \mathcal{A}, \mu)$. Thus XX.15.7.1.(iii) holds for $p = 1$ for a decomposable measure space if and only if it is saturated. Show that XX.15.7.1.(ii) for $p = 1$ always holds for a decomposable measure space.

XX.15.9.11. [LL97] (a) Use Tonelli's Theorem to prove the following version of Minkowski's Inequality:

THEOREM. [MINKOWSKI'S INEQUALITY, GENERAL VERSION] Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be σ-finite measure spaces, and $1 \le p < \infty$. If f is a nonnegative $(\mu \times \nu)$-measurable function on $X \times Y$, then

$$\int_Y \left[\int_X f(x,y)^p \, d\mu(x)\right]^{1/p} d\nu(y) \ge \left(\int_X \left[\int_Y f(x,y) \, d\nu(y)\right]^p d\mu(x)\right)^{1/p}.$$

If $1 < p < \infty$, equality and finiteness imply there are nonnegative measurable functions g on X and h on Y such that $f(x,y) = g(x)h(y)$ a.e.

[Set $H(x) = \int_Y f(x,y)\,d\nu(y)$ and bound $\int_X H^p\,d\mu = \int_X H(x)\cdot H(x)^{p-1}\,d\mu(x)$ using Hölder's Inequality.]

(b) Use (a) to give an alternate proof of the usual Minkowski Inequality XX.15.2.7. in the σ-finite case. [Reduce to the case where f and g are nonnegative and take Y to be a two-point space with counting measure.]

(c) Give a counterexample to the last statement in the theorem if $p = 1$.

XX.15.9.12. If $n \in \mathbb{N}$, write $n = 2^m + k$ for some $m \geq 0$ and $0 \leq k < 2^m$. Let f_n be the characteristic (indicator) function of the interval $\left[\frac{k}{2^m}, \frac{k+1}{2^m}\right]$.

(a) Show that $f_n \to 0$ in $\mathcal{L}^p([0,1], \mathcal{L}, \lambda)$ for $1 \leq p < \infty$.

(b) Show that $f_n \to 0$ in measure.

(c) Show there is no $x \in [0,1]$ such that $f_n(x) \to 0$ (in fact, $(f_n(x))$ does not converge for any $x \in [0,1]$).

XX.15.9.13. Let $1 < p < \infty$, and q its conjugate exponent, and let $(X, \mathcal{A}, \mu)$ be a measure space.

(a) Prove the *Clarkson inequalities* [Cla36]:
If $p \leq 2$ and $x, y \in L^p(X, \mathcal{A}, \mu)$, then

$$\left\|\frac{x+y}{2}\right\|_p^p + \left\|\frac{x-y}{2}\right\|_p^p \geq \frac{1}{2}\|x\|_p^p + \frac{1}{2}\|y\|_p^p$$

$$\left\|\frac{x+y}{2}\right\|_p^q + \left\|\frac{x-y}{2}\right\|_p^q \leq \left[\frac{1}{2}\|x\|_p^p + \frac{1}{2}\|y\|_p^p\right]^{q-1}$$

and the reversed inequalities hold if $p \geq 2$. [Note that if $p = 2$ the inequalities reduce to the Parallelogram Law (XX.11.2.6.).]

(b) Use the Clarkson inequalities to prove that $L^p(X, \mathcal{A}, \mu)$ is uniformly convex (XX.11.11.15.) for $1 < p < \infty$.

XX.16. C*-Algebras

C*-algebras are the nicest kinds of Banach algebras, and have a beautiful theory with profound applications. We will touch on only some of the basics of this extensive theory here; see [Bla06] for a much more comprehensive treatment.

XX.16.1. Banach *-Algebras and C*-Algebras

XX.16.1.1. DEFINITION. An *involution* on a Banach algebra A is a conjugate-linear isometric antiautomorphism of order two, usually denoted $x \mapsto x^*$. In other words, $(x+y)^* = x^* + y^*$, $(xy)^* = y^*x^*$, $(\lambda x)^* = \bar{\lambda}x^*$, $(x^*)^* = x$, $\|x^*\| = \|x\|$ for all $x, y \in A$, $\lambda \in \mathbb{C}$. A *Banach *-algebra* is a Banach algebra with an involution.

An *(abstract) C*-algebra* is a Banach *-algebra A satisfying the *C*-axiom*:

$$\|x^*x\| = \|x\|^2 \text{ for all } x \in A$$

The deceptively simple and innocuous C*-axiom turns out to be extremely powerful, forcing rigid structure on a C*-algebra. For example, it follows that the norm is completely determined by the algebraic structure and is thus unique (XX.16.2.34.), that *-homomorphisms of C*-algebras are automatically contractive (XX.16.1.11.), and that every C*-algebra can be isometrically represented as a concrete C*-algebra of operators (XX.16.4.35.). One obvious, but useful, consequence is that in a C*-algebra, $x^*x = 0 \Rightarrow x = 0$. [In fact, in a C*-algebra, $\sum x_j^* x_j = 0$ implies that each $x_j = 0$ (XX.16.3.2.(i), XX.16.3.3.).]

XX.16.1.2. In many older references, abstract C*-algebras were called *B*-algebras*, with the name "C*-algebra" reserved for concrete C*-algebras. The term "C*-algebra," first introduced in [Seg47] (for concrete C*-algebras, but viewed in a somewhat abstract manner), did not become universal until well after the publication of [Dix69] in 1964 (there were occasional references to "B*-algebras" in the literature at least as late as 1980; see even [Lax02]). According to [DB86, p. 6], the "C" in "C*-algebra" originally meant "closed", and not, as commonly believed, "continuous", although the interpretation as standing for "continuous" is nicely in line with the modern point of view of C*-algebra theory as "noncommutative topology."

The issue of terminology is clouded by the fact that several different (but ultimately equivalent) axiom schemes have been used for C*-algebras over the years. For example, it is easily seen that the C*-axiom, along with submultiplicativity of the norm, implies that the involution is isometric, so it is unnecessary to include isometry of the involution as an axiom. The C*-axiom has sometimes been replaced by the apparently weaker axiom that $\|x^*x\| = \|x^*\|\|x\|$ for all x. It turns out that this weaker axiom, along with the Banach algebra axioms, also implies isometry of the involution (a much harder result), so the weakened axiom is equivalent to the C*-axiom. See also XX.16.3.4.. See [DB86] for details about the C*-algebra axioms.

XX.16.1.3. EXAMPLES.

(i) $\mathcal{B}(\mathcal{H})$ with the usual algebraic operations, involution, and operator norm, is a C*-algebra for any Hilbert space $\mathcal{H}$ (). If $\mathcal{H}$ is n-dimensional, we obtain that the $n \times n$ matrices $\mathbb{M}_n = \mathcal{B}(\mathbb{C}^n)$ form a C*-algebra with the usual involution (conjugate transpose) and operator norm. More generally, any norm-closed *-subalgebra of $\mathcal{B}(\mathcal{H})$ is a C*-algebra; such C*-algebras are called *concrete C*-algebras*. For example, the algebra $\mathcal{K}(\mathcal{H})$ of compact operators () on a Hilbert space $\mathcal{H}$ is a concrete C*-algebra. If $\mathcal{H}$ is infinite-dimensional, $\mathcal{K}(\mathcal{H})$ is nonunital; thus a C*-algebra need not be unital. We denote by $\mathbb{K}$ the C*-algebra of compact operators on a separable, infinite-dimensional Hilbert space.

(ii) Let X be a locally compact Hausdorff space, and $C_0(X)$ the complex-valued continuous functions on X vanishing at infinity. Give $C_0(X)$ its usual pointwise operations and supremum norm. Define an involution by $f^*(x) = \overline{f(x)}$. Then $C_0(X)$ is a commutative C*-algebra. In fact, every commutative C*-algebra is of this form (XX.16.2.5.). $C_0(X)$ has a unit (identity) if and only if X is compact; in this case, we usually write $C(X)$. More generally, if B is a C*-algebra, then the set $C_0(X, B)$ of (norm-)continuous functions from X to B vanishing at infinity, with pointwise operations and supremum norm, is a C*-algebra. In particular, $C_0(X, \mathbb{M}_n) \cong M_n(C_0(X))$ is a C*-algebra. (In fact, a matrix algebra over any C*-algebra is a C*-algebra (**??**); this is a special case of the tensor product for C*-algebras (**??**)).

(iii) Let G be a locally compact topological group with (left) Haar measure μ. Then $L^1(G, \mu)$ becomes a Banach *-algebra under convolution. It is not a C*-algebra unless G is trivial. This example will be treated in more detail in **??**.

XX.16.1.4. If A is a Banach algebra and J is a closed ideal ("ideal" will always mean "two-sided ideal" unless otherwise specified) in A, then the quotient norm makes A/J into a Banach algebra. If A is a Banach *-algebra and J is a *-ideal (i.e. closed under *), then A/J is a Banach *-algebra. It turns out that if A is a C*-algebra and J is a closed ideal in A, then J is automatically a *-ideal and A/J is a C*-algebra in the quotient norm (XX.16.3.14.).

XX.16.1.5. A Banach algebra is separable if and only if it is countably generated as a Banach algebra (a countably generated algebra over $\mathbb{Q}(i)$ is countable). A C*-algebra is separable if and only if it is countably generated as a C*-algebra.

XX.16.1..1 Unitization

XX.16.1.1. A Banach algebra, even a C*-algebra, need not be unital (e.g. $\mathcal{K}(\mathcal{H})$, $C_0(X)$ for X non-compact). However, every nonunital Banach algebra A can be embedded in a unital Banach algebra $A^\dagger$ (XX.12.1.6.). If A is a Banach *-algebra, for $(a, \lambda) \in A^\dagger$ define $(a, \lambda)^* = (a^*, \bar{\lambda})$; this is an involution making $A^\dagger$ a (unital) Banach *-algebra. With the norm of XX.12.1.6. $A^\dagger$ is not a C*-algebra, but:

XX.16.1.2. Proposition. If A is a C*-algebra, the operator norm on $A^\dagger$ as left multiplication operators on A, i.e.

$$\|(a, \lambda)\| = \sup\{\|ab + \lambda b\| : \|b\| = 1\}$$

is a C*-norm on $A^\dagger$ extending the norm of A.

Proof: $A^\dagger$ is a subalgebra of $\mathcal{B}(A)$ with the operator norm; thus it is a normed algebra, and in particular the norm is submultiplicative. If $(a, \lambda) \in A^\dagger$ and $b \in A$, $\|b\| = 1$, then $(a, \lambda)^*(a, \lambda) = (a^*a + \lambda a^* + \bar{\lambda}a, \lambda\bar{\lambda})$, so

$$\|ab + \lambda b\|^2 = \|(ab + \lambda b)^*(ab + \lambda b)\| = \|(b^*a^* + \bar{\lambda}b^*)(ab + \lambda b)\|$$
$$= \|b^*(a^*ab + \lambda a^*b + \bar{\lambda}ab + \lambda\bar{\lambda}b)\| \leq \|a^*ab + \lambda a^*b + \bar{\lambda}ab + \lambda\bar{\lambda}b\| \leq \|(a, \lambda)^*(a, \lambda)\|$$

and taking the supremum over all b we obtain $\|(a, \lambda)\|^2 \leq \|(a, \lambda)^*(a, \lambda)\|$, and the opposite inequality follows from submultiplicativity (first use this inequality and submultiplicativity to conclude that $\|(a, \lambda)^*\| =$

$\|(a,\lambda)\|$). A embeds in $A^\dagger$ by $a \mapsto (a,0)$, so $\|(a,0)\| = \sup_{\|b\|=1} \|ab\| \leq \|a\|$, with equality (for $a \neq 0$) if $b = \frac{a^*}{\|a\|}$. $A^\dagger$ is complete since A is complete and $A^\dagger/A$ is one-dimensional (XX.2.1.2.). 👍

The algebra $A^\dagger$ contains A as a (closed) ideal, and $A^\dagger/A \cong \mathbb{C}$. If A is unital, $A^\dagger \cong A \oplus \mathbb{C}$ as C*-algebras (under the map $(a,\lambda) \mapsto (a - \lambda 1, \lambda)$).

XX.16.1.3. As an example, if X is a locally compact noncompact Hausdorff space, it is easy to see that $C_0(X)^\dagger \cong C(X^\dagger)$, where $X^\dagger$ is the one-point compactification of X.

XX.16.1.4. A bounded homomorphism between the Banach algebras A and B extends uniquely to a bounded unital homomorphism from $A^\dagger$ to $B^\dagger$. A *-homomorphism between Banach *-algebras extends to a unital *-homomorphism between the unitizations.

Special Elements in a C*-Algebra

In a C*-algebra, certain types of elements have standard names arising from operator theory, reflecting the types of operators they become when the C*-algebra is represented as a concrete C*-algebra of operators:

XX.16.1.5. Definition. Let A be a C*-algebra and $x \in A$. Then x is

self-adjoint if $x = x^*$.

normal if $x^*x = xx^*$.

a *projection* if $x = x^* = x^2$.

a *partial isometry* if x^*x is a projection.

If A is unital, then x is

an *isometry* if $x^*x = 1$.

a *coisometry* if $xx^* = 1$.

unitary if $x^*x = xx^* = 1$.

XX.16.1.6. The self-adjoint elements of A form a closed real vector subspace A_{sa} of A. (Note, however, that A_{sa} is not closed under multiplication unless A is commutative.) If A is unital, then the set of unitaries of A forms a group $\mathcal{U}(A)$. Every self-adjoint or unitary element is normal. If x is self-adjoint, then e^{ix} is unitary. 0 and 1 are projections; isometries (and, in particular, unitaries) are partial isometries. Coisometries are too; in fact, x is a partial isometry if and only if $x = xx^*x$ [one direction is obvious; for the other, if x^*x is a projection and $y = x - xx^*x$, then $y^*y = 0$, so $y = 0$]. Thus if x is a partial isometry, then so is x^*.

XX.16.1.7. If x is any element, then $a = (x + x^*)/2$ and $b = (x - x^*)/2i$ are self-adjoint, and $x = a + ib$; thus $A_{sa} + iA_{sa} = A$. The elements a and b are called the *real* and *imaginary* parts of x. It is obvious from their definitions that $\|a\|, \|b\| \leq \|x\|$.

Norm and Spectrum

XX.16.1.8. It follows from the C*-axiom that every nonzero projection, and hence every nonzero partial isometry (in particular, every unitary), has norm 1. Thus, if x is unitary, then $\sigma_A(x) \subseteq \{\lambda : |\lambda| \leq 1\}$. Since $x^{-1} = x^*$ is also unitary and hence $\sigma_A(x^{-1}) = \{\lambda^{-1} : \lambda \in \sigma_A(x)\}$ is also contained in the unit disk, $\sigma_A(x)$ is actually contained in the unit circle.

The next two results give important properties of the spectrum and norm for self-adjoint and, more generally, normal elements of a C*-algebra.

XX.16.1.9. PROPOSITION. If x is self-adjoint, then $\sigma_A(x) \subseteq \mathbb{R}$.

PROOF: If x is self-adjoint, then e^{ix} is unitary, so

$$\sigma_A(e^{ix}) = \{e^{i\lambda} : \lambda \in \sigma_A(x)\}$$

(XX.12.4.3.(i)) is contained in the unit circle. 👍

XX.16.1.10. PROPOSITION. If A is a C*-algebra and $x \in A$ is normal (e.g. self-adjoint), then $r_\sigma(x) = \|x\|$, i.e. there is a $\lambda \in \sigma_A(x)$ with $|\lambda| = \|x\|$.

PROOF: If x is self-adjoint, then from the C*-axiom $\|x^2\| = \|x\|^2$, and by iteration $\|x^{2^n}\| = \|x\|^{2^n}$ for all n. Thus $r_\sigma(x) = \lim_{n\to\infty} \|x^{2^n}\|^{2^{-n}} = \|x\|$. More generally, if y is normal, then

$$r_\sigma(y) = \lim_{n\to\infty} \|y^{2^n}\|^{2^{-n}} = \lim_{n\to\infty} \|(y^*)^{2^n} y^{2^n}\|^{2^{-n-1}}$$

$$= \lim_{n\to\infty} \|(y^*y)^{2^n}\|^{2^{-n-1}} = [r_\sigma(y^*y)]^{1/2} = \|y^*y\|^{1/2} = \|y\| \ .$$

👍

As a consequence, *-homomorphisms between C*-algebras are automatically contractive:

XX.16.1.11. COROLLARY. If A is a Banach *-algebra, B a C*-algebra, and $\phi : A \to B$ a *-homomorphism, then $\|\phi\| \leq 1$.

PROOF: If $x \in A$, then $\sigma_B(\phi(x)) \cup \{0\} \subseteq \sigma_A(x) \cup \{0\}$. Thus

$$\|\phi(x)\|^2 = \|\phi(x^*x)\| = r_\sigma(\phi(x^*x)) \leq r_\sigma(x^*x) \leq \|x^*x\| \leq \|x\|^2 \ .$$

👍

If A is a unital Banach algebra and B is a unital Banach subalgebra, and $x \in B$, then it is not necessarily true that $\sigma_B(x) = \sigma_A(x)$ (XX.12.3.11.). But if A is a C*-algebra, the spectra are the same:

XX.16.1.12. Corollary. If B is a unital C*-subalgebra of a unital C*-algebra A and $x \in B$, then $\sigma_B(x) = \sigma_A(x)$. If B is a general C*-subalgebra of a general C*-algebra A, and $x \in B$, then $\sigma_B(x) \cup \{0\} = \sigma_A(x) \cup \{0\}$.

Proof: This is true if $x = x^*$ by XX.12.3.12. and XX.16.1.9.. For general x, if $x - \lambda 1$ is invertible in A, then so are $(x - \lambda 1)^*(x - \lambda 1)$ and $(x - \lambda 1)(x - \lambda 1)^*$. Thus they are invertible in B, so $x - \lambda 1$ is left and right invertible in B. 👍

XX.16.2. Commutative C*-Algebras and Continuous Functional Calculus

The main result of this section is *Gelfand's Theorem* (sometimes called the *Gelfand-Naimark Theorem*, although this name is more commonly used for a different theorem, cf. XX.16.4.35.):

XX.16.2.1. Theorem. (i) Let A be a commutative unital C*-algebra. Then there is a compact Hausdorff space X such that A is isometrically *-isomorphic to $C(X)$.

(ii) X can be recovered from $C(X)$ either as $\mathrm{Prim}(C(X)) = \mathrm{Maxspec}(C(X))$ (XIII.7.10.20., XX.16.4.39.) with the hull-kernel topology, or as the set $\widehat{C(X)}$ of unital *-homomorphisms from $C(X)$ to $\mathbb{C}$ with the topology of elementwise convergence (weak-* topology). In particular, if $C(X) \cong C(Y)$, then X is homeomorphic to Y.

(iii) If X and Y are compact Hausdorff spaces and $\phi : X \to Y$ is a continuous function, then $\check{\phi} : C(Y) \to C(X)$ defined by $\check{\phi}(f) = f \circ \phi$ is a unital *-homomorphism, and every unital *-homomorphism arises in this manner.

(iv) The correspondences $X \leftrightarrow C(X)$ and $\phi \leftrightarrow \check{\phi}$ give a contravariant category equivalence between the category of compact Hausdorff spaces and continuous functions and the category of commutative unital C*-algebras and unital *-homomorphisms.

XX.16.2.2. As a result, all the topology of compact Hausdorff spaces is encoded in the corresponding C*-algebras, and in principle all of topology (of compact Hausdorff spaces) can be done on the C*-algebra level. In practice, this is certainly not the way to do most topology! However, the point of view that a general C*-algebra is a "noncommutative topological space" is very powerful and underlies much of the modern theory and applications of C*-algebras. Interaction with topology has gone both ways: ideas and techniques from topology, particularly K-theory, have proved fundamentally useful in operator algebra theory, and on the other hand operator algebra methods have been of significant use in some parts of topology.

XX.16.2.3. There is much more fine structure associated with the category equivalence. For example, if X and Y are compact Hausdorff spaces and $\phi : X \to Y$ is continuous, the *-homomorphism $\check{\phi} : C(Y) \to C(X)$ is surjective (i.e. a quotient map, cf. XX.16.3.15.) if and only if ϕ is injective, and $\check{\phi}$ is injective if and only if ϕ is surjective (i.e. a quotient map, cf. XIII.8.3.13.). The closed ideals of $C(X)$ are in natural one-one correspondence with the closed sets in X: the ideal of $C(X)$ corresponding to a closed subset Z of X is the set J_Z of continuous functions from X to $\mathbb{C}$ vanishing on Z. The quotient C*-algebra $C(X)/J_Z$ is naturally isomorphic to $C(Z)$ via restriction of functions (the Tietze Extension Theorem () for compact Hausdorff spaces is included in this fact, since it implies that every element of $C(Z)$ can be extended to an element of $C(X)$, cf. XX.10.3.12.).

The Nonunital Case

XX.16.2.4. There is a nonunital version of XX.16.2.1., but it cannot be stated quite so cleanly. The commutative C*-algebras are easy to describe: they are all of the form $C_0(X)$, the complex-valued continuous functions vanishing at infinity on a locally compact Hausdorff space X. But the *-homomorphisms from $C_0(X)$ to $C_0(Y)$ do not generally correspond to continuous functions from Y to X. For example, a constant function from $\mathbb{R}$ to $\mathbb{R}$ does not give a *-homomorphism from $C_0(\mathbb{R})$ to $C_0(\mathbb{R})$, and conversely the zero homomorphism from $C_0(\mathbb{R})$ to $C_0(\mathbb{R})$ does not come from a continuous function from $\mathbb{R}$ to $\mathbb{R}$ (there are many less trivial examples too). Instead, the *-homomorphisms from $C_0(X)$ to $C_0(Y)$ can be described as corresponding to *proper* () continuous functions from open subsets of Y to X.

Alternatively, it is much cleaner to consider pointed compact Hausdorff spaces $(Z, *)$, where Z is a compact Hausdorff space and $*$ is a fixed basepoint in Z. There is a natural correspondence with locally compact Hausdorff spaces: if X is locally compact, associate X with $(X^\dagger, \infty)$, where $X^\dagger$ is the one-point compactification of X (). Conversely, if $(Z, *)$ is a pointed compact Hausdorff space, associate the locally compact Hausdorff space $Z \setminus \{*\}$. The pointed space $(Z, *)$ corresponds to a compact Hausdorff space if and only if $*$ is an isolated point in Z. Then, if X is locally compact, we have that $C_0(X)$ is naturally isomorphic to the ideal of $C(X^\dagger)$ consisting of functions which are zero at ∞, i.e. if $(Z, *)$ is a pointed compact Hausdorff space, the associated commutative C*-algebra is the algebra of complex-valued continuous functions on Z vanishing at $*$. It is then easy to see that the *-homomorphisms from $C_0(X)$ to $C_0(Y)$ exactly correspond to continuous functions from $Y^\dagger$ to $X^\dagger$ sending ∞ to ∞, i.e. basepoint-preserving continuous maps. (For example, the extreme case of the zero homomorphism corresponds to the constant function from $Y^\dagger$ to $X^\dagger$ sending everything to ∞.) Thus, as a slight extension of XX.16.2.1., we obtain:

XX.16.2.5. THEOREM. (i) Let A be a commutative C*-algebra. Then there is a compact Hausdorff space Z and point $* \in Z$ such that A is isometrically *-isomorphic to $C^*(Z, *) := C_0(X)$, where $X = Z \setminus \{*\}$ is locally compact.

(ii) X can be recovered from $C_0(X)$ as $\mathrm{Prim}(C_0(X)) = \mathrm{Maxspec}(C_0(X))$ with the hull-kernel topology. Z can be recovered from $C^*(Z, *)$ as the set $\widehat{C^*(Z, *)}$ of *-homomorphisms from $C^*(Z, *)$ to $\mathbb{C}$ with the topology of elementwise convergence (weak-* topology), with $*$ corresponding to the zero homomorphism. In particular, if $C_0(X) \cong C_0(Y)$ for locally compact Hausdorff spaces X and Y, then X is homeomorphic to Y.

(iii) If $(Z, *_Z)$ and $(W, *_W)$ are pointed compact Hausdorff spaces and $\phi : Z \to W$ is a pointed continuous function (i.e. ϕ is continuous and $\phi(*_Z) = *_W$), then $\check{\phi} : C^*(W, *_W) \to C^*(Z, *_Z)$ defined by $\check{\phi}(f) = f \circ \phi$ is a *-homomorphism, and every *-homomorphism arises in this manner.

(iv) The correspondences $(Z, *) \leftrightarrow C^*(Z, *)$ and $\phi \leftrightarrow \check{\phi}$ give a contravariant category equivalence between the category of pointed compact Hausdorff spaces and pointed continuous functions and the category of commutative C*-algebras and *-homomorphisms.

XX.16.2.6. The fine structure described in XX.16.2.3. persists in this setting, but care must be exercised in phrasing it. Details are left to the interested reader.

Proof of the Theorem

We now prove Gelfand's Theorem. We will only prove the unital version XX.16.2.1.; the proof of the nonunital version XX.16.2.5. is a straightforward variation, but the additional technicalities detract from

an intuitive appreciation of the argument. We first prove (ii) and (iii), which are fairly elementary (given Urysohn's Lemma), and then return to (i) which requires some nontrivial Banach algebra theory. The proof will actually give some fine structure beyond the statement of the theorem.

We begin with a characterization of the maximal ideals of a $C(X)$.

XX.16.2.7. LEMMA. Let X be a compact Hausdorff space. For each $p \in X$, the set M_p of all functions in $C(X)$ which vanish at p is a maximal ideal in $C(X)$, and every maximal ideal of $C(X)$ is of this form. If $p, q \in X$, $p \neq q$, then $M_p \neq M_q$.

PROOF: Let $p \in X$. It is obvious that $C(X)/M_p$ is isomorphic to $\mathbb{C}$ via the correspondence $f \mapsto f(p)$. Since the quotient is a field, M_p is a maximal ideal in $C(X)$. Conversely, suppose M is a maximal ideal in $C(X)$, and suppose that there is no point of X for which all functions in M vanish. For each $p \in X$, there is an $f_p \in M$ with $f_p(p) \neq 0$. The set $U_p = \{x \in X : f_p(x) \neq 0\}$ is an open set in X containing p, and $\{U_p : p \in X\}$ is an open cover of X. By compactness, there is a finite subcover $\{U_{p_1}, \ldots, U_{p_n}\}$. Set

$$g = f_{p_1}\bar{f}_{p_1} + \cdots + f_{p_n}\bar{f}_{p_n} \in M$$

and note that $g(x) > 0$ for every $x \in X$. Thus g is invertible in $C(X)$, a contradiction since a proper ideal cannot contain an invertible element. Thus there is some $p \in X$ at which all functions in M vanish, so $M \subseteq M_p$, and $M = M_p$ by maximality. Since functions in $C(X)$ separate points of X by Urysohn's Lemma, and constant functions are in $C(X)$, we have $M_p \neq M_q$ if $p \neq q$. 👍

XX.16.2.8. Thus $p \leftrightarrow M_p$ is a one-one correspondence between X and $\mathrm{Maxspec}(C(X))$. If ϕ is a unital *-homomorphism from $C(X)$ to $\mathbb{C}$, then the kernel of ϕ is a maximal ideal of $C(X)$, hence of the form M_p for some $p \in X$, and ϕ must just be evaluation $\hat{p}$ at p, i.e. $\phi(f) = \hat{p}(f) = f(p)$. Thus there is also a natural one-one correspondence between X and $\widehat{C(X)}$, so as sets X, $\mathrm{Maxspec}(C(X))$, and $\widehat{C(X)}$ can be naturally identified.

XX.16.2.9. We now show how the topology of X can be recovered as the hull-kernel topology on $\mathrm{Maxspec}(C(X))$. If E is a subset of $X \cong \mathrm{Maxspec}(C(X))$, recall that the closure $\tilde{E}$ of E in the hull-kernel topology consists of all M_p such that $J := \cap_{q \in E} M_q \subseteq M_p$. The ideal J clearly consists of all f such that $f(q) = 0$ for all $q \in E$. If $\bar{E}$ is the closure in X of E regarded as a subset of X, and $p \in \bar{E}$, then every $f \in J$ vanishes at p by continuity, so $M_p \in \tilde{E}$. But if $p \notin \bar{E}$, by Urysohn's Lemma there is an $f \in C(X)$ such that $f = 0$ on $\bar{E}$ and $f(p) = 1$; this f is in J but not M_p, so $M_p \notin \tilde{E}$. Thus $\tilde{E} = \bar{E}$ and the correspondence $p \leftrightarrow M_p$ is a homeomorphism.

XX.16.2.10. Now consider the topology of pointwise convergence on $\widehat{C(X)}$: $\hat{p}_i \to \hat{p}$ if and only if $\hat{p}_i(f) \to \hat{p}(f)$ for every $f \in C(X)$, i.e. $f(p_i) \to f(p)$ for all $f \in C(X)$. If $p_i \to p$ in X, this condition is clearly satisfied. If $p_i \not\to p$ in X, there is an open neighborhood U of p such that $p_i \notin U$ for a cofinal set of i. By Urysohn's Lemma there is a function $f \in C(X)$ with $f(p) = 1$ and $f = 0$ on U^c, and $f(p_i) \not\to f(p)$ for this f, i.e. $\hat{p}_i \not\to \hat{p}$. Thus $p \leftrightarrow \hat{p}$ is a homeomorphism.

XX.16.2.11. Finally, we observe that every primitive ideal (XX.16.4.39.) of $C(X)$ is of the form M_p. By definition, primitive ideals are the kernels of irreducible representations. Every irreducible representation of a commutative C*-algebra is one-dimensional, hence a unital *-homomorphism to $\mathbb{C}$, hence $\hat{p}$ for some $p \in X$, and its kernel is M_p. Alternatively, every primitive ideal is a closed prime ideal (XX.16.4.11.), so it suffices to prove the following fact:

XX.16.2.12. Proposition. Let X be a compact Hausdorff space, and J a prime ideal of $C(X)$. Then there is a unique $p \in X$ such that $O_p \subseteq J \subseteq M_p$, where

$$O_p = \{f \in C(X) : f = 0 \text{ in a neighborhood of } p\} .$$

The straightforward proof is left to the reader (cf. [GJ76, 7.15]). Since O_p is dense in M_p, it follows that every closed prime ideal of $C(X)$ is maximal.

XX.16.2.13. This completes the proof of (ii). We now turn to (iii). Let X and Y be compact Hausdorff spaces. If $\phi : X \to Y$ is continuous, it is obvious that $\check{\phi} : C(Y) \to C(X)$, defined by $\check{\phi}(f) = f \circ \phi$, is well defined and is a unital *-homomorphism. Conversely, let α be a unital *-homomorphism from $C(Y)$ to $C(X)$. For any $p \in X$, $\hat{p} \circ \alpha$ is a unital *-homomorphism from $C(Y)$ to $\mathbb{C}$, hence $\hat{p} \circ \alpha = \hat{q}$ for a unique $q \in Y$. Set $\phi(p) = q$. This defines a function $\phi : X \to Y$, and $\alpha(f) = f \circ \phi$ for all $f \in C(X)$, and in particular $f \circ \phi \in C(X)$ for all $f \in C(Y)$. It remains only to show that ϕ is continuous. The argument is similar to the one in XX.16.2.10.. If ϕ is discontinuous at $p \in X$, then there is a net (p_i) in X with $p_i \to p$ in X but $\phi(p_i) \not\to \phi(p)$ in Y. There is an open neighborhood U of $\phi(p)$ in Y with $\phi(p_i) \notin U$ for a cofinal set of i. By Urysohn's Lemma there is an $f \in C(Y)$ with $f(\phi(p)) = 1$ and $f = 0$ on U^c. Then $f(\phi(p_i)) \not\to f(\phi(p))$, i.e. $f \circ \phi$ is not continuous at p, a contradiction. Thus ϕ is continuous.

Now we tackle (i). We will need to bring in some Banach algebra machinery. If A is a unital commutative Banach algebra, write $\hat{A}$ for the set of unital homomorphisms from A to $\mathbb{C}$. Recall the definitions of spectrum and spectral radius ().

XX.16.2.14. Proposition. Let A be a unital commutative Banach algebra, and $\phi \in \hat{A}$. If $x \in A$, then $\phi(x) \in \sigma_A(x)$. In particular, $|\phi(x)| \leq r_\sigma(x) \leq \|x\|$. Thus ϕ is bounded and $\|\phi\| = 1$.

Proof: Since $\phi(x - \phi(x)1) = 0$, $x - \phi(x)1$ is not invertible in A. The inequality in the second statement is then obvious, so $\|\phi\| \leq 1$. But $\phi(1) = 1$, so $\|\phi\| = 1$. 👍

XX.16.2.15. Corollary. Let A be a unital commutative C*-algebra, and $\phi \in \hat{A}$. Then ϕ is a *-homomorphism.

Proof: It suffices to show that if $x = x^* \in A$, then $\phi(x) \in \mathbb{R}$. But $\sigma_A(x) \subseteq \mathbb{R}$ by XX.16.1.9.. 👍

There is a converse to XX.16.2.14.:

XX.16.2.16. PROPOSITION. Let A be a unital commutative Banach algebra and $x \in A$. If $\lambda \in \sigma_A(x)$, then there is a $\phi \in \hat{A}$ with $\phi(x) = \lambda$.

PROOF: Since $x - \lambda 1$ is not invertible in A, it generates a proper ideal of A which is contained in a maximal ideal M of A. Then M is closed (XX.12.2.17.), so A/M is a Banach algebra which is a field. Thus $A/M \cong \mathbb{C}$ (XX.12.3.28.), and the quotient map $\phi : A \to A/M$ can be regarded as an element of $\hat{A}$ with $\phi(x - \lambda 1) = 0$. 👍

XX.16.2.17. Let A be a unital commutative Banach algebra. By XX.16.2.14., $\hat{A}$ can be regarded as a subset of the closed unit ball B of A^*. It is easily checked that $\hat{A}$ is closed in B in the weak-* topology (topology of pointwise convergence on A). Since B is a compact Hausdorff space in the weak-* topology (), $\hat{A}$ is a compact Hausdorff space in the topology of pointwise convergence on A. If $x \in A$, define $\check{x} : \hat{A} \to \mathbb{C}$ by $\check{x}(\phi) = \phi(x)$ for $\phi \in \hat{A}$. Then $\check{x} \in C(\hat{A})$.

XX.16.2.18. DEFINITION. The map $\gamma : A \to C(\hat{A})$ defined by $\gamma(x) = \check{x}$ is a unital homomorphism, called the *Gelfand transform* of A.

We have that γ is bounded and $\|\gamma\| = 1$ by XX.16.2.14.. The Gelfand transform is not injective or surjective for general unital commutative Banach algebras. However:

XX.16.2.19. LEMMA. Let A be a unital commutative C*-algebra. Then the Gelfand transform $\gamma : A \to C(\hat{A})$ is an isometric *-isomorphism.

PROOF: It follows from XX.16.2.15. that γ is a *-homomorphism. Let $x \in A$. Then by () there is a $\lambda \in \sigma_A(x^*x)$ with $|\lambda| = \|x^*x\| = \|x\|^2$, and hence by XX.16.2.16. there is a $\phi \in \hat{A}$ with $|\phi(x)|^2 = |\phi(x^*x)| = \|x^*x\| = \|x\|^2$. Since $\|\gamma\| = 1$, γ is isometric, and hence A can be regarded as the *-subalgebra $\gamma(A)$ of $C(\hat{A})$, which is complete and thus closed. The subalgebra $\gamma(A)$ clearly separates points of $\hat{A}$ and contains the constant functions, so $\gamma(A) = C(\hat{A})$ by the Stone-Weierstrass Theorem (XX.10.2.3.). 👍

XX.16.2.20. This completes the proof of (i). Part (iv) is essentially just a recapitulation of (i)–(iii); the only technicality is the easily verified fact that if X, Y, and Z are compact Hausdorff spaces and $\phi : X \to Y$ and $\psi : Y \to Z$ are continuous, then $(\psi \circ \phi)\check{} = \check{\phi} \circ \check{\psi}$.

This completes the proof of Theorem XX.16.2.1.. 💪

Applications

Probably the most important application of Gelfand's Theorem is continuous functional calculus, discussed in XX.16.2.25.. But here are a couple of other applications of some interest.

XX.16.2.21. Let X be a topological space. Let $BC(X)$ be the set of bounded continuous complex-valued functions on X. With pointwise addition and multiplication, pointwise complex conjugation as adjoint, and supremum norm, $BC(X)$ becomes a unital commutative C*-algebra. Thus $\widehat{BC(X)} \cong C(Y)$ for a compact Hausdorff space Y. Each point of X gives, by point evaluation, an element of $\widehat{BC(X)}$ and hence a point of Y, and it is easy to check that the induced map ϕ from X to Y is continuous. If X is completely regular, a simple argument yields that ϕ is a homeomorphism onto its image, so X can be identified with a subspace of Y. In this case, it is straightforward to identify Y with the Stone-Čech compactification βX. In fact, realizing βX as $\widehat{BC(X)}$ or $\mathrm{Prim}(BC(X))$ is perhaps the most elegant and efficient construction of the Stone-Čech compactification.

XX.16.2.22. Here is another interesting and modestly useful application. Give $A = L^\infty(\mathbb{R})$ pointwise addition, multiplication, and complex conjugation, and the usual essential supremum norm. Then A becomes a unital commutative C*-algebra, so $A \cong C(Y)$ for some compact Hausdorff space Y. The space Y is rather horrendous as a topological space: it is extremally disconnected and not first countable. But it is occasionally useful to realize A as an algebra of continuous functions on a bad space instead of as measurable functions on a nicer space. The same construction can be done for $L^\infty(X, \mathcal{A}, \mu)$ for any measure space $(X, \mathcal{A}, \mu)$. If done for $\mathbb{N}$ with counting measure one obtains $Y = \beta\mathbb{N}$ as in XX.16.2.21.. These $L^\infty(X, \mathcal{A}, \mu)$ are commutative von Neumann algebras (XX.5.5.1.) when realized as algebras of multiplication operators on $L^2(X, \mathcal{A}, \mu)$.

Continuous Functional Calculus

The classification of commutative C*-algebras leads to a far-reaching and powerful extension of holomorphic functional calculus (XX.12.4.).

XX.16.2.23. Let A be a unital C*-algebra, and x a normal (e.g. self-adjoint or unitary) element of A, i.e. $x^*x = xx^*$. Let B be the C*-subalgebra of A generated by x and 1; B is the closure of the set of polynomials in x and x^*. Then B is a unital commutative C*-algebra, and thus $B \cong C(X)$ for a compact Hausdorff space $X = \hat{B}$.

XX.16.2.24. The space $\hat{B}$ can be easily described. If $\phi \in \hat{B}$, then $\phi(x) \in \sigma_B(x) = \sigma_A(x)$ (XX.16.2.14., XX.16.1.12.). Conversely, for each $\lambda \in \sigma_A(x)$ there is a unique $\phi_\lambda \in \hat{B}$ with $\phi_\lambda(x) = \lambda$ by XX.16.2.16. [for uniqueness, if $\phi, \psi \in \hat{B}$ with $\phi(x) = \psi(x) = \lambda$, then $\phi(x^*) = \psi(x^*) = \bar{\lambda}$ by XX.16.2.15., so $\phi(p(x, x^*)) = \psi(p(x, x^*)) = p(\lambda, \bar{\lambda})$ for any polynomial p of two variables with complex coefficients; such elements are dense in B, so $\phi = \psi$]. Thus

$$\hat{B} = \{\phi_\lambda : \lambda \in \sigma_A(x)\} .$$

More precisely, the function $\check{x} : \hat{B} \to \mathbb{C}$ defined by $\check{x}(\phi_\lambda) = \lambda$ is a bijection from $\hat{B}$ to $\sigma_A(x)$. Since $\check{x}$ is continuous and $\hat{B}$ and $\sigma_A(x)$ are compact Hausdorff spaces, it is a homeomorphism. We thus have:

XX.16.2.25. Theorem. [Continuous Functional Calculus, Unital Version] Let A be a unital C*-algebra, x a normal element of A, and B the C*-subalgebra of A generated by x and 1. Then there is an isometric *-isomorphism $\theta : C(\sigma_A(x)) \to B$ with $\theta(\iota) = x$, where $\iota(\lambda) = \lambda$ for $\lambda \in \sigma_A(x) \subseteq \mathbb{C}$.

XX.16.2.26. We have that θ is just $(\check{x})^{\check{}}$. If $f \in C(\sigma_A(x))$, we normally write $f(x)$ instead of $\theta(f)$; thus $\iota(x) = x$. This notation is consistent with previous notation: if p is a polynomial with complex coefficients, then $p(x)$ is the element of B defined in XX.12.4.1.. More generally, if f is holomorphic on an open disk containing $\sigma_A(x)$, then $f(x)$ is the element defined by a power series as in XX.12.4.3.. Thus "functional calculus" can be thought of as a way to apply suitable functions to elements of a C*-algebra. Note that holomorphic functional calculus is defined for arbitrary elements of a C*-algebra (or even a general Banach algebra), but continuous functional calculus only works for normal elements of a C*-algebra.

There is a nonunital version of continuous functional calculus, which can be easily proved from the unital version by simply adding a unit (XX.16.1.2.). If X is a compact subset of $\mathbb{C}$, write $C_0(X)$ for the set of continuous functions $f : X \cup \{0\} \to \mathbb{C}$ with $f(0) = 0$.

XX.16.2.27. Theorem. [Continuous Functional Calculus, General Version] Let A be a C*-algebra, x a normal element of A, and B the C*-subalgebra of A generated by x. Then there is an isometric *-isomorphism $\theta : C_0(\sigma_A(x)) \to B$ with $\theta(\iota) = x$, where $\iota(\lambda) = \lambda$ for $\lambda \in \sigma_A(x) \cup \{0\} \subseteq \mathbb{C}$.

Note that if $0 \notin \sigma_A(x)$, then A is automatically unital and 1 is in the C*-subalgebra of A generated by x.

The following properties of functional calculus are easy consequences:

XX.16.2.28. Proposition. Let A be a C*-algebra and $x \in A$ a normal element. Then

(i) For any $f \in C_0(\sigma_A(x))$, $\sigma_A(f(x)) = \{f(\lambda) : \lambda \in \sigma_A(x)\}$.

(ii) If $f \in C_0(\sigma_A(x))$ and $g \in C_0(f(\sigma_A(x))) = C_0(\sigma_A(f(x)))$, so $g \circ f \in C_0(\sigma_A(x))$, then $(g \circ f)(x) = g(f(x))$.

(iii) If $f_n, f \in C_0(\sigma_A(x))$ and $f_n \to f$ uniformly on $\sigma_A(x)$, then $f_n(x) \to f(x)$.

(iv) If B is a C*-algebra and $\phi : A \to B$ a *-homomorphism, then $\phi(f(x)) = f(\phi(x))$ for any $f \in C_0(\sigma_A(x))$.

There is a useful joint continuity generalization of (iii):

XX.16.2.29. Proposition. Let Y be a compact subset of $\mathbb{C}$, and (f_n) a sequence of elements of $C_0(Y)$ converging uniformly on Y to f. Let A be a C*-algebra, (x_n) a sequence of normal elements of A with $x_n \to x \in A$ and $\sigma_A(x_n) \subseteq Y$ (so $\sigma_A(x) \subseteq Y$). Then $f_n(x_n) \to f(x)$.

Proof: Let $\epsilon > 0$, and approximate f uniformly on Y within $\epsilon/4$ by a function of the form $g(\lambda) = p(\lambda, \bar{\lambda})$, where p is a polynomial of two variables (XX.10.3.4.); then $g(x) = p(x, x^*)$, so

$$\|f_n(x_n) - f(x)\| \leq$$

$$\|f_n(x_n) - f(x_n)\| + \|f(x_n) - g(x_n)\| + \|p(x_n, x_n^*) - p(x, x^*)\| + \|g(x) - f(x)\|.$$

If n is large enough that $|f_n - f|$ is uniformly less than $\epsilon/4$ on Y, the first term is less than $\epsilon/4$; the second and fourth terms are $< \epsilon/4$ by choice of g, and the third term goes to 0 as $n \to \infty$ by continuity of addition, multiplication, and involution. Thus $\|f_n(x_n) - f(x)\| < \epsilon$ for all sufficiently large n. 👍

This result is often used when (f_n) is a constant sequence.

Another simple consequence of functional calculus is:

XX.16.2.30. Corollary. Let A be a C*-algebra, and x a normal element of A. Then

x is self-adjoint if and only if $\sigma_A(x) \subseteq \mathbb{R}$.

x is unitary if and only if $\sigma_A(x) \subseteq \{\lambda : |\lambda| = 1\}$.

x is a projection if and only if $\sigma_A(x) \subseteq \{0, 1\}$.

Proof: (i): Let $f(\lambda) = Re(\lambda) = \frac{1}{2}(\lambda + \bar{\lambda})$. Then $f(x) = \frac{1}{2}(x + x^*)$ is the real part of x. We have $f(x) = x$ if and only if $f = \iota$ on $\sigma_A(x)$, i.e. if and only if $\sigma_A(x) \subseteq \mathbb{R}$. The other parts are similar. 👍

Uniqueness of Norm on a C*-Algebra

Another important consequence of Gelfand's Theorem is that the norm on a C*-algebra is unique in a strong sense. Thus C*-algebras are quite rigid.

We first prove one of the fine structure properties of commutative C*-algebras (XX.16.2.3.).

XX.16.2.31. Lemma. Let A and B be commutative C*-algebras, and let $\alpha : A \to B$ be a *-homomorphism. If α is injective, it is isometric.

Proof: Write $A = C^*(Z, *)$ and $B = C^*(W, *)$. We have $\alpha = \check{\phi}$ for a pointed continuous function $\phi : (W, *) \to (Z, *)$. If α is injective, then ϕ is surjective: set $Y = \phi(W)$ and suppose there is a $p \in Z \setminus Y$. By Urysohn's Lemma there is an $f \in C(Z)$ with $f = 0$ on Y and $f(p) = 1$. Then $f \in C^*(Z, *)$ since $* \in Y$, and $\alpha(f) = 0$, contradicting that α is injective.

Thus, if $f \in C^*(Z, *)$, we have

$$\|f\| = \sup_{p \in Z} |f(p)| = \sup_{q \in W} |f(\phi(q))| = \|\alpha(f)\| .$$

👍

XX.16.2.32. Corollary. Let A and B be C*-algebras, $\alpha : A \to B$ an injective *-homomorphism. Then α is isometric.

Proof: If $x \in A$, then $\|x\|^2 = \|x^*x\|$ and $\|\alpha(x)\|^2 = \|\alpha(x^*x)\|$, so replacing A and B by $C^*(x^*x)$ and $C^*(\alpha(x^*x))$ respectively, it suffices to assume A and B are commutative, where the result follows from the lemma. 👍

XX.16.2.33. Corollary. If A is a C*-algebra with respect to a norm $\|\cdot\|$, then there is no other C*-norm $\|\cdot\|'$ on A (with the same algebraic structure and involution), even incomplete.

Proof: Let B be the completion of A with respect to $\|\cdot\|'$. Then B is a C*-algebra, and the natural injective *-homomorphism from $(A, \|\cdot\|)$ to B is isometric. 👍

XX.16.2.34. A *-algebra thus has at most one norm making it a (complete) C*-algebra; if it has one, it has no other (even incomplete) norm satisfying the C*-axiom (XX.16.2.33.). [A C*-algebra can have other C*-seminorms; and a *-algebra (e.g. a polynomial ring) can have many different (incomplete) norms satisfying the C*-axiom.] Note that by XX.16.1.10., the norm in a C*-algebra is completely determined by the algebraic structure: if $x \in A$, then

$$\|x\| = \|x^*x\|^{1/2} = [r_\sigma(x^*x)]^{1/2}$$

and $r_\sigma(x^*x)$ is a purely algebraic quantity.

XX.16.3. Algebraic and Order Theory of C*-Algebras

Positive Elements in a C*-Algebra

XX.16.3.1. DEFINITION. Let A be a C*-algebra. An element $x \in A$ is *positive* if $x = x^*$ and $\sigma_A(x) \subseteq [0, \infty)$. The set of positive elements in A is denoted A_+. If $x \in A_+$, we write $x \geq 0$.

Note that by XX.16.1.12., the property of being positive is independent of the containing C*-algebra, i.e. if B is a C*-subalgebra of A, then $B_+ = B \cap A_+$. A positive element of $C_0(X)$ is just a function taking only nonnegative real values.

The following facts are obvious from functional calculus:

XX.16.3.2. PROPOSITION. Let A be a C*-algebra and $x, y \in A$. Then

(i) If $x \geq 0$ and $-x \geq 0$, then $x = 0$.

(ii) If x is normal, then $x^*x \geq 0$. In particular, if $x = x^*$, then $x^2 \geq 0$.

(iii) If $x \geq 0$, then $\|x\| = \max\{\lambda : \lambda \in \sigma(x)\}$.

(iv) If $x = x^*$ and $\|x\| \leq 2$, then $x \geq 0$ if and only if $\|1 - x\| \leq 1$ (in $\tilde{A}$).

(v) If $x, y \geq 0$ and $xy = yx$, then $x + y$ and xy are positive.

(vi) If $x = x^*$, then there is a unique decomposition $x = x_+ - x_-$, where $x_+, x_- \geq 0$ and $x_+x_- = 0$. We have $x_+, x_- \in C^*(x)$. [$x_+ = f(x)$ and $x_- = g(x)$, where $f(t) = \max(t, 0)$ and $g(t) = -\min(t, 0)$.] Thus every element of A is a linear combination of four positive elements.

(vii) Every positive element of a C*-algebra has a unique positive square root. More generally, if $x \geq 0$ and α is a positive real number, there is a positive element $x^\alpha \in C^*(x)_+$; these elements satisfy $x^\alpha x^\beta = x^{\alpha+\beta}$, $x^1 = x$, and $\alpha \mapsto x^\alpha$ is continuous. If x is invertible x^α is also defined for $\alpha \leq 0$.

(viii) $(x, \lambda) \geq 0$ in $A^\dagger$ if and only if $x = x^*$ and $\lambda \geq \|x_-\|$.

For (vii), set $x^\alpha = g_\alpha(x)$, where $g_\alpha(t) = t^\alpha$. Then $g_{\alpha^{-1}}(x^\alpha) = x$. If $b \in A_+$ with $g_{\alpha^{-1}}(b) = x$, then x commutes with b, hence x^α commutes with b since it is a limit of polynomials in x; thus $b = x^\alpha$ in $C^*(x^\alpha, b) \subseteq A$ (we clearly have uniqueness in a commutative C*-algebra).

Two crucial facts about positive elements are significant generalizations of (ii) and (v):

XX.16.3.3. PROPOSITION. Let A be a C*-algebra. Then

(i) A_+ is a closed cone () in A; in particular, if $x, y \geq 0$ then $x + y \geq 0$.

(ii) If $x \in A$, then $x^*x \geq 0$.

PROOF: To prove (i), since $\mathbb{R}_+A_+ \subseteq A_+$ it suffices to show that $A_+ \cap B$ is a closed convex set, where $B = B_1(A)$ is the closed unit ball in A. But $A_+ \cap B$ is the intersection of the closed convex sets A_{sa}, B, and $\{x : \|1 - x\| \leq 1\}$ (XX.16.3.2.(iv)).

The proof of property (ii) uses the fact that if $x = a + ib \in A$ with $a, b \in A_{sa}$, then $x^*x \geq 0$ if and only if $xx^* \geq 0$ by XX.12.3.20., and

$$x^*x + xx^* = 2a^2 + 2b^2 \geq 0$$

by (i) and XX.16.3.2.(ii). If $x^*x = c = c_+ - c_-$ as in XX.16.3.2.(vi) and $y = xc_-$, then $-y^*y = c_-^3 \geq 0$, so

$$yy^* = (y^*y + yy^*) + (-y^*y) \geq 0$$

and thus $y^*y \geq 0$. So $y^*y = 0$ by XX.16.3.2.(i), $c_- = 0$, $x^*x \geq 0$. 👍

XX.16.3.4. These properties were mysterious in the early days of the subject, and property (ii) was originally assumed as an axiom for C*-algebras, in the equivalent form that $1 + x^*x$ is invertible for all x. (GELFAND, NAIMARK, and SEGAL were all convinced that the additional axiom was superfluous, and said so in their papers.) Property (i) was proved independently in [Fuk52] and [KV53], and (ii) was proved by KAPLANSKY (cf. [Sch52]; this is one of the few significant results in mathematics whose proof first appeared in the *Mathematical Reviews*!) [Kap68] and [DB86] contain an account of the history of the development of the C*-axioms.

XX.16.3.5. COROLLARY. If A is a C*-algebra and $a \in A_+$, then $x^*ax = (a^{1/2}x)^*(a^{1/2}x) \geq 0$ for any $x \in A$.

By XX.16.3.2.(vi), there are "many" positive elements of a C*-algebra. Unital C*-algebras also have "many" unitaries:

XX.16.3.6. PROPOSITION. Every element of a unital C*-algebra A is a linear combination of four unitaries. In fact, if $x = x^* \in A$ and $\|x\| \leq 2$, then x is a sum of two unitaries in $\mathcal{U}(A)_o$ (where $\mathcal{U}(A)_o$ is the connected component of 1 in $\mathcal{U}(A)$).

PROOF: Set $a = x/2$. Then $1 - a^2 \geq 0$ and $a \pm i(1-a^2)^{1/2}$ are unitaries. If $0 \leq t \leq 1$, then $(ta \pm i(1-t^2a^2)^{1/2})$ gives a path of unitaries from $\pm i1$ to $a \pm i(1-a^2)^{1/2}$, so $a \pm i(1-a^2)^{1/2} \in \mathcal{U}(A)_o$. 👍

Invertible elements have a polar decomposition analogous to ():

XX.16.3.7. Proposition. Let A be a unital C*-algebra, and $x \in A$ an invertible element. Then there are a unique unitary $u \in A$ and $a \in A_+$ with $x = ua$. In fact, $a = (x^*x)^{1/2}$ and $u = x(x^*x)^{-1/2}$.

Proof: If $u = x(x^*x)^{-1/2}$ (note that x^*x is invertible), then $u^*u = 1$, and in particular u is left invertible. We have $uu^* = x(x^*x)^{-1}x^*$ is invertible, hence u is also right invertible, i.e. u is invertible and $u^{-1} = u^*$, so u is unitary. Obviously u and $a = (x^*x)^{1/2} \geq 0$ give such a decomposition. For uniqueness, if $x = ua = vb$, then $x^*x = a^2 = b^2$, so $a = b$ (XX.16.3.2.(vii)), and then $u = v = xa^{-1}$. 👍

Noninvertible elements of a C*-algebra do not have an analogous polar decomposition in general; but if x is any element of a C*-algebra A and $0 < \alpha < 1/2$, then there is a $u \in A$ (not unique in general) such that $x = u(x^*x)^\alpha$, so x has an approximate polar decomposition.

XX.16.3.8. Because of XX.16.3.3.(i), it makes sense in a C*-algebra A to write $x \leq y$ if $y - x \geq 0$. This defines a translation-invariant partial order on A (it is usually only used on A_{sa}). Note that $x \leq y$ is well defined independent of the containing C*-algebra. If $x = x^*$ and $\sigma_A(x) \subseteq [\alpha, \beta]$, then $\alpha 1 \leq x \leq \beta 1$ (in $A^\dagger$). If $a \leq b$, then $x^*ax \leq x^*bx$ for any x. If $x \in A$, $a \in A_+$, then $x^*ax \leq x^*(\|a\|1)x = \|a\|x^*x$. In $C_0(X)$, if f and g are self-adjoint (i.e. real-valued), then $f \leq g$ in $C_0(X)$ if and only if $f(x) \leq g(x)$ for all $x \in X$.

XX.16.3.9. Proposition. Let A be a unital C*-algebra, $x, y \in A$. If $0 \leq x \leq y$ and x is invertible, then y is invertible and $0 \leq y^{-1} \leq x^{-1}$.

Proof: If x is invertible, then $\epsilon 1 \leq x$ for some $\epsilon > 0$, so $\epsilon 1 \leq y$ and y is invertible by XX.16.2.1., and $x^{-1}, y^{-1} \geq 0$. The inequality $y^{-1} \leq x^{-1}$ is obvious from XX.16.2.1. if x and y commute, and in particular if $y = 1$. For the general case, if $x \leq y$, then

$$y^{-1/2}xy^{-1/2} \leq y^{-1/2}yy^{-1/2} = 1$$

$$1 \leq (y^{-1/2}xy^{-1/2})^{-1} = y^{1/2}x^{-1}y^{1/2}$$

$$y^{-1} = y^{-1/2}1y^{-1/2} \leq y^{-1/2}(y^{1/2}x^{-1}y^{1/2})y^{-1/2} = x^{-1}.$$

👍

Approximate Units

While a C*-algebra need not be unital, it always contains an approximate unit (sometimes called an approximate identity) which can often be used as a substitute. Some, but not all, other Banach algebras have approximate units in an analogous sense.

XX.16.3.10. Definition. Let A be a C*-algebra. An *approximate unit* for A is a net (h_λ) of positive elements of A of norm ≤ 1, indexed by a directed set Λ, such that $h_\lambda x \to x$ for all $x \in A$. If $h_\lambda \leq h_\mu$ for $\lambda \leq \mu$, the approximate unit (h_λ) is *increasing*.

An approximate unit (h_λ) is *idempotent* if each h_λ is a projection; it is *almost idempotent* if $h_\lambda \ll h_\mu$ for $\lambda < \mu$.

An approximate unit (h_λ) is *sequential* if $\Lambda = \mathbb{N}$; it is *continuous* if $\Lambda = (0, \infty)$ (or a cofinal subinterval) and $\lambda \mapsto h_\lambda$ is continuous.

In many references, approximate units are assumed to be increasing, but we will not do so since there are situations where this assumption is not natural. At the other extreme, the assumption that $\|h_\lambda\| \leq 1$ for all λ, or even that $\|h_\lambda\|$ is bounded, is not universal.

An approximate unit in a unital C*-algebra is just a net of (eventually) invertible positive elements in the unit ball converging to 1.

If A is a C*-algebra and I is a dense (two-sided) ideal in A (the case $I = A$ is the most important one!), let Λ_I be the set of all positive elements of I of norm strictly less than 1. Give Λ_I its ordering as a subset of A_+.

XX.16.3.11. PROPOSITION.

(i) Λ_I is a directed set.

(ii) Λ_I is an increasing approximate unit for A.

PROOF: (i): By XX.16.3.9.(iii), $h \mapsto (1-h)^{-1} - 1$ is an order-isomorphism of Λ_I onto I_+, which is a directed set. (The computation is done in $A^\dagger$, but it is easy to check that the map and its inverse $h \mapsto 1 - (1+h)^{-1}$ map I into I by considering the quotient map $A^\dagger \to A^\dagger/I$.)

(ii): It suffices to show that for any $x \in A$, the decreasing net

$$\{x^*(1-h)x : h \in \Lambda_I\}$$

converges to 0, for then

$$\|(1-h)x\|^2 = \|x^*(1-h)^2x\| \leq \|x^*(1-h)x\| \to 0.$$

Since Λ_I is dense in Λ_A [if $x \in A_+$, choose $y \in I$ close to $x^{1/2}$; then $y^*y \in I_+$ is close to x], we need only find for each x and ϵ an $h \in \Lambda_A$ with $\|x^*(1-h)x\| < \epsilon$. By XX.16.3.2.(vi), we may assume $x \geq 0$ and $\|x\| < 1$. But then $\|x(1-x^{1/n})x\| < \epsilon$ for sufficiently large n. ☝

XX.16.3.12. COROLLARY. If A is a C*-algebra and I is a dense (two-sided) ideal in A, then there is an increasing approximate unit for A contained in I. If A is separable, then the increasing approximate unit may be chosen to be sequential or continuous.

To construct an increasing sequential approximate unit for a separable A, let $\{x_n\}$ be a dense set in A, and inductively find h_n in Λ_I with $h_n \geq h_{n-1}$ and $\|h_n x_k - x_k\| < 1/n$ for $1 \leq k \leq n$. For a continuous approximate unit, set $h_t = (n+1-t)h_n + (t-n)h_{n+1}$ for $n \leq t \leq n+1$.

Closed Ideals and Quotients

In this section, "ideal" means "two-sided ideal" unless otherwise specified.

XX.16.3.13. PROPOSITION. Let A be a C*-algebra, and J a closed ring-theoretic ideal in A. Then J is closed under scalar multiplication.

PROOF: This is obvious if A is unital. For general A, let (h_λ) be an approximate unit for A. If $x \in J$ and $\alpha \in \mathbb{C}$, then $(\alpha h_\lambda)x \in J$ for all λ and $(\alpha h_\lambda)x = \alpha(h_\lambda x) \to \alpha x$. Since J is closed, $\alpha x \in J$. ☝

XX.16.3.14. PROPOSITION. Let J be a closed ideal in a C*-algebra A, and π the quotient map from A to the Banach algebra A/J. Then

(i) J is self-adjoint (so J is a C*-algebra and there is an induced involution on A/J).

(ii) If (h_λ) is an approximate unit for J, then for all $x \in A$,

$$\|\pi(x)\| = \lim_\lambda \|x(1-h_\lambda)\| = \inf \|x(1-h_\lambda)\|.$$

(iii) A/J is a C*-algebra in the quotient norm.

PROOF: (i): If $x \in J$, then $(x^*x)^{1/n} \in J$ for all n.

$$\|x^* - (x^*x)^{1/n}x^*\|^2 = \|x - x(x^*x)^{1/n}\|^2$$

$$= \|(1-(x^*x)^{1/n})x^*x(1-(x^*x)^{1/n})\| \to 0.$$

(ii): $\|\pi(x)\| = \inf\{\|x+y\| : y \in I\} \leq \inf \|x - xh_\lambda\|$. But if $y \in J$, then

$$\|x - xh_\lambda\| \leq \|(x+y)(1-h_\lambda)\| + \|y - yh_\lambda\| \leq \|x+y\| + \|y - yh_\lambda\|,$$

so $\limsup \|x - xh_\lambda\| \leq \|\pi(x)\|$.

(iii): For any $x \in A$,

$$\|\pi(x)\|^2 = \inf \|x(1-h_\lambda)\|^2 = \inf \|(1-h_\lambda)x^*x(1-h_\lambda)\|$$

$$\leq \inf \|x^*x(1-h_\lambda)\| = \|\pi(x^*x)\| = \|\pi(x)^*\pi(x)\|.$$

XX.16.3.15. COROLLARY. Let A and B be C*-algebras, $\phi : A \to B$ a *-homomorphism. Then $\phi(A)$ is closed in B, and therefore a C*-subalgebra which is isometrically isomorphic to A/J, where $J = Ker(\phi)$.

PROOF: J is closed since ϕ is continuous (XX.16.1.11.), and ϕ induces an injective *-homomorphism from the C*-algebra A/J to B, which is an isometry by XX.16.2.32.. 

XX.16.3.16. PROPOSITION. Let A be a C*-algebra.

(i) If I and J are closed ideals in A, then $I \cap J = IJ$, where IJ is the set of finite sums of elements of the form xy with $x \in I$, $y \in J$.

(ii) If I is a closed ideal in A and J is a closed ideal of I, then J is an ideal of A.

(iii) If I, J, K are closed ideals of A, then $(I+K) \cap (J+K) = (I \cap J) + K$.

PROOF: (i): Clearly $IJ \subseteq I \cap J$, and any product of two elements of $I \cap J$ is in IJ. But it is an easy consequence of functional calculus that any self-adjoint element of a C*-algebra is a product of two elements (in fact, any element of a C*-algebra is the product of two elements, so it is even unnecessary to allow finite sums in the definition of IJ).

(ii): I is itself a C*-algebra, hence has an approximate unit (h_λ). If $x \in A$ and $y \in J$, then $y \in I$, so $h_\lambda y \to y$, and thus $xh_\lambda y \to xy$. We have $xh_\lambda \in I$ and thus $(xh_\lambda)y \in J$ for all λ since J is an ideal of I, and so $xy \in J$ since J is closed. A similar argument shows that $yx \in J$.

(iii) follows immediately from (i) and the fact that

$$(I+K)(J+K) \subseteq IJ + K \subseteq (I \cap J) + K \subseteq (I+K) \cap (J+K)$$

(true in any ring). 👍

XX.16.3.17. A C*-algebra can have many nonclosed ideals, and their structure can be enormously complicated. (See, for example, [GJ76] for a description of the ideal structure of $C(X)$.) Several of the properties of closed ideals can fail for nonclosed ideals: they need not be self-adjoint, a self-adjoint ideal need not be hereditary or even positively generated, and an ideal of an ideal of A need not be an ideal of A. See [Bla06] for examples.

XX.16.4. Representations of Banach *-Algebras and C*-Algebras

Before about 1980, representation theory was the core of the theory of C*-algebras. It has since become less central, but it is still an extremely important part of the theory. Many applications of the theory involve representations. And there are even basic structural facts about C*-algebras which can only be reasonably obtained via representation theory.

XX.16.4.1. DEFINITION. A *representation* of a Banach *-algebra A is a *-homomorphism from A to $\mathcal{B}(\mathcal{H})$ for some Hilbert space $\mathcal{H}$. (Technically this should be called a *-representation; we will not consider representations which are not *-representations.) We will mostly only consider representations of C*-algebras.

Two representations π and ρ of A on $\mathcal{X}$ and $\mathcal{Y}$ respectively are *(unitarily) equivalent* if there is a unitary operator $U \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$ with $U\pi(x)U^* = \rho(x)$ for all $x \in A$.

A *subrepresentation* of a representation π on $\mathcal{H}$ is the restriction of π to a closed invariant subspace of $\mathcal{H}$ (a subspace $\mathcal{Y}$ of $\mathcal{H}$ is *invariant* if $\pi(x)\xi \in \mathcal{Y}$ for all $x \in A$, $\xi \in \mathcal{Y}$).

A representation is *irreducible* if it has no nontrivial closed invariant subspaces.

If π_i $(i \in \Lambda)$ is a representation of A on $\mathcal{H}_i$, then the *sum* $\oplus_i \pi_i$ of the π_i is the diagonal sum acting on $\oplus_i \mathcal{H}_i$. If each π_i is equivalent to a fixed representation ρ, then $\oplus_i \pi_i$ is a *multiple* or *amplification* of ρ by *card*(Λ).

XX.16.4.2. A representation is always norm-decreasing (XX.16.1.11.) and hence continuous. Thus the kernel of a representation is a closed ideal. A representation with kernel 0 is called *faithful*. By XX.16.2.32., a faithful representation of a C*-algebra is isometric.

XX.16.4.3. If J is a closed ideal of A, then any representation of A/J gives a representation of A by composition with the quotient map, whose kernel contains J. Conversely, if π is a representation of A whose kernel contains J, then π drops to a representation of A/J.

XX.16.4.4. PROPOSITION. If π is a representation of A on $\mathcal{H}$ and $\mathcal{X}$ is a closed subspace of $\mathcal{H}$, then the following are equivalent:

(i) $\mathcal{X}$ is invariant under $\pi(A)$.

(ii) $\mathcal{X}^\perp$ is invariant under $\pi(A)$.

(iii) $P_\mathcal{X} \in \pi(A)'$.

XX.16.4.5. If $\mathcal{N}$ is the largest subspace of $\mathcal{H}$ on which $\pi(x) = 0$ for all $x \in A$, then $\mathcal{N}$ is closed, and $\mathcal{X} = \mathcal{N}^\perp$ is an invariant subspace, called the *essential subspace* of π. $\mathcal{X}$ is the closed span of $\{\pi(x)\xi : x \in A,\ \xi \in \mathcal{H}\}$. If A is unital, then $P_\mathcal{X} = \pi(1_A)$. The representation π is *nondegenerate* (or *essential*) if $\mathcal{X} = \mathcal{H}$. An irreducible representation is always nondegenerate.

XX.16.4.6. PROPOSITION. Let π be a representation of a C*-algebra A on $\mathcal{H}$, and $\mathcal{X}$ the essential subspace of π. If (h_λ) is an approximate unit for A, then $\pi(h_\lambda) \to P_\mathcal{X}$ strongly.

PROOF: Fix $x \in A$ and $\zeta \in \mathcal{X}$. Since $h_\lambda x \to x$ in norm, $\pi(h_\lambda x) \to \pi(x)$ in norm, so $\pi(h_\lambda x)\zeta \to \pi(x)\zeta$. We have

$$\pi(h_\lambda)[\pi(x)\zeta] = \pi(h_\lambda x)\zeta \to \pi(x)\zeta.$$

Since vectors of the form $\pi(x)\zeta$ ($x \in A$, $\zeta \in \mathcal{X}$) are dense in $\mathcal{X}$, and (h_λ) is uniformly bounded, for any $\zeta \in \mathcal{X}$ we have $\pi(h_\lambda)\zeta \to \zeta$. Since $\pi(h_\lambda)\eta = 0$ for $\eta \in \mathcal{X}^\perp$, for any $\xi \in \mathcal{H}$ write $\xi = \zeta + \eta$ with $\zeta \in \mathcal{X}$, $\eta \in \mathcal{X}^\perp$; then

$$\pi(h_\lambda)\xi = \pi(h_\lambda)\zeta + \pi(h_\lambda)\eta = \pi(h_\lambda)\zeta \to \zeta = P_\mathcal{X}\xi\ .$$

XX.16.4.7. PROPOSITION. If J is a closed ideal in A, let $\mathcal{E}$ be the essential subspace of $\pi|_J$. Then $\mathcal{E}$ is invariant under $\pi(A)$, so $P_\mathcal{E} \in \pi(A)'$.

PROOF: Fix an approximate unit (h_λ) for J. If $\xi \in \mathcal{E}$, then $\pi(h_\lambda)\xi \to \xi$ (XX.16.4.6.). If $x \in A$, then $\pi(xh_\lambda)\xi \in \mathcal{E}$ since $xh_\lambda \in J$, and $\pi(xh_\lambda)\xi = \pi(x)[\pi(h_\lambda)\xi] \to \pi(x)\xi$ since $\pi(x)$ is continuous; thus $\pi(x)\xi \in \mathcal{E}$ since $\mathcal{E}$ is closed. 

XX.16.4.8. If J is a closed ideal in A, let $\mathcal{E}$ be the essential subspace of $\pi|_J$. Then $\mathcal{E}$ is invariant under $\pi(A)$, so π decomposes into a sum of a representation essential on J and a representation which is zero on J (a representation of A/J). Conversely, if ρ is a nondegenerate representation of J on an $\mathcal{H}$, and (h_λ) is an approximate unit for J, then for any $a \in A$ the net $(\rho(ah_\lambda))$ converges strongly in $\mathcal{B}(\mathcal{H})$ to an operator we call $\rho_A(a)$ (cf. **??**), defining a representation of A extending ρ, and we have $\rho_A(A)'' = \rho(J)''$. (This ρ_A is the unique extension of ρ to a representation of A on $\mathcal{H}$.)

XX.16.4.9. Note that for a nondegenerate representation π, the strong (or weak) closure of $\pi(A)$ is $\pi(A)''$ by the Bicommutant Theorem (XX.5.5.2.); for a general π, the strong closure of $\pi(A)$ is $P_{\mathcal{X}}\pi(A)''$, where $\mathcal{X}$ is the essential subspace of π. (Note that $P_{\mathcal{X}}$ is a central projection in $\pi(A)''$.)

We get the following fact from an application of the Bicommutant Theorem:

XX.16.4.10. PROPOSITION. Let π be a representation of a C*-algebra A on a Hilbert space $\mathcal{H}$. Then the following are equivalent:

(i) π is irreducible.

(ii) $\pi(A)' = \mathbb{C}I$.

(iii) $\pi(A)'' = \mathcal{B}(\mathcal{H})$.

(iv) $\pi(A)$ is strongly dense in $\mathcal{B}(\mathcal{H})$.

It follows from XX.16.4.8. that if π is an irreducible representation of A, and J is a closed ideal of A, then $\pi|_J$ is either zero or irreducible.

XX.16.4.11. PROPOSITION. The kernel of an irreducible representation of a C*-algebra is a (closed) prime ideal.

PROOF: The kernel of any representation is closed. Let π be an irreducible representation of a C*-algebra A on $\mathcal{H}$. Replacing A by $A/\ker(\pi)$ we may assume π is faithful. Suppose there are nonzero ideals J and K of A with $J \cap K = \{0\}$. If (h_λ) and (k_μ) are increasing approximate units for J and K respectively, then $(\pi(h_\lambda))$ and $(\pi(k_\mu))$ converge strongly to the projections P and Q onto the closures of $\pi(J)\mathcal{H}$ and $\pi(K)\mathcal{H}$. Then P and Q are nonzero projections in $\mathcal{B}(\mathcal{H})$, and $P \perp Q$. Since $\pi(J)\mathcal{H}$ and $\pi(K)\mathcal{H}$ are invariant under $\pi(A)$, we have $P, Q \in \pi(A)'$, a contradiction.

XX.16.4.12. If π is a representation of a C*-algebra A on a Hilbert space $\mathcal{H}$, and $0 \neq \xi \in \mathcal{H}$, then the set $\{\pi(x)\xi : x \in A\}$ is an invariant subspace of $\mathcal{H}$, and thus its closure is also invariant. If the closure is all of $\mathcal{H}$, ξ is called a *cyclic vector* for π. A representation of A with a cyclic vector is called a *cyclic representation* of A. A cyclic representation is nondegenerate. A simple Zorn's Lemma argument shows that every nondegenerate representation is a direct sum of cyclic representations (in a highly nonunique way in general). If π is an irreducible representation of A on $\mathcal{H}$, then every nonzero vector in $\mathcal{H}$ is a cyclic vector for π.

Positive Linear Functionals and States

The connection between C*-algebras and Hilbert spaces is made via the notion of a state:

XX.16.4.13. DEFINITION. Let A be a C*-algebra. A linear functional ϕ on A is *positive*, written $\phi \geq 0$, if $\phi(x) \geq 0$ whenever $x \geq 0$. A *state* on A is a positive linear functional of norm 1. Denote by $\mathcal{S}(A)$ the set of all states on A, called the *state space* of A.

XX.16.4.14. PROPOSITION. A positive linear functional is bounded.

PROOF: Let ϕ be a positive linear functional on a C*-algebra A. It suffices to show ϕ is bounded on A_+ by XX.16.3.2.(vi); if it is not, for each n choose $x_n \geq 0$ with $\|x_n\| = 1$ and $\phi(x_n) \geq 4^n$, and then $x = \sum_{n=1}^{\infty} 2^{-n} x_n$ satisfies $\phi(x) \geq 2^{-n}\phi(x_n) \geq 2^n$ for all n, a contradiction. 👍

XX.16.4.15. EXAMPLES.

(i) If A is a concrete C*-algebra of operators acting nondegenerately on $\mathcal{H}$ and $\xi \in \mathcal{H}$, and $\phi_\xi(x) = \langle x\xi, \xi\rangle$ for $x \in A$, then ϕ_ξ is a positive linear functional on A of norm $\|\xi\|^2$, so ϕ_ξ is a state if $\|\xi\| = 1$. Such a state is called a *vector state* of A. This example is the origin of the term "state": in the mathematical formulation of quantum mechanics, the states of a physical system are given by probability distributions (unit vectors in an L^2-space), and observables are self-adjoint operators; the value of the observable T on the state ξ is $\langle T\xi, \xi\rangle$ (cf. [BR87]).

(ii) By the Riesz Representation Theorem, there is a one-one correspondence between bounded linear functionals on $C_0(X)$ and finite regular complex Baire measures (complex Radon measures) on X. A bounded linear functional is positive if and only if the corresponding complex measure takes only nonnegative real values (i.e. is an ordinary measure). Thus the states on $C_0(X)$ are precisely given by the regular Baire probability measures on X. Any nonzero homomorphism from $C_0(X)$ to $\mathbb{C}$ is a state by XX.16.2.14., XX.16.2.15., and XX.16.3.2.(ii) and (vii).

A positive linear functional takes real values on self-adjoint elements, and thus $\phi(x^*) = \overline{\phi(x)}$ for any x if $\phi \geq 0$. So if ϕ is a positive linear functional on A, then ϕ defines a pre-inner product on A by $\langle x, y\rangle_\phi = \phi(y^*x)$. Thus we get the CBS inequality:

XX.16.4.16. PROPOSITION. Let A be a C*-algebra, ϕ a positive linear functional on A, x, $y \in A$. Then $|\phi(y^*x)|^2 \leq \phi(x^*x)\phi(y^*y)$. More symmetrically, $|\phi(xy)|^2 \leq \phi(xx^*)\phi(y^*y)$.

XX.16.4.17. PROPOSITION. Let A be a C*-algebra and ϕ a bounded linear functional on A. Then

(i) If $\phi \geq 0$, then $\|\phi\| = \sup\{\phi(x) : x \geq 0,\ \|x\| = 1\} = \lim \phi(h_\lambda)$ for any approximate unit (h_λ) for A (in particular, $\|\phi\| = \phi(1_A)$ if A is unital), and ϕ extends to a positive linear functional on $A^\dagger$ by setting $\phi(1) = \|\phi\|$ (or $\phi(1) = t$ for any $t \geq \|\phi\|$). In particular, any state on A extends uniquely to a state on $A^\dagger$.

(ii) If A is unital and $\phi(1_A) = \|\phi\|$, then $\phi \geq 0$.

PROOF: For the first part of (i), if (h_λ) is an approximate unit for A, we have

$$\|\phi\| \geq \sup\{\phi(x) : x \geq 0,\ \|x\| = 1\} \geq \sup \phi(h_\lambda)\ ;$$

but if $y \in A$, $\|y\| = 1$, $|\phi(y)|^2 > \|\phi\|^2 - \epsilon$, then, using XX.16.4.16.,

$$\|\phi\|^2 - \epsilon < |\phi(y)|^2 = \lim |\phi(h_\lambda^{1/2} y)|^2 \leq \liminf \phi(h_\lambda)\phi(y^* y) \leq \|\phi\| \liminf \phi(h_\lambda).$$

The second statement of (i) follows from the first and XX.16.3.2.(viii).

To prove (ii), if $x \geq 0$, restrict ϕ to $C^*(x, 1) \cong C(X)$; then ϕ corresponds to a complex measure μ on X, and $\mu(X) = |\mu|(X)$, so $\mu \geq 0$. A more elementary alternate argument can be based on XX.16.1.10.: if $\phi(1_A) = \|\phi\| = 1$, and $x \geq 0$, suppose $\phi(x) \notin [0, \infty)$. Then there is a $\lambda \in \mathbb{C}$ and $\rho \geq 0$ with $\sigma_A(x) \subseteq D = \{z \in \mathbb{C} : |z - \lambda| \leq \rho\}$, but $\phi(x) \notin D$. If $y = x - \lambda 1_A$, then y is normal and $\|y\| = r_\sigma(y) \leq \rho$, so $|\phi(x) - \lambda| = |\phi(y)| \leq \|y\| \leq \rho$, a contradiction. 👍

XX.16.4.18. Any sum or nonnegative scalar multiple of positive linear functionals on a C*-algebra A is positive. A weak-* limit of a net of positive linear functionals on A is positive. XX.16.4.17.(i) shows that if ϕ and ψ are positive linear functionals on A, then $\|\phi + \psi\| = \|\phi\| + \|\psi\|$. In particular, a convex combination of states is a state, so if A is unital, $\mathcal{S}(A)$ is a compact convex subset of the dual of A. If A is nonunital, then $\mathcal{S}(A)$, though convex, is not compact or even locally compact, but the set of positive linear functionals on A of norm ≤ 1 is in natural one-one correspondence with $\mathcal{S}(A^\dagger)$, which is a compact convex set.

XX.16.4.19. Definition. A state of a C*-algebra A is *pure* if it is an extreme point of $\mathcal{S}(A)$. Denote the set of pure states of A by $\mathcal{P}(A)$.

XX.16.4.20. If A is unital, then $\mathcal{S}(A)$ is the closed convex hull of the pure states; in general, the set of positive linear functionals of norm ≤ 1 is the closed convex hull of the pure states and the zero functional. The pure states of $C_0(X)$ are precisely the homomorphisms to $\mathbb{C}$, i.e. the states corresponding to point masses (XX.16.4.15.(ii)).

Extension and Existence of States

XX.16.4.21. Proposition. If A is a C*-algebra and B a C*-subalgebra, then every state on B extends to a state on A.

Proof: If A is a C*-algebra and ϕ is a state on A, then by XX.16.4.17.(i) ϕ extends to a state on $A^\dagger$. If A is a unital C*-algebra and B a unital C*-subalgebra, and ϕ is a state on B, by the Hahn-Banach Theorem () ϕ extends to a linear functional ψ on A of norm 1. Since $\psi(1) = \phi(1) = 1$, ψ is a state on A. If B is a (not necessarily unital) C*-subalgebra of a (not necessarily unital) C*-algebra A, and ϕ is a state on B, first extend ϕ to $B^\dagger$, regard $B^\dagger$ as a unital C*-subalgebra of $A^\dagger$ and extend to $A^\dagger$, and then restrict to A to get an extension of ϕ to a state on A. 👍

XX.16.4.22. If ϕ is a pure state on a C*-subalgebra of a (not necessarily unital) C*-algebra A, then the set of extensions of ϕ to A is a weak-* compact convex subset of $\mathcal{S}(A)$, and any extreme point of this set (extreme points exist by the Krein-Milman Theorem ()) is a pure state of A. Thus we get:

XX.16.4.23. PROPOSITION. Let A be a C*-algebra, $x \in A_{sa}$. Then there is a pure state ϕ on A with $|\phi(x)| = \|x\|$.

PROOF: Note that there is a pure state (homomorphism) ϕ on $C^*(x) \cong C_0(\sigma_A(x))$ with $|\phi(x)| = r_\sigma(x) = \|x\|$, and extend ϕ to a pure state on A. ☝

There is also a noncommutative version of the Jordan Decomposition Theorem for signed measures:

XX.16.4.24. THEOREM. Let A be a C*-algebra, and ϕ a bounded self-adjoint linear functional on A. Then there are unique positive linear functionals ϕ_+ and ϕ_- on A with $\phi = \phi_+ - \phi_-$ and $\|\phi\| = \|\phi_+\| + \|\phi_-\|$.

Since every linear functional ϕ can be canonically written as $\phi_{re} + i\phi_{im}$ with ϕ_{re}, ϕ_{im} self-adjoint [define ϕ^* by $\phi^*(x) = \overline{\phi(x^*)}$, and let $\phi_{re} = (\phi + \phi^*)/2$, $\phi_{im} = (\phi - \phi^*)/2i$], every bounded linear functional can be written canonically as a linear combination of four states. A simple consequence of this and the Hahn-Banach Theorem is:

XX.16.4.25. COROLLARY. Let A be a C*-algebra, $x \in A$.

(i) If $\phi(x) = 0$ for all $\phi \in \mathcal{S}(A)$, then $x = 0$.

(ii) $x = x^*$ if and only if $\phi(x) \in \mathbb{R}$ for all $\phi \in \mathcal{S}(A)$.

(iii) $x \geq 0$ if and only if $\phi(x) \geq 0$ for all $\phi \in \mathcal{S}(A)$.

In fact, $\mathcal{S}(A)$ can be replaced by $\mathcal{P}(A)$ in this result.

The GNS Construction

The GNS construction, discovered independently by GELFAND and NAIMARK [GN43] and I. SEGAL [Seg47] (the essential idea appeared earlier in [Gel41]), while quite simple, is an "ingenious construction" (E. HILLE [Hil43]) and one of the most fundamental ideas of the theory of operator algebras. It provides a method for manufacturing representations of C*-algebras.

XX.16.4.26. Let A be a C*-algebra, ϕ a positive linear functional on A. Put a pre-inner product on A by $\langle x, y\rangle_\phi = \phi(y^*x)$. If

$$N_\phi = \{x \in A : \phi(x^*x) = 0\},$$

then N_ϕ is a closed left ideal of A, and $\langle \cdot\,, \cdot \rangle_\phi$ drops to an inner product on A/N_ϕ. If $a \in A$, let $\pi_\phi(a)$ be the left multiplication operator by a on A/N_ϕ, i.e. $\pi_\phi(a)(x + N_\phi) = ax + N_\phi$. Since

$$x^*a^*ax \leq \|a\|^2 x^*x$$

(XX.16.3.8.), $\pi_\phi(a)$ is a bounded operator and $\|\pi_\phi(a)\| \leq \|a\|$; so $\pi_\phi(a)$ extends to a bounded operator, also denoted $\pi_\phi(a)$, on the completion (Hilbert space) $\mathcal{H}_\phi = L^2(A, \phi)$ of A/N_ϕ. The representation π_ϕ is called the *GNS representation* of A associated with ϕ.

XX.16.4.27. There is also a (unique) distinguished vector $\xi_\phi \in \mathcal{H}_\phi$ such that $\phi(a) = \langle \pi_\phi(a)\xi_\phi, \xi_\phi\rangle_\phi$ (and $\|\xi_\phi\|^2 = \|\phi\|$). If A is unital, then ξ_ϕ is just the image of 1_A in $\mathcal{H}_\phi$. In general, let $\tilde{\phi}$ be the unique extension of ϕ to $A^\dagger$ with $\|\tilde{\phi}\| = \|\phi\|$; then from $\tilde{\phi}(1) = \lim \phi(h_\lambda) = \lim \phi(h_\lambda^2)$, where (h_λ) is an approximate unit for A, it follows that $\tilde{\phi}((1-h_\lambda)^2) \to 0$, so A/N_ϕ is dense in $A^\dagger/N_{\tilde{\phi}}$ and thus $\mathcal{H}_\phi$ can be identified with $\mathcal{H}_{\tilde{\phi}}$, and ξ_ϕ may be taken to be $\xi_{\tilde{\phi}}$. This ξ_ϕ is a cyclic vector for π_ϕ, i.e. $\pi_\phi(A)\xi_\phi$ is dense in $\mathcal{H}_\phi$.

XX.16.4.28. This construction is the inverse of XX.16.4.15.(i): if π is a representation of A on a Hilbert space $\mathcal{H}$ and ξ is a cyclic vector for π, and $\phi(a) = \langle \pi(a)\xi, \xi\rangle$, then $(\mathcal{H}_\phi, \pi_\phi, \xi_\phi)$ is unitarily equivalent to $(\mathcal{H}, \pi, \xi)$. Thus there is a precise one-one correspondence between positive linear functionals on A and (cyclic) representations of A with a specified cyclic vector.

XX.16.4.29. Example. Let $A = n$, with Tr the (ordinary) trace on A. Then $\mathcal{H}_{\mathrm{Tr}}$ can be identified with $\mathbb{M}_n$ with the Hilbert-Schmidt norm, with $\xi_{\mathrm{Tr}} = I$. The action π_{Tr} is the ordinary one by left multiplication. $\mathbb{M}_n$ acting on itself in this way is called the *standard form* representation of $\mathbb{M}_n$. Its commutant is also isomorphic (or, more naturally, anti-isomorphic) to $\mathbb{M}_n$, acting by right multiplication.

XX.16.4.30. If ϕ is a positive linear functional on A, then ϕ has a canonical extension to a positive linear functional on $\mathcal{B}(\mathcal{H}_\phi)$ of the same norm, also denoted ϕ, by $\phi(T) = \langle T\xi_\phi, \xi_\phi\rangle_\phi$.

The next simple result is a version of the Radon-Nikodým Theorem (the classical Radon-Nikodým theorem is essentially the special case where $A = L^\infty(X, \mu)$ for a finite measure space (X, μ), and $\phi(f) = \int f\, d\mu$).

XX.16.4.31. Proposition. Let ϕ and ψ be positive linear functionals on A, with $\psi \leq \phi$ (i.e. $\psi(x) \leq \phi(x)$ for all $x \in A_+$). Then there is a unique operator $T \in \pi_\phi(A)' \subseteq \mathcal{B}(\mathcal{H}_\phi)$, with $0 \leq T \leq I$, such that $\psi(x) = \phi(T\pi_\phi(x)) = \langle T\pi_\phi(x)\xi_\phi, \xi_\phi\rangle_\phi$ for all $x \in A$.

Proof: For $x, y \in A$, define $(\pi_\phi(x)\xi_\phi, \pi_\phi(y)\xi_\phi) = \psi(y^*x)$. Then $(\cdot\,,\cdot)$ extends to a bounded sesquilinear form (pre-inner product) on $\mathcal{H}_\phi$, and thus there is a $T \in (\mathcal{H}_\phi)$, $0 \leq T \leq I$, such that $(\eta, \zeta) = \langle T\eta, \zeta\rangle_\phi$ for all $\eta, \zeta \in \mathcal{H}_\phi$ (**??**). If $x, y, z \in A$, then

$$\langle T\pi_\phi(x)[\pi_\phi(z)\xi_\phi], \pi_\phi(y)\xi_\phi\rangle_\phi = \psi(y^*(xz)) = \psi((x^*y)^*z)$$

$$= \langle T\pi_\phi(z)\xi_\phi, \pi_\phi(x^*)[\pi_\phi(y)\xi_\phi]\rangle_\phi = \langle \pi_\phi(x)T[\pi_\phi(z)\xi_\phi], \pi_\phi(y)\xi_\phi\rangle_\phi$$

so, fixing x and letting y, z range over A, we conclude that $T\pi_\phi(x) = \pi_\phi(x)T$. 👍

XX.16.4.32. In fact, if $\psi \leq \phi$ and $\omega = \phi - \psi$, so that $\phi = \psi + \omega$, then π_ϕ is unitarily equivalent to the subrepresentation of $\pi_\psi \oplus \pi_\omega$ with cyclic vector $\xi_\psi \oplus \xi_\omega$, and T is projection onto the first coordinate, compressed to this subspace.

Because of the abundance of states on a C*-algebra described in (XX.16.4.23.), every C*-algebra has many representations. We can say even more:

XX.16.4.33. PROPOSITION. If ϕ is a state of A, then π_ϕ is irreducible if and only if ϕ is a pure state.

PROOF: It follows immediately from XX.16.4.31. and XX.16.4.10. that if π_ϕ is irreducible, then any positive linear functional $\psi \leq \phi$ is a multiple of ϕ, and hence ϕ is pure. Conversely, if ϕ is pure, suppose there is a projection P in $\pi_\phi(A)'$, $P \neq 0, I$. Then $P\xi_\phi \neq 0$, for otherwise

$$0 = \pi_\phi(x)P\xi_\phi = P[\pi_\phi(x)\xi_\phi]$$

for all $x \in A$, so $P = 0$. Similarly, $(I-P)\xi_\phi \neq 0$. For $x \in A$, write

$$\phi_1(x) = \langle \pi_\phi(x)P\xi_\phi, P\xi_\phi\rangle_\phi = \phi(P\pi_\phi(x))$$

$$\phi_2(x) = \langle \pi_\phi(x)(I-P)\xi_\phi, (I-P)\xi_\phi\rangle_\phi = \phi((I-P)\pi_\phi(x)).$$

Then ϕ_1, ϕ_2 are positive linear functionals on A, $\phi = \phi_1 + \phi_2$, and $\phi_1 = \lambda\phi$, $\phi_2 = (1-\lambda)\phi$ for some λ, $0 < \lambda < 1$, because ϕ is pure. For any $\epsilon > 0$, there is an $x \in A$ with $\|\pi_\phi(x)\xi_\phi - P\xi_\phi\|_\phi < \epsilon$ and $\|\pi_\phi(x)\xi_\phi\|_\phi^2 = \phi(x^*x) = \|P\xi_\phi\|_\phi^2$. Then $\|(I-P)\pi_\phi(x)\xi_\phi\|_\phi = \|(I-P)(\pi_\phi(x)\xi_\phi - P\xi_\phi)\|_\phi < \epsilon$, and

$$(1-\lambda)\|P\xi_\phi\|_\phi^2 = (1-\lambda)\phi(x^*x) = \phi_2(x^*x) = \|(I-P)\pi_\phi(x)\xi_\phi\|_\phi^2 < \epsilon^2$$

contradicting $\lambda \neq 1$ and therefore the existence of P. Thus $\pi_\phi(A)' = \mathbb{C}I$. 👍

XX.16.4.34. COROLLARY. If A is a C*-algebra and $x \in A$, then there is an irreducible representation π of A with $\|\pi(x)\| = \|x\|$.

PROOF: Let $\pi = \pi_\phi$, where ϕ is a pure state of A with $\phi((xx^*)^2) = \|(xx^*)^2\| = \|x\|^4$ (XX.16.4.23.). Then

$$\|x\|^2 = \langle xx^*, xx^*\rangle_\phi^{1/2} = \|xx^*\|_\phi = \|\pi(x)x^*\|_\phi \leq \|\pi(x)\|\|x^*\|_\phi \leq \|\pi(x)\|\|x\| \ .$$

👍

By considering sums of irreducible representations, we obtain

XX.16.4.35. COROLLARY. [GELFAND-NAIMARK THEOREM] If A is a C*-algebra, then A has a faithful representation, i.e. A is isometrically isomorphic to a concrete C*-algebra of operators on a Hilbert space $\mathcal{H}$. If A is separable, then $\mathcal{H}$ may be chosen to be separable.

XX.16.4.36. PROPOSITION. Let A be a C*-algebra, B a C*-subalgebra of A, and ρ a representation of B on a Hilbert space $\mathcal{H}_0$. Then ρ can be extended to a representation π of A on a (possibly) larger Hilbert space $\mathcal{H}$, i.e. there is a Hilbert space $\mathcal{H}$ containing $\mathcal{H}_0$ and a representation π of A on $\mathcal{H}$ such that $\mathcal{H}_0$ is invariant under $\pi|_B$ and $\pi|_B$ agrees with ρ on $\mathcal{H}_0$. If ρ is irreducible, then π may be chosen irreducible.

PROOF: Since every representation is a direct sum of cyclic representations, it suffices to show the result for ρ cyclic, i.e. ρ is the GNS representation corresponding to a state ψ of B. Extend ψ to a state ϕ of A (with ϕ pure if ψ is pure; see XX.16.4.22.), and let π be its GNS representation. 👍

XX.16.4.37. Thus every C*-algebra can be faithfully represented on a Hilbert space, but the representation is highly nonunique in general. The major part of representation theory is concerned with how to describe the possibilities. There is a relatively small class of C*-algebras () for which a concrete description of the representations is even possible.

Using the GNS construction, we can obtain an extension of XX.16.4.17.(i) and a sharpening of XX.16.4.21. in the case that the subalgebra is an ideal. This result is also closely related to XX.16.4.8..

XX.16.4.38. PROPOSITION. Let J be a closed ideal in a C*-algebra A, and ψ a positive linear functional on J. Then there is a unique extension of ψ to a positive linear functional ϕ on A with $\|\phi\| = \|\psi\|$. If (h_λ) is an increasing approximate unit for J, then $\phi(x) = \lim \psi(h_\lambda x) = \lim \psi(x h_\lambda)$ for all $x \in A$; if $x \in A_+$, then

$$\phi(x) = \lim \psi(x^{1/2} h_\lambda x^{1/2}) = \sup \psi(x^{1/2} h_\lambda x^{1/2}).$$

Any other positive linear functional ϕ' on A extending ψ satisfies $\phi' \geq \phi$.

PROOF: By XX.16.4.21. there is a ϕ extending ψ with $\|\phi\| = \|\psi\|$, but we will not use this result. Instead we define ϕ directly as follows.

Let π_ψ be the GNS representation of J on $\mathcal{H}_\psi$ with cyclic vector ξ_ψ. Extend π_ψ to a representation π of A on $\mathcal{H}_\psi$ as in XX.16.4.8.. Then ξ_ψ defines a positive linear functional ϕ on A by $\phi(x) = \langle \pi(x)\xi_\psi, \xi_\psi \rangle$. We have $\|\phi\| = \|\xi_\psi\|^2 = \|\psi\|$, and $(\mathcal{H}_\phi, \pi_\phi, \xi_\phi)$ can be naturally identified with $(\mathcal{H}_\psi, \pi, \xi_\psi)$. Since $\pi(h_\lambda) \to I$ strongly, we have, for any $x \in A$,

$$\psi(h_\lambda x) = \langle \pi(h_\lambda)\pi(x)\xi_\psi, \xi_\psi \rangle \to \langle \pi(x)\xi_\psi, \xi_\psi \rangle = \phi(x)$$

and similarly $\psi(x h_\lambda) \to \phi(x)$ and, if $x \geq 0$, $\psi(x^{1/2} h_\lambda x^{1/2}) \to \phi(x)$.

If ϕ' is any extension of ψ to a positive linear functional on A, and $x \in A_+$, then $\phi'(x) \geq \phi'(x^{1/2} h_\lambda x^{1/2}) = \psi(x^{1/2} h_\lambda x^{1/2})$ for all λ, so $\phi'(x) \geq \phi(x)$. Thus $\omega = \phi' - \phi$ is a positive linear functional, and we have $\|\phi'\| = \|\phi\| + \|\omega\| = \|\psi\| + \|\omega\|$, so if $\|\phi'\| = \|\psi\|$, then $\omega = 0$, $\phi' = \phi$. 👍

Primitive Ideal Space and Spectrum

It is common in mathematics (e.g. in algebraic geometry) to associate to a ring A a topological space of ideals of A, generally either the set of prime ideals (denoted $\mathrm{Spec}(A)$) or the set of maximal ideals (denoted $\mathrm{Maxspec}(A)$), with the hull-kernel topology (XIII.7.10.20.). For C*-algebras, the most useful variant is to consider the primitive ideal space:

XX.16.4.39. DEFINITION. Let A be a C*-algebra. A *primitive ideal* of A is an ideal which is the kernel of an irreducible representation of A. Denote by $\mathrm{Prim}(A)$ the set of primitive ideals of A. The topology on $\mathrm{Prim}(A)$ is the hull-kernel topology, i.e. $\{J_i\}^- = \{J : J \supseteq \cap J_i\}$.

XX.16.4.40. A primitive ideal is closed by XX.16.4.2. and prime by XX.16.4.11.. By XX.16.4.34., the intersection of the primitive ideals of a C*-algebra A is $\{0\}$. By considering irreducible representations of A/J, it follows that every closed ideal J of A is an intersection of primitive ideals. In particular, every maximal ideal is primitive. There is thus a natural one-one correspondence between the closed sets in $\mathrm{Prim}(A)$ and the closed ideals of A. If A is commutative, then every closed prime ideal is maximal and hence primitive, and $\mathrm{Prim}(A)$ agrees with the set $\mathrm{Maxspec}(A)$ and may be identified with $\hat{A}$ as in XX.16.2.1..

XX.16.4.41. If J is a closed ideal in A, then we can identify $\mathrm{Prim}(A/J)$ with

$$\mathrm{Prim}_J(A) = \{K \in \mathrm{Prim}(A) : J \subseteq K\},$$

the corresponding closed set in $\mathrm{Prim}(A)$. If $K \in \mathrm{Prim}(A)$, $J \not\subseteq K$, and π is an irreducible representation of A with kernel K, then $\pi|J$ is an irreducible representation of J (XX.16.4.8.) with kernel $K \cap J$. So there is a map ρ_J from

$$\mathrm{Prim}^J(A) = \{K \in \mathrm{Prim}(A) : J \not\subseteq K\}$$

to $\mathrm{Prim}(J)$, defined by $\rho_J(K) = K \cap J$, which is surjective by XX.16.4.8.. Also, ρ_J is injective: if $K_1, K_2 \in \mathrm{Prim}(A)$ and $K_1 \cap J = K_2 \cap J \neq J$, then by XX.16.3.16.(iii) we have

$$(K_1 + K_2) \cap (J + K_2) = (K_1 \cap J) + K_2 = (K_2 \cap J) + K_2 = K_2$$

and, since K_2 is prime and $J + K_2 \neq K_2$, we have $K_1 + K_2 = K_2$, $K_1 \subseteq K_2$. Symmetrically, $K_2 \subseteq K_1$, so $K_1 = K_2$. Thus $\mathrm{Prim}(J)$ may be identified with $\mathrm{Prim}^J(A) = \mathrm{Prim}(A) \setminus \mathrm{Prim}_J(A)$, an open set in $\mathrm{Prim}(A)$.

XX.16.4.42. If J is a closed ideal in a C*-algebra A and $x \in A$, write $\|x\|_J$ for the norm of x mod J. If $\{J_i\}$ is any collection of closed ideals in A and $J = \cap J_i$, then $\|\cdot\|_J = \sup_i \|\cdot\|_{J_i}$ (by XX.16.2.33. it suffices to note that this formula defines a C*-norm on A/J); and if (J_i) is an increasing net of closed ideals with $J = [\cup J_i]^-$, then $\|\cdot\|_J = \inf_i \|\cdot\|_{J_i}$ (this follows immediately from the definition of the quotient norm). A simple consequence is:

XX.16.4.43. Proposition. Let A be a C*-algebra.

(i) If $x \in A$, define $\check{x} : \mathrm{Prim}(A) \to \mathbb{R}_+$ by $\check{x}(J) = \|x\|_J$. Then $\check{x}$ is lower semicontinuous.

(ii) If $\{x_i\}$ is a dense set in the unit ball of A, and $U_i = \{J \in \mathrm{Prim}(A) : \check{x}_i(J) > 1/2\}$, then $\{U_i\}$ forms a base for the topology of $\mathrm{Prim}(A)$.

(iii) If $x \in A$ and $\lambda > 0$, then $\{J \in \mathrm{Prim}(A) : \check{x}(J) \geq \lambda\}$ is compact (but not necessarily closed) in $\mathrm{Prim}(A)$.

Proof: Part (i) is obvious. For (ii), let $J \in \mathrm{Prim}(A)$. A neighborhood of J is a set of the form $V = \{I \in \mathrm{Prim}(A) : K \not\subseteq I\}$ for a closed ideal K not contained in J. Choose $y \in K \setminus J$, and $0 < \epsilon \leq \frac{1}{2}\|y\|_J^2$, and let $x = f_\epsilon(y^*y)$. Then $x \in K$, and $\|x\| = \|x\|_J = 1$. Choose x_i with $\|x_i - x\| < 1/2$; then $J \in U_i$ and $U_i \subseteq V$. To show (iii), let $\{K_i : i \in \Omega\}$ be a set of closed ideals in A, K the closed ideal generated by $\cup K_i$ (so $K = [\sum K_i]^-$), and

$$U_i = \{J \in \mathrm{Prim}(A) : K_i \not\subseteq J\}.$$

Then $\{U_i\}$ is an open cover of $F = \{J \in \mathrm{Prim}(A) : \check{x}(J) \geq \lambda\}$ if and only if $\|x\|_K < \lambda$. In this case, there are $i_1, \ldots, i_n$ such that if $K_0 = K_{i_1} + \cdots + K_{i_n}$, then $\|x\|_{K_0} < \lambda$, so $\{U_{i_1}, \ldots, U_{i_n}\}$ is a cover of F. ☝

XX.16.4.44. Corollary. $\mathrm{Prim}(A)$ is a locally compact space T_0-space which is compact if A is unital. If A is separable, then $\mathrm{Prim}(A)$ is second countable.

Actually, there are several inequivalent definitions of local compactness used for non-Hausdorff spaces (XIII.11.8.20.), so the statement that $\mathrm{Prim}(A)$ is "locally compact" is ambiguous in the non-Hausdorff case. To be precise, if A is a C*-algebra, then XX.16.4.43. shows that every point of $\mathrm{Prim}(A)$ has a neighborhood base of compact sets, i.e. $\mathrm{Prim}(A)$ satisfies XIII.11.8.20.(ii). But a point need not have any closed compact neighborhood, i.e. $\mathrm{Prim}(A)$ does not necessarily satisfy XIII.11.8.20.(iii).

XX.16.4.45. The function $\check{x}$ of XX.16.4.43. is not continuous in general; in fact, if $\mathrm{Prim}(A)$ is not Hausdorff, then the $\check{x}$ cannot all be continuous since $\{\check{x} : x \in A\}$ separates the points of $\mathrm{Prim}(A)$. But if $\mathrm{Prim}(A)$ is Hausdorff, XX.16.4.43.(iii) shows that $\check{x}$ is continuous for all $x \in A$. If A is commutative, or more generally if x is in the center of A, then $\check{x}$ is continuous.

XX.16.4.46. Examples.

(i) Let $A = \mathbb{K}^\dagger$. Then $\mathrm{Prim}(A) = \{0, \mathbb{K}\}$; $\{\mathbb{K}\}$ is a closed point, and $\{0\}$ is a dense open point. Thus $\mathrm{Prim}(A)$ homeomorphic to the Sierpiński space and is not T_1.

(ii) Let A be the C*-algebra of all sequences of elements of $\mathbb{M}_2$ which converge to a diagonal matrix. Then $\mathrm{Prim}(A)$ consists of a sequence of points simultaneously converging to two closed points at infinity. Thus $\mathrm{Prim}(A)$ is T_1 but not Hausdorff.

(iii) Let A be the C*-algebra of all sequences in $\mathbb{K}^\dagger$ converging to a scalar multiple of 1. Then $\mathrm{Prim}(A)$ is the one-point compactification of a disjoint union of two-point spaces as in (i).

If A is commutative, then Gelfand's Theorem (XX.16.2.1.) identifies elements of A with continuous functions on $\hat{A} \cong \mathrm{Prim}(A)$.

XX.16.4.47. For a general C*-algebra A we define $\hat{A}$ to be the set of unitary equivalence classes of irreducible representations of A. There is a natural map from $\hat{A}$ onto $\mathrm{Prim}(A)$ sending π to $ker(\pi)$. This map is not injective in general, i.e. there can be inequivalent representations with the same kernel. There is also an obvious map from $\mathcal{P}(A)$ onto $\hat{A}$, sending a pure state to its GNS representation; the composite map from $\mathcal{P}(A)$ to $\mathrm{Prim}(A)$ is continuous and open when $\mathcal{P}(A)$ is given the relative weak-* topology. The quotient topology (XIII.8.1.1.) on $\hat{A}$ from $\mathcal{P}(A)$, which coincides with the weak topology (XIII.5.1.8.) for the map of $\hat{A}$ onto $\mathrm{Prim}(A)$, is the unique topology on $\hat{A}$ making the maps $\mathcal{P}(A) \to \hat{A}$ and $\hat{A} \to \mathrm{Prim}(A)$ continuous and open (XIII.8.5.1.), but $\hat{A}$ is not T_0 unless the map to $\mathrm{Prim}(A)$ is injective (and hence a homeomorphism).

By XX.16.4.8., if J is a closed ideal in A, we may identify $\hat{J}$ and $\mathrm{Prim}(J)$ with open subsets of $\hat{A}$ and $\mathrm{Prim}(A)$ respectively; the complements are naturally identified with $\widehat{A/J}$ and $\mathrm{Prim}(A/J)$. We may do the same with $\mathcal{P}(J)$ since if $\phi \in \mathcal{P}(A)$, then either $\phi|_J = 0$ or $\phi|J$ is a pure state of J.

XX.16.4.48. Another way of describing the topology on $\hat{A}$ is to fix a Hilbert space $\mathcal{H}$ and let $\mathrm{Irr}_{\mathcal{H}}(A)$ be the set of irreducible representations of A on $\mathcal{H}$. $\mathrm{Irr}_{\mathcal{H}}(A)$ has a natural topology, the topology of elementwise convergence, and the map from $\mathrm{Irr}_{\mathcal{H}}(A)$ to $\hat{A}$ is continuous and open, i.e. $\hat{A}$ has the quotient topology from $\mathrm{Irr}_{\mathcal{H}}(A)$ (more care must be taken in describing the topology if A has irreducible representations of different dimensions. The difficulty can be avoided by stabilization (XX.16.4.55.) if A is separable, since there are natural homeomorphisms $[A \otimes \mathbb{K}]\hat{} \cong \hat{A}$ and $\mathrm{Prim}(A \otimes \mathbb{K}) \cong \mathrm{Prim}(A)$.) This procedure also yields a Borel structure (the *Mackey Borel structure*) on $\hat{A}$, the quotient of the natural Borel structure on $\mathrm{Irr}_{\mathcal{H}}(A)$ induced by its topology, which is finer than the Borel structure on $\hat{A}$ induced by its topology, and which is more useful than the topology if $\hat{A}$ is not T_0 (e.g. the Mackey Borel structure separates points of $\hat{A}$).

Matrix Algebras and Stable Algebras

As an example of a basic fact which can be proved easily by representation theory but for which there seems to be no decent space-free proof, we observe that a matrix algebra over a C*-algebra is also a C*-algebra.

XX.16.4.49. If $\mathcal{H}$ is a Hilbert space, then $\mathcal{B}(\mathcal{H}^n)$ is naturally isomorphic to the matrix algebra $M_n(\mathcal{B}(\mathcal{H}))$. (More generally, $\mathcal{B}(\mathcal{H}^n, \mathcal{H}^m)$ can be identified with the $m \times n$ matrices over $\mathcal{B}(\mathcal{H})$.) So if A is a concrete C*-algebra of operators on $\mathcal{H}$, then the matrix algebra $M_n(A)$ acts naturally as a concrete C*-algebra of operators on $\mathcal{H}^n$ (it is easily seen to be complete). The adjoint of a matrix (a_{ij}) is the matrix (b_{ij}), where $b_{ij} = a_{ji}^*$.

XX.16.4.50. Thus, if A is a C*-algebra, we need only to take a faithful representation π of A on a Hilbert space $\mathcal{H}$; then π defines entrywise a faithful representation $\pi^{(n)}$ of $M_n(A)$ (with involution defined as above) on $\mathcal{H}^n$, and thus $M_n(A)$ is a C*-algebra with the induced operator norm.

XX.16.4.51. By XX.16.2.34., this operator norm is the unique C*-norm on $M_n(A)$ with this involution. When we use matrix algebras over C*-algebras, we will always implicitly use this involution and norm. Note that there is no explicit formula for the norm of a matrix in terms of the entries in general (e.g. if $A = \mathbb{M}_3$ and $n = 2$, cf. XX.12.6.6.). There is, however, a simple estimate: if $a = (a_{ij})$ is a matrix, then

$$\max_{i,j} \|a_{ij}\| \leq \|a\| \leq \sum_{i,j} \|a_{ij}\|$$

since it is easily seen that if b is a matrix with exactly one nonzero entry x, then $\|b\| = \|x\|$.

XX.16.4.52. $M_n(A)$ is isomorphic to $A \otimes \mathbb{M}_n = A \otimes_{\mathbb{C}} \mathbb{M}_n$ (), and it is convenient to use tensor product notation in matrix algebras. In $\mathbb{M}_n$, let e_{ij} be the matrix with 1 in the (i,j)'th entry and zeroes elsewhere, and write $a \otimes e_{ij}$ for the element of $M_n(A)$ with a in the (i,j)'th entry and zeroes elsewhere. The e_{ij} are called the *standard matrix units* in $\mathbb{M}_n$. (There is a similar set of standard matrix units in $\mathbb{K}$.)

XX.16.4.53. As in XX.16.4.49., $\mathcal{B}(\mathcal{H}^\infty)$ can be identified with an algebra of infinite matrices over $\mathcal{B}(\mathcal{H})$ (although it is impossible to give an explicit description of which matrices give bounded operators). If A is a concrete C*-algebra of operators on $\mathcal{H}$, let $M_\infty(A)$ denote the infinite matrices over A with only finitely many nonzero entries. Then $M_\infty(A)$ acts naturally as a *-algebra of bounded operators on $\mathcal{H}^\infty$, and its closure in $\mathcal{B}(\mathcal{H}^\infty)$ is denoted $A \otimes \mathbb{K}$.

XX.16.4.54. If A is an (abstract) C*-algebra, we can form $M_\infty(A)$ in the same manner, and by choosing a faithful representation π of A, $M_\infty(A)$ may be identified with $M_\infty(\pi(A))$ and thus given a norm. Using the uniqueness of norm on $M_n(A)$ for each n, it is easily seen that the norm on $M_\infty(A)$ does not depend on the choice of π.

XX.16.4.55. Definition. The completion of $M_\infty(A)$ is called the *stable algebra* of A, denoted $A \otimes \mathbb{K}$.

This is also a special case of a tensor product of C*-algebras, hence the notation.

XX.16.4.56. Definition. A C*-algebra A is *stable* if $A \cong A \otimes \mathbb{K}$. Two C*-algebras A and B are *stably isomorphic* if $A \otimes \mathbb{K} \cong B \otimes \mathbb{K}$.

Note that a stable C*-algebra is always nonunital.

XX.16.4.57. PROPOSITION. $\mathcal{K}(\mathcal{H}) \otimes \mathbb{M}_n = \mathcal{K}(\mathcal{H}^n)$ and $\mathcal{K}(\mathcal{H}) \otimes \mathbb{K} = \mathcal{K}(\mathcal{H}^\infty)$. In particular,

$$\mathbb{K} \cong M_n(\mathbb{K}) \cong \mathbb{M}_n \otimes \mathbb{K} \cong \mathbb{K} \otimes \mathbb{M}_n$$

for all n, and $\mathbb{K}$ is isomorphic to $\mathbb{K} \otimes \mathbb{K}$.

XX.16.4.58. Similarly, it is easily verified that $(A \otimes \mathbb{K}) \otimes \mathbb{K} \cong A \otimes \mathbb{K}$ for any A, so the stable algebra $A \otimes \mathbb{K}$ of a C*-algebra A is a stable C*-algebra, and A is stably isomorphic to $A \otimes \mathbb{K}$. Two stable C*-algebras are stably isomorphic if and only if they are isomorphic. In the same way, A and $M_n(A)$ are stably isomorphic for any A and n. Stably isomorphic C*-algebras are "the same up to 'size';" a stable C*-algebra has uniformly infinite "size." (This must be taken with a grain of salt in the non-σ-unital case, but can be made precise in a nice way for σ-unital C*-algebras). If X is a locally compact Hausdorff space, then $C_0(X) \otimes \mathbb{K} \cong C_0(X, \mathbb{K})$ (XX.16.1.3.).

XX.16.5. Universal and Enveloping C*-Algebras

XX.16.6. Exercises

XX.16.6.1. Use XX.16.2.14. and XX.16.2.16. to give an alternate proof of XX.16.1.9., as follows. Let B be a commutative C*-algebra, which may be assumed unital by XX.16.1.2., and $x = x^* \in B$.

(a) Suppose $\lambda = \alpha + i\beta \in \sigma_B(x)$ with $\alpha, \beta \in \mathbb{R}$. By XX.16.2.16. there is a $\phi \in \hat{B}$ with $\phi(x) = \lambda$.

(b) For $t \in \mathbb{R}$, set $x_t = x + it1$. Then $\|x_t\|^2 = \|x_t^* x_t\| = \|x^2 + t^2 1\| \leq \|x^2\| + t^2 = \|x\|^2 + t^2$.

(c) On the other hand, $\phi(x_t) = \alpha + i(\beta + t)$, so $|\phi(x_t)|^2 = \alpha^2 + (\beta + t)^2$.

(d) Since $|\phi(x_t)| \leq \|x_t\|$ by XX.16.2.14., we have

$$\alpha^2 + (\beta + t)^2 \leq \|x\|^2 + t^2$$

for all $t \in \mathbb{R}$. Show that this implies that $\beta = 0$.

(e) If A is a general not necessarily commutative C*-algebra (which may be assumed unital) and $x = x^* \in A$, the above argument can be applied to the C*-subalgebra B of A generated by x and 1. Why does this give an alternate proof of the full result XX.16.1.9. (what is the relation between $\sigma_B(x)$ and $\sigma_A(x)$)?

XX.16.6.2. (a) Let I be a closed bounded interval in $\mathbb{R}$, and A the set of bounded functions from I to $\mathbb{C}$ whose real and imaginary parts are in $\mathfrak{BC}_1(I)$ (XVI.2.5.2.). Give A pointwise operations and supremum norm. Show that A is a (unital) commutative C*-algebra. [Use XVI.2.10.7..]

(b) Let B be the set of regulated functions on I (V.8.6.7.). Show that B is a (unital) C*-subalgebra of A containing $C(I)$.

(c) Show that $\hat{B}$ is homeomorphic to $I \times \{0, 1\}$ with the order topology from the lexicographic ordering (). The quotient map to $I \cong \widehat{C(I)}$ is projection onto the first coordinate. Note that $\hat{B}$ is not metrizable, so B is not separable (this has an easy direct proof too).

(d) Try to describe $\hat{A}$. (Note that $\hat{B}$ is a quotient of $\hat{A}$.)

XX.16.6.3. Let A be the set of bounded uniformly continuous functions from $\mathbb{R}$ to $\mathbb{C}$. Show that A is a proper unital C*-subalgebra of $BC(\mathbb{R})$. Thus $\hat{A}$ is a quotient of $\widehat{BC(\mathbb{R})} \cong \beta\mathbb{R}$. Describe the quotient map.

Chapter XXI

Nonlinear Functional Analysis

XXI.1. Calculus on Banach Spaces

Much of vector calculus can be generalized to functions between Banach spaces and, more generally, topological vector spaces. The general principle is that "differentiable" is interpreted as "approximately linear" in an appropriate sense. The main technicalities in the infinite-dimensional case are due to two facts: (1) linear transformations between Banach spaces are not necessarily continuous (bounded), and (2) Banach spaces have various weak topologies distinct from the norm topology.

Banach spaces can be either real or complex. There will thus be two parallel theories; although the basic definitions and results are essentially identical, we must be careful to distinguish them. Thus we fix a field $\mathbb{F}$, either $\mathbb{R}$ or $\mathbb{C}$.

XXI.1.1. Differentiable Functions Between Banach Spaces

We can use the definition of differentiability from vector calculus almost verbatim in the Banach space case:

XXI.1.1.1. DEFINITION. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces (over $\mathbb{F}$), U an open subset of $\mathcal{X}$, $f : U \to \mathcal{Y}$ a function, and $a \in U$. Then

(i) f is *approximately linear* at a if there is a linear ($\mathbb{F}$-linear) transformation $L : \mathcal{X} \to \mathcal{Y}$ such that

$$\lim_{h \to 0} \frac{f(a+h) - f(a) - L(h)}{\|h\|} = 0 \ .$$

(i) f is *differentiable* at a if there is a bounded linear ($\mathbb{F}$-linear) transformation $L : \mathcal{X} \to \mathcal{Y}$ such that

$$\lim_{h \to 0} \frac{f(a+h) - f(a) - L(h)}{\|h\|} = 0 \ .$$

XXI.1.1.2. Of course, the condition in the definition is equivalent to

$$\lim_{h\to 0} \frac{\|f(a+h)-f(a)-L(h)\|}{\|h\|} = 0 \ .$$

The definition is dependent on the choice of $\mathbb{F}$, and when it is necessary to distinguish between $\mathbb{R}$ and $\mathbb{C}$ we may use the terms "approximately $\mathbb{F}$-linear" and "$\mathbb{F}$-differentiable." Complex Banach spaces have an underlying structure as real Banach spaces, and a $\mathbb{C}$-differentiable function is $\mathbb{R}$-differentiable with respect to the underlying real structures; but since an $\mathbb{R}$-linear function is not $\mathbb{C}$-linear in general, an $\mathbb{R}$-differentiable function is not necessarily $\mathbb{C}$-differentiable.

XXI.1.1.3. In the finite-dimensional case, there is no difference between differentiability and approximate linearity, and a differentiable function is automatically continuous. But the notions are distinct in the infinite-dimensional case: an unbounded linear transformation is obviously approximately linear, but neither differentiable nor continuous. But we have:

XXI.1.1.4. Proposition. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces, U an open subset of $\mathcal{X}$, $f : U \to \mathcal{Y}$ a function, and $a \in U$. Then f is differentiable at a if and only if f is approximately linear and continuous at a.

In particular, a linear or affine function is differentiable (by our definition) if and only if it is continuous. Proof: Half the proof is the same as in (): if f is differentiable at a, and L is a bounded operator as in the definition, and $\epsilon > 0$, there is a δ, $0 < \delta < 1$, such that $\|L(h)\| < \frac{\epsilon}{2}$ and

$$\|f(a+h)-f(a)-L(h)\| < \frac{\|f(a+h)-f(a)-L(h)\|}{\|h\|} < \frac{\epsilon}{2}$$

if $\|h\| < \delta$. We then have, for $\|h\| < \delta$,

$$\|f(a+h)-f(a)\| = \|f(a+h)-f(a)-L(h)+L(h)\| \le \|f(a+h)-f(a)-L(h)\| + \|L(h)\| < \frac{\epsilon}{2}+\frac{\epsilon}{2} = \epsilon \ .$$

For the other direction, suppose f is continuous at a and there is a linear transformation L as in the definition of approximate linearity. Choose δ, $0 < \delta < 1$, so that

$$\|f(a+h)-f(a)\| < \frac{\epsilon}{2}$$

$$\|f(a+h)-f(a)-L(h)\| < \frac{\epsilon\|h\|}{2} < \frac{\epsilon}{2}$$

for $\|h\| < \delta$. Then, if $\|h\| < \delta$,

$$\|L(h)\| = \|[f(a+h)-f(a)]-[f(a+h)-f(a)-L(h)]\| \le \|f(a+h)-f(a)\|+\|f(a+h)-f(a)-L(h)\| < \frac{\epsilon}{2}+\frac{\epsilon}{2} = \epsilon$$

so L is continuous and f is differentiable at a. 👍

This proof actually shows slightly more than the stated result, but not when combined with the following observation:

XXI.1.1.5. PROPOSITION. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces, U an open subset of $\mathcal{X}$, $f : U \to \mathcal{Y}$ a function, and $a \in U$. If f is approximately linear at a, then the L in the definition is unique.

PROOF: Suppose L_1 and L_2 are linear transformations from $\mathcal{X}$ to $\mathcal{Y}$ with

$$\lim_{h\to 0} \frac{\|f(a+h) - f(a) - L_1(h)\|}{\|h\|} = 0$$

$$\lim_{h\to 0} \frac{\|f(a+h) - f(a) - L_2(h)\|}{\|h\|} = 0$$

and let $\epsilon > 0$. There is a δ, $0 < \delta < 1$, such that

$$\frac{\|f(a+h) - f(a) - L_1(h)\|}{\|h\|} < \frac{\epsilon}{2}$$

$$\frac{\|f(a+h) - f(a) - L_2(h)\|}{\|h\|} < \frac{\epsilon}{2}$$

for $\|h\| < \delta$. Then, if $\|h\| < \delta$,

$$\frac{\|L_2(h) - L_1(h)\|}{\|h\|} = \frac{\|[f(a+h) - f(a) - L_1(h)] - [f(a+h) - f(a) - L_2(h)]\|}{\|h\|}$$

$$\leq \frac{\|f(a+h) - f(a) - L_1(h)\|}{\|h\|} + \frac{\|f(a+h) - f(a) - L_2(h)\|}{\|h\|} < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \ .$$

Let $x \in \mathcal{X}$, $\|x\| = 1$. Then, if $0 < \alpha < \delta$, $\|\alpha x\| < \delta$, so

$$\frac{\|L_2(\alpha x) - L_1(\alpha x)\|}{\|\alpha x\|} = \|L_2(x) - L_1(x)\| < \epsilon$$

and since $\epsilon > 0$ is arbitrary, $L_1(x) = L_2(x)$. Since x is an arbitrary vector of norm 1, $L_1 = L_2$. 👍

XXI.1.1.6. DEFINITION. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces, U an open subset of $\mathcal{X}$, $f : U \to \mathcal{Y}$ a function, and $a \in U$. If f is differentiable at a, the *derivative* of f at a is the unique operator $Df(a)$ satisfying

$$\lim_{h\to 0} \frac{f(a+h) - f(a) - Df(a)h}{\|h\|} = 0 \ .$$

We will only use the notation $Df(a)$ if f is differentiable at a, i.e. if $Df(a)$ is a bounded operator. Thus $Df(a) \in \mathcal{B}(\mathcal{X}, \mathcal{Y})$.

XXI.1.1.7. Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces, U an open subset of $\mathcal{X}$, and $f : U \to \mathcal{Y}$ a function. We say f is differentiable on U if it is differentiable at every point of U. If so, Df is a function from $\mathcal{X}$ to $\mathcal{B}(\mathcal{X}, \mathcal{Y})$. We say f is *continuously differentiable*, or $\mathcal{C}^1$, on U if Df is a continuous function from U to $\mathcal{B}(\mathcal{X}, \mathcal{Y})$ with its norm topology.

We can also define higher-order differentiability since $\mathcal{B}(\mathcal{X}, \mathcal{Y})$ is itself a Banach space: f is second-order differentiable at $a \in U$ if Df is differentiable at a, and f is $\mathcal{C}^2$ on U if Df is $\mathcal{C}^1$ on U. Higher-order differentiability and $\mathcal{C}^r$ $(2 < r \leq \infty)$ can be defined analogously.

XXI.1.1.8. EXAMPLE. [Die60, 8.3.2] Let A be a unital Banach algebra, and write A^{-1} for the set of invertible elements in A. Then A^{-1} is an open set in A (XX.12.2.11.). Define $f : A^{-1} \to A^{-1} \subseteq A$ by $f(x) = x^{-1}$. Then f is continuous on A^{-1} (XX.12.2.14.). In fact, f is differentiable on A^{-1} and, if $a \in A^{-1}$, $[Df(a)]x = a^{-1}xa^{-1}$. For note that if $u \in A$, $\|u\| < 1$, then $1 + u \in A^{-1}$ and the infinite series

$$\sum_{k=0}^{\infty}(-1)^k u^k$$

converges to $(1 + u)^{-1}$ (XX.12.2.9.); we then have that

$$\sum_{k=2}^{\infty}(-1)^k u^k = u^2 \sum_{k=0}^{\infty}(-1)^k u^k = \left[\sum_{k=0}^{\infty}(-1)^k u^k\right] - 1 + u$$

converges to $(1 + u)^{-1} - 1 + u = u^2(1 + u)^{-1}$. Thus we obtain (XX.12.2.9.)

$$\|(1 + u)^{-1} - 1 + u\| = \|u^2(1 - u)^{-1}\| \leq \|u\|^2 \frac{1}{1 - \|u\|} = \frac{\|u\|^2}{1 - \|u\|} \ .$$

If $h \in A$, $\|h\| < \|a^{-1}\|^{-1}$, then $\|a^{-1}h\| < 1$, so $1 + a^{-1}h \in A^{-1}$ and hence $a + h = a(1 + a^{-1}h)$ is invertible, with inverse $(1 + a^{-1}h)^{-1}a^{-1}$, and

$$(a + h)^{-1} - a^{-1} = [(1 + a^{-1}h)^{-1} - 1]a^{-1} \ .$$

Thus, taking $u = a^{-1}h$ above, we have

$$\|(a + h)^{-1} - a^{-1} + a^{-1}ha^{-1}\| = \|([(1 + a^{-1}h)^{-1} - 1] + a^{-1}h)a^{-1}\| \leq \|a^{-1}\|\|(1 + a^{-1}h)^{-1} - 1 + a^{-1}h\|$$

$$\leq \|a^{-1}\| \frac{\|a^{-1}h\|^2}{1 - \|a^{-1}h\|} = \frac{\|a^{-1}\|^3\|h\|^2}{1 - \|a^{-1}h\|} \leq 2\|a^{-1}\|^3\|h\|^2$$

if $\|h\| \leq \frac{1}{2\|a^{-1}\|}$. Thus, for $\|h\| \leq \frac{1}{2\|a^{-1}\|}$,

$$\frac{\|(a + h)^{-1} - a^{-1} + a^{-1}ha^{-1}\|}{\|h\|} \leq 2\|a^{-1}\|^3\|h\|$$

which goes to 0 as $h \to 0$.

XXI.1.2. The Implicit and Inverse Function Theorems

The Implicit and Inverse Function Theorems, and the General Implicit/Inverse Function Theorem VIII.5.2.1., have nearly verbatim versions for functions between Banach spaces.

XXI.1.2.1. If $\mathcal{X}$ and $\mathcal{Y}$ are Banach spaces, there are many ways of defining a norm on $\mathcal{X} \times \mathcal{Y}$ giving the product topology (). Any of these can be used in this section, but for specificity let us standardize on the ∞-norm: $\|(x, y)\| = \max(\|x\|, \|y\|)$.

XXI.1.2.2. We also need to define analogs of $D_x f$ and $D_y f$. If L is a linear transformation from $\mathcal{X} \times \mathcal{Y}$ to $\mathcal{Z}$, write $L_{\mathcal{X}}$ for the linear transformation from $\mathcal{X}$ to $\mathcal{Z}$ given by $L_{\mathcal{X}}(x) = L(x, 0)$, and $L_{\mathcal{Y}}$ the linear transformation from $\mathcal{Y}$ to $\mathcal{Z}$ given by $L_{\mathcal{Y}}(y) = L(0, y)$. If L is bounded, then $L_{\mathcal{X}}$ and $L_{\mathcal{Y}}$ are bounded (and conversely). If f is a function from an open subset U of $\mathcal{X} \times \mathcal{Y}$ to $\mathcal{Z}$, and $(a, b) \in U$, and f is differentiable at (a, b), write $D_{\mathcal{X}} f(a, b) = [Df(a, b)]_{\mathcal{X}}$ and $D_{\mathcal{Y}} f(a, b) = [Df(a, b)]_{\mathcal{Y}}$. Then $D_{\mathcal{X}} f(a, b) \in \mathcal{B}(\mathcal{X}, \mathcal{Z})$ and $D_{\mathcal{Y}} f(a, b) \in \mathcal{B}(\mathcal{Y}, \mathcal{Z})$.

The statements of the theorems are as follows:

XXI.1.2.3. Theorem. [Implicit Function Theorem, Banach Smooth Version] Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces, U an open subset of $\mathcal{X} \times \mathcal{Y}$, $F : U \to \mathcal{Y}$ a function, and $(a, b) \in U$ with $F(a, b) = 0$. Suppose F is $\mathcal{C}^r$ on U for some r, $1 \leq r \leq \infty$. If $D_{\mathcal{Y}} F(a, b)$ is invertible, then there are:

(i) An open set V in $\mathcal{X} \times \mathcal{Y}$ containing (a, b), with $V \subseteq U$, such that $D_{\mathcal{Y}} F(x, y)$ is invertible for all $(x, y) \in V$;

(ii) An open set W in $\mathcal{X}$ containing a;

(iii) A unique function $f : W \to \mathcal{Y}$ such that $f(a) = b$ and, for all $x \in W$, $(x, f(x)) \in V$ and

$$F(x, f(x)) = 0 \ .$$

Additionally, f is $\mathcal{C}^r$ on W, and for any $x \in W$, we have

$$Df(x) = -D_{\mathcal{Y}} F(x, f(x))^{-1} D_{\mathcal{X}} F(x, f(x))$$

(in particular, $D_{\mathcal{Y}} F(x, f(x))$ is invertible for all $x \in W$).

XXI.1.2.4. Theorem. [Inverse Function Theorem, Banach Space Version] Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces, U an open subset of $\mathcal{X}$, $F : U \to \mathcal{Y}$ a $\mathcal{C}^r$ function for some r, $1 \leq r \leq \infty$, and $a \in U$. If $Df(a)$ is invertible, then there is a neighborhood V of a, $V \subseteq U$, such that

(i) f is one-to-one on V.

(ii) $f(V)$ is open in $\mathcal{Y}$.

(iii) $Df(x)$ is invertible for all $x \in V$.

(iv) f^{-1} is $\mathcal{C}^r$ on $f(V)$ and, for all $y \in f(V)$,

$$D(f^{-1})(y) = [Df(f^{-1}(y))]^{-1} \ .$$

XXI.1.2.5. Theorem. [General Implicit/Inverse Function Theorem] Let $\mathcal{X}$, $\mathcal{Y}$, and $\mathcal{Z}$ be Banach spaces, U an open subset of $\mathcal{X} \times \mathcal{Y}$, $F : U \to \mathcal{Z}$ a $\mathcal{C}^r$ function, $a \in \mathcal{X}$, $b \in \mathcal{Y}$, $c \in \mathcal{Z}$ with $(a, b) \in U$ and $F(a, b) = c$. If $D_{\mathcal{Y}} F(a, b)$ is invertible, then there are:

(i) An open neighborhood V of (a, b) in $\mathcal{X} \times \mathcal{Y}$, contained in U, such that $D_{\mathcal{Y}} F(x, y)$ is invertible for all $(x, y) \in V$;

(ii) An open neighborhood W of (a, c) in $\mathcal{X} \times \mathcal{Z}$;

(iii) A unique function $G : W \to \mathcal{Y}$ satisfying $G(a, c) = b$ and, for all $(x, z) \in W$, $(x, G(x, z)) \in V$ and

$$F(x, G(x, z)) = z \ .$$

Additionally, G is $\mathcal{C}^r$ on W, and for all $(x, z) \in W$,

$$[DG(x, z)](h, k) = -[D_{\mathcal{Y}} F(x, G(x, z))^{-1} D_{\mathcal{X}} F(x, G(x, z))]h + [D_{\mathcal{Y}} F(x, G(x, z))^{-1}]k$$

for $h \in \mathcal{X}, k \in \mathcal{Y}$.

XXI.1.2.6. Note that in these theorems it is allowed for $\mathcal{X}$, $\mathcal{Y}$, and/or $\mathcal{Z}$ to be the zero Banach space; this is mostly uninteresting except if the $\mathcal{X}$ in XXI.1.2.5. is zero, in which case the result is precisely the Inverse Function Theorem XXI.1.2.4..

XXI.1.2.7. The special case of the Inverse Function Theorem XXI.1.2.4. where f is linear is the Bounded Inverse Theorem. (But the Bounded Inverse Theorem is used in the proof or, depending on one's point of view, is implicit in the assumption that $Df(a)$ is invertible.)

Proofs of the Theorems

We gave two proofs of the theorems in the finite-dimensional case. The induction proof () will not work in the Banach space case, but the fixed-point proof () does with little modification.

XXI.1.2.8. It will suffice to prove the Inverse Function Theorem XXI.1.2.4., since then XXI.1.2.5. will follow as in () (cf. ()), and as in (), the Implicit Function Theorem XXI.1.2.3. is a corollary of XXI.1.2.5. by taking $\mathcal{Z} = \mathcal{Y}$ and $c = 0$, and setting $f(x) = G(x, 0)$.

The Rank and Straightening Theorems

XXI.1.2.9. There are serious difficulties in generalizing the Rank and Straightening Theorems to the infinite-dimensional case, due to at least four problems:

(i) A bounded operator between Banach spaces need not have closed range.

(ii) A closed subspace of a Banach space, even the null space or closure of the range of a bounded operator, need not have a closed complementary subspace.

(iii) A Banach space does not have a canonical basis, and need not have any (Schauder) basis at all.

(iv) It is unclear in the infinite-dimensional case how to define "constant rank."

Even if the Banach spaces are Hilbert spaces, so (ii) does not occur and (iii) can be managed, (i) and (iv) make a full analog of the Rank Theorem impossible.

Nonetheless, there are infinite-dimensional versions of the theorems, with some additional hypotheses:

XXI.1.3. Integration in Banach Spaces

XXI.2. Calculus of Variations

Running roughly parallel to ordinary calculus on the real line or Euclidean space is another version of calculus called *calculus of variations*, which can be thought of as calculus on function spaces. A nutshell description is that the calculus of variations is the study of what functions maximize or minimize an associated quantity (actually, as pointed out in [GF63], this should be called "calculus of variations in the narrow sense," since there is much more to calculus than solving max/min problems, but calculus on function spaces is not well developed beyond this aspect). Two elementary but critical examples are:

(i) Of all curves between two fixed endpoints, the (unique) one with the minimum arc length is a straight line segment ("a line is the shortest distance between two points").

(ii) Of all plane figures bounded by a curve of fixed arc length, the (unique) one of maximum area is a circle (disk).

A somewhat more sophisticated example is the *brachistochrone problem*: of all curves through two fixed points, the one along which a particle will travel under the force of gravity in the least time is a cycloid ().

The historical development of the calculus of variations is also in parallel with the development of ordinary calculus, and many of the big names are the same: Newton, the Bernoullis, Leibniz, Euler (considered the "father" of the calculus of variations), Lagrange, Legendre, Jacobi, Weierstrass, and more recently Hilbert, Lebesgue, Noether, Hadamard, Tonelli, and Marston Morse. It has gone through periods of intense study and relative neglect, with a recent resurgence of interest, in part due to its close connections with control theory.

The place of the calculus of variations in mathematics is somewhere between ordinary calculus, differential geometry, and the theory of differential equations. The calculus of variations is usually thought of as part of "applied mathematics" but, as with differential equations, it cannot be cleanly categorized as such (indeed, the distinction between "pure" and "applied" mathematics is a very hazy one in general!) Although much of the calculus of variations historically predates the development of functional analysis, a modern treatment falls most appropriately under "nonlinear functional analysis."

The calculus of variations is one of the parts of mathematics most intimately connected with physics (although the applications now go far beyond physics to many areas of pure and applied mathematics). The connection is not only historical, with many of the motivations and applications of the theory coming from important problems in physics, but goes much deeper: the "variational principles" of the calculus of variations can be viewed not only as mathematical principles, but also as deep and fundamental physical laws ("principles of least action"). See [HT96] for a delightful and mostly nontechnical treatment.

Our treatment of the calculus of variations will be far from complete; we will merely try to hit the high points and place the theory in context. There are a number of texts covering the theory in detail, such as [Bol61], [For60], [Car65]–[Car67],[**?**], [Bli46], [Par62], [vB04], [Ewi85], [GH96a]–[GH96b], [JLJ98], ..., and several Russian texts available in English translation such as [Akh88], [Esc62], [GF63]. For "calculus of variations in the large," see [Mor96] and [**?**]. See [Gol80] for a history of the subject through the nineteenth century.

XXI.2.1. The Isoperimetric Problem

XXI.2.1.1. As pointed out by Dirichlet, there is a subtle gap in the proof of the isoperimetric problem we have outlined. We have shown that no simple closed curve of arc length L other than a circle can enclose

a region of maximal area; thus we have only shown that a circle is the only simple closed curve which *can* enclose a maximal area, not that it *does*. In other words, we have shown that *if* there is *any* curve enclosing a maximal area, it must be a circle, but we have not yet shown there is a curve realizing the maximum. Filling this gap turns out to be quite tricky – we must use some type of compactness argument.

XXI.2.1.2. For a simple example of the difficulty, consider the following argument (attributed to PERRON). This argument may seem silly, but it is actually far less silly than it appears. Let N be the largest natural number. If n is any natural number other than 1, then $n^2 > n$, so N cannot be n. Therefore $N = 1$.

Chapter XXII

Measure and Topology; Generalized Functions and Distributions

This chapter covers two seemingly distinct subjects: Borel measures on locally compact spaces, and the theory of generalized functions and distributions on $\mathbb{R}$ and $\mathbb{R}^n$. The common theme is that both can be naturally and profitably regarded in functional analysis terms, as continuous linear functionals on spaces of ordinary functions.

XXII.1. Measures on Locally Compact Spaces

XXII.1.1. Regular Measures

XXII.1.2. The Riesz Representation Theorem

XXII.2. Distributions

XXII.2.1. Generalized Functions on $\mathbb{R}$

XXII.2.1.1. The notion of a real-valued (or complex-valued) function on a space seems to entail specification of its values at points of the space. But a functional analysis point of view is to regard functions as themselves points of another space, with properties not closely tied to their values at particular points (e.g. as objects which can be integrated).

XXII.2.1.2. This shift of point of view already appears when L^p spaces are considered. The elements of L^p are technically not functions, but equivalence classes of functions which agree a.e.; thus it does not make sense to talk about the value of an "L^p-function" at any particular point – only the general behavior at "most" points is determined and relevant.

XXII.2.1.3. Another example is the "Dirac δ-function": this is a fictitious function with certain desirable properties which no actual function can have. We have an interpretation of this "function" as a measure (point mass), but we want to somehow regard it as a "generalized function."

XXII.2.1.4. There are (at least) two worthwhile approaches toward generalizing the notion of a function which are well developed in the literature, via functionals on spaces of "test functions" and as limits of ordinary functions. We will begin with the first approach, which was the first historically and which is the dominant one, and return to the second in (). It is useful to have both points of view, since some aspects of the theory are simpler from each.

XXII.2.1.5. We will work on a general open set Ω in $\mathbb{R}$ or, later, $\mathbb{R}^n$, which we may take to be connected without essential loss of generality (the analysis on a general open set can be almost completely reduced to the connected components). Thus, in the one-dimensional case, we may take Ω to be an open interval. The most important case is $\Omega = \mathbb{R}$ (or, later, $\mathbb{R}^n$).

We begin with two natural sets of actual functions on an open interval $\Omega \subseteq \mathbb{R}$:

XXII.2.1.6. DEFINITION. An *ordinary function* on Ω is a function from Ω to $\mathbb{R}$ (or $\mathbb{C}$) which is Lebesgue measurable, and Lebesgue integrable over each closed bounded subinterval of Ω. Denote the set of ordinary functions by $\mathcal{L}^1_{\text{loc}}(\Omega)$ ("locally integrable functions"). Write $L^1_{\text{loc}}(\Omega)$ for the set of equivalence classes of locally integrable functions, with functions agreeing a.e. identified.

A *test function* is a $\mathcal{C}^\infty$ function from Ω to $\mathbb{R}$ (or $\mathbb{C}$) with compact support, i.e. which is zero outside a compact (closed bounded) subinterval of Ω. Denote the set of test functions by $\mathcal{D}(\Omega) = \mathcal{C}^\infty_c(\Omega)$ (or just $\mathcal{D}$ if Ω is understood); the notation $\mathcal{K}(\Omega)$ is also common in the literature.

We also write $\mathcal{E}(\Omega)$ for $\mathcal{C}^\infty(\Omega)$, the set of $\mathcal{C}^\infty$ functions on Ω with no restriction on support and not necessarily bounded. We have $\mathcal{D}(\Omega) \subseteq \mathcal{E}(\Omega)$.

As usual, by slight abuse we will think of the elements of $L^1_{\text{loc}}(\Omega)$ as "functions" although, as noted above, it does not make sense to consider their values at individual points. The sets $\mathcal{L}^1_{\text{loc}}(\Omega)$, $L^1_{\text{loc}}(\Omega)$, and $\mathcal{D}(\Omega)$ are vector spaces in the obvious way. The set $\mathcal{C}(\Omega)$ of continuous functions on Ω is a subspace of $\mathcal{L}^1_{\text{loc}}(\Omega)$, and the quotient map from $\mathcal{L}^1_{\text{loc}}(\Omega)$ to $L^1_{\text{loc}}(\Omega)$ is injective on this subspace, i.e. there is a natural embedding of $\mathcal{C}(\Omega)$ into $L^1_{\text{loc}}(\Omega)$. Since $\mathcal{D}(\Omega) \subseteq \mathcal{E}(\Omega) \subseteq \mathcal{C}(\Omega)$, they can be regarded as subspaces of $L^1_{\text{loc}}(\Omega)$.

XXII.2.1.7. Each ordinary function f defines a linear functional on $\mathcal{D}(\Omega)$ by

$$\langle f, \phi \rangle = \int_\Omega f \phi \, d\lambda$$

for $\phi \in \mathcal{D}(\Omega)$. (Note that for each ϕ, the integral is really over a compact subinterval.) These linear functionals are actually defined on a much larger space of functions than $\mathcal{D}$, e.g. the space of bounded measurable functions on Ω with compact support, but we only apply them to test functions for reasons which will become apparent. The notation suggests an inner product, and in fact extends the standard inner product on $\mathcal{D}(\Omega)$ regarded as a subspace of $\mathcal{L}^1_{\text{loc}}(\Omega)$. The inner product view is a useful one, cf. ().

If $f = g$ a.e., then f and g define the same linear functional. Conversely:

XXII.2.1.8. PROPOSITION. Let f and g be ordinary functions. If $\langle f, \phi\rangle = \langle g, \phi\rangle$ for all test functions ϕ, then $f = g$ a.e.

PROOF: By linearity, it suffices to show that if f is an ordinary function and $\langle f, \phi\rangle = 0$ for every test function ϕ, then $f = 0$ a.e. Fix an interval $[a, b] \subseteq \Omega$, and for $x \in [a, b]$ define

$$F(x) = \int_a^x f\, d\mu \ .$$

Then F is absolutely continuous on $[a, b]$, and $F' = f$ a.e. on $[a, b]$. Suppose F is not constant on $[a, b]$, and fix $x_1, x_2 \in (a, b)$ with $F(x_1) < F(x_2)$, and fix a real number c with $F(x_1) < c < F(x_2)$. By continuity, there are disjoint closed subintervals $[a_1, b_1]$ and $[a_2, b_2]$ of $[a, b]$ containing x_1 and x_2 respectively in their interiors, such that $F(x) < c$ for all $x \in [a_1, b_1]$ and $F(x) > c$ for all $x \in [a_2, b_2]$. Then there is a $\mathcal{C}^\infty$ function ψ supported on $[a_1, b_1] \cup [a_2, b_2]$, with ψ positive on $[a_1, b_1]$ and negative on $[a_2, b_2]$, and such that

$$\int_{a_2}^{b_2} \psi(t)\, dt = -\int_{a_1}^{b_1} \psi(t)\, dt \ .$$

Set

$$\phi(x) = \int_a^x \psi(t)\, dt$$

for $x \in \mathbb{R}$. Then ϕ is $\mathcal{C}^\infty$ and vanishes outside $[a, b]$, hence is a test function, and $\phi' = \psi$. Using Integration by Parts, we have, since $\phi(a) = \phi(b) = 0$ and $(F - c)' = f$ a.e.,

$$\int_{\mathbb{R}} f\phi\, d\lambda = \int_a^b f\phi\, d\lambda = (F(b) - c)\phi(b) - (F(a) - c)\phi(a) - \int_a^b (F(t) - c)\psi(t)\, dt$$

$$= -\int_a^b (F(t) - c)\psi(t)\, dt = -\int_{a_1}^{b_1} (F(t) - c)\psi(t)\, dt - \int_{a_2}^{b_2} (F(t) - c)\psi(t)\, dt > 0$$

since both integrals are strictly negative because the integrands are strictly negative, contradicting that $\int_{\mathbb{R}} f\phi\, d\lambda = 0$.

Thus F is constant on $[a, b]$ (actually identically 0 since $F(a) = 0$), and hence $f = F' = 0$ a.e. on $[a, b]$. Since $[a, b]$ is arbitrary, $f = 0$ a.e. on Ω.

Convergence in $\mathcal{D}(\Omega)$

XXII.2.1.9. We define convergence of sequences in $\mathcal{D}$ as follows. If (ϕ_n) is a sequence in $\mathcal{D}$, $\phi \in \mathcal{D}$, then $\phi_n \to \phi$ in $\mathcal{D}$ if and only if there is a fixed closed bounded interval $[a, b] \subseteq \Omega$ such that all ϕ_n vanish outside $[a, b]$ and $\phi_n^{(k)} \to \phi^{(k)}$ uniformly on $[a, b]$ for each $k \geq 0$.

Note that this notion of convergence is strictly stronger than uniform convergence of (ϕ_n) and all its derivatives, since the ϕ_n must all be supported on the same fixed compact subinterval.

XXII.2.1.10. This notion of convergence of sequences in $\mathcal{D}$ is precisely convergence of sequences for a certain locally convex vector space topology on $\mathcal{D}$ (XXII.2.1.14.). Although this topology is not first countable, continuity of linear functionals is completely determined by convergence of sequences in $\mathcal{D}$ (XXII.2.1.15.).

XXII.2.1.11. PROPOSITION. Let $f \in \mathcal{L}^1_{\text{loc}}(\Omega)$. Then the linear functional defined on $\mathcal{D}(\Omega)$ by f is sequentially continuous in the sense that if $\phi_n \to \phi$ in $\mathcal{D}(\Omega)$, then $\langle f, \phi_n\rangle \to \langle f, \phi\rangle$.

PROOF: If $\phi_n \to \phi$, fix an $[a,b]$ outside which all ϕ_n vanish. Since $\phi_n \to \phi$ uniformly on $[a,b]$, they are uniformly bounded, i.e. there is an M such that $|\phi_n(x)| \le M$ for all n and all $x \in [a,b]$. We have $f\phi_n \to f\phi$ pointwise on $[a,b]$, and $|f\phi_n| \le M|f|$ on $[a,b]$, so

$$\int_{\mathbb{R}} f\phi_n \, d\lambda = \int_a^b f\phi_n \, d\lambda \to \int_a^b f\phi \, d\lambda = \int_{\mathbb{R}} f\phi \, d\lambda$$

by the Dominated Convergence Theorem. 👍

It follows (XXII.2.1.15.) that the linear functional is actually continuous for the topology on $\mathcal{D}$. Note that we did not use the full strength of convergence in $\mathcal{D}$ in the proof: the linear functional is even continuous for the weaker topology on $\mathcal{D}$ as a subspace of $\mathcal{C}_c(\Omega)$ with its topology from ().

Topology and Convergence in $\mathcal{D}(\Omega)$

XXII.2.1.12. Let $I = [a,b]$ be an interval. Define norms $\|\cdot\|_n$ $(n \ge 0)$ on $\mathcal{C}^\infty([a,b])$ by

$$\|\phi\|_{n,I} = \sum_{k=0}^{n} \left[\max_{a \le x \le b} |\phi^{(k)}(x)| \right] .$$

Then $\mathcal{C}^\infty([a,b])$ is a Fréchet space with its topology from this family of norms (), and

$$\mathcal{C}^\infty_0([a,b]) = \{\phi \in \mathcal{C}^\infty([a,b]) : \phi^{(k)}(a) = \phi^{(k)}(b) = 0 \text{ for all } k \ge 0\}$$

is a closed subspace, hence also a Fréchet space. If $[a,b] \subseteq \Omega$, then $\mathcal{C}^\infty_0([a,b])$ can be naturally considered a subspace of $\mathcal{C}^\infty_c(\Omega)$, and

$$\mathcal{C}^\infty_c(\Omega) = \bigcup_{[a,b]\subseteq\Omega} \mathcal{C}^\infty_0([a,b]) = \bigcup_{n=1}^{\infty} \mathcal{C}^\infty_0([a_n,b_n])$$

where $([a_n,b_n])$ is an increasing sequence of intervals with union Ω. We give $\mathcal{D} = \mathcal{C}^\infty_c(\Omega)$ the inductive limit topology. Note that if $[a,b] \subseteq [c,d]$, the embedding of $\mathcal{C}^\infty_0([a,b])$ into $\mathcal{C}^\infty_0([c,d])$ is a homeomorphism onto its image, which is a closed set; thus the restriction of the inductive limit topology to $\mathcal{C}^\infty_0([a,b])$ is its Fréchet topology. The topology on $\mathcal{D}(\Omega)$ is locally convex, but not metrizable (not first countable).

XXII.2.1.13. Alternatively, we can give a local base at 0 for the topology on $\mathcal{D}$ as follows. Let $\boldsymbol{c} = (c_1, c_2, \dots)$ be a sequence of strictly positive real numbers. Then for each $n \in \mathbb{N}$ set

$$U_{n,\boldsymbol{c}} = \{\phi \in \mathcal{D}(\Omega) : |\phi^{(k)}(x)| < c_m \text{ for } a_m \le x \le b_m \ \forall m, 0 \le k \le n\} .$$

It is a straightforward exercise to show that these sets are convex and open and (for all n and $\boldsymbol{c}$) form a local base at 0, and translates a local base at any ϕ.

XXII.2.1.14. PROPOSITION. If (ϕ_n) is a sequence in $\mathcal{D}(\Omega)$, $\phi \in \mathcal{D}(\Omega)$, then $\phi_n \to \phi$ in the inductive limit topology if and only if $\phi_n \to \phi$ in the sense of XXII.2.1.9..

PROOF: It is obvious that if $\phi_n \to \phi$ in the sense of XXII.2.1.9., then $\phi_n \to \phi$ in the inductive limit topology. Conversely, suppose $\phi_n \to 0$ in the inductive limit topology. Then clearly $\phi_n^{(k)} \to 0$ uniformly on Ω for all k (for any k and $\epsilon > 0$ consider $U_{k,\boldsymbol{c}}$, where $\boldsymbol{c} = (\epsilon, \epsilon, \dots)$). To see that the ϕ_n must all vanish outside some fixed $[a_m, b_m]$, suppose not. Then, passing to a subsequence, we may assume that for each n there is an $x_n \in \Omega$ with $x_n \notin [a_n, b_n]$ and $\phi_n(x_n) \neq 0$. Choose a decreasing sequence (c_n) of strictly positive real numbers with $c_n < |\phi_n(x_n)|$. If $\boldsymbol{c} = (c_1, c_2, \dots)$, then $\phi_n \notin U_{1,\boldsymbol{c}}$ for any n, a contradiction. 👍

XXII.2.1.15. COROLLARY. A linear functional f on $\mathcal{D}(\Omega)$ is continuous if and only if $\langle f, \phi_n \rangle \to \langle f, \phi \rangle$ whenever $\phi_n \to \phi$.

PROOF: A linear functional on $\mathcal{D}(\Omega)$ is continuous if and only if its restriction to $\mathcal{C}_0^\infty([a,b])$ is continuous for every $[a,b] \subseteq \Omega$. But $\mathcal{C}_0^\infty([a,b])$ is metrizable, so continuity of functionals on it is determined by sequential continuity. 👍

XXII.2.1.16. PROPOSITION. A linear functional f on $\mathcal{D}(\Omega)$ is continuous if and only if, for every closed bounded interval $I \subseteq \Omega$, there is an n and $c > 0$ such that

$$|f(\phi)| \leq c\|\phi\|_{n,I}$$

for all ϕ supported in I.

PROOF: If the condition is satisfied and $\phi_k \to \phi$ in $\mathcal{D}(\Omega)$, all the ϕ_k are supported in some I. Let n and c correspond to I. The restriction of f to the functions supported in I is bounded with respect to the norm $\|\cdot\|_{n,I}$, hence continuous (), and hence is also continuous with respect to the stronger $\mathcal{D}$-topology.

Conversely, if the condition is not satisfied for some I, there is for each n a ϕ_n supported in I such that $f(\phi_n) = 1$ and $\|\phi_n\|_{n,I} < \frac{1}{n}$. Then $\phi_n \to 0$ in $\mathcal{D}(\Omega)$ but $f(\phi_n) \not\to 0$, so f is not continuous. 👍

XXII.2.1.17. Similarly, if (I_n) is an increasing sequence of closed bounded intervals with union Ω, we give $\mathcal{E}(\Omega)$ the topology defined by the norms $\|\cdot\|_{n,I_n}$. Thus $\phi_n \to \phi$ in $\mathcal{E}(\Omega)$ if and only if $\phi_n^{(k)} \to \phi^{(k)}$ u.c. on Ω for every k. Then $\mathcal{E}(\Omega)$ is a Fréchet space. Note that the topology on $\mathcal{D}(\Omega)$ is strictly stronger than the relative topology from $\mathcal{E}(\Omega)$. ✋

Generalized Functions

We thus make the following definition:

XXII.2.1.18. DEFINITION. A *generalized function* or *distribution* on Ω is a (sequentially) continuous linear functional on $\mathcal{D}(\Omega)$. A generalized function which is defined by an ordinary function as above is called an *ordinary function*. Denote the set of generalized functions on Ω by $\mathcal{D}'(\Omega)$ (or just $\mathcal{D}'$ if Ω is understood); $\mathcal{K}'(\Omega)$ is also used.

There is slight abuse of terminology here: an ordinary function in this sense corresponds to an a.e. equivalence class of ordinary functions in the sense of XXII.2.1.6., via the correspondence $f \mapsto \langle f, \cdot \rangle$. This correspondence is injective by XXII.2.1.8., i.e. $L^1_{\text{loc}}(\Omega)$ can be thought of as a subspace of the vector space $\mathcal{D}'(\Omega)$.

The notation $\mathcal{D}'$ is standard in distribution theory for the dual space (cf. ()), and has nothing to do with derivatives as defined in XXII.2.1.25.; the notation $\mathcal{D}^*$ would be less confusing, but we stick to convention.

There are many other generalized functions:

XXII.2.1.19. EXAMPLES. (i) Define δ by

$$\langle \delta, \phi \rangle = \phi(0) \ .$$

If $\phi_n \to \phi$ in $\mathcal{D}(\mathbb{R})$, then certainly $\phi_n \to \phi$ pointwise, so $\langle \delta, \phi_n \rangle \to \langle \delta, \phi \rangle$, and δ is continuous. This is the "Dirac δ-function."

(ii) More generally, let μ be a Radon measure on $\mathbb{R}$, i.e. a signed or complex Borel measure which is finite on bounded sets. Define a linear functional on $\mathcal{D}(\mathbb{R})$ by

$$\langle \mu, \phi \rangle = \int_{\mathbb{R}} \phi \, d\mu \ .$$

If ϕ is supported in $[a, b]$, $\mu|_{[a,b]}$ is finite, so the integral is defined. If $\phi_n \to \phi$ in $\mathcal{D}$, the ϕ_n are all supported in some $[a, b]$ and converge uniformly to ϕ, so, since $\mu|_{[a,b]}$ is finite,

$$\int_{\mathbb{R}} \phi_n \, d\mu = \int_a^b \phi_n \, d\mu \to \int_a^b \phi \, d\mu = \int_{\mathbb{R}} \phi \, d\mu \ .$$

Thus the linear functional is continuous. By the Radon-Nikodým Theorem, the ordinary functions can be identified with the Radon measures which are absolutely continuous with respect to Lebesgue measure: if $\mu \ll \lambda$, then μ is identified with its density function $\left[\frac{d\mu}{d\lambda}\right]$.

(iii) Functions which are not ordinary functions can define generalized functions. For example, $f(x) = \frac{1}{x}$ is not an ordinary function since it is not locally integrable around 0. But we can use Cauchy principal value to define a linear functional:

$$\langle f, \phi \rangle = (PV) \int_{\mathbb{R}} \frac{\phi(x)}{x} \, d\lambda$$

$$= \lim_{\epsilon \to 0} \left[\int_{-\infty}^{-\epsilon} \frac{\phi(x)}{x} \, dx + \int_{\epsilon}^{\infty} \frac{\phi(x)}{x} \, dx \right]$$

$$= \lim_{\epsilon \to 0} \left[\int_{\epsilon}^{\infty} \frac{\phi(x)}{x} \, dx - \int_{\epsilon}^{\infty} \frac{\phi(-x)}{x} \, dx \right]$$

$$= \lim_{\epsilon \to 0} \int_{\epsilon}^{\infty} \frac{\phi(x) - \phi(-x)}{x} \, dx \ .$$

Since ϕ is differentiable at 0,

$$\lim_{x \to 0} \frac{\phi(x) - \phi(-x)}{x}$$

exists (and equals $2\phi'(0)$), i.e. $\psi(x) = \frac{\phi(x) - \phi(-x)}{x}$ extends to a continuous function on $\mathbb{R}$ (with compact support); so

$$\langle f, \phi \rangle = \int_{0}^{\infty} \frac{\phi(x) - \phi(-x)}{x} \, dx \ .$$

This linear functional is obviously continuous, and this generalized function is commonly denoted $\frac{1}{x}$.

(iv) We can do higher-order versions of (i) and (ii): for any k, we can define

$$\langle \delta^{(k)}, \phi \rangle = (-1)^k \phi^{(k)}(0)$$

and, more generally, if μ is a Radon measure,

$$\langle \mu^{(k)}, \phi \rangle = (-1)^k \int_{\mathbb{R}} \phi^{(k)} \, d\mu$$

(the reason for the conventional factor of $(-1)^k$ will appear in XXII.2.1.25.).

(v) Define

$$\langle f, \phi \rangle = \sum_{k=0}^{\infty} \phi^{(k)}(k)$$

(this is a finite sum for any ϕ).

XXII.2.1.20. There is a natural topology on $\mathcal{D}'(\Omega)$, the topology of pointwise convergence ("weak-* topology"). A local base for this topology at 0 consists of sets of the form

$$U(\phi_1, \ldots, \phi_m, \epsilon) = \{ f \in \mathcal{D}'(\Omega) : |\langle f, \phi_k \rangle| < \epsilon \text{ for } 1 \leq k \leq m \}$$

where $\phi_1, \ldots, \phi_m \in \mathcal{D}(\Omega)$ and $\epsilon > 0$. A net (f_i) in $\mathcal{D}'(\Omega)$ converges to $f \in \mathcal{D}'(\Omega)$ if and only if $\langle f_i, \phi \rangle \to \langle f, \phi \rangle$ for all $\phi \in \mathcal{D}(\Omega)$. This topology is discussed in more detail in ().

XXII.2.1.21. In references and applications, this topology is rarely if ever referred to explicitly; practically all use is in terms of convergence of sequences of generalized functions, i.e. a sequence (f_n) in $\mathcal{D}'(\Omega)$ converges to $f \in \mathcal{D}'(\Omega)$ if and only if $\langle f_n, \phi \rangle \to \langle f, \phi \rangle$ for all $\phi \in \mathcal{D}(\Omega)$; in most references, the topology is simply described via convergence of sequences. (Actually, although this topology is not first countable, it is completely determined, at least on bounded sets, by convergence of sequences just as the topology on $\mathcal{D}(\Omega)$, so the sequential approach is not as sloppy as it might appear.)

Multiplication of Generalized Functions by Smooth Functions

XXII.2.1.22. If f is an ordinary function and α is a $\mathcal{C}^\infty$ function on Ω, not necessarily of compact support or even bounded, we can define αf by usual function multiplication, and it is an ordinary function. If ϕ is a test function, then $\alpha\phi$ is also a test function, and

$$\langle \alpha f, \phi \rangle = \int_\Omega (\alpha f)\phi \, d\lambda = \int_\Omega f(\alpha\phi) \, d\lambda = \langle f, \alpha\phi \rangle \ .$$

Thus, if f is a generalized function, we can define αf as a generalized function by

$$\langle \alpha f, \phi \rangle = \langle f, \alpha\phi \rangle$$

for $\phi \in \mathcal{D}$. If $\phi_n \to \phi$ in $\mathcal{D}$, then all the ϕ_n are supported in some interval $[a, b]$, hence $\alpha\phi_n$ is also supported in $[a, b]$, and by repeated applications of the product rule and standard limit theorems we have $(\alpha\phi_n)^{(k)} \to (\alpha\phi)^{(k)}$ uniformly on $[a, b]$ for each k, i.e. $\alpha\phi_n \to \alpha\phi$ in $\mathcal{D}$, so

$$\langle \alpha f, \phi_n \rangle = \langle f, \alpha\phi_n \rangle \to \langle f, \alpha\phi \rangle = \langle \alpha f, \phi \rangle$$

and αf is a continuous functional. This product agrees with the pointwise product if f is an ordinary function, and αf is again an ordinary function.

XXII.2.1.23. Although the product of an ordinary function with a locally bounded measurable function is well defined and is another ordinary function, there is no reasonable definition of the product of a generalized function with an ordinary function which is not infinitely differentiable (), let alone the product of two generalized functions.

Differentiation of Generalized Functions

Ordinary functions do not have (ordinary) derivatives in general. Even a function which is differentiable everywhere need not have a derivative which is an ordinary function. However, remarkably, generalized functions have (generalized) derivatives of all orders if the "derivative" is properly defined.

XXII.2.1.24. To get started, suppose f is an ordinary function on Ω which is absolutely continuous on each closed bounded subinterval; then f' (defined a.e.) is an ordinary function (XIX.5.2.21.). If ϕ is a test function supported in $[a, b]$, then using Integration by Parts (XIX.5.5.2.) we have:

$$\langle f', \phi \rangle = \int_\Omega f'\phi \, d\lambda = \int_a^b f'\phi \, d\lambda$$

$$= f(b)\phi(b) - f(a)\phi(a) - \int_a^b f\phi' \, d\lambda = -\int_a^b f\phi' \, d\lambda = -\int_\Omega f\phi' \, d\lambda = -\langle f, \phi' \rangle$$

since $\phi(a) = \phi(b) = 0$.

We thus make the following definition:

XXII.2.1.25. Definition. Let f be a generalized function on Ω. Define a new generalized function Df on Ω by

$$\langle Df, \phi \rangle = -\langle f, \phi' \rangle$$

for $\phi \in \mathcal{D}(\Omega)$.

XXII.2.1.26. Since ϕ' is also a test function for every $\phi \in \mathcal{D}$, $\langle Df, \phi\rangle$ is defined. And since whenever $\phi_n \to \phi$ in $\mathcal{D}$, $\phi_n' \to \phi'$ in $\mathcal{D}$, the linear functional Df is (sequentially) continuous.

XXII.2.1.27. If f is differentiable (everywhere) on Ω in the ordinary sense, and f' is an ordinary function, then $Df = f'$ (regarded as a generalized function). More generally, if f is locally absolutely continuous on Ω, i.e. absolutely continuous on closed bounded subintervals of Ω, then Df in the distributional sense is an ordinary function which agrees (a.e.) with the ordinary derivative of f. But if f is not locally absolutely continuous, even if f is differentiable everywhere, the generalized function Df in this sense is not an ordinary function and does not agree with the ordinary derivative of f.

XXII.2.1.28. **Terminology:** There is an inconsistency in the literature about names for this type of derivative. The terms *distributional derivative* and *weak derivative* are used synonymously by most authors, but not always in the same sense: some authors use these terms only in the case where the derivative of an ordinary function in the distributional sense is again an ordinary function. Since it is inefficient to have two terms for the same thing, we will use *distributional derivative* in the general setting (i.e. every generalized function has a distributional derivative which is again a generalized function), and use the term *weak derivative* only in the case where the distributional derivative (and, therefore, the original function too) is an ordinary function. Thus an ordinary function always has a distributional derivative, but may or may not have a weak derivative (if it has a weak derivative, we say it is *weakly differentiable*).

Note also that weak derivatives, when they exist at all, are only determined a.e.; thus it is an abuse of language to talk about *the* weak derivative of a function. If g is a weak derivative for f, then any function equal to g a.e. is also a weak derivative for f (and in fact for any function equal to f a.e.)

XXII.2.1.29. The notation Df for the distributional derivative is in conflict with the notation of () which should cause no confusion. The term "weak derivative," as we use it, also has an unfortunate slight incongruity: we can have a function, e.g. (), which is differentiable but not weakly differentiable.

XXII.2.1.30. If f is locally absolutely continuous on Ω, then it is weakly differentiable on Ω, and its ordinary derivative (defined a.e.) is a weak derivative. Conversely, if f is an ordinary function which is weakly differentiable, then f is equal a.e. to a locally absolutely continuous function g whose ordinary derivative is a weak derivative for f (XXII.2.1.50.). Thus the notions of weak differentiability and weak derivative are (up to a.e. ambiguity) not really a new concept in the one-dimensional case. The situation is much more delicate in higher dimensions: a weakly differentiable function need not even be equal a.e. to a continuous function on any open set (). It is the higher-dimensional case where weak derivatives are especially important.

XXII.2.1.31. We can, of course, repeat the process to define derivatives of all orders: if f is a generalized function, we define $D^n f$ by

$$\langle D^n f, \phi\rangle = (-1)^n \langle f, \phi^{(n)}\rangle$$

for $\phi \in \mathcal{D}$. Thus every generalized function is infinitely differentiable in the distributional sense.

XXII.2.1.32. Examples. (i) Let f be the step function (Heaviside function) $\chi_{[0,+\infty)}$. If ϕ is a test function supported in $[a, b]$, with $a < 0 < b$, we have

$$\phi(0) = \phi(0) - \phi(a) = \int_a^0 \phi'\, d\lambda$$

by the Fundamental Theorem of Calculus and, since $\int_a^0 \phi'\,d\lambda + \int_0^b \phi'\,d\lambda = \int_a^b \phi'\,d\lambda = \phi(b) - \phi(a) = 0$, we have

$$\phi(0) = -\int_0^b \phi'\,d\lambda = -\int_a^b f\phi'\,d\lambda = -\langle f, \phi'\rangle = \langle Df, \phi\rangle$$

so Df is the Dirac δ-function.

(ii) More generally, if f is a measurable function of locally bounded variation, then f can be regarded as the cdf for a Radon measure μ (), and Df is the generalized function defined by μ (XXII.2.1.19.(ii)).

(iii) Let $f(x) = \log|x|$ $(x \neq 0)$. Then f is an ordinary function. If ϕ is a test function, supported in $[-n, n]$, and we set $\psi(x) = \phi(x) - \phi(-x)$ for $x \in \mathbb{R}$, we have

$$\langle Df, \phi\rangle = -\langle f, \phi'\rangle = -\int_{-n}^{n} f\phi'\,d\lambda$$

$$= -\int_{-n}^{0} f\phi'\,d\lambda - \int_0^n f\phi'\,d\lambda = -\lim_{\epsilon\to 0}\left[\int_{-n}^{-\epsilon} f\phi'\,d\lambda + \int_\epsilon^n f\phi'\,d\lambda\right]$$

$$= -\lim_{\epsilon\to 0}\left[\int_\epsilon^n \phi'(-x)\log x\,dx + \int_\epsilon^n \phi'(x)\log x\,dx\right]$$

$$= -\lim_{\epsilon\to 0}\int_\epsilon^n [\phi'(x) + \phi'(-x)]\log x\,dx = -\lim_{\epsilon\to 0}\int_\epsilon^n \psi'(x)\log x\,dx\ .$$

We can evaluate this last integral by parts to obtain

$$\int_\epsilon^n \psi'(x)\log x\,dx = \psi(n)\log n - \psi(\epsilon)\log\epsilon - \int_\epsilon^n \frac{\psi(x)}{x}\,dx\ .$$

We have $\psi(n) = 0$, and

$$\lim_{\epsilon\to 0}\psi(\epsilon)\log\epsilon = \lim_{\epsilon\to 0}\left[\frac{\phi(\epsilon) - \phi(-\epsilon)}{\epsilon}(\epsilon\log\epsilon)\right] = \left[\lim_{\epsilon\to 0}\frac{\phi(\epsilon) - \phi(-\epsilon)}{\epsilon}\right]\left[\lim_{\epsilon\to 0}\epsilon\log\epsilon\right] = 2\phi'(0)\cdot 0 = 0\ .$$

Thus we have

$$\langle Df, \phi\rangle = -\lim_{\epsilon\to 0}\int_\epsilon^n \psi'(x)\log x\,dx$$

$$= -\lim_{\epsilon\to 0}\left[-\psi(\epsilon)\log\epsilon - \int_\epsilon^n \frac{\psi(x)}{x}\,dx\right] = \lim_{\epsilon\to 0}\int_\epsilon^n \frac{\phi(x) - \phi(-x)}{x}\,dx = \left\langle \frac{1}{x}, \phi\right\rangle$$

so Df is the generalized function $\frac{1}{x}$ of XXII.2.1.19.(iii).

The Product Rule holds for the limited multiplication we have defined:

XXII.2.1.33. PROPOSITION. Let f be a generalized function, and α a $\mathcal{C}^\infty$ function. Then

$$D(\alpha f) = \alpha' f + \alpha(Df) \ .$$

PROOF: If ϕ is a test function, we have

$$\begin{aligned} \langle D(\alpha f), \phi\rangle &= -\langle \alpha f, \phi'\rangle = -\langle f, \alpha\phi'\rangle \\ &= -\langle f, (\alpha\phi)' - \alpha'\phi\rangle = -\langle f, (\alpha\phi)'\rangle + \langle f, \alpha'\phi\rangle \\ &= \langle Df, \alpha\phi\rangle + \langle f, \alpha'\phi\rangle = \langle \alpha(Df), \phi\rangle + \langle \alpha' f, \phi\rangle \ . \end{aligned}$$

A Unified Approach

Multiplication by smooth functions and differentiation are examples of a general class of extensions to distributions of operations on test functions.

XXII.2.1.34. PROPOSITION. Let Ω_1 and Ω_2 be regions, and $T : \mathcal{D}(\Omega_1) \to \mathcal{D}(\Omega_2)$ a (sequentially) continuous linear function. If there is a (sequentially) continuous (automatically linear) function $T^* : \mathcal{D}(\Omega_2) \to \mathcal{D}(\Omega_1)$ such that

$$\langle T\phi, \psi\rangle = \langle \phi, T^*\psi\rangle$$

for all $\phi \in \mathcal{D}(\Omega_1)$, $\psi \in \mathcal{D}(\Omega_2)$, then there is a unique (sequentially) continuous extension $\bar{T} : \mathcal{D}'(\Omega_1) \to \mathcal{D}'(\Omega_2)$ of T. The extension $\bar{T}$ satisfies

$$\langle \bar{T} f, \psi\rangle = \langle f, T^*\psi\rangle$$

for all $f \in \mathcal{D}'(\Omega_1)$, $\psi \in \mathcal{D}(\Omega_2)$. $\bar{T}$ is also linear.

PROOF: For $f \in \mathcal{D}'(\Omega_1)$, the formula defines a linear functional $\bar{T}f$ on $\mathcal{D}(\Omega_2)$, so we need only check that this linear functional is (sequentially) continuous, i.e. if $f \in \mathcal{D}'(\Omega_1)$ and $\psi_n \to \psi$ in $\mathcal{D}(\Omega_2)$, then $\langle \bar{T}f, \psi_n\rangle \to \langle \bar{T}f, \psi\rangle$. But

$$\langle \bar{T}f, \psi_n\rangle = \langle f, T^*\psi_n\rangle \to \langle f, T^*\psi\rangle = \langle \bar{T}f, \psi\rangle$$

by continuity of T^* and f.

Uniqueness of $\bar{T}$ follow from the density of $\mathcal{D}(\Omega_1)$ in $\mathcal{D}'(\Omega_1)$ () and continuity of T^*, and linearity is straightforward.

This result is often used in the case $\Omega_1 = \Omega_2$.

XXII.2.1.35. EXAMPLES. (i) Let Ω be a region and $\alpha \in \mathcal{C}^\infty(\Omega)$. Set $\Omega_1 = \Omega_2 = \Omega$ and $T\phi = \alpha\phi$. Then the hypotheses are satisfied with $T^* = T$, and $\bar{T}$ is multiplication by α in the sense of XXII.2.1.22..

(ii) Let $\Omega_1 = \Omega_2 = \Omega$, and $T\phi = \phi'$. Then the hypotheses are satisfied with $T^* = -T$, and $\bar{T}$ is distributional differentiation D.

(iii) Let $c \in \mathbb{R}$, and let Ω_1 be a region. Set $\Omega_2 = c + \Omega_1$ and $T_c\phi(x) = \phi(x - c)$. Then the hypotheses are satisfied with $T_c^* = T_{-c}$, and $\bar{T}_c$ is "translation by c."

(iv) Let Ω_1 be a region, and $\Omega_2 = -\Omega = \{-x : x \in \Omega\}$. Define $R : \Omega_1 \to \Omega_2$ by $(R\phi)(x) = \phi(-x)$. Then the hypotheses are satisfied with $R^* = R$, and $\bar{R}$ is "reflection."

We can alternately phrase distributional differentiation in usual terms via translation. We state this only for $\Omega = \mathbb{R}$, but the same can be done with care for general Ω.

XXII.2.1.36. PROPOSITION. let $f \in \mathcal{D}'(\mathbb{R})$. Then

$$Df = \lim_{\epsilon \to 0} \frac{1}{\epsilon} (T_\epsilon f - f) \ .$$

(where $\mathcal{D}'(\mathbb{R})$ has the topology of pointwise convergence, cf. XXII.2.1.20.).

Convolution

We now restrict to the case $\Omega = \mathbb{R}$.

XXII.2.1.37. Recall (XVIII.5.1.4.) that if ϕ and ψ are test functions, then the convolution $\phi * \psi$ is defined by

$$(\phi * \psi)(x) = \int_{-\infty}^{\infty} \phi(y)\psi(x - y)\, dy$$

and that $\phi * \psi$ is again a test function (XVIII.5.1.7., XVIII.5.1.8.). We have $\phi * \psi = \psi * \phi$ ().

XXII.2.1.38. PROPOSITION. Let (ϕ_n), ϕ, ψ be in $\mathcal{D}(\mathbb{R})$, with $\phi_n \to \phi$ in $\mathcal{D}(\mathbb{R})$. Then $\phi_n * \psi \to \phi * \psi$ in $\mathcal{D}(\mathbb{R})$.

PROOF: This follows immediately from XVIII.5.1.16., XVIII.5.1.7., and XVIII.5.1.8.. 👍

XXII.2.1.39. Let θ be a fixed element of $\mathcal{D}(\mathbb{R})$. Define $S_\theta : \mathcal{D}(\mathbb{R}) \to \mathcal{D}(\mathbb{R})$ by $S_\theta\phi = \theta * \phi$. Then S_θ is linear, and continuous by XXII.2.1.38.. If $\phi, \psi \in \mathcal{D}(\mathbb{R})$, we have

$$\langle S_\theta\phi, \psi \rangle = \int_{-\infty}^{\infty} (\phi * \theta)(x)\psi(x)\, dx = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \phi(y)\theta(x - y)\psi(x)\, dy\, dx$$

$$= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \phi(y)[R\theta](y - x)\psi(x)\, dx\, dy = \int_{-\infty}^{\infty} \phi(y)([R\theta] * \phi)(y)\, dy = \langle \phi, S_{R\theta}\psi \rangle$$

(the integrals are actually only over a bounded rectangle). So the hypotheses of XXII.2.1.34. are satisfied with $S_\theta^* = S_{R\theta}$, and thus S_θ extends to $\bar{S}_\theta : \mathcal{D}'(\mathbb{R}) \to \mathcal{D}'(\mathbb{R})$. If $f \in \mathcal{D}'(\mathbb{R})$, we define $f * \theta = \bar{S}_\theta f$, i.e. for $\psi \in \mathcal{D}(\mathbb{R})$ we have

$$\langle f * \theta, \psi \rangle = \langle f, (R\theta) * \psi \rangle \ .$$

Thus the convolution of a generalized function with a test function is defined, extending usual convolution. We can also write $\theta * f = f * \theta$.

XXII.2.1.40. Continuity of $\bar{S}_\theta$ means that, if $f_n \to f$ in $\mathcal{D}'(\mathbb{R})$, then $f_n * \theta \to f * \theta$ in $\mathcal{D}'(\mathbb{R})$.

XXII.2.1.41. Proposition. Let $f \in \mathcal{D}'(\mathbb{R})$ and $\theta \in \mathcal{D}(\mathbb{R})$. Then $D(f * \theta) = (Df) * \theta$.

Proof: If $\psi \in \mathcal{D}(\mathbb{R})$, then

$$\langle D(f * \theta), \psi \rangle = -\langle f * \theta, \psi' \rangle = -\langle f, (R\theta) * (\psi') \rangle = -\langle f, [(R\theta) * \psi]' \rangle = \langle Df, (R\theta) * \psi \rangle = \langle (Df) * \theta, \psi \rangle$$

by (). 👍

XXII.2.1.42. Example. Let $\phi, \psi \in \mathcal{D}(\mathbb{R})$. Then

$$\langle \delta * \phi, \psi \rangle = \langle \delta, (R\phi) * \psi \rangle = [(R\phi) * \psi](0) = \int_{-\infty}^{\infty} \phi(-y)\psi(0-y)\, dy = \langle \phi, \psi \rangle$$

so $\delta * \phi = \phi$, i.e. convolution with δ is the identity on $\mathcal{D}(\mathbb{R})$.

We will show () that whenever $f \in \mathcal{D}'(\mathbb{R})$ and $\theta \in \mathcal{D}(\mathbb{R})$, we have that $f * \theta$ is actually an ordinary function which is $\mathcal{C}^\infty$, i.e. $f * \theta \in \mathcal{E}(\mathbb{R})$. It is in $\mathcal{D}(\mathbb{R})$ if and only if f has compact support (XXII.2.1.56.).

Integration of Generalized Functions on $\mathbb{R}$

We will show that every generalized function has an antiderivative in $\mathcal{D}'$, and two antiderivatives must differ by a constant.

XXII.2.1.43. Definition. Let

$$\mathcal{D}_0(\Omega) = \left\{ \phi \in \mathcal{D}(\Omega) : \int_\Omega \phi(x)\, dx = 0 \right\}$$

(denoted $\mathcal{D}_0$ when Ω is understood). $\mathcal{D}_0$ is a closed subspace of $\mathcal{D}$.

XXII.2.1.44. A function ϕ is in $\mathcal{D}_0$ if and only if $\phi = \psi'$ for some $\psi \in \mathcal{D}$: if $\psi \in \mathcal{D}$, supported in $[a,b]$, then

$$\int_\Omega \psi'(x)\,dx = \int_a^b \psi'(x)\,dx = \psi(b) - \psi(a) = 0$$

and, conversely, if $\phi \in \mathcal{D}_0$, supported on $[a,b]$, for $x \in \Omega$ set

$$\psi(x) = \int_a^x \phi(t)\,dt\ .$$

Then $\psi' = \phi$, and ψ is supported on $[a,b]$. In fact, each $\phi \in \mathcal{D}_0$ is the derivative of a *unique* $\psi \in \mathcal{D}$ (since such ψ must have compact support). Thus there is a linear map $\rho : \mathcal{D}_0 \to \mathcal{D}$ sending ϕ to ψ, which is continuous (i.e. $\psi \mapsto \psi'$ is a linear homeomorphism from $\mathcal{D}$ onto $\mathcal{D}_0$); $\rho(\psi') = \psi$ for any $\psi \in \mathcal{D}$.

XXII.2.1.45. There is a projection π from $\mathcal{D}$ onto $\mathcal{D}_0$, although not a canonical one. Fix a test function ϕ_1 with $\int_\Omega \phi_1(x)\,dx = 1$, and for $\phi \in \mathcal{D}$ set

$$\pi(\phi) = \phi - \left[\int_\Omega \phi(x)\,dx\right]\phi_1\ .$$

Then π is an idempotent linear map from $\mathcal{D}$ onto $\mathcal{D}_0$. If $\phi_n \to \phi$ in $\mathcal{D}$, then

$$\int_\Omega \phi_n(x)\,dx = \langle 1, \phi_n\rangle \to \langle 1, \phi\rangle = \int_\Omega \phi(x)\,dx$$

and it follows that π is continuous.

XXII.2.1.46. If $f \in \mathcal{D}'$, define $I(f)$ by

$$\langle I(f), \phi\rangle = -\langle f, \rho(\pi(\phi))\rangle\ .$$

Since π and ρ are continuous and linear, $I(f) \in \mathcal{D}'$. If $\phi \in \mathcal{D}$, we have

$$\langle DI(f), \phi\rangle = -\langle I(f), \phi'\rangle = \langle f, \rho(\pi(\phi'))\rangle = \langle f, \phi\rangle$$

since $\pi(\phi') = \phi'$ and $\rho(\phi') = \phi$. Thus $DI(f) = f$, i.e. $I(f)$ is an antiderivative for f.

XXII.2.1.47. Note that the generalized function $I(f)$ depends on the choice of π and hence ϕ_1, and thus is not canonical. However, by XXII.2.1.49., the ambiguity is only up to adding a constant. The next simple result is key, not just here but in the applications of distribution theory to differential equations generally:

XXII.2.1.48. Proposition. Let $f \in \mathcal{D}'$. If $Df = 0$, then f is a constant function (regarded as a generalized function).

Proof: If $\phi \in \mathcal{D}_0$, then $\phi = \psi'$ for a $\psi \in \mathcal{D}$, so

$$\langle f, \phi\rangle = \langle f, \psi'\rangle = -\langle Df, \psi\rangle = 0\ .$$

Set $C = \langle f, \phi_1\rangle$, where ϕ_1 is as in XXII.2.1.45.. Then, for general $\phi \in \mathcal{D}$, we have $\phi = \alpha\phi_1 + \pi(\phi)$, where $\alpha = \int_\Omega \phi(x)\,dx$, so

$$\langle f, \phi\rangle = \langle f, \alpha\phi_1\rangle + \langle f, \pi(\phi)\rangle = \alpha C = \langle C, \phi\rangle\ .$$

XXII.2.1.49. Corollary. Let $f, g \in \mathcal{D}'$. If $Df = Dg$, then f and g differ by a constant.

XXII.2.1.50. If f is an ordinary function, and F is an antiderivative for f in the ordinary sense (i.e. F is locally absolutely continuous and $F' = f$ a.e., cf. ()), then F is an antiderivative in the distribution sense. Thus if g is a generalized function with a weak derivative Dg which is an ordinary function, and G is an ordinary antiderivative for Dg, then $G = g$ plus a constant a.e., i.e. g is equal a.e. to a locally absolutely continuous function (in particular, g is an ordinary function) whose ordinary derivative is equal to Dg a.e.

Support of a Generalized Function

XXII.2.1.51. Recall that the (closed) support of a real- or complex-valued continuous function f is the closure of its cozero set, i.e.

$$supp(f) = \overline{\{x : f(x) \neq 0\}} \ .$$

The support of a discontinuous ordinary function is somewhat tricky to define directly (). But the support of a generalized function is easy to define:

XXII.2.1.52. Definition. Let f be a generalized function, and $E \subseteq \mathbb{R}$ a closed set. Then f is *supported on* E (or *carried on* E) if $\langle f, \phi \rangle = 0$ for every test function ϕ whose (closed) support is disjoint from E. The smallest closed set on which f is supported is called the *support* of f.

For this to make sense, it must be shown that there is a smallest such set. By the next result, the support does indeed exist and is the intersection of all closed sets on which f is supported (there is at least one such set, $\mathbb{R}$).

XXII.2.1.53. Proposition. Let f be a generalized function, and $\{E_i : i \in I\}$ a collection of closed sets in $\mathbb{R}$. If f is supported on each E_i, then f is supported on $E = \cap_{i \in I} E_i$.

Proof: Let ϕ be a test function whose support K is disjoint from E. The open sets $U_i = \mathbb{R} \setminus E_i$ cover K. Since K is compact, a finite number $U_{i_1}, \ldots, U_{i_n}$ cover K. The sets $\{U_{i_1}, \ldots, U_{i_n}, \mathbb{R} \setminus K\}$ are a finite open cover of $\mathbb{R}$. Let $\{h_1, \ldots, h_{n+1}\}$ be a smooth partition of unity subordinate to a shrinking of this open cover (), and set $\phi_j = h_j \phi$. Then the ϕ_j are test functions, and $\phi = \phi_1 + \cdots + \phi_{n+1}$. We have $\phi_{n+1} = 0$ since the support of h_{n+1} is disjoint from K. For $1 \leq j \leq n$ we have $\langle f, \phi_j \rangle = 0$ since the support of ϕ_j is disjoint from E_{i_j}. Thus $\langle f, \phi \rangle = 0$ and f is supported on E. 👍

XXII.2.1.54. Thus the support of a generalized function is defined. Note that the support of a nonzero generalized function is nonempty (the support of 0 is $\emptyset$). If f is a continuous ordinary function, the support of f as a generalized function is just the (closed) support of f as a continuous function. More generally, if f is an ordinary function, then the support of f as a generalized function is the complement of the largest open set U for which $f = 0$ a.e. on U (in fact, the support of a Radon measure μ, regarded as a generalized function, is the complement of the largest open μ-null set; cf. XIII.1.6.6. for existence of such an open set). Thus the support of a function need not be compact. If ϕ is a test function, the (closed) support of ϕ' is contained in the support of ϕ, so if f is a generalized function, the support of f' is contained in the support of f.

XXII.2.1.55. EXAMPLES. (i) The support of δ, or $\delta^{(k)}$ for any k, is $\{0\}$.

(ii) It is not true that $\langle f, \phi\rangle = 0$ in general if ϕ just vanishes on the support of f. For example, if ϕ is a test function with $\phi(0) = 0$ but $\phi'(0) \neq 0$, then $\langle \delta', \phi\rangle \neq 0$. However, if $\phi^{(n)}$ vanishes on the support of f for all n, it is true that $\langle f, \phi\rangle = 0$, since such a ϕ is a limit in $\mathcal{D}$ of a sequence of test functions vanishing in a neighborhood of $supp(f)$.

Distributions with Compact Support

The notion of support of a generalized function is arguably more interesting for generalized functions on $\mathbb{R}^n$, $n > 1$, since in that case a generalized function can be supported on a curve or surface. But even on $\mathbb{R}$, generalized functions with compact support are especially important.

XXII.2.1.56. If f is a generalized function on Ω with compact support S, and $\phi \in \mathcal{D}(\Omega)$, then $\langle f, \phi\rangle$ depends only on the values of ϕ in a neighborhood of S, not on all of Ω: if Λ is an open neighborhood of S contained in Ω, and ϕ and ψ are test functions with $\phi = \psi$ on Λ, then $\psi = \phi + (\psi - \phi)$, and the support of $\psi - \phi$ is disjoint from S, so $\langle f, \psi - \phi\rangle = 0$ and

$$\langle f, \psi\rangle = \langle f, \phi\rangle + \langle f, \psi - \phi\rangle = \langle f, \phi\rangle \ .$$

XXII.2.1.57. The distribution f does not even depend in any essential way on Ω, and can be extended in a natural way to a much larger class of "test functions." Let Λ be an open neighborhood of S whose closure is compact and contained in Ω, and let h be a $\mathcal{C}^\infty$ function supported in Λ and identically 1 on a smaller neighborhood of S. If ψ is any $\mathcal{C}^\infty$ function on $\mathbb{R}$, then $\phi = h\psi \in \mathcal{D}(\Omega)$ and $(1-h)\psi$ is a $\mathcal{C}^\infty$ function on $\mathbb{R}$ whose support is disjoint from S, so it makes sense to define $\langle f, (1-h)\psi\rangle = 0$ and, since $\psi = \phi + (1-h)\psi$,

$$\langle f, \psi\rangle = \langle f, \phi\rangle + \langle f, (1-h)\psi\rangle = \langle f, \phi\rangle \ .$$

If (ψ_n) is a sequence in $\mathcal{C}^\infty(\mathbb{R})$, and there is a $\mathcal{C}^\infty$ function ψ on $\mathbb{R}$ such that $\psi_n^{(k)} \to \psi^{(k)}$ uniformly on Λ for each k, irrespective of what values the ψ_n and ψ take outside Λ, set $\phi_n = h\psi_n$ and $\phi = h\psi$; then $\phi_n, \phi \in \mathcal{D}(\Omega)$ and $\phi_n \to \phi$, so

$$\langle f, \psi_n\rangle = \langle f, \phi_n\rangle \to \langle f, \phi\rangle = \langle f, \psi\rangle \ .$$

Thus the extended linear functional f has a much broader continuity property: it is continuous for the relative topology on $\mathcal{D}(\Omega)$ from the Fréchet topology of $\mathcal{E}(\Omega)$, and extends uniquely to a continuous linear functional on $\mathcal{E}(\Omega)$. Conversely, the restriction to $\mathcal{D}(\Omega)$ of a continuous linear functional on $\mathcal{E}(\Omega)$ is in $\mathcal{D}'(\Omega)$. In fact, we have:

XXII.2.1.58. PROPOSITION. Let Ω be a region. The restrictions to $\mathcal{D}(\Omega)$ of continuous linear functionals on $\mathcal{E}(\Omega)$ are precisely the generalized functions on Ω of compact support.

XXII.2.1.59. Thus we can identify the space $\mathcal{E}'(\Omega)$ of continuous linear functionals on $\mathcal{E}(\Omega)$ with the generalized functions on Ω of compact support.

Topology on $\mathcal{D}'(\Omega)$

XXII.2.1.60. We now discuss the topology on $\mathcal{D}'(\Omega)$ (XXII.2.1.20.) in more detail.

A simple but important property of this topology is that differentiation is continuous:

XXII.2.1.61. PROPOSITION. Let (f_i) be a net in $\mathcal{D}'(\Omega)$. If $f_i \to f$ in $\mathcal{D}'(\Omega)$, then $Df_i \to Df$.

PROOF:

$$\langle Df_i, \phi\rangle = -\langle f_i, \phi'\rangle \to -\langle f, \phi'\rangle = \langle Df, \phi\rangle$$

for any $\phi \in \mathcal{D}(\Omega)$. 👍

By iteration, if $f_i \to f$, then $D^k f_i \to D^k f$ for any k.

XXII.2.1.62. If (f_n) is a sequence (even net) of ordinary functions on Ω, and $f_n \to f$ u.c., then $f_n \to f$ in $\mathcal{D}'(\Omega)$. But the restriction of the topology of $\mathcal{D}'(\Omega)$, even to $\mathcal{C}^\infty(\Omega)$, is far weaker than the topology of u.c. convergence; see XXII.2.1.63..

XXII.2.1.63. EXAMPLES. (i) Let (f_n) be a sequence of locally absolutely continuous functions on Ω, converging u.c. to f on Ω. Then the sequence (f_n') converges to Df in $\mathcal{D}'(\Omega)$. If f is also absolutely continuous, then $f_n' \to f'$ in $\mathcal{D}'(\Omega)$. Note that (f_n') does not converge to f' in any usual functional sense (cf. I.6.1.18.).

(ii) Here is an interesting example of (i). Let $f_n(x) = \frac{1}{n}\sin nx$. Then $f_n \to 0$ uniformly on $\mathbb{R}$. Thus the sequence $f_n'(x) = \cos nx$ converges to 0 in $\mathcal{D}'(\mathbb{R})$, i.e.

$$\lim_{n\to\infty}\left(\int_{\mathbb{R}} \phi(x)\cos nx\, dx\right) = 0$$

for any $\phi \in \mathcal{D}(\mathbb{R})$ (this can be verified directly by integration by parts). This is a version of the Riemann-Lebesgue Lemma (). Note that (f_n') does not converge to 0 in any ordinary functional sense, even pointwise.

Perhaps the most important property of $\mathcal{D}'(\Omega)$ with this topology is that it is (sequentially) complete:

XXII.2.1.64. THEOREM. Let (f_n) be a sequence in $\mathcal{D}'(\Omega)$, and suppose the sequence $(\langle f_n, \phi\rangle)$ converges (i.e. is a Cauchy sequence) for every $\phi \in \mathcal{D}(\Omega)$. Then there is a $f \in \mathcal{D}'(\Omega)$ with $f_n \to f$.

XXII.2.1.65. The definition of f is obvious: if $\phi \in \mathcal{D}(\Omega)$, define

$$\langle f, \phi\rangle = \lim_{n\to\infty}\langle f_n, \phi\rangle\ .$$

It is easily verified that this f is a linear functional on $\mathcal{D}(\Omega)$. We need to show that f is continuous, i.e. $f \in \mathcal{D}'(\Omega)$; then $f_n \to f$ by definition. For this we need a Lemma which is perhaps of independent interest:

XXII.2.1.66. LEMMA. Let (f_n) be a sequence in $\mathcal{D}(\Omega)$ such that $(\langle f_n, \phi\rangle)$ converges for every $\phi \in \mathcal{D}(\Omega)$. Notationally write

$$\langle f, \phi\rangle = \lim_{n\to\infty} \langle f_n, \phi\rangle \ .$$

If (ϕ_n) is a sequence in $\mathcal{D}(\Omega)$ with $\phi_n \to \phi$ in $\mathcal{D}(\Omega)$, then the sequence $(\langle f_n, \phi_n\rangle)$ converges to $\langle f, \phi\rangle$.

XXII.2.1.67. Using the Lemma, we prove that the limit functional is continuous, completing the proof of XXII.2.1.64..

PROOF: It suffices to show that if $\phi_n \to 0$ in $\mathcal{D}(\Omega)$, then $\langle f, \phi_n\rangle \to 0$. If not, passing to a subsequence, there is an $\epsilon > 0$ such that $|\langle f, \phi_n\rangle| > 2\epsilon$ for all n. Then for each n there is an m_n such that $|\langle f_{m_n}, \phi_n\rangle| > \epsilon$. But the subsequence $\langle f_{m_n}, \phi\rangle$ converges to $\langle f, \phi\rangle$ for any ϕ, so by the Lemma $\langle f_{m_n}, \phi_n\rangle \to \langle f, 0\rangle = 0$, a contradiction. 👍

XXII.2.1.68. It remains to prove Lemma XXII.2.1.66..

Infinite Series

XXII.2.1.69. Convergence of infinite series in $\mathcal{D}(\Omega)$ and in $\mathcal{D}'(\Omega)$ has the evident meaning: convergence of the sequence of partial sums. Thus in $\mathcal{D}(\Omega)$ we have

$$\phi = \sum_{k=1}^{\infty} \phi_k$$

if and only if all the ϕ_k are supported in the same compact subinterval of Ω and $\sum_{k=1}^{\infty} \phi_k^{(m)}$ converges uniformly to $\phi^{(m)}$ for all m.

In $\mathcal{D}'(\Omega)$ we have

$$f = \sum_{k=1}^{\infty} f_k$$

if and only if

$$\sum_{k=1}^{\infty} \langle f_k, \phi\rangle$$

converges to $\langle f, \phi\rangle$ for all $\phi \in \mathcal{D}(\Omega)$. By XXII.2.1.64., if

$$\sum_{k=1}^{\infty} \langle f_k, \phi\rangle$$

converges for all $\phi \in \mathcal{D}(\Omega)$, then the series $\sum_{k=1}^{\infty} f_k$ converges in $\mathcal{D}'(\Omega)$.

XXII.2.1.70. Because of the linearity and continuity of differentiation, term-by-term differentiation is valid in both $\mathcal{D}(\Omega)$ and $\mathcal{D}'(\Omega)$: if $\phi = \sum_{k=1}^{\infty} \phi_k$ in $\mathcal{D}(\Omega)$, then $\sum_{k=1}^{\infty} \phi_k^{(m)}$ converges to $\phi^{(m)}$ in $\mathcal{D}(\Omega)$ for any m, and if $f = \sum_{k=1}^{\infty} f_k$ in $\mathcal{D}'(\Omega)$, then $\sum_{k=1}^{\infty} D^m f_k$ converges to $D^m f$ in $\mathcal{D}'(\Omega)$ for any m.

We can decompose an arbitrary distribution as a convergent series of distributions of compact support whose supports "go off to infinity":

XXII.2.1.71. PROPOSITION. Let f be a distribution on $\Omega \subseteq \mathbb{R}$. Then there is a convergent series

$$f = \sum_{k=1}^{\infty} f_k$$

where the f_k have compact support S_k and any compact subset of Ω meets only finitely many S_k.

PROOF: Cover Ω by a sequence $\{I_n : n \in \mathbb{Z}\}$ of open intervals such that $\bar{I}_n$ is compact and contained in Ω, and so that only consecutive $\bar{I}_n$ overlap (), and let $\{h_n : n \in \mathbb{Z}\}$ be a smooth partition of unity subordinate to the I_n (). Set $f_n = h_n f$. Then $h_n f$ is a distribution on Ω whose support is contained in $\bar{I}_n$. If C is a compact subset of Ω, then only finitely many I_n meet C. If $\phi \in \mathcal{D}(\Omega)$, then

$$\langle f, \phi \rangle = \sum_{n \in \mathbb{Z}} \langle f, h_n \phi \rangle = \sum_{n \in \mathbb{Z}} \langle h_n f, \phi \rangle$$

(the sums converge since only finitely many terms are nonzero), so

$$f = \sum_{n \in \mathbb{Z}} h_n f \ .$$

XXII.2.2. Order of Generalized Functions and a Sequential Approach

XXII.2.2.1. DEFINITION. Let Ω be an open interval in $\mathbb{R}$, and $f \in \mathcal{D}'(\Omega)$. Then f has *order* $\leq m$ if there are ordinary functions $f_0, f_1, \ldots, f_m$ such that

$$\langle f, \phi \rangle = \sum_{k=0}^{m} \langle f_k, \phi^{(k)} \rangle$$

for all $\phi \in \mathcal{D}(\Omega)$. The distribution f has *order* m if it has order $\leq m$ but does not have order $\leq m-1$. Write $s(f) = m$ if f has order m.

XXII.2.2.2. In the one-dimensional case, this definition can be simplified. Note that if f is an ordinary function and F is any antiderivative of f, then $\langle f, \phi\rangle = -\langle F, \phi'\rangle$. So if $f \in \mathcal{D}'(\Omega)$ has order $\leq m$ via ordinary functions $f_0, \ldots, f_m$, and for each k we let F_k be a function with $F_k^{(m-k)} = f_k$, then for any ϕ we have

$$\langle f, \phi\rangle = \sum_{k=0}^{m} \langle f_k, \phi^{(k)}\rangle = \sum_{k=0}^{m} (-1)^{m-k} \langle F_k, \phi^{(m)}\rangle = \left\langle \sum_{k=0}^{m} (-1)^{m-k} F_k, \phi^{(m)} \right\rangle$$

i.e. there is an ordinary function F such that $\langle f, \phi\rangle = \langle F, \phi^{(m)}\rangle$, and it follows that f is the m'th distributional derivative of an ordinary function. (Things are more complicated in the multidimensional case.)

XXII.2.2.3. Examples. (i) A distribution has order 0 if and only if it is an ordinary function.

(ii) If f is an ordinary function, then $D^m f$ has order $\leq m$ for any m, and will have order $\leq m-1$ if and only if f is absolutely continuous; if f' is absolutely continuous it will have order $\leq m-2$, etc.

(iii) As a special case of (ii) δ has order ≤ 1 by (), but does not have order 0 by (i), so $s(\delta) = 1$.

(iv) More generally, if μ is a Radon measure on $\mathbb{R}$, regarded as a generalized function as in (), then $s(\mu) \leq 1$; $s(\mu) = 0$ if and only if $\mu \ll \lambda$ by the Radon-Nikodým Theorem.

(v) The distribution of () on $\mathbb{R}$ does not have finite order. There is a similar example on any Ω, taking a strictly increasing sequence (x_k) approaching the right end of Ω and setting

$$\langle f, \phi\rangle = \sum_{k=1}^{\infty} \phi^{(k)}(x_k)$$

for $\phi \in \mathcal{D}(\Omega)$ (this is a finite sum for any such ϕ).

XXII.2.2.4. By XXII.2.2.3.(v), a distribution on Ω need not have finite order. But it is a remarkable and significant fact that a distribution on Ω always has locally finite order (XXII.2.2.6.).

XXII.2.2.5. If Ω and Λ are open intervals in $\mathbb{R}$, with $\Lambda \subseteq \Omega$, there is a restriction map from $\mathcal{D}'(\Omega)$ to $\mathcal{D}'(\Lambda)$ (since $\mathcal{D}(\Lambda)$ is a subspace of $\mathcal{D}(\Omega)$), which is neither injective nor surjective if $\Lambda \neq \Omega$. We will be especially interested in the case where Λ is *compactly contained* in Ω, i.e. the closure of Λ is bounded and contained in Ω (we write $\Lambda \subseteq_c \Omega$; notations such as $\Lambda \subset\subset \Omega$ are also sometimes used).

We will prove the following theorem:

XXII.2.2.6. Theorem. Let $\Lambda \subseteq_c \Omega$ and $f \in \mathcal{D}'(\Omega)$. Then the restriction of f to Λ has finite order.

XXII.2.2.7. The idea of the proof is to show that the restriction of f to Λ is not only in $\mathcal{D}'(\lambda)$, i.e. continuous for the usual topology on $\mathcal{D}(\Lambda)$, but actually continuous for a weaker topology determined by only finitely many derivatives. This will be established using two lemmas.

XXII.2.2.8. LEMMA. Let $\Lambda = (a,b)$ be compactly contained in Ω, and $f \in \mathcal{D}'(\Omega)$. Then there is an $m \in \mathbb{N}$ and a constant C such that

$$|\langle f, \phi\rangle| \leq C \sum_{k=0}^{m} \|\phi^{(k)}\|_\infty$$

for all $\phi \in \mathcal{D}(\Lambda)$.

PROOF: Suppose not. Then for each m there is a $\phi_m \in \mathcal{D}(\Lambda)$ such that

$$|\langle f, \phi_m\rangle| > m \sum_{k=0}^{m} \|\phi_m^{(k)}\|_\infty \ .$$

This inequality is unchanged if ϕ_m is multiplied by a nonzero constant, so we may assume that

$$\sum_{k=0}^{m} \|\phi_m^{(k)}\|_\infty = \frac{1}{m}$$

by renormalizing ϕ_m; thus $|\langle f, \phi_m\rangle| > 1$ for all m. Then $\phi_m \to 0$ in $\mathcal{D}'(\Omega)$ since the ϕ_m are all supported in $\bar{\Lambda}$ and $\lim_{m\to\infty} \|\phi_m^{(k)}\|_\infty = 0$ for all k. Thus $\langle f, \phi_m\rangle \to 0$ since f is continuous, a contradiction. 👍

XXII.2.2.9. LEMMA. Let $\Lambda = (a,b)$ be compactly contained in Ω, and $f \in \mathcal{D}'(\Omega)$. Then there is an $m \in \mathbb{N}$ and a constant C_2 such that

$$|\langle f, \phi\rangle| \leq C_2 \sum_{k=1}^{m+1} \|\phi^{(k)}\|_2$$

for all $\phi \in \mathcal{D}(\Lambda)$, where

$$\|\phi\|_2 = \left[\int_a^b \phi^2 \, d\lambda\right]^{1/2} \ .$$

PROOF: Let m and C be as in XXII.2.2.8., and let $\phi \in \mathcal{D}(\Lambda)$. For $0 \leq k \leq m$, we have, for all $x \in [a,b]$,

$$\phi^k(x) = \int_a^x \phi^{(k+1)} \, d\lambda \ .$$

Applying the CBS inequality with the function $\phi^{(k+1)}$ and the constant function 1, we have, for $x \in [a,b]$,

$$|\phi^{(k)}(x)|^2 = \left|\int_a^x 1 \cdot \phi^{(k+1)} \, d\lambda\right|^2 \leq \left[\int_a^x 1^2 \, d\lambda\right] \left[\int_a^x (\phi^{(k+1)})^2 \, d\lambda\right]$$

$$\leq \left[\int_a^b 1^2 \, d\lambda\right] \left[\int_a^b (\phi^{(k+1)})^2 \, d\lambda\right] = (b-a)\|\phi^{(k+1)}\|_2^2$$

and thus

$$\|\phi^{(k)}\|_\infty \leq \sqrt{b-a}\|\phi^{(k+1)}\|_2$$

$$|\langle f, \phi\rangle| \leq C \sum_{k=0}^{m} \|\phi^{(k)}\|_\infty \leq C\sqrt{b-a} \sum_{k=1}^{m+1} \|\phi^{(k)}\|_2 \ .$$

We now prove Theorem XXII.2.2.6..

PROOF: Let $\Lambda = (a, b) \subseteq_c \Omega$, and let m and C_2 be as in Lemma XXII.2.2.9.. Put an inner product on $\mathcal{D}(\Lambda)$ by

$$\langle \phi, \psi\rangle = \sum_{k=1}^{m+1} \left[\int_a^b \phi^{(k)} \psi^{(k)} \, d\lambda \right]$$

and let $\|\cdot\|$ be the corresponding norm. Then f is a bounded linear functional on $\mathcal{D}(\Lambda), \|\cdot\|)$ by Lemma XXII.2.2.9., so extends to a bounded linear functional on the completion $\mathcal{H}$. We may identify $\mathcal{H}$ with a subspace of

$$\bigoplus_{k=1}^{m+1} L^2([a, b])$$

with its natural Hilbert space norm. By the Riesz Representation Theorem (), there is a vector $\xi \in \mathcal{H}$ such that

$$\langle f, \eta\rangle = \langle \xi, \eta\rangle$$

for all $\eta \in \mathcal{H}$ (where $\langle\cdot,\cdot\rangle$ on the left is the action of f on $\mathcal{H}$ and the $\langle\cdot,\cdot\rangle$ on the right is the inner product in $\mathcal{H}$). We have

$$\eta = (f_1, \ldots, f_{n+1})$$

for some $f_1, \ldots, f_{m+1} \in \mathcal{L}^2([a, b]) \subseteq \mathcal{L}^1([a, b])$, i.e.

$$\langle f, \phi\rangle = \sum_{k=1}^{m+1} \langle f_k, \phi^{(k)}\rangle \ .$$

Putting together XXII.2.2.6. and XXII.2.2.2., we can rephrase the result:

XXII.2.2.10. THEOREM. Let f be a distribution on $\Omega \subseteq \mathbb{R}$, and Λ an open interval compactly contained in Ω. Then there is an $m \in \mathbb{N} \cup \{0\}$ and an absolutely continuous function F on $\bar{\Lambda}$ such that the restriction of f to Λ is $D^m F$ in $\mathcal{D}'(\Lambda)$.

XXII.2.2.11. Note that under the hypotheses of XXII.2.2.10.:

(i) If the conclusion holds for some m, the F is not quite unique, but it is unique up to adding a polynomial of degree $< m$ (regarded as an ordinary function), by repeated applications of XXII.2.1.49..

(ii) If the conclusion holds for some m, it also holds for all larger m by just taking antiderivatives. The smallest such m is one more than the order of f as defined in XXII.2.2.1..

XXII.2.2.12. If f has compact support S in Ω, and Λ is an open neighborhood of S compactly contained in Ω, let $h \in \mathcal{D}(\Lambda)$ with h identically 1 on a smaller neighborhood of S. Then the restriction of f to Λ is hf, and the extension of hf to $\mathcal{C}^\infty(\mathbb{R})$ (XXII.2.1.57.) is the same as the extension of f. The restriction of f to Λ has finite order, and it follows that f itself has finite order, i.e. is the m'th distributional derivative of an absolutely continuous function, for some m.

Using XXII.2.1.71., we obtain:

XXII.2.2.13. Corollary. Let Ω be an open interval in $\mathbb{R}$, and $f \in \mathcal{D}'(\Omega)$. Then there is a sequence (F_k) of absolutely continuous functions on Ω (some of the F_k may be 0) and a sequence (m_k) in $\mathbb{N} \cup \{0\}$ such that

(i) Each F_k has compact support $S_k \subseteq \Omega$.

(ii) Any compact subset of Ω meets only finitely many S_k.

(iii) The infinite series

$$\sum_{k=0}^{\infty} D^{m_k} F_k$$

converges to f in $\mathcal{D}'(\Omega)$.

Conversely, any such infinite series with the F_k continuous (or just locally integrable) and satisfying (i) and (ii) converges to an element of $\mathcal{D}'(\Omega)$.

We can extend the finite order to convergent sequences:

XXII.2.2.14. Theorem. Let Ω be an open interval in $\mathbb{R}$, and (f_n), f with $f_n \to f$ in $\mathcal{D}'(\Omega)$. If $\Lambda \subseteq_c \Omega$, then there is a sequence (F_n) of absolutely continuous functions and an absolutely continuous F, and an m such that:

(i) All the F_n and F are supported on a compact set $C \subseteq \Omega$ containing Λ.

(ii) $F_n \to F$ uniformly on C.

(iii) The restrictions of $D^m F_n$ and $D^m F$ to Λ agree with the restrictions of f_n and f to Λ.

In particular, the restrictions of the f_n and f to Λ have uniformly bounded order.

Thus every convergent sequence in $\mathcal{D}'(\Omega)$ is locally the sequence of derivatives of some fixed order of a uniformly convergent sequence of (absolutely) continuous functions. (This is only true for *sequences*, not nets! The distinction is related to the fact that a weak-* convergent sequence in the dual of a Banach space must be uniformly bounded (XX.8.4.7.), but a weak-* convergent net need not be. In fact, even a convergent net of real numbers is not necessarily bounded.)

This result is equivalent to:

XXII.2.2.15. THEOREM. Let Ω be an open interval in $\mathbb{R}$, and $(f_n) \in \mathcal{D}'(\Omega)$ with $f_n \to 0$ in $\mathcal{D}'(\Omega)$. If $\Lambda \subseteq_c \Omega$, then there is a sequence (F_n) of absolutely continuous functions, and an m such that:

(i) All the F_n are supported on a compact set $C \subseteq \Omega$ containing Λ.

(ii) $F_n \to 0$ uniformly on C.

(iii) The restrictions of $D^m F_n$ to Λ agree with the restrictions of f_n to Λ.

In particular, the restrictions of the f_n to Λ have uniformly bounded order.

XXII.2.2.16. Theorem XXII.2.2.15. is not an immediate special case of XXII.2.2.14., but follows easily: under the hypotheses of XXII.2.2.15. we get (F_n) and F satisfying the conclusion of XXII.2.2.14., with $D^m F = 0$, so we can replace F_n by $F_n - F$ to get XXII.2.2.15.. Conversely, under the hypotheses of XXII.2.2.14., applying XXII.2.2.15. to the sequence $f_n - f$ we get an m_1 and a sequence $G_n \to 0$ with $D^{m_1} G_n = f_n - f$. Also, by XXII.2.2.10. there is an m_2 and F so that $f = D^{m_2} F$ on Λ. We may increase m_1 or m_2 by taking suitable antiderivatives, so we may assume $m_1 = m_2 = m$. Then we may take $F_n = G_n + F$.

Thus it suffices to prove XXII.2.2.15.. The proof follows the scheme of the proof of XXII.2.2.6., using modified versions of the two lemmas.

XXII.2.2.17. LEMMA. Let $\Lambda = (a, b)$ be compactly contained in Ω, and (f_n) a sequence in $\mathcal{D}'(\Omega)$ converging to 0. Then there is an $m \in \mathbb{N}$ and a constant C such that

$$|\langle f_n, \phi \rangle| \leq C \sum_{k=0}^{m} \|\phi^{(k)}\|_\infty$$

for all $\phi \in \mathcal{D}(\Lambda)$ and all n.

PROOF: Suppose not. Then for each m there is a $\phi_m \in \mathcal{D}(\Lambda)$ such that

$$|\langle f_n, \phi_m \rangle| > m \sum_{k=0}^{m} \|\phi_m^{(k)}\|_\infty$$

for infinitely many n. This inequality is unchanged if ϕ_m is multiplied by a nonzero constant, so we may assume that

$$\sum_{k=0}^{m} \|\phi_m^{(k)}\|_\infty = \frac{1}{m}$$

by renormalizing ϕ_m; thus, for each m, $|\langle f_n, \phi_m \rangle| > 1$ for infinitely many n. Inductively choose a strictly increasing sequence (n_m) so that $|\langle f_{n_m}, \phi_m \rangle| > 1$ for all m. Then $\phi_m \to 0$ in $\mathcal{D}'(\Omega)$ since the ϕ_m are all supported in $\bar{\Lambda}$ and $\lim_{m\to\infty} \|\phi_m^{(k)}\|_\infty = 0$ for all k. Thus $\langle f_{n_m}, \phi_m \rangle \to 0$ by XXII.2.1.66., a contradiction. ☝

XXII.2.2.18. LEMMA. Let $\Lambda = (a,b)$ be compactly contained in Ω, and (f_n) a sequence in $\mathcal{D}'(\Omega)$ converging to 0. Then there is an $m \in \mathbb{N}$ and a constant C_2 such that

$$|\langle f_n, \phi\rangle| \leq C_2 \sum_{k=1}^{m+1} \|\phi^{(k)}\|_2$$

for all $\phi \in \mathcal{D}(\Lambda)$ and all n, where

$$\|\phi\|_2 = \left[\int_a^b \phi^2 \, d\lambda\right]^{1/2}.$$

PROOF: The proof is essentially identical to the proof of XXII.2.2.9.. 👍

XXII.2.2.19. Thus, if we let $\mathcal{H}$ be the completion of $\mathcal{D}(\Lambda)$ with respect to the inner product

$$\langle \phi, \psi\rangle = \sum_{k=1}^{m+1} \left[\int_a^b \phi^{(k)}\psi^{(k)} \, d\lambda\right]$$

the sequence (f_n), regarded as a sequence in $\mathcal{H}$, is uniformly bounded and converges to 0 weakly, i.e. $\langle f_n, \eta\rangle \to 0$ for any $\eta \in \mathcal{H}$ (it suffices to check this for $\eta = \phi \in \mathcal{D}(\Lambda)$, where it is true by assumption).

Convolutions Revisited

A significant consequence of the local finite order of distributions is:

XXII.2.2.20. THEOREM. Let $f \in \mathcal{D}'(\mathbb{R})$ and $\phi \in \mathcal{D}(\mathbb{R})$. Then $f * \phi$ is an ordinary function which is $\mathcal{C}^\infty$.

PROOF: It suffices to show that the restriction of $f * \phi$ to any interval $[c,d]$ is an ordinary function which is $\mathcal{C}^\infty$. As in XVIII.5.1.11., the restriction of $f * \phi$ to $[c,d]$ is the same as the restriction of $g * \phi$ to $[c,d]$, where g is the restriction of f to a suitable finite interval. So we may assume f has compact support, and thus finite order, i.e. there is a continuous function F and $k \geq 0$ such that $f = D^k F$. Then $f * \phi = D^k(F * \phi)$. But $F * \phi$ is $\mathcal{C}^\infty$ (XVIII.5.1.8.), so $D^k(F * \phi) = (F * \phi)^{(k)}$ is also $\mathcal{C}^\infty$. 👍

There is a direct proof of this theorem not using (explicitly) the finite order result [].

XXII.2.2.21. DEFINITION. An *ai-sequence* is a sequence (ϕ_n) of nonnegative functions in $\mathcal{D}(\mathbb{R})$ such that

(i) ϕ_n is supported on $[-\delta_n, \delta_n]$ for some sequence (δ_n) with $0 < \delta_n \leq 1$ for all n and $\lim_{n\to\infty} \delta_n = 0$.

(ii) $\displaystyle\int_{-\infty}^{\infty} \phi_n(x)\, dx = \int_{-\delta_n}^{\delta_n} \phi_n(x)\, dx = 1.$

The requirement that the ϕ_n be nonnegative is not essential, but simplifies some arguments.

XXII.2.2.22. PROPOSITION. Let (ϕ_n) be an ai-sequence, and $\psi \in \mathcal{D}(\mathbb{R})$. Then $\phi_n * \psi \to \psi$ in $\mathcal{D}(\mathbb{R})$.

PROOF: Fix ψ. If ψ is supported on $[a,b]$, then $\phi_n * \psi^{(k)}$ is supported on $[a-1, b+1]$ for all n and k. Fix k. If $\epsilon > 0$, then since $\psi^{(k)}$ is uniformly continuous there is a $\delta > 0$ [not the Dirac delta function!] such that $|\psi^{(k)}(x) - \psi^{(k)}(y)| < \epsilon$ whenever $|x-y| < \delta$. Fix N such that $\delta_n < \delta$ for all $n \geq N$. If $n \geq N$, then, for any x, we have

$$\psi^{(k)}(x) - \epsilon = \int_{-\delta_n}^{\delta_n} \phi_n(y)[\psi^{(k)}(x) - \epsilon]\,dy \leq (\phi_n * \psi)^{(k)}(x) = [\phi_n * (\psi^{(k)})](x) = \int_{-\delta_n}^{\delta_n} \phi_n(y)\psi^{(k)}(x-y)\,dy$$

$$\leq \int_{-\delta_n}^{\delta_n} \phi_n(y)[\psi^{(k)}(x) + \epsilon]\,dy = \psi^{(k)}(x) + \epsilon\ .$$

So $(\phi_n * \psi)^{(k)} \to \psi^{(k)}$ uniformly. 👍

XXII.2.2.23. $\mathcal{D}(\mathbb{R})$ is an associative, commutative topological algebra under convolution. It does not have a unit (the Dirac delta function is the "theoretical unit," cf. XXII.2.1.42.). What XXII.2.2.22. says is that an ai-sequence is an *approximate identity* or *approximate unit* (hence the terminology).

XXII.2.2.24. PROPOSITION. Let (ϕ_n) be an ai-sequence, and $f \in \mathcal{D}'(\mathbb{R})$. Then $f * \phi_n \to f$ in $\mathcal{D}'(\mathbb{R})$.

PROOF: Let $\psi \in \mathcal{D}(\mathbb{R})$. Then

$$\langle f * \phi_n, \psi \rangle = \langle f, (R\phi_n) * \psi \rangle \to \langle f, \psi \rangle$$

since $(R\phi_n)$ is also an ai-sequence. 👍

XXII.2.2.25. THEOREM. $\mathcal{D}(\mathbb{R})$ is dense in $\mathcal{D}'(\mathbb{R})$ (hence $\mathcal{E}(\mathbb{R})$, $C(\mathbb{R})$, and $L^1_{\text{loc}}(\mathbb{R})$ are also dense).

PROOF: If $f \in \mathcal{D}'(\mathbb{R})$, let f_n be the restriction of f to $[-n, n]$. It is clear that $f_n \to f$ in $\mathcal{D}'(\mathbb{R})$. So distributions of compact support are dense in $\mathcal{D}'(\mathbb{R})$. Now let f be a distribution of compact support. If (ϕ_n) is an ai-sequence, then $f * \phi_n$ is a $\mathcal{C}^\infty$ function by XXII.2.2.20., and has compact support (), hence is in $\mathcal{D}(\mathbb{R})$, and $f * \phi_n \to f$ in $\mathcal{D}'(\mathbb{R})$ by XXII.2.2.24.. 👍

Using a somewhat more delicate argument, it can be similarly shown that $\mathcal{D}(\Omega)$ is dense in $\mathcal{D}'(\Omega)$ for any Ω.

We can extend convolution to distributions of compact support. As in (), we have:

XXII.2.2.26. PROPOSITION. Let $f \in \mathcal{D}'(\mathbb{R})$ have support in $[a,b]$. If $\phi \in \mathcal{D}(\mathbb{R})$ has support in $[c,d]$, then $f * \phi$ has support in $[a+c, b+d]$. In particular, $f * \phi \in \mathcal{D}(\mathbb{R})$.

XXII.2.2.27. Now let $f, g \in \mathcal{D}'(\mathbb{R})$, with g of compact support. We can define $f * g$ by

$$\langle f * g, \psi \rangle = \langle f, (\bar{R}g) * \psi \rangle$$

(note that $\bar{R}g$ also has compact support). This extends the previous definition of $f * g$ if $g \in \mathcal{D}(\mathbb{R})$.

XXII.2.2.28. We can also define $g * f$ to be $f * g$. This definition makes additional sense because of the next fact, which generalizes ().

XXII.2.2.29. PROPOSITION. Let $g \in \mathcal{D}'(\mathbb{R})$ with compact support. Then $S_g : \mathcal{D}(\mathbb{R}) \to \mathcal{D}(\mathbb{R})$ defined by $S_g(\phi) = g * \phi$ extends to $\tilde{S}_g : \mathcal{E}(\mathbb{R}) \to \mathcal{E}(\mathbb{R})$, and $(\tilde{S}_g \phi) * \psi = \tilde{S}_g(\phi * \psi)$ for all $\phi \in \mathcal{E}(\mathbb{R})$, $\psi \in \mathcal{D}(\mathbb{R})$. [Recall that if $\phi \in \mathcal{E}(\mathbb{R})$, $\psi \in \mathcal{D}(\mathbb{R})$, then $\phi * \psi$ is defined and in $\mathcal{E}(\mathbb{R})$.]

XXII.2.2.30. Thus if $f, g \in \mathcal{D}'(\mathbb{R})$ and g has compact support, and $\phi \in \mathcal{D}(\mathbb{R})$, then $f * \phi \in \mathcal{E}(\mathbb{R})$, so $\tilde{S}_g(f * \phi)$ makes sense. Thus we get a map $\bar{S}_g : \mathcal{D}'(\mathbb{R}) \to \mathcal{D}'(\mathbb{R})$ defined by $[\bar{S}_g f]\phi = \tilde{S}_g(f * \phi)$ for $\phi \in \mathcal{D}(\mathbb{R})$. It is straightforward to check that $\tilde{S}_g(f * \phi) = (f * g) * \phi$, so we may write $g * f$ for $\bar{S}_g f$, in agreement with previous notation.

A Sequential Approach

XXII.2.2.31. Let $f \in \mathcal{D}'(\Omega)$, and let $\Lambda = (a, b) \subseteq_c \Omega$. Fix an m and an absolutely continuous F such that the restriction of f to Λ is $D^m F$. Choose a sequence (p_n) of polynomials converging uniformly to F on $[a, b]$ by the Weierstrass Approximation Theorem. Then the sequence $(p_n^{(m)})$ of m'th derivatives converges in $\mathcal{D}'(\Lambda)$ to the restriction of f. Thus f is represented on Λ by the sequence (p_n) and the number m, abbreviated $((p_n), m)$. (We could equally well use $\mathcal{C}^\infty$ functions instead of polynomials.) Using such an approximating sequence makes description of the derivative in $\mathcal{D}'(\Omega)$ easy: Df is represented by the same sequence (p_n) and the number $m + 1$.

XXII.2.2.32. Such a representing sequence is not unique, but if (q_n) is another representing sequence of polynomials (or $\mathcal{C}^\infty$ functions) for the same m, then $p_n - q_n \to 0$ uniformly on $[a, b]$. One can also have a representing sequence for a larger m by taking suitable antiderivatives (agreeing at some fixed point of $[a, b]$, say a). Thus, on Λ, f is represented by an equivalence class of sequences of polynomials (or $\mathcal{C}^\infty$ functions), where the equivalence relation is the one generated by these two types of equivalences.

We can for convenience consider more general representing sequences (f_n), where each f_n is $\mathcal{C}^\infty$ and (f_n) converges uniformly on $[a, b]$ to a continuous function f which is not necessarily absolutely continuous, and $k \geq 0$. For such a sequence, let F_n be the antiderivative of f_n vanishing at a, and $m = k + 1$; then $((F_n), m)$ is a representing sequence of the previous type.

XXII.2.2.33. Thus distributions on Ω can be defined as objects locally represented by pairs $((f_n), k)$, where (f_n) is a uniformly convergent sequence of $\mathcal{C}^\infty$ functions and $k \geq 0$. Two pairs $((f_n), k)$ and $((g_n), \ell)$ (with, say, $k \leq \ell$) locally represent the same distribution if the sequence $(f_n - g_n^{(\ell - k)})$ converges uniformly to 0. All the basic properties of distributions can be developed rather elegantly this way with modest prerequisites (e.g. Lebesgue integration is not needed). For example, if a distribution is represented locally by $((f_n), k)$, its distributional derivative is locally represented by $((f_n), k + 1)$. And the pairing with test

functions is also easily defined: if F is a distribution on Ω, and $\phi \in \mathcal{D}(\Omega)$, let $[a,b]$ be a closed bounded interval contained in Ω containing the support of ϕ, and let $((f_n),k)$ represent f on $[a,b]$; then the sequence

$$(-1)^k \int_a^b f_n(x)\phi^{(k)}(x)\,dx$$

converges to a number $\langle F,\phi\rangle$ which is readily shown (using integration by parts) to be independent of the choice of $[a,b]$ or the representing sequence and k. Note that only Riemann integration is used here.

Thus each distribution is locally a "k'th order limit of a uniformly convergent sequence of smooth functions" (cf. I.6.1.18.). This approach, which is strongly reminiscent of the construction of the real numbers via Cauchy sequences (III.5.2.), is described in detail in [AMS73].

XXII.2.2.34. The description can be streamlined: a distribution F is locally represented by a pair (f,k), where f is a continuous function and $k \geq 0$. Such a pair corresponds to a pair $((f_n),k)$, where (f_n) is a sequence of C^∞ functions converging uniformly to f [if $((g_n),k)$ is another local representation equivalent to $((f_n),k)$, then (f_n) and (g_n) have the same limit]. We have (f,k) equivalent to (g,ℓ) $(k \leq \ell)$ if $g \in \mathcal{C}^{\ell-k}$ and $f - g^{(\ell-k)}$ is a polynomial of degree less than k. If a distribution is locally represented by (f,k), its distributional derivative is locally represented by $(f,k+1)$, and if $\phi \in \mathcal{D}(\Omega)$, and the distribution F is locally represented on an $[a,b]$ by (f,k), we have

$$\langle F,\phi\rangle = (-1)^k \int_a^b f(x)\phi^k(x)\,dx\ .$$

This approach, developed in [], is clean but it is harder to derive some properties than in the sequence approach.

XXII.2.2.35. If $\Lambda_1 \subseteq \Lambda_2 \subseteq_c \Omega$, and (p_n) is a representing sequence for f with order m_1 on Λ_1, a compatible representing sequence for f on Λ_2 can be obtained. For if (q_n)

XXII.2.3. Distributions on $\mathbb{R}^n$

This section will largely be a repeat in greater generality of the previous two sections, which are of course the special case $n = 1$. Although most of the theory works identically, we have somewhat pedantically done the $n = 1$ case separately first, for a couple of reasons:

(i) The case $n = 1$ is a little easier to follow conceptually, and is also technically easier in some places.

(ii) There are a few results which are special (or at least much easier to state) in the case $n = 1$. For example, there are tricky issues with complicated (connected) regions which do not arise in the one-dimensional case, where we only need to work with intervals.

XXII.2.4. Tempered Distributions

XXII.2.4.1. It turns out to be important and useful to consider a somewhat larger class of test functions. We let $\mathcal{S}$ be the set of $\mathcal{C}^\infty$ functions from $\mathbb{R}^n$ to $\mathbb{R}$ (or $\mathbb{C}$) which do not necessarily have compact support, but which "vanish rapidly at infinity" (see () for the precise definition). Then $\mathcal{S}$ is a vector space with a natural topology, and we consider the space $\mathcal{S}'$ of continuous linear functionals on $\mathcal{S}$.

XXII.2.4.2. We have $\mathcal{D} \subseteq \mathcal{S}$. The relative $\mathcal{S}$-topology on $\mathcal{D}$ is not the same as the topology from XXII.2.1.12. (strictly weaker), but any continuous linear functional on $\mathcal{S}$ defines a continuous linear functional on $\mathcal{D}$, thus a generalized function or distribution. The distributions obtained are called *tempered distributions* since they are the distributions with controlled growth at infinity.

XXII.2.4.3. There are several good reasons for working with $\mathcal{S}$ (and $\mathcal{S}'$) rather than $\mathcal{D}$. Two of the most important are:

(i) The topology on $\mathcal{D}$ is not metrizable (not first countable), but the topology on $\mathcal{S}$ is metrizable, and in fact $\mathcal{S}$ is a Fréchet space.

(ii) The Fourier transform on $\mathbb{R}^n$ sends $\mathcal{S}$ into $\mathcal{S}$, and in fact sends $\mathcal{S}$ homeomorphically onto $\mathcal{S}$ (), and hence dualizes to a linear homeomorphism on $\mathcal{S}'$.

XXII.3. Sobolev Spaces

XXII.3.1. Definition of Sobolev Spaces

If Ω is an open set in $\mathbb{R}^n$ and $p \geq 1$, write $L^p(\Omega)$ for $L^p(\Omega, \mathcal{L}, \lambda)$.

XXII.3.1.1. Definition. Let Ω be an open set in $\mathbb{R}^n$, $m \in \mathbb{N} \cup \{0\}$, and $1 \leq p < \infty$. The *Sobolev space* $W^{m,p}(\Omega)$ is the set of all ordinary functions f such that f and all the distributional derivatives $D^\alpha f$ of order $\leq m$ are ordinary functions in $\mathcal{L}^p(\Omega)$, with functions agreeing a.e. identified. If $f \in W^{m,p}(\Omega)$, set

$$\|f\|_{m,p} = \left[\sum_{0 \leq |\alpha| \leq m} \|D^\alpha f\|_p^p \right]^{1/p} .$$

XXII.3.1.2. Since $L^p(\Omega) \subseteq L^1_{\text{loc}}(\Omega)$, the definition makes sense, and an element of $W^{m,p}(\Omega)$ is weakly differentiable of order at least m. To be really careful, we should define $\mathcal{W}^{m,p}(\Omega)$ to be the set of functions and $W^{m,p}(\Omega)$ the quotient by the functions which are 0 a.e., but this is a little messy since weak derivatives are only well defined up to a.e. equivalence, so we will adhere to the usual sloppiness and regard

$$W^{m,p}(\Omega) \subseteq L^p(\Omega) \subseteq L^1_{\text{loc}}(\Omega) \subseteq \mathcal{D}'(\Omega) .$$

It is easily checked that $\| \cdot \|_{m,p}$ is a norm on $W^{m,p}(\Omega)$. We have $W^{0,p}(\Omega) = L^p(\Omega)$; $W^{m,p}(\Omega) \subseteq W^{k,p}(\Omega)$ for any p if $0 \leq k \leq m$ (but note that the norms do not agree). If $f \in W^{m,p}(\Omega)$ and $|\alpha| \leq m$, then $D^\alpha f \in W^{m-|\alpha|,p}(\Omega)$ and $\|D^\alpha f\|_{m-|\alpha|,p} \leq \|f\|_{m,p}$, i.e. differential operators are bounded operators between Sobolev spaces.

XXII.3.1.3. If $n = 1$, the elements of $W^{m,p}(\Omega)$ ($m \geq 1$) are functions f which are $m-1$-times continuously differentiable, for which $f^{(m-1)}$ is locally absolutely continuous, and for which $f^{(k)} \in \mathcal{L}^p(\Omega)$ for $0 \leq k \leq m$ (we do not have to make any identifications in this case, so the elements are honest functions). But if $n > 1$, the situation is much more subtle (). If Ω is nice and m is sufficiently large ($m > n/p$), each element of $W^{m,p}(\Omega)$ is represented by a unique continuous function (), but this is not true for smaller m in general, and elements of $W^{m,p}(\Omega)$ do not have canonical representatives.

XXII.3.2. Sobolev Inequalities and Embedding Theorems

XXII.3.2.1. There is a collection of inequalities and embeddings of Sobolev spaces which are collectively called "Sobolev inequalities" or "the Sobolev embedding theorem," since they are mainly due to Sobolev [Sob63] but improved by Morrey [Mor40] and Gagliardo [Gag58]. The name *Sobolev inequalities* is probably better, since the essence of the results is the inequalities and the "embeddings" are a straightforward consequence, and the "embeddings" are actually not always embeddings (there can be a nontrivial kernel in some cases).

XXII.3.2.2. The inequalities only work on regions Ω which are "sufficiently nice"; the required niceness varies in different results. We will not carefully describe the various niceness conditions; cf. e.g. [AF03]. A reasonable sufficient condition for all results is that the boundary $\partial\Omega$ be *strongly locally Lipschitz*, which in the case where $\partial\Omega$ is compact means $\partial\Omega$ is locally the graph of a Lipschitz function. This condition is satisfied in many cases of interest:

Ω is bounded and convex.

Ω is a regular open set () and $\bar{\Omega}$ is a smooth manifold with compact boundary.

If $\partial\Omega$ is unbounded, the conditions are much more subtle, but are satisfied e.g. if Ω is a finite intersection of half-spaces, such as an open quadrant in $\mathbb{R}^2$.

The topology of Ω does not seem to enter in, and can be fairly complicated (but perhaps not too complicated). For example, an annulus in $\mathbb{R}^2$ or the interior or exterior of a solid smooth n-holed torus (even knotted) in $\mathbb{R}^3$ satisfies the niceness conditions.

XXII.4. Differential Equations and Distributions

Functional analysis methods and the theory of distributions play a fundamental role in the modern theory of differential equations, particularly PDEs. In this section, we describe some of the core features. Our treatment of this vast subject is far from comprehensive; a full treatment would include most of the theory of PDEs (a subject in which the author is not an expert).

When solving an equation (or solving a problem) in a particular space, it is often advantageous to work in a larger space with better completeness or compactness properties, and/or where the equation is better behaved. The most basic example is defining and working with the real numbers themselves (e.g. to find roots of polynomials). Another example is the use of currents and Hausdorff measure in geometric measure theory (). The idea is to show that the equation (problem) has a solution in the extended setting, and then argue that the solution actually is of the kind sought (i.e. is in the original space). In the case of differential equations (ordinary or partial), one tries to show that the equation has a "weak solution" in a space of generalized functions, and then via a regularity argument conclude that the weak solution is an actual solution.

XXII.4.1. Ordinary Differential Equations and Generalized Functions

XXII.4.2. Partial Differential Equations and Generalized Functions

XXII.4.3. Exercises

XXII.4.3.1. (a) Let $g \in \mathcal{D}'(\mathbb{R})$ with compact support. Show that $\tilde{S}_g$ (cf. ()) is continuous from $\mathcal{E}(\mathbb{R})$ to $\mathcal{E}(\mathbb{R})$.

(b) Let $g \in \mathcal{D}'(\mathbb{R})$ with compact support. Show that $\bar{S}_g$ () is continuous from $\mathcal{D}'(\mathbb{R})$ to $\mathcal{D}'(\mathbb{R})$, i.e. if $f_n \to f$ in $\mathcal{D}'(\mathbb{R})$, then $f_n * g \to f * g$ in $\mathcal{D}'(\mathbb{R})$.

(c) Let $f \in \mathcal{D}'(\mathbb{R})$, and (g_n) a sequence in $\mathcal{D}'(\mathbb{R})$ all of whose supports are contained in a fixed finite interval. Show that $f * g_n \to f * g$ in $\mathcal{D}'(\mathbb{R})$.

(d) What if in (c) the supports of the g_n are compact but not contained in a fixed bounded interval?

(e) Show that if $f, g, h \in \mathcal{D}'(\mathbb{R})$ and two of them have compact support, then $(f * g) * h = f * (g * h)$.

Chapter XXIII

Topological Groups and Abstract Harmonic Analysis

XXIII.1. Topological Groups

XXIII.1.1. Groups and Homomorphisms

To make this manuscript more self-contained, we give here a quick summary of the theory of groups. This topic more properly belongs in an algebra text, and there are many such texts which cover this vast and fundamental subject in far greater detail.

XXIII.1.1.1. DEFINITION. A *group* is a pair $(G, *)$, where G is a set and $*$ is a binary operation on G, i.e. a function $(x, y) \mapsto x * y$ from $G \times G$ to G, satisfying

(Ass) $*$ is *associative*: $x * (y * z) = (x * y) * z$ for all $x, y, z \in G$.

(Id) There is a *unit* or *identity* for $*$, an element $e \in G$ with $e * x = x * e = x$ for all $x \in G$.

(Inv) For each $x \in G$ there is an element $x^{-1} \in G$ with $x * x^{-1} = x^{-1} * x = e$.

A set with an associative binary operation is called a *semigroup*. A semigroup with an identity is sometimes called a *monoid*.

As usual, the operation $*$ is part of the definition of a group, so it is technically an abuse of terminology to make the common statement "Let G be a group." (We will nonetheless often abuse terminology in this way.)

XXIII.1.1.2. The operation in a group or semigroup is not necessarily commutative, i.e. the identity $x * y = y * x$ does not necessarily hold for all $x, y \in G$. A group whose operation is commutative is called a *commutative group* or *abelian group*, and similarly for semigroups.

XXIII.1.1.3. If $(G, *)$ is a group, the group operation is usually written multiplicatively, i.e. writing xy for $x * y$, and the identity e is often written 1. If $(G, *)$ is abelian, it is customary (but not universal) to write the operation as addition, writing $x + y$ for $x * y$. If additive notation is used, the identity e is written 0, and the inverse x^{-1} of an element x written $-x$. In many natural examples of groups, the group operation is really addition or multiplication, defined in usual ways. Semigroup notation is often similar. Because of associativity, for any x the elements xxx, $xxxx$, etc., are unambiguously defined; we denote by x^n ($n \in \mathbb{N}$) the element which is a product of n x's. In a group, x^n is also defined for $n < 0$ as the product of n copies of x^{-1}, and $x^0 = e$; then $x^n x^m = x^{n+m}$ for all $n, m \in \mathbb{Z}$. In additive notation, x^n is denoted nx.

XXIII.1.1.4. The operation in a group has both left and right cancellation: if $xz = yz$, then

$$x = x(zz^{-1}) = (xz)z^{-1} = (yz)z^{-1} = y(zz^{-1}) = y$$

and similarly if $xy = xz$, then $y = z$. In particular, the identity is unique: if $xy = x$ or $yx = x$ for some $x \in G$, then $y = e$ (and in particular $zy = yz = z$ for all $z \in G$); and inverses are unique: if $xy = e$ or $yx = e$, then $y = x^{-1}$ (and in particular $xy = yx = e$). We also have that $e^{-1} = e$ and that e is the unique idempotent in G, i.e. $xx = x$ if and only if $x = e$. Semigroups, even abelian monoids, do not have cancellation in general.

Homomorphisms

Homomorphisms (group-homomorphisms) are functions or maps between groups which respect the group operation:

XXIII.1.1.5. Definition. Let $(G, *_G)$ and $(H, *_H)$ be groups. A *group-homomorphism* (or just *homomorphism* if there is no possible confusion) is a function $\phi : G \to H$ such that

$$\phi(x *_G y) = \phi(x) *_H \phi(y)$$

for all $x, y \in G$. A *group-isomorphism* (or just *isomorphism* if there is no possible confusion) is a bijective group-homomorphism.

We usually just write the condition as $\phi(xy) = \phi(x)\phi(y)$, but it should be observed that the operations on the left and right are different unless the groups are the same.

The simple proof of the next result, and subsequent propositions, is left to the reader:

XXIII.1.1.6. Proposition. Let $\phi : G \to H$ be a homomorphism. Then

(i) $\phi(e_G) = e_H$.

(ii) $\phi(x^{-1}) = [\phi(x)]^{-1}$ for all $x \in G$.

(iii) If ϕ is an isomorphism, then $\phi^{-1} : H \to G$ is also an isomorphism (i.e. is a homomorphism).

An isomorphism is just an identification of the groups, which are abstractly identical. In a general homomorphism from G to H, elements of G are identified together in H in a very systematic way (XXIII.1.1.21.), but the essential character of the group operation is preserved.

"Homomorphism is a kind of *systematically abridged translation*. The original is not only translated into another language, but also abridged so that what results finally from translation and abbreviation is uniformly, systematically condensed into one-half or one-third or some other fraction of the original extension. Subtleties may be lost by such abridgement but everything that is in the original is represented by something in the translation, and, on a reduced scale, the relations are preserved."

G. Polya[1]

Subgroups and Cosets

XXIII.1.1.7. A subset of a group which is itself a group under the same operation is called a subgroup of the group. More precisely, if G is a group, then a subset H of G is a *subgroup* if

(i) H is *closed* under the group operation, i.e. if $x, y \in H$, then $xy \in H$.

(ii) The identity e_G is in H.

(iii) For all $x \in H$, x^{-1} is also in H.

(of course, (ii) is automatic from (i) and (iii)).

XXIII.1.1.8. Every group G has at least two subgroups: G itself and $\{e\}$. Other subgroups, which may or may not exist, are called *nontrivial subgroups*. Any intersection of subgroups is a subgroup. In particular, if $A \subseteq G$, then there is a smallest subgroup $\langle A \rangle$ of G containing A, the intersection of all subgroups of G containing A (there is at least one such subgroup, G), called the subgroup of G generated by A. This subgroup can be concretely described as the set of all finite products of powers, positive and negative, of elements of A (including the "empty product" e). In particular, if $A = \{x\}$, the subgroup $\langle A \rangle = \langle x \rangle$ is the set of all integer powers of x, called the *cyclic subgroup* of G generated by x. A cyclic subgroup is always abelian.

The next result generalizes XXIII.1.1.6.:

XXIII.1.1.9. Proposition. Let G and G' be groups, and $\phi : G \to G'$ a homomorphism.
(i) If H is a subgroup of G, then $\phi(H)$ is a subgroup of G'.
(ii) If H' is a subgroup of G', then $\phi^{-1}(H')$ is a subgroup of G.
In particular, the range of ϕ is a subgroup of G'.

XXIII.1.1.10. Definition. Let H be a subgroup of a group G, and $x \in G$. The *left coset* of H containing x is the subset $xH = \{xy : y \in H\}$ of G. The *right coset* is the set $Hx = \{yx : y \in H\}$.

Note that since $e \in H$, $x \in xH$ and $x \in Hx$ for any x. If G is abelian and the operation is written additively, cosets are normally written $x + H$ (there is no distinction between left and right cosets in the abelian case).

[1] "Generalization, Specialization, Analogy," *Induction and Analogy in Mathematics*; reprinted in *New Directions in the Philosophy of Mathematics*, ed. T. Tymoczko, p. 118.

XXIII.1.1.11. PROPOSITION. Let H be a subgroup of G. Then any two left cosets of H in G are either identical or disjoint. In fact, for any $x, y \in G$, the following are equivalent:

(i) $xH \cap yH \neq \emptyset$.

(ii) $xH = yH$.

(iii) $y^{-1}x \in H$.

An analogous statement holds for right cosets (with $y^{-1}x$ replaced by xy^{-1} in (iii)).

XXIII.1.1.12. Write G/H for the set of left cosets of H in G, and $H\backslash G$ for the set of right cosets. These sets are called *homogeneous spaces* and are naturally themselves groups in good cases (XXIII.1.1.20.).

Normal Subgroups

XXIII.1.1.13. If G is not abelian, the left and right cosets of a subgroup do not coincide in general (except for the coset $H = eH = He$ itself). But they do if H is "nicely situated" in G:

XXIII.1.1.14. PROPOSITION. Let H be a subgroup of a group G. The following are equivalent:

(i) Every left coset of H in G is also a right coset.

(ii) For every $x \in G$, $xH = Hx$.

(iii) For every $x \in G$ and $y \in H$, $x^{-1}yx \in H$ (i.e. $x^{-1}Hx = H$).

XXIII.1.1.15. DEFINITION. A subgroup H of a group G is *normal* (in G) if the conditions of XXIII.1.1.14. are satisfied.

XXIII.1.1.16. Note that normality of a subgroup depends on both G and H in general. The trivial subgroups G and $\{e\}$ are always normal. If G is abelian, every subgroup of G is normal.

Homomorphisms and Normal Subgroups

XXIII.1.1.17. PROPOSITION. Let $\phi : G \to G'$ be a group-homomorphism.
(i) If H' is a normal subgroup of G', then $\phi^{-1}(H')$ is a normal subgroup of G.
(ii) If ϕ is surjective and H is a normal subgroup of G, then $\phi(H)$ is a normal subgroup of G'.

The conclusion of (ii) is not necessarily true if ϕ is not surjective. In fact, $\phi(G)$ need not be a normal subgroup of G' in general.

XXIII.1.1.18. As a special case of (i), if $\phi : G \to G'$ is a homomorphism, define the *kernel* of ϕ to be

$$ker(\phi) = \phi^{-1}(\{e_{G'}\}) = \{x \in G : \phi(x) = e_{G'}\} \ .$$

Then $ker(\phi)$ is a normal subgroup of G.

Quotient Groups

XXIII.1.1.19. As a converse to XXIII.1.1.18., suppose H is a subgroup of G. Try to put a binary operation on the set of (left or right) cosets of H in G by $(xH)(yH) = xyH$. Then

XXIII.1.1.20. Proposition. (i) The operation $(xH)(yH) = xyH$ is well defined if and only if H is a normal subgroup of G.

(ii) If H is normal in G, this operation makes the set of cosets into a group, called the *quotient group* of G by H or G mod H, denoted G/H.

(iii) If H is normal in G, the map $x \mapsto xH$ from G to G/H is a (surjective) homomorphism with kernel H.

The First Isomorphism Theorem

The next result, although quite easy, is called the *First Isomorphism Theorem* of group theory (there are also a second, third, and sometimes fourth; see books on abstract algebra).

XXIII.1.1.21. Proposition. [First Isomorphism Theorem of Group Theory] Let G and G' be groups, H a normal subgroup of G, and $\phi : G \to G'$ a homomorphism.

(i) If $H \subseteq ker(\phi)$, then ϕ drops to a well-defined homomorphism $\bar{\phi} : G/H \to G'$ defined by $\bar{\phi}(xH) = \phi(x)$, which is injective if and only if $H = ker(\phi)$.

(ii) If $H = \ker(\phi)$, then $\phi(G)$ is isomorphic to G/H via $\bar{\phi}$. In particular, if ϕ is surjective, then $G' \cong G/H$ via $\bar{\phi}$.

XXIII.1.2. Topological Groups

XXIII.1.2.1. Definition. A *topological group* is a group G with a topology such that the group operation $(x, y) \mapsto xy$ is a continuous function from $G \times G$ to G (i.e. multiplication is jointly continuous on G), and inversion $x \mapsto x^{-1}$ is a continuous function from G to G.

XXIII.1.2.2. Note that both the group operation and the topology are parts of the definition of a topological group; thus it is technically incorrect to say "Let G be a topological group" (although we do it all the time). In fact, a group can have many different topologies making it into a topological group.

XXIII.1.2.3. EXAMPLES. (i) Let G be any group. Then G is a topological group with the discrete topology or the indiscrete topology.

A topological group with the indiscrete topology is not very interesting. However, a group with the discrete topology is much more interesting than might be at first anticipated. In fact, we can regard the theory of groups (with no topology) as a special case of the theory of topological groups by using the discrete topology (although this is logically circular if not done properly).

(ii) The additive group $\mathbb{R}$ (or $\mathbb{R}^n$) with its ordinary topology is a topological group. More generally, the additive group of any normed vector space is a topological group with the topology induced by the norm.

(iii) Let $GL_n(\mathbb{R})$ be the multiplicative group of invertible $n \times n$ matrices with real entries, with the relative topology as a subset of $M_n(\mathbb{R}) \cong \mathbb{R}^{n^2}$. Then $GL_n(\mathbb{R})$ is a topological group.

(iv) Any subgroup of a topological group is a topological group with the relative topology.

(v) Groups of homeomorphisms of topological spaces can often be given natural topologies making them into topological groups, although the details can be subtle (cf. XXIII.1.7.8.–XXIII.1.7.14.).

These examples barely scratch the surface of the possibilities.

The condition defining a topological group can be streamlined:

XXIII.1.2.4. PROPOSITION. Let G be a group with a topology. Then G is a topological group under the given topology if and only if the map $\phi : G \times G \to G$ given by $\phi(x, y) = x^{-1}y$ is continuous.

PROOF: If G is a topological group, then ϕ is a composition of multiplication and inversion, hence continuous. Conversely, if ϕ is continuous, then

$$x \mapsto (x, e) \mapsto x^{-1}e = x^{-1}$$

is continuous, and hence

$$(x, y) \mapsto (x^{-1}, y) \mapsto (x^{-1})^{-1}y = xy$$

is continuous, so G is a topological group in the given topology. 👍

XXIII.1.2.5. Joint continuity of multiplication in a topological group implies separate continuity (). But separate continuity of multiplication does not imply joint continuity (Exercise XXIII.1.7.6.). There are situations where separate continuity does imply joint continuity ().

Here is a useful consequence of the joint continuity of multiplication and continuity of inversion:

XXIII.1.2.6. PROPOSITION. Let G be a topological group, I a directed set, and (x_i), (y_i) nets in G over I. Suppose $x_i y_i \to z$. Then

(i) If $x_i \to x$, then $y_i \to x^{-1}z$.

(ii) If $y_i \to y$, then $x_i \to zy^{-1}$.

PROOF: (i): We have

$$y_i = x^{-1}xx_i^{-1}(x_i y_i) \to x^{-1}xx^{-1}z \ .$$

The proof of (ii) is similar. 👍

Translations and Homogeneity

XXIII.1.2.7. DEFINITION. Let G be a topological group, and $g \in G$. The functions λ_g, ρ_g from G to G defined by

$$\lambda_g(x) = gx$$
$$\rho_g(x) = xg$$

are called *left translation* and *right translation* by g respectively.

XXIII.1.2.8. PROPOSITION. Let G be a topological group, and $g \in G$. Then the left and right translations λ_g and ρ_g are homeomorphisms from G to G. If $g \neq e$, these homeomorphisms have no fixed points.

PROOF: Translations are continuous by (separate) continuity of the group operation. Left translation λ_g has inverse $\lambda_{g^{-1}}$, hence is a bijection and a homeomorphism; similarly ρ_g has inverse $\rho_{g^{-1}}$. If $\lambda_g(x) = x$ for some $x \in G$, i.e. $gx = x$, then $g = (gx)x^{-1} = xx^{-1} = e$, and similarly for ρ_g. 👍

XXIII.1.2.9. COROLLARY. If G is a topological group, then the topology of G is *homogeneous*, i.e. if $x, y \in G$, then there is a homeomorphism from G to G sending x to y.

PROOF: $\lambda_{yx^{-1}}$ is such a homeomorphism. 👍

Thus a topological group "looks the same" around every point.

XXIII.1.2.10. Similarly, *inversion* ι, where $\iota(x) = x^{-1}$, is a continuous map from G to G which is its own inverse, i.e. ι is a homeomorphism.

The next result, although simple, appears quite bizarre and surprising at first glance, and is a dramatic illustration of the maxim that being open is not the opposite of being closed for subsets of a topological space. See Exercise XXIII.1.7.2. for a generalization.

XXIII.1.2.11. PROPOSITION. Let G be a topological group. Any open subgroup of G is closed.

PROOF: Let H be an open subgroup of G. Then, for any $g \in G$, the left coset gH is the image of H under the homeomorphism λ_g, and hence gH is also open. The complement of H in G is the union of the nonidentity left cosets of H in G, hence open. 👍

See Exercise XXIII.1.7.2. for an alternate proof.

Fundamental Systems of Neighborhoods

XXIII.1.2.12. If G is a topological group and U is a neighborhood of e, then for any $g \in G$ $gU = \lambda_g(U)$ and $Ug = \rho_g(U)$ are neighborhoods of g, and conversely if V is a neighborhood of g then $g^{-1}V$ and Vg^{-1} are neighborhoods of e. Thus to describe a topological group topology on a group G, it suffices to specify the neighborhoods of e.

XXIII.1.2.13. If A and B are subsets of G, write $AB = \{xy : x \in A, y \in B\}$, and $A^2 = AA$. If A, B, C are subsets of G, then $(AB)C = A(BC)$ by associativity; call this subset ABC. Products of more than three subsets can be defined similarly. A^n has an unambiguous meaning for any $n \in \mathbb{N}$, and $A^n A^m = A^{n+m}$.

If $A \subseteq G$, write $A^{-1} = \iota(A) = \{x^{-1} : x \in A\}$.

XXIII.1.2.14. Proposition. If G is a topological group, $A, B \subseteq G$, and one of A, B is open, then AB is open. If A is open, then A^{-1} is also open.

Proof: If B is open, then $aB = \lambda_a(B)$ is open for each $a \in A$, so $AB = \cup_{a \in A} aB$ is open. The proof if A is open is similar. $A^{-1} = \iota(A)$ is open if A is. 👍

XXIII.1.2.15. Proposition. Let G be a topological group. The collection $\mathcal{N}_e$ of neighborhoods of e has the following properties:

(i) If $U \in \mathcal{N}_e$, then there is a $V \in \mathcal{N}_e$ with $V^2 \subseteq U^\circ$.

(ii) There is a $W \in \mathcal{N}_e$ with $W = W^{-1}$ and $W \subseteq U^\circ$.

(iii) For every $g \in G$, there is a $V \in \mathcal{N}_e$ with $gVg^{-1} \subseteq U^\circ$.

Proof: (i): Let $\mu : G \times G \to G$ be multiplication, i.e. $\mu(x, y) = xy$. Then $\mu^{-1}(U^\circ)$ is an open neighborhood of (e, e) in $G \times G$, hence contains a neighborhood of the form $V_1 \times V_2$ where each V_j is in $\mathcal{N}_e$. Set $V = V_1 \cap V_2$.
(ii): Set $W = U^\circ \cap (U^\circ)^{-1}$.
(iii): Set $V = g^{-1}U^\circ g = \rho_g(\lambda_{g^{-1}}(U^\circ)) = \lambda_{g^{-1}}(\rho_g(U^\circ))$, which is in $\mathcal{N}_e$. 👍

XXIII.1.2.16. Corollary. If G is a topological group, and $\mathcal{F}$ is a local base at e for the topology (not necessarily consisting of open sets), then $\mathcal{F}$ has the following properties:

(i) If $U, V \in \mathcal{F}$, then there is a $W \in \mathcal{F}$ with $W \subseteq U \cap V$.

(ii) If $U \in \mathcal{F}$ and $g \in U$, then there is a $V \in \mathcal{F}$ with $Vg \subseteq U$.

(iii) If $U \in \mathcal{F}$, then there is a $V \in \mathcal{F}$ with $V^{-1}V \subseteq U$.

(iv) If $U \in \mathcal{F}$ and $g \in G$, then there is a $V \in \mathcal{F}$ with $gVg^{-1} \subseteq U$.

Such an $\mathcal{F}$ has additional properties such as:

(iiia) If $U \in \mathcal{F}$, there is a $V \in \mathcal{F}$ with $V^2 \subseteq U$.

(iiib) If $U \in \mathcal{F}$, there is a $V \in \mathcal{F}$ with $V^{-1} \subseteq U$.

In fact, (iiia) and (iiib) together are equivalent to (iii).

XXIII.1.2.17. DEFINITION. Let G be a group. A *fundamental system of neighborhoods of* e is a nonempty collection $\mathcal{F}$ of subsets of G, each containing e, satisfying (i)–(iv) of XXIII.1.2.16. (or equivalently (i), (ii), (iiia), (iiib), (iv)).

Note that in this definition, there is no specified topology on G, so the sets in $\mathcal{F}$ are not "neighborhoods" of e in G in the usual sense of the term. But the terminology is justified by:

XXIII.1.2.18. THEOREM. Let G be a group. If $\mathcal{F}$ is a fundamental system of neighborhoods of e in G, then there is a unique topology $\mathcal{T}$ on G making G a topological group, for which $\mathcal{F}$ is a local base at e.

XXIII.1.2.19. So a topological group topology on a group G can be specified by giving a fundamental system of neighborhoods of e, and every topological group topology on G arises in this manner. Specifying a topology via a fundamental system of neighborhoods of e is one of the most convenient ways of defining topologies on groups.

Products of Closed Sets

In contrast with XXIII.1.2.14., even a product of two closed sets in a topological group is not closed in general (). But it is if one of the sets is compact:

XXIII.1.2.20. PROPOSITION. Let G be a topological group, and A and B closed subsets of G. If one of A, B is compact, then AB is closed.

PROOF: Suppose A is compact. Let $z \in \overline{AB}$. Fix a net $(x_i y_i)$ in AB with $x_i y_i \to z$ (This can be done without any form of Choice, cf. ().) Passing to a subnet if necessary, we may assume $x_i \to x$ for some $x \in A$ by compactness. Then $y_i \to x^{-1}z$ by XXIII.1.2.6., and hence $x^{-1}z \in B$ since B is closed. Thus $z = x(x^{-1}z) \in AB$. The proof if B is compact is similar. 👍

Homogeneous Spaces and Quotients

XXIII.1.2.21. If G is a topological group and H a subgroup of G, not necessarily normal, we can form the left coset space G/H. Since G/H is a set-theoretic quotient of G, i.e. there is a natural quotient map $\pi : G \to G/H$, we may give G/H the quotient topology. G/H with this topology is called the *homogeneous space* of G by H (the terminology is justified by XXIII.1.2.22.(ii)).

XXIII.1.2.22. PROPOSITION. Let G be a topological group and H a subgroup of G. Let G/H be the homogeneous space. Then

(i) The quotient map $\pi : G \to G/H$ is continuous and open.

(ii) If $g \in G$, the map $\bar{\lambda}_g : G/H \to G/H$ defined by $\bar{\lambda}_g(xH) = gxH$ is a well-defined homeomorphism, and in particular the topology of G/H is homogeneous in the sense of XXIII.1.2.9.. The map $(g, xH) \mapsto \lambda_g(xH) = gxH$ is continuous from $G \times G/H$ to G/H.

PROOF: (i) The quotient map π is continuous by definition of the quotient topology. If U is open in G, then $\pi^{-1}(\pi(U)) = UH$, which is open in G by XXIII.1.2.14.; hence $\pi(U)$ is open in G/H by definition of the quotient topology.

(ii): If $xH = yH$, i.e. $y = xz$ for some $z \in H$, then $gy = gxz$, so $gy \in gxH$, i.e. $gyH = gxH$ and $\bar{\lambda}_g$ is well defined, and is a bijection since $\bar{\lambda}_g^{-1} = \bar{\lambda}_{g^{-1}}$. If $V \subseteq G/H$ is open, then $\pi^{-1}(V)$ is open in G, so $\lambda_{g^{-1}}(\pi^{-1}(V))$ is open in G since $\lambda_{g^{-1}}$ is a homeomorphism on G; thus $\bar{\lambda}_g^{-1}(V) = \pi(\lambda_{g^{-1}}(\pi^{-1}(V)))$ is open by (i). So $\bar{\lambda}_g$ is continuous. Since $\bar{\lambda}_g^{-1} = \bar{\lambda}_{g^{-1}}$ is also continuous, $\bar{\lambda}_g$ is a homeomorphism. For the last statement, if $x, y \in G$, then $\bar{\lambda}_{yx^{-1}}$ sends xH to yH, so G/H is homogeneous. 👍

XXIII.1.2.23. PROPOSITION. Let G be a topological group, and H a closed normal subgroup. Then

(i) G/H is a topological group in the quotient topology.

(ii) If G' is another topological group, and $\phi : G \to G'$ a continuous homomorphism whose kernel contains H, then the induced homomorphism $\psi : G/H \to G'$ () is continuous.

PROOF: (i): Let $\bar{V}$ be an open set in G/H, and let $V = \pi^{-1}(\bar{V})$. Then V is open in G. Since μ is continuous, $U = \mu^{-1}(V)$ is open in $G \times G$. The quotient map $\pi \times \pi$ from $G \times G$ to $(G/H) \times (G/H)$ is open, so $\bar{U} = (\pi \times \pi)(U)$ is open in $(G/H) \times (G/H)$, and $\bar{U} = \bar{\mu}^{-1}(\bar{V})$. Thus $\bar{\mu}$ is continuous. A similar argument shows that $\bar{\iota}$ is continuous on G/H. 👍

The homeomorphisms $\bar{\lambda}_g$ are an example of a group action:

XXIII.1.2.24. DEFINITION. Let G be a topological group and X a topological space. A *group action* of G on X is a continuous function $(g, x) \mapsto \alpha_g(x)$ from $G \times X$ to X such that $\alpha_e(x) = x$ and $\alpha_{gh}(x) = \alpha_g(\alpha_h(x))$ for all $x \in X$, $g, h \in G$.

XXIII.1.2.25. The point $\alpha_g(x)$ is often written $g \cdot x$. For fixed g, α_g is a continuous function from X to X with inverse $\alpha_{g^{-1}}$, i.e. α_g is a homeomorphism from X to X. The map $\alpha : G \to Homeo(X)$ is a group-homomorphism, which is continuous if $Homeo(X)$ is given the topology of pointwise convergence.

Separation Axioms

Topological groups automatically have nice separation properties:

XXIII.1.2.26. PROPOSITION. Let G be a topological group. The following are equivalent:

(i) G is T_0.

(ii) G is Hausdorff.

(iii) G is completely regular.

PROOF: (iii) $\Rightarrow$ (ii) $\Rightarrow$ (i) is trivial. Since the topology on G comes from a uniform structure (XXIII.1.3.4.), if G is T_0, it is completely regular, so (i) $\Rightarrow$ (iii). 👍

XXIII.1.2.27. There is a simple direct proof that a topological group is T_3, and hence that a T_0 topological group is Hausdorff; cf. Exercise XXIII.1.7.3..

XXIII.1.2.28. Corollary. A second countable T_0 topological group is metrizable.

One can do much better (XXIII.1.3.7.).

Closed Subgroups

XXIII.1.2.29. Proposition. Let G be a topological group, and H a subgroup. Then G/H is Hausdorff (completely regular) if and only if H is closed in G.

XXIII.1.2.30. Proposition. Let G be a topological group, and H a subgroup of G. Then $\bar{H}$ is also a subgroup of G. If H is a normal subgroup, so is $\bar{H}$.

XXIII.1.2.31. Thus $\overline{\{e\}}$ is the smallest closed subgroup of G. It is normal, and $G/\overline{\{e\}}$ is the largest Hausdorff quotient group of G. Any continuous homomorphism from G into a Hausdorff topological group factors through $G/\overline{\{e\}}$. The space $G/\overline{\{e\}}$ is the maximal T_0 quotient of G in the sense of XIII.8.3.10..

Products of Topological Groups

XXIII.1.2.32. Proposition. Any product of topological groups is a topological group with the product topology.

Inverse Limits

Connectedness

XXIII.1.2.33. Proposition. Let G be a topological group. If U is any open neighborhood of e in G, then the subgroup of G generated by U is open, and coincides with the subgroup of G generated by $\bar{U}$.

Proof: The subset $[U \cup (U^{-1})]^n$ of G is open for each n by XXIII.1.2.14.. The subgroup of G generated by U is $\cup_{n=1}^{\infty}[U \cup (U^{-1})]^n$. Since an open subgroup is closed (XXIII.1.2.11.), this subgroup contains $\bar{U}$. 👍

XXIII.1.2.34. Corollary. Let G be a connected topological group. Then every neighborhood of e generates G as a group.

Proof: Every open subgroup of a topological group is clopen, so a connected topological group cannot contain any proper open subgroups. Every neighborhood of e in G contains an open neighborhood of e. 👍

XXIII.1.2.35. PROPOSITION. Let G be a topological group and H a subgroup. If H and G/H are connected, then G is connected.

PROOF: Suppose H is connected and G is not connected. Let U and V be nonempty disjoint clopen sets in G with $U \cup V = G$. Since each left coset of H is connected, it is entirely contained in either U or V, i.e. U and V are each unions of left cosets of H. But then $\pi(U)$ and $\pi(V)$ are disjoint clopen subsets of G/H, so G/H is not connected. 👍

XXIII.1.2.36. PROPOSITION. Let G be a topological group. Then the connected component of the identity e is a closed normal subgroup H of G, and G/H is totally disconnected.

PROOF: Let H be the connected component of e in G. Then H is a closed subset of G. $H \times H$ is a connected subset of $G \times G$, and hence its image H^2 in G under multiplication is connected, and contains e; thus $H^2 \subseteq H$, i.e. H is closed under multiplication. Similarly, H^{-1} is connected and contains e, thus $H^{-1} \subseteq H$ and H is closed under inversion. So H is a subgroup of G. If $g \in G$, then gHg^{-1} is a connected subset of G, hence $gHg^{-1} \subseteq H$. Then $H = g^{-1}(gHg^{-1})g \subseteq g^{-1}Hg \subseteq H$, so $g^{-1}Hg = H$ and H is normal.

To see that G/H is totally disconnected, it suffices to show that the connected component of $\bar{e}$ in G/H is $\{\bar{e}\}$. Let K be the connected component of $\bar{e}$ in G/H, and $G' = \pi^{-1}(K)$. Then G' is a subgroup of G and $G'/H \cong K$ is connected, and since H is connected, G' is connected by XXIII.1.2.35.. Since $H \subseteq G'$, we have $G' = H$ so $K = \{\bar{e}\}$. 👍

XXIII.1.3. Uniformities on Topological Groups

Every topological group has a natural uniform structure (actually three natural uniform structures which may or may not coincide). In fact, these uniform structures are one of the models for general uniform structures ().

XXIII.1.3.1. DEFINITION. Let $(G, \mathcal{T})$ be a topological group.

(i) The *left uniform structure* $\mathcal{L}$ on G is the uniform structure generated by the sets

$$L_U = \{(x, y) \in G \times G : x^{-1}y \in U\}$$

as U ranges over all open neighborhoods of e in G.

(ii) The *right uniform structure* $\mathcal{R}$ on G is the uniform structure generated by the sets

$$R_U = \{(x, y) \in G \times G : xy^{-1} \in U\}$$

as U ranges over all open neighborhoods of e in G.

(iii) The *two-sided uniform structure* $\mathcal{U}$ on G is the uniform structure generated by the sets L_U and R_U as U ranges over all open neighborhoods of e in G.

XXIII.1.3.2. The uniform structures $\mathcal{L}$ and $\mathcal{R}$ coincide in many cases, e.g. if G is compact () or abelian, but not in general (). The uniform structure $\mathcal{U}$ coincides with $\mathcal{L}$ or $\mathcal{R}$ if and only if $\mathcal{L} = \mathcal{R}$.

XXIII.1.3.3. PROPOSITION. Let G be a topological group. The following are equivalent:

(i) $\mathcal{L} = \mathcal{R}$.

(ii) $\mathcal{L} = \mathcal{U}$.

(iii) $\mathcal{R} = \mathcal{U}$.

(iv) G has a fundamental system of neighborhoods of e invariant under all inner automorphisms, i.e. neighborhoods U such that $gUg^{-1} = U$ for all $g \in G$.

However, even though the uniform structures do not coincide in general, they all define the given topology on G:

XXIII.1.3.4. PROPOSITION. Let $(G, \mathcal{T})$ be a topological group. Then the topology on G defined by any of the three uniform structures $\mathcal{L}$, $\mathcal{R}$, $\mathcal{U}$ is $\mathcal{T}$.

XXIII.1.3.5. PROPOSITION. Let G be a topological group. Then

(i) The translations λ_g are uniformly continuous for $\mathcal{L}$ and $\mathcal{U}$, for every $g \in G$.

(ii) The translations ρ_g are uniformly continuous for $\mathcal{R}$ and $\mathcal{U}$, for every $g \in G$.

(iii) Inversion ι is uniformly continuous for $\mathcal{U}$.

Inversion is not uniformly continuous for $\mathcal{L}$ or $\mathcal{R}$ in general: inversion interchanges $\mathcal{L}$ and $\mathcal{R}$. In fact:

XXIII.1.3.6. PROPOSITION. Let G be a topological group. The following are equivalent:

(i) The translations λ_g are uniformly continuous for $\mathcal{R}$, for every $g \in G$.

(ii) The translations ρ_g are uniformly continuous for $\mathcal{L}$, for every $g \in G$.

(iii) Inversion ι is uniformly continuous for $\mathcal{L}$.

(iv) Inversion ι is uniformly continuous for $\mathcal{R}$.

(v) $\mathcal{L} = \mathcal{R} (= \mathcal{U})$.

Metrization

It is an immediate corollary of XXIII.1.3.4. and () that a first countable topological group is metrizable, since $\mathcal{L}$, $\mathcal{R}$, and $\mathcal{U}$ are all countably generated if G is first countable. There is a more precise result:

XXIII.1.3.7. Corollary. Every first countable Hausdorff topological group is metrizable under a left-invariant metric which generates the uniformity $\mathcal{L}$.

XXIII.1.3.8. If d is a left-invariant metric for G, then the metric $d'(g,h) = d(g^{-1}, h^{-1})$ is right-invariant and defines the topology of G (and the uniformity $\mathcal{R}$), so "left-invariant" can be replaced by "right-invariant" in XXIII.1.3.7..

However, G does not have a two-sided invariant metric in general; in fact, it has a two-sided invariant metric if and only if it satisfies the conditions of XXIII.1.3.6.. There is a metric giving the uniformity $\mathcal{U}$ if G is first countable, for example

$$d'(g,h) = d(g,h) + d(g^{-1}, h^{-1})$$

if d is left-invariant; but d' is neither left- or right-invariant unless $\mathcal{L} = \mathcal{R} = \mathcal{U}$.

Completion

XXIII.1.3.9. Definition. A topological group G is *complete* if it is complete with respect to the uniformity $\mathcal{U}$.

A group which is complete in this sense is often called *Raikov-complete*.

XXIII.1.3.10. Proposition. Let G be a complete topological group, and H a subgroup. Then

(i) H is complete if and only if it is closed in G.

(ii) If H is normal, then G/H is complete.

XXIII.1.3.11. Theorem. Let G be a topological group. Then there is a complete topological group $\bar{G}$ containing G as a dense subgroup. $\bar{G}$ is unique up to topological isomorphism which is the identity on G. $\bar{G}$ is called the *completion*, or *Raikov completion*, of G.

XXIII.1.3.12. A topological group G does not generally have a completion with respect to $\mathcal{L}$ or $\mathcal{R}$ (more precisely, the completion of G with respect to $\mathcal{L}$ or $\mathcal{R}$ as a uniform space, called the *Weil completion* of G, does not have a compatible structure as a topological group in general); in fact, it has such a completion (as a topological group) if and only if $\mathcal{L} = \mathcal{R}$.

XXIII.1.4. Locally Compact Topological Groups

Topological groups which are locally compact and Hausdorff are especially important, and have a lot of nice associated structure which allows analysis to be done on them.

XXIII.1.4.1. Definition. A *locally compact group* is a locally compact Hausdorff topological group, i.e. a topological group whose topology is locally compact and Hausdorff. A *compact group* is a compact Hausdorff topological group.

Thus the words "Hausdorff" and "topological" will be understood in the names "locally compact group" and "compact group."

XXIII.1.4.2. Examples. (i) The additive group $\mathbb{R}$, or $\mathbb{R}^n$, with its usual topology, is a locally compact group.

(ii) The group $GL_n(\mathbb{R})$ (XXIII.1.2.3.(iii)) is locally compact (in its usual topology).

(iii) $\mathbb{T}$ is a compact group (in its usual topology). Any product of copies of $\mathbb{T}$ is a compact goup.

(iv) Any group with the discrete topology is a locally compact group.

(v) Any closed subgroup of a locally compact group is locally compact.

(vi) The additive group of an infinite-dimensional normed vector space is not a locally compact group in the norm topology.

(vii) The additive group $\mathbb{Q}$ is not a locally compact group in its usual topology (the relative topology from $\mathbb{R}$). But it is in the discrete topology.

By homogeneity, we obtain:

XXIII.1.4.3. Proposition. A Hausdorff topological group G is locally compact if and only if there is a compact neighborhood of e in G.

XXIII.1.4.4. Proposition. Let G be a locally compact group. Then G has an open subgroup which is σ-compact. If G is connected, it is σ-compact.

Proof: Let U be a neighborhood of e in G with $\bar{U}$ compact. Let H be the subgroup of G generated by U. Then H is open and is the subgroup of G generated by $\bar{U}$ (XXIII.1.2.33.). If $V = U \cup U^{-1}$, then $\bar{V}$ is compact and generates H. We have that $\bar{V}^2$ is compact since it is the image of $\bar{V} \times \bar{V}$ under multiplication; by induction, $\bar{V}^n$ is compact for all n. Thus $H = \cup_{n=1}^{\infty} \bar{V}^n$ is σ-compact. 👍

XXIII.1.4.5. Corollary. Let G be a locally compact group. Then G partitions into clopen subsets, each of which is σ-compact and thus Lindelöf. So G is paracompact and hence normal.

Proof: The cosets of a σ-compact open subgroup give such a partition. 👍

XXIII.1.4.6. Corollary. Let G be a locally compact group. The following are equivalent:

(i) G is second countable.

(ii) G is first countable and σ-compact.

(iii) G is first countable and compactly generated.

XXIII.1.4.7. Corollary. If G is a first countable (equivalently, metrizable) locally compact group, then G has an open subgroup which is second countable.

XXIII.1.4.8. Proposition. Let G be a topological group, K a compact subset of G, and U an open neighborhood of K. Then there is an open neighborhood V of e in G such that $KV \subseteq U$.

Proof: For each $g \in K$, $ge \in U$, so by joint continuity there are neighborhoods W_g of g and V_g of e with $W_g V_g \subseteq U$. The W_g cover K, so there is a finite subcover $\{W_{g_1}, \ldots, W_{g_n}\}$. Set $V = V_{g_1} \cap \cdots \cap V_{g_n}$. If $g \in K$, then $g \in W_{g_k}$ for some k, so $gV \subseteq W_{g_k} V \subseteq W_{g_k} V_{g_k} \subseteq U$. Thus $KV \subseteq U$. 👍

Similarly, we have:

XXIII.1.4.9. Proposition. Let G be a topological group, K a compact subset of G, and U an open neighborhood of e. Then there is an open neighborhood V of e in G such that $g^{-1}Vg \subseteq U$ for all $g \in K$.

Proof: For each $g \in K$, $g^{-1}eg = e$, so by joint continuity there are neighborhoods W_g of g and V_g of e with $h^{-1}V_g h \subseteq U$ for all $h \in W_g$. The W_g cover K, so there is a finite subcover $\{W_{g_1}, \ldots, W_{g_n}\}$. Set $V = V_{g_1} \cap \cdots \cap V_{g_n}$. If $g \in K$, then $g \in W_{a_k}$ for some k, so $g^{-1}Vg \subseteq g^{-1}V_{g_k}g \subseteq U$. 👍

XXIII.1.4.10. Proposition. Let G be a (necessarily locally compact) group. If U is a compact open neighborhood of e in G, then U contains a compact open subgroup of G.

Proof: There is a neighborhood V of e with $V = V^{-1}$ and $UV \subseteq U$ (XXIII.1.4.8. with $K = U$). Then $V^2 \subseteq U$, and by induction $V^n \subseteq U$. Thus the subgroup of G generated by V, which is open, is contained in U. 👍

XXIII.1.4.11. THEOREM. Let G be a locally compact group. Then every neighborhood of e in G contains a compact subgroup H such that G/H is metrizable. If G is compactly generated, the subgroup H may be chosen normal.

PROOF: First let U be a compact neighborhood of e in G, and let G_0 be the subgroup of G generated by U. Then G_0 is an open subgroup. If H is a subgroup of G_0, then G/H is a separated union of cosets of G_0/H; hence G/H is metrizable if G_0/H is metrizable. Thus it suffices to show the last statement, i.e. that if G is generated by a compact symmetric neighborhood U of e, then for any neighborhood V of e, G has a compact normal subgroup H contained in V with G/H metrizable (first countable).

Fix a neighborhood V, which we may take to be compact and symmetric. Set $V_1 = V$. Generate a decreasing sequence (V_n) of symmetric compact neighborhoods of e such that $g^{-1}V_{n+1}g \subseteq V_n$ for all $g \in U$ (XXIII.1.4.9.) and such that $V_{n+1}^2 \subseteq V_n$. Set $H = \cap_n V_n$. Then H is a compact subgroup of G, and $g^{-1}Hg \subseteq H$ for all $g \in U$; since U generates G, H is normal in G. If $\pi : G \to G/H$ is the quotient map, the sets $(\pi(V_n))$ are compact neighborhoods of the identity which form a local neighborhood base by XIII.11.1.13.. Thus G/H is first countable. 👍

XXIII.1.4.12. PROPOSITION. Every locally compact group is complete.

XXIII.1.4.13. PROPOSITION. Let G be a locally compact group and H a closed subgroup. Then G/H is locally compact in the quotient topology. So if H is normal, G/H is a locally compact group.

The next result is closely related to the Open Mapping Theorem for Banach spaces (), with a similar proof based on the Baire Category Theorem. This result is a special case of XXIII.1.6.2..

XXIII.1.4.14. THEOREM. [OPEN MAPPING THEOREM FOR LOCALLY COMPACT GROUPS] Let G and G' be locally compact groups, and ϕ a continuous group homomorphism from G onto G'. If G is σ-compact (so G' is also σ-compact), then ϕ is an open mapping, and thus G' is topologically isomorphic to $G/\ker(\phi)$.

As in the Banach space case (), we also get a Closed Graph Theorem for locally compact groups:

XXIII.1.4.15. THEOREM. [CLOSED GRAPH THEOREM FOR LOCALLY COMPACT GROUPS] Let G and G' be σ-compact locally compact groups, and $\phi : G \to G'$ a homomorphism. If the graph $\Gamma(\phi)$ is a closed subset of $G \times G'$, then ϕ is continuous.

PROOF: $G \times G'$ is locally compact and σ-compact, and $\Gamma(\phi)$ is a closed subgroup, hence also locally compact and σ-compact. The map $\pi_G : (x, \phi(x)) \mapsto x$ is a continuous bijective homomorphism from $\Gamma(\phi)$ onto G, hence a topological isomorphism by XXIII.1.4.14.; thus the inverse map ψ is continuous, and hence $\phi = \pi_{G'} \circ \psi$ is continuous. 👍

XXIII.1.4.16. Corollary. Let G be a group, and let $\mathcal{T}$ be a Hausdorff topology on G, not necessarily a topological group topology. Then there is at most one topology on G stronger than $\mathcal{T}$ making it into a σ-compact locally compact group.

Proof: Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be topologies stronger than $\mathcal{T}$ making G into a locally compact σ-compact group, and let ϕ be the identity map from $(G, \mathcal{T}_1)$ to $(G, \mathcal{T}_2)$. The graph of ϕ is the diagonal in $G \times G$. The product topology $\mathcal{T}_1 \times \mathcal{T}_2$ on $G \times G$ is stronger than the topology $\mathcal{T} \times \mathcal{T}$. Since $\mathcal{T}$ is Hausdorff, the diagonal is closed in $G \times G$ for the topology $\mathcal{T} \times \mathcal{T}$, and hence also closed in the topology $\mathcal{T}_1 \times \mathcal{T}_2$. Thus ϕ has closed graph and is therefore continuous, i.e. $\mathcal{T}_1$ is stronger than $\mathcal{T}_2$. The same argument with $\mathcal{T}_1$ and $\mathcal{T}_2$ interchanged shows that $\mathcal{T}_2$ is stronger than $\mathcal{T}_1$. 👍

XXIII.1.4.17. XXIII.1.4.14.–XXIII.1.4.16. are false in general without "σ-compact": the additive group $\mathbb{R}$ is a locally compact group in either the ordinary topology or the discrete topology. The $\mathcal{T}$ in XXIII.1.4.16. is also necessary in general if G is uncountable: $\mathbb{R}$ has discontinuous group-automorphisms (using AC).

XXIII.1.4.18. XXIII.1.4.16. does *not* say that a group has at most one σ-compact Hausdorff topology making it into a topological group. In fact, there is an abelian group G which has $2^{\aleph_0}$ mutually nonequivalent topological group topologies, each of which is compact and metrizable [Fuc59] (where two topological group topologies $\mathcal{T}_1$ and $\mathcal{T}_2$ on a group G are *equivalent* if $(G, \mathcal{T}_1)$ and $(G, \mathcal{T}_2)$ are isomorphic as topological groups). ✋

However, we do have:

XXIII.1.4.19. Corollary. The only locally compact group topology on a countable group is the discrete topology.

Any closed subgroup of a locally compact group is locally compact (). Conversely:

XXIII.1.4.20. Theorem. Let G be a Hausdorff topological group, and H a subgroup which is locally compact in the relative topology. Then H is a closed subgroup of G.

XXIII.1.5. Polish Groups and Baire Groups

XXIII.1.5.1. Definition. A *Polish group* is a topological group which is a Polish space (), i.e. homeomorphic to a separable complete metric space.

XXIII.1.5.2. There is a large overlap between the class of locally compact groups and the class of Polish groups: the overlap consists precisely of the second countable locally compact groups (XXIII.1.4.6.). The theory of Polish groups is to a large extent similar and parallel to the theory of locally compact groups. Except for one little thing: Polish groups which are not locally compact do not have Haar measure, so the most crucial tool for analysis is lacking. Thus the theory of Polish groups is not as satisfactory overall as that of locally compact groups.

There are many important topological groups which are Polish but not locally compact, for example:

XXIII.1.5.3. Examples. (i) The additive group of any separable Banach space is a Polish group.

(ii) The multiplicative group of invertible elements in any separable Banach algebra is a Polish group in the relative norm topology (),().

(iii) The group of unitary operators on a separable Hilbert space is a Polish group under the strong or weak operator topologies (which coincide on this group; cf. ()).

(iv) The group of homeomorphisms of a compact metric space is a Polish group in the topology of uniform convergence ().

(v) The group of isometries of a separable complete metric space is a Polish group in the topology of pointwise convergence (which coincides with the topology of u.c. convergence; cf. ()).

(vi) Any closed subgroup of a Polish group is a Polish group.

(vii) A countable product of Polish groups is a Polish group.

XXIII.1.5.4. There is one sense in which Polish groups are nicer than locally compact groups: there is a universal Polish group $\tilde{G}$, a Polish group with the property that every Polish group is topologically isomorphic to a closed subgroup of $\tilde{G}$. In fact, the group of homeomorphisms of the Hilbert cube with the topology of uniform convergence is such a universal group ([Usp86]; cf. [Kec95, 9.18]).

XXIII.1.6. Open Mappings and Automatic Continuity

In this section, we collect together some miscellaneous results about when surjective homomorphisms of topological groups are automatically open mappings, and when group operations and group actions are automatically continuous.

We first give simple criteria for when homomorphisms are continuous or open:

XXIII.1.6.1. Proposition. Let G and G' be topological groups, and $\phi : G \to G'$ a group-homomorphism. Then:

(i) If ϕ is continuous at one point, then it is continuous everywhere.

(ii) ϕ is an open mapping if and only if, for every open neighborhood U of e, $\phi(U)$ has nonempty interior (i.e. contains a nonempty open set).

Proof: (i): Suppose ϕ is continuous at g, i.e. if $g_i \to g$, then $\phi(g_i) \to \phi(g)$. If $x_i, x \in G$ and $x_i \to x$, then $gx^{-1}x_i \to g$, so

$$\phi(g)\phi(x)^{-1}\phi(x_i) = \phi(gx^{-1}x_i) \to \phi(g)$$

and thus

$$\phi(x_i) = \phi(x)\phi(g)^{-1}\phi(g)\phi(x)^{-1}\phi(x_i) \to \phi(x)\phi(g)^{-1}\phi(g) = \phi(x) \ .$$

The first main result is a general version of XXIII.1.4.14.:

XXIII.1.6.2. THEOREM. [OPEN MAPPING THEOREM FOR σ-COMPACT GROUPS] Let G and G' be topological groups, with G' a Baire group, and ϕ a continuous group homomorphism from G onto G'. If G is σ-compact (so G' is also σ-compact), then ϕ is an open mapping, and thus G' is topologically isomorphic to $G/\ker(\phi)$.

PROOF: The homomorphism ϕ factors topologically through $G/\ker(\phi)$, so we may assume without loss of generality that ϕ is a bijection. Let $G = \cup_{n=1}^{\infty} K_n$, with K_n compact. Then $G' = \cup_{n=1}^{\infty} \phi(K_n)$, and $\phi(K_n)$ is compact and hence closed in G' since G' is Hausdorff. By the Baire Category Theorem, some $\phi(K_n)$ has nonempty interior V. The restriction of ϕ to K_n is a homeomorphism, so ϕ^{-1} is continuous on V since V is open. Since V is nonempty, ϕ^{-1} is continuous (XXIII.1.6.1.(i)), i.e. ϕ is an open map. 👍

XXIII.1.6.3. Note that no hypothesis on G beyond σ-compactness is needed, not even an assumption that G is Hausdorff. This proof is attributed to H. GLÖCKNER, who observed that the local compactness hypothesis on G in many references is not necessary.

XXIII.1.6.4. COROLLARY. Let G be a countable group. Then the only Polish topological group topology on G is the discrete topology.

XXIII.1.7. Exercises

XXIII.1.7.1. Let G be the additive group of real numbers. Give G the Sorgenfrey topology (XIII.7.10.14.). Show that the group operation (addition) is jointly continuous (i.e. continuous from $G \times G$ to G), but that inversion (negation) is not continuous. Thus $(\mathbb{R}, +)$ with this topology is not a topological group.

XXIII.1.7.2. Let G be a topological group, and A a subset of G. Show that the closure of A is contained in AV for any neighborhood V of e, and in particular $\bar{U} \subseteq U^2$ if U is a neighborhood of e in G. [If $g \in \bar{A}$, then $gV^{-1} \cap A \neq \emptyset$.]

XXIII.1.7.3. (a) Use XXIII.1.7.2. and XXIII.1.2.15.(i) to give a direct proof that a topological group is T_3 (cf. XIII.7.5.1.).

(b) Give a direct proof that a T_0 topological group is Hausdorff.

XXIII.1.7.4. (a) Let G be a topological group and H a subgroup. If H contains a neighborhood of e, show that H is open. Thus the hypothesis in XXIII.1.2.33. that U be an open neighborhood can be relaxed to just requiring that U be a neighborhood.

(b) Show that a closed subgroup of a topological group is either open or nowhere dense.

XXIII.1.7.5. Let G be a topological group, and U an open neighborhood of e in G. Set $W = \cup_{n=1}^{\infty} U^n$.

(a) Show that W is a clopen subset of G.

(b) W need not be a subgroup of G. [Consider $\{0, 1\} \subseteq \mathbb{Z}$ with the discrete topology.]

(c) If G is connected, then $W = G$.

XXIII.1.7.6. How much of the theory of topological groups requires joint continuity of multiplication? That is, if we change the definition of a topological group G to only require continuity of inversion and separate continuity of multiplication (i.e. that ι and λ_g, ρ_g are continuous for all $g \in G$), how much of the theory persists? [Consider the case where G is an infinite group with the finite complement topology.]

XXIII.1.7.7. For a topological space X to have a group structure making it a topological group, i.e. for X to be homeomorphic to a topological group, it is necessary that X be homogeneous. But this is far from sufficient, even if X is compact and metrizable.

(a) The Hilbert cube $\mathbb{H}$ is homogeneous (), but not homeomorphic to a topological group. [Every continuous function from $\mathbb{H}$ to $\mathbb{H}$ has a fixed point ().]

(b) S^n for even $n > 0$ is not homeomorphic to a topological group. [Use ().]

In fact, S^n is homeomorphic to a topological group if and only if n is 0, 1, or 3 (), ().

Groups of Homeomorphisms

If X is a topological space, the group $\mathrm{Homeo}(X)$ of homeomorphisms of X can be given various topologies, e.g. the topology of pointwise convergence or the compact-open topology (which is the topology of u.c. convergence if X is metrizable ()). $\mathrm{Homeo}(X)$ is sometimes, but not always, a topological group under these topologies. The next several problems explore when $\mathrm{Homeo}(X)$, or various natural subgroups, is or is not a topological group.

XXIII.1.7.8. Let X be a Hausdorff space. Give $\mathrm{Homeo}(X)$ the compact-open topology. Show that multiplication is jointly continuous.

XXIII.1.7.9. Let X be a compact Hausdorff space. Show that $\mathrm{Homeo}(X)$ is a topological group under the compact-open topology (which is the topology of uniform convergence).

XXIII.1.7.10. [Are46a] Let X be the space $\mathbb{N}_0 \cup \{\frac{1}{n} : n \in \mathbb{N}\}$, with its relative topology from $\mathbb{R}$. Then X is a locally compact metrizable space. Show that inversion is not continuous in $\mathrm{Homeo}(X)$. [Consider ϕ_n, where $\phi_n(n) = \frac{1}{n}$, $\phi_n(m) = m - 1$ if $m > n$, $\phi_n\left(\frac{1}{m}\right) = \frac{1}{m+1}$ if $m \geq n$, and $\phi_n(x) = x$ otherwise.]

It is shown in [Are46a] that if X is locally compact and locally connected, then inversion in $\mathrm{Homeo}(X)$ is continuous in the compact-open topology, and hence $\mathrm{Homeo}(X)$ is a topological group in this topology.

XXIII.1.7.11. Let X be a topological space. Give $\mathrm{Homeo}(X)$ the topology of pointwise convergence. Then multiplication is separately continuous.

XXIII.1.7.12. Give $\mathrm{Homeo}(\mathbb{R}^2)$ the topology of pointwise convergence. Show that multiplication is not jointly continuous, and that inversion is not continuous.

XXIII.1.7.13. Let $X = \mathbb{R}$ or $[0, 1]$. Show that the topology of pointwise convergence on $\mathrm{Homeo}(X)$ coincides with the compact-open topology (topology of u.c. convergence), and that $\mathrm{Homeo}(X)$ is a topological group under this topology.

XXIII.1.7.14. Let X be a metric space. Show that the group $\mathrm{Isom}(X)$ of isometries (isometric bijections) of X is a topological group in the topology of pointwise convergence.

XXIII.1.7.15. Group Topologies on $\mathbb{Z}$, $\mathbb{Q}$, and $\mathbb{R}$. If G is a group and H a (Hausdorff) topological group, and $\phi : G \to H$ is an injective homomorphism, G can be identified with $\phi(G)$ and given the relative topology, which makes G into a (Hausdorff) topological group. In particular, if H is a (Hausdorff) topological group and x is an element of H of infinite order, the map $n \mapsto x^n$ from $\mathbb{Z}$ to H can be used to give a (Hausdorff) topological group topology on $\mathbb{Z}$. This gives an enormous variety of nonequivalent (XXIII.1.4.18.) group topologies on $\mathbb{Z}$.

(a) Let S be a nonempty subset of $\mathbb{R}$. If $G = \mathbb{Z}, \mathbb{Q}$, or $\mathbb{R}$, map G into $\prod_{s\in\mathcal{S}} \mathbb{T}$ by sending $x \in G$ to the point $\phi_S(x)$ with s-coordinate $e^{2\pi isx}$. Show that if $G = \mathbb{Z}$ or $\mathbb{Q}$, then ϕ_S is injective unless S is contained in a cyclic subgroup of $(\mathbb{Q}, +)$, and if $G = \mathbb{R}$, then ϕ_S is injective unless S is contained in a cyclic subgroup of $(\mathbb{R}, +)$. In these cases, give G the relative topology $\mathcal{T}_S$. The topology $\mathcal{T}_S$ is metrizable (first countable) if and only if S is countable.

(b) Let $\mathcal{B}$ be a Hamel basis for $\mathbb{R}$ over $\mathbb{Q}$ consisting of irrational numbers. If S_1, S_2 are distinct nonempty subsets of $\mathcal{B}$ (not singletons if $G = \mathbb{R}$), show that the topologies $\mathcal{T}_{S_1}$ and $\mathcal{T}_{S_2}$ are nonequivalent. Conclude that there are $2^{2^{\aleph_0}}$ mutually nonequivalent Hausdorff topologies on G making $(G, +)$ a topological group. These topologies are all totally bounded, i.e. the completion is compact. These topologies are all weaker than the ordinary topology on G.

(c) The topologies $\mathcal{T}_S$ are by no means all the Hausdorff topological group topologies on $(\mathbb{Q}, +)$: for example, the discrete topology, the relative topology from $\mathbb{R}$, and the $\boldsymbol{n}$-adic topologies (III.5.3.9.) are not among them. (The completions with respect to these topologies are locally compact but noncompact.) But there are exactly $2^{2^{\aleph_0}}$ distinct topologies on $\mathbb{Q}$. The only locally compact or Polish topological group topology on $(\mathbb{Q}, +)$ is the discrete topology. Similar statements are true for $(\mathbb{Z}, +)$.

(d) If G is any infinite abelian group of cardinality κ, then G has 2^{2^κ} mutually nonequivalent Hausdorff topological group topologies [Pod77]. In particular, $(\mathbb{R}, +)$ has $2^{2^{2^{\aleph_0}}}$ mutually nonequivalent Hausdorff topological group topologies. Using that $(\mathbb{R}, +)$ is isomorphic to the direct sum of $2^{\aleph_0}$ copies of $(\mathbb{Q}, +)$, construct from (b) for $\mathbb{Q}$ a family of $2^{2^{2^{\aleph_0}}}$ mutually nonequivalent totally bounded Hausdorff topological group topologies on $(\mathbb{R}, +)$. The additive group of any separable Banach space is also isomorphic to $\mathbb{R}$.

XXIII.2. Haar Measure

The most important tool for analysis on locally compact groups is Haar measure. Every locally compact group has an essentially unique translation-invariant measure called Haar measure. Haar measure generalizes Lebesgue measure on $\mathbb{R}$ or $\mathbb{R}^n$ and is of similar use and importance. And the fact that topological groups which are not locally compact do not have a similar translation-invariant measure is a serious obstacle to their study.

XXIII.2.1. Definition and Existence

XXIII.2.1.1. Definition. Let G be a Hausdorff topological group. A *left Haar measure* on G is a measure μ defined on the Baire sets in G, with the following properties:

(i) $\mu(U) > 0$ for every nonempty open Baire set U in G.

(ii) $\mu(K) < \infty$ for every compact G_δ K in G.

(iii) μ is *left invariant*: $\mu(\lambda_g(A)) = \mu(A)$ for every $g \in G$ and every Baire set A in G.

A *right Haar measure* on G is a measure μ on the Baire sets in G satisfying (i), (ii), and

(iii′) μ is *right invariant*: $\mu(\rho_g(A)) = \mu(A)$ for every $g \in G$ and every Baire set A in G.

If G is abelian, there is no difference between a left Haar measure and a right Haar measure on G. However, if G is not abelian a left Haar measure need not be a right Haar measure, and conversely (XXIII.2.2.6.(c)). If G is second countable, the Baire sets are the same as the Borel sets in G, so (i) holds for all open sets and (ii) holds for all compact sets in G.

Conditions (i) and (ii) are nondegeneracy conditions: without (i) the zero measure would be a left and right Haar measure, and without (ii) the measure in which every nonempty set has infinite measure would be a left and right Haar measure.

XXIII.2.1.2. Examples. (i) Lebesgue measure is a (left and right) Haar measure on $\mathbb{R}$ or $\mathbb{R}^n$ with addition.

(ii) A (left or right) Haar measure on $\mathbb{T}$ can be described in several equivalent ways. One simple way is to identify it with $[0, 1)$ by $t \leftrightarrow e^{2\pi it}$ and transfer Lebesgue measure on $[0, 1)$ to $\mathbb{T}$. One could also take arc length measure on $\mathbb{T}$ (or 1-dimensional Hausdorff measure) to obtain the same measure up to a factor of 2π.

(iii) Counting measure is a (left or right) Haar measure on any discrete group.

(iv) Any positive scalar multiple of a left Haar measure on G is a left Haar measure, and similarly for right Haar measures.

The main theorem is:

XXIII.2.1.3. Theorem. Let G be a locally compact group. Then there is a left Haar measure on G, which is unique up to positive scalar multiple. There is also a right Haar measure on G, unique up to a positive scalar multiple. Conversely, any (Hausdorff) topological group with a left or right Haar measure is locally compact.

XXIII.2.2. Haar Integrals

By the results of (), there is an entirely equivalent formulation of Haar measure as an integral or as a positive linear functional.

XXIII.2.2.1. DEFINITION. Let G be a locally compact group. A *left Haar integral* on G is a nonzero positive linear functional I on $C_c(G)$ which is *left invariant*: $I(g \cdot \phi) = I(\phi)$ for all $g \in G$, $\phi \in C_c(G)$, where $(g \cdot \phi)(x) = \phi(gx)$, i.e. $g \cdot \phi = \phi \circ \lambda_g$. A *right Haar integral* is a nonzero positive linear functional I on $C_c(G)$ which is *right invariant*: $I(\phi \cdot g) = I(\phi)$ for all $g \in G$, $\phi \in C_c(G)$, where $(\phi \cdot g)(x) = \phi(xg)$, i.e. $\phi \cdot g = \phi \circ \rho_g$.

XXIII.2.2.2. By the Riesz Representation Theorem (), a positive linear functional on $C_c(G)$ is given by integration with respect to a Baire measure. So if I is a left Haar integral on G, then

$$I(\phi) = \int_G \phi \, d\mu$$

for a Baire measure μ.

XXIII.2.2.3. PROPOSITION. If I is a left Haar integral on G, then μ is a left Haar measure on G, and similarly for a right Haar integral.

Conversely:

XXIII.2.2.4. PROPOSITION. If μ is a left Haar measure on G, then I defined by $I(\phi) = \int_G \phi \, d\mu$ is a left Haar integral on G, and similarly for a right Haar measure.

Thus Theorem XXIII.2.1.3. is equivalent to:

XXIII.2.2.5. THEOREM. Let G be a locally compact group. Then there is a left Haar integral on G, which is unique up to positive scalar multiple. There is also a right Haar integral on G, unique up to a positive scalar multiple.

The Haar integral is easier and more elementary to describe and find than the Haar measure in many cases:

XXIII.2.2.6. EXAMPLES. (i) For $\mathbb{R}$ with addition, the Haar integral (left and right) is simply given by Riemann integration: if $\phi \in C_c(\mathbb{R})$,

$$I(\phi) = \int_{-\infty}^{+\infty} \phi(t) \, dt \ .$$

This is not really an improper Riemann integral since ϕ has compact support: it is an ordinary Riemann (or even Cauchy) integral over a finite interval, which varies from function to function.

(ii) The (normalized) Haar integral on $\mathbb{T}$ is also given by Riemann integration: if $\phi \in C_c(\mathbb{T}) = C(\mathbb{T})$, then

$$I(\phi) = \int_0^1 \phi(e^{2\pi i t})\, dt \ .$$

(iii) Here is perhaps the simplest example of a locally compact group for which left and right Haar measure (or integral) are different: the real "$ax + b$ group." Let

$$G = \left\{ \begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix} : a, b \in \mathbb{R}, a > 0 \right\} \ .$$

G is a subgroup of $GL(2, \mathbb{R})$, i.e. is a group under matrix multiplication. G can be identified as a set with the open right half-plane $\mathbb{R}_+ \times \mathbb{R}$ in $\mathbb{R}^2$ by

$$\begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix} \longleftrightarrow (a, b)$$

and given the topology from this identification (which agrees with the subspace topology from $GL(2, \mathbb{R})$ regarded as an open subset of $M_2(\mathbb{R}) \cong \mathbb{R}^4$). From this point of view, the group operations are given by

$$(a, b)(x, y) = (ax, ay + b)$$

$$(a, b)^{-1} = \left(\frac{1}{a}, -\frac{b}{a}\right)$$

(cf. ()); the identity is $(1, 0)$. Since these operations are continuous, G is a locally compact group (it is even a Lie group).

If $g = (a, b) \in G$, left multiplication by g is an affine map $(x, y) \mapsto (ax, ay + b)$ which is differentiable with constant derivative $\begin{bmatrix} a & 0 \\ 0 & a \end{bmatrix}$ and Jacobian a^2.

Consider the linear functional I on G given for $\phi \in C_c(G)$ by

$$I(\phi) = \int_G \frac{\phi(x, y)}{x^2}\, dA = \int_0^{+\infty} \int_{-\infty}^{+\infty} \frac{\phi(x, y)}{x^2}\, dy\, dx$$

(since the support of ϕ is a compact subset of the open right half-plane, the integral is only really over a sufficiently large closed rectangle on which $\frac{1}{x^2}$ is bounded, hence is a proper Riemann integral). Then I is a nonzero positive linear functional on $C_c(G)$. If $g = (a, b) \in G$, then by the change-of-variables formula, writing $u = ax$, $v = ay + b$, we have

$$I(g \cdot \phi) = \int_0^{+\infty} \int_{-\infty}^{+\infty} \frac{\phi(ax, ay + b)}{x^2}\, dy\, dx = \int_0^{+\infty} \int_{-\infty}^{+\infty} \frac{\phi(ax, ay + b)}{a^2 x^2} a^2\, dy\, dx$$

$$= \int_0^{+\infty} \int_{-\infty}^{+\infty} \frac{\phi(u, v)}{u^2}\, dv\, du = I(\phi)$$

(the integrals are actually over suitably large compact regions in G; cf. XXIII.2.9.3.). Thus I is a left Haar integral on G. The corresponding left Haar measure is given by

$$\mu(A) = \int_A \frac{1}{x^2}\, d\lambda(x, y)$$

for A a Borel set in G, where λ is Lebesgue measure on $\mathbb{R}^2$.

Similarly, right multiplication by $g = (a, b)$ is given by $(x, y) \mapsto (xa, xb + y)$, with derivative $\begin{bmatrix} a & 0 \\ b & 1 \end{bmatrix}$ and Jacobian a. Thus the functional

$$I_r(\phi) = \int_0^{+\infty} \int_{-\infty}^{+\infty} \frac{\phi(x, y)}{x} \, dy \, dx$$

is a right Haar integral on G, with right Haar measure

$$\mu(A) = \int_A \frac{1}{x} \, d\lambda(x, y)$$

for A Borel. Thus left and right Haar measures on G are different (XXIII.2.9.3.).

G is called the "$ax + b$ group" since it is isomorphic to the group of all order-preserving invertible affine transformations of $\mathbb{R}$, i.e. transformations of the form $f(x) = ax + b$, $a > 0$. One can similarly take the subgroup

$$\left\{ \begin{bmatrix} A & b \\ 0 & 1 \end{bmatrix} : A \in GL_n(\mathbb{R}), b \in \mathbb{R}^n \right\}$$

of $GL_{n+1}(\mathbb{R})$ of affine transformations of $\mathbb{R}^n$; restrict to such matrices where $det(A) > 0$ to get the connected component of the identity (orientation-preserving affine transformations), or to $A \in SO(n)$ to get the orientation-preserving affine isometries (rigid motions, cf. III.12.1.6.) of $\mathbb{R}^n$. There is a similar "$ax + b$ group" for any vector space over any field, or even modules over rings; some of these have topologies making them interesting topological groups (see e.g. [Bla83]).

XXIII.2.3. Invariant Measures for Group Actions

XXIII.2.4. Properties of Haar Measure

XXIII.2.5. The Modular Function

XXIII.2.6. Measures on Homogeneous Spaces

XXIII.2.7. Extending Haar Measure

XXIII.2.8. Measurable Groups

XXIII.2.9. Exercises

XXIII.2.9.1. Let G be a locally compact group.

(a) Show that there is a neighborhood of e in G which is a compact G_δ, which contains a neighborhood of e which is an open Baire set. [Use that G is completely regular.]

(b) Show that if μ is a left Haar measure on G, then there is a nonempty open Baire set V in G with $\mu(V) < \infty$.

(c) Conversely, if μ is a left invariant Baire measure on G for which there is a nonempty open Baire set V with $\mu(V) < \infty$, then $\mu(K) < \infty$ for every compact G_δ K. [K can be covered by finitely many left translates of V.]

Thus condition (ii) in the definition of a left Haar measure can be replaced by

(ii′) There is a nonempty open Baire set V in G with $\mu(V) < \infty$.

The same change can be made in the definition of a right Haar measure.

XXIII.2.9.2. Here is a warmup for Example XXIII.2.2.6.(c). Let $G = \mathbb{R}_+$ be the positive real numbers with multiplication.

(a) Show that the linear functional on $C_c(G)$ given for $\phi \in C_c(G)$ by

$$I(\phi) = \int_0^\infty \frac{\phi(x)}{x}\, dx$$

is (left and right) invariant, hence is a Haar integral. Write down the corresponding Haar measure.

(b) Show the result of (a) alternately by noting that $x \mapsto e^x$ is a topological isomorphism from $(\mathbb{R}, +)$ to $(\mathbb{R}_+, \cdot)$ and transferring the Haar integral on $\mathbb{R}$ to $\mathbb{R}_+$ using the change-of-variables formula.

XXIII.2.9.3. (a) In example XXIII.2.2.6.(c), give a more careful argument about regions of integration in the application of the change-of-variables formula in showing I is left invariant.

(b) Show by example that I is not right invariant, i.e. that the left and right Haar integrals for G are truly different. (Caution: this involves more than just showing that $I \neq I_r$.)

XXIII.2.9.4. (a) Let $G = GL(2, \mathbb{R})$. Identify G with an open set in $\mathbb{R}^4$ by

$$\begin{bmatrix} x & y \\ z & w \end{bmatrix} \longleftrightarrow (x, y, z, w)\ .$$

As in XXIII.2.2.6.(c), show that the linear functional defined for $\phi \in C_c(G)$ by

$$I(\phi) = \int_G \frac{\phi(x, y, z, w)}{(xw - yz)^2}\, d\lambda(x, y, z, w)$$

(the integral is actually a Riemann integral over a suitable compact region) is both a left and right Haar integral for G. Note that the denominator is the square of the determinant.

(b) Show similarly that if $G = GL(n, \mathbb{R})$, identified with an open set in $\mathbb{R}^{n^2}$, the left and right Haar integral is given by

$$I(\phi) = \int_G \frac{\phi(x_{ij})}{|Det(x_{ij})|^n}\, d\lambda(x_{ij})$$

where (x_{ij}) symbolically denotes the n^2-tuple $(x_{11}, \ldots, x_{nn})$, or the corresponding matrix. (Note that the case $n = 1$ is XXIII.2.9.2..)

XXIII.3. Group Algebras and Unitary Representations

One of the most important applications of the existence of Haar measure on locally compact groups is that certain Banach algebras can be associated to any locally compact group which have the "same" representation theory as the group. These Banach algebras are a crucial tool in showing that locally compact groups have a nice representation theory, and in developing a theory of analysis on locally compact groups (*abstract harmonic analysis*).

XXIII.3.1. The Group Algebra

The simplest algebra, the prototype for the others, is the group algebra.

XXIII.3.1.1. DEFINITION. Let G be a group (with no topology, or the discrete topology). The *group algebra* of G is the set $\mathbb{C}G$ of formal finite complex linear combinations

$$\mathbb{C}G = \left\{ f = \sum_{x \in G} \alpha_x \cdot x \right\}$$

of elements of G, where $\alpha_x \in \mathbb{C}$ for each x and only finitely many α_x are nonzero. The sum and product are defined in the obvious way:

$$\left(\sum_{x \in G} \alpha_x \cdot x \right) + \left(\sum_{x \in G} \beta_x \cdot x \right) = \sum_{x \in G} (\alpha_x + \beta_x) \cdot x$$

$$\left(\sum_{x \in G} \alpha_x \cdot x \right) \left(\sum_{x \in G} \beta_x \cdot x \right) = \sum_{y \in G} \sum_{z \in G} (\alpha_y \beta_z) \cdot yz = \sum_{x \in G} \left(\sum_{yz = x} \alpha_y \beta_z \right) \cdot x = \sum_{x \in G} \left(\sum_{y \in G} \alpha_y \beta_{y^{-1}x} \right) \cdot x$$

(all the sums are really finite sums, so rearrangement and grouping is legitimate).

XXIII.3.1.2. $\mathbb{C}G$ is clearly an algebra over $\mathbb{C}$, with unit $\sum_{x \in G} \alpha_x \cdot x$, where $\alpha_e = 1$ and $\alpha_x = 0$ for $x \neq e$. $\mathbb{C}G$ is commutative if and only if G is abelian.

XXIII.3.1.3. $\mathbb{C}G$ is perhaps better thought of as the set of all functions from G to $\mathbb{C}$ with finite support, identifying $f = \sum_{x \in G} \alpha_x \cdot x$ with the function $f(x) = \alpha_x$. The addition then is just usual addition of functions, and multiplication is "convolution":

$$(f * g)(x) = \sum_{y \in G} f(y) g(y^{-1}x) \ .$$

The unit is then χ_e. There is a natural subgroup of the group of units of $\mathbb{C}G$ isomorphic to G: $x \mapsto \chi_x$.

Representations

In its most general form, a *representation* of a group G on a set X is a homomorphism from G to the group of bijections of X (i.e. representing G as a group of transformations of X). If X has some structure (e.g. linear and/or topological), it is normally required that representations preserve the structure. Most commonly, X is a vector space and the bijections are required to be linear:

XXIII.3.1.4. DEFINITION. Let G be a group and V a vector space over $\mathbb{F}$. A *representation* of G on V is a homomorphism from G to the group of invertible linear transformations of V.

We will only consider the case $\mathbb{F} = \mathbb{C}$, i.e. representations on complex vector spaces.

Similarly, we may define a representation of an algebra:

XXIII.3.1.5. DEFINITION. Let A be a (unital) algebra over $\mathbb{F}$ and V a vector space over $\mathbb{F}$. A *representation* of A on V is a (unital) homomorphism from A to $\mathcal{L}(V)$.

We will again only consider the case $\mathbb{F} = \mathbb{C}$. In this section, we will only consider unital representations; later nonunital algebras and representations will be used, in which case there are some additional technicalities needed.

XXIII.3.1.6. Note that in XXIII.3.1.4. and XXIII.3.1.5., the representation is not required to be injective. An injective representation is called *faithful*.

One of the most important uses of the group algebra is in studying representations of the group:

XXIII.3.1.7. PROPOSITION. Let G be a group and V a complex vector space. There is a natural one-one correspondence between representations of G on V and (unital) representations of $\mathbb{C}G$ on V: if G is regarded as a subgroup of the group of units of $\mathbb{C}G$, then any unital representation of $\mathbb{C}G$ on V restricts to a representation of G on V, and every representation of G on V extends uniquely to a representation of $\mathbb{C}G$ on V. The two are inverse processes.

PROOF: This is almost obvious. If π is a representation of G on V, extend π to $\mathbb{C}G$ by setting

$$\pi\left(\sum_{x\in G} \alpha_x \cdot x\right) = \sum_{x\in G} \alpha_x \pi(x)$$

(the sums are really finite sums). The algebra homomorphism property of the extended π is routine to check, as are the rest of the assertions. 👍

XXIII.3.1.8. EXAMPLES. (i) Let G be any group. The representation ι of G on $\mathbb{C}$ with $\iota(x) = 1$ for all $x \in G$ is called the *trivial representation* of G. The corresponding representation of $\mathbb{C}G$ is the homomorphism $\iota : \mathbb{C}G \to \mathbb{C}$ given by $\iota(f) = f(e)$.

(ii) If G is any group, there are two important representations of G on $\mathbb{C}G$. For $x \in G$, define $\lambda(x) \in \mathcal{L}(\mathbb{C}G)$ by

$$[\lambda(x)f](y) = f(x^{-1}y) \ .$$

This λ is called the *left regular representation* of G. Similarly, define $\rho(x) \in \mathcal{L}(\mathbb{C}G)$ by

$$[\rho(x)f](y) = f(yx) \ .$$

This ρ is the *right regular representation* of G. (Putting inverses in the right places in these formulas to make them representations can be a delicate matter.) The corresponding representations of $\mathbb{C}G$ on $\mathbb{C}G$ are by left and right convolution: $\lambda(f)g = f * g$ and $\rho(f)g = g * \tilde{f}$, where $\tilde{f}(x) = f(x^{-1})$.

XXIII.3.1.9. There is an extensive algebraic theory of group representations, especially of finite groups, which we will not describe since it is really algebra, not analysis. Some of this theory will be subsumed in the theory of unitary representations of locally compact groups, described below.

The *-Algebra Structure of the Group Algebra

The group algebra $\mathbb{C}G$ has a natural structure as a *-algebra:

XXIII.3.1.10. DEFINITION. Let G be a group, with group algebra $\mathbb{C}G$. Define an involution on $\mathbb{C}G$ by

$$f^*(x) = \overline{f(x^{-1})} \ .$$

XXIII.3.1.11. The following properties of the involution are easily established for all $f, g \in \mathbb{C}G$, $\alpha \in \mathbb{C}$:

(i) $(f+g)^* = f^* + g^*$

(ii) $(\alpha f)^* = \bar{\alpha} f^*$

(iii) $(f * g)^* = g^* * f^*$

(iv) $(f^*)^* = f$.

[Property (iii) is a graphic example of the overuse of $*$ in functional analysis!]

With this involution, $\mathbb{C}G$ becomes a *-algebra in the sense of (). The elements of G, regarded as units in $\mathbb{C}G$, are "unitaries": $\chi_{x^{-1}} = (\chi_x)^{-1} = (\chi_x)^*$ for any $x \in G$.

*-Representations of *-Algebras

XXIII.3.1.12. DEFINITION. Let A be a (unital) *-algebra and V a complex inner product space. A **-representation* of A on V is a *-homomorphism π from A to $\mathcal{B}(V)$ with its involution from the inner product, i.e. π is an algebra-homomorphism with $\pi(x^*) = \pi(x)^*$ for all $f \in A$.

We usually only consider *-representations of *-algebras on Hilbert spaces, but occasionally we will want to use *-representations on incomplete inner product spaces. The additional generality is inconsequential, since any bounded operator on a normed vector space extends uniquely to the completion (). We rarely consider representations of *-algebras which are not *-representations, and occasionally "representation" will be taken to mean "*-representation" when there is no possibility of confusion (but we will try to be careful, if sometimes pedantic!)

Unitary Representations and *-Representations

We have the following analog of XXIII.3.1.4.:

XXIII.3.1.13. DEFINITION. Let G be a group and V a complex inner product space. A *unitary representation* of G is a homomorphism from G to the group $\mathcal{U}(V)$ of unitary operators on V ().

Again, we usually only consider unitary representations of groups on Hilbert spaces, but occasionally we will want to use unitary representations on incomplete inner product spaces.

XXIII.3.1.14. Unitary representations of groups are especially important for two reasons: (1) they do indeed arise naturally in many applications, and (2) unlike the theory of general representations which is largely intractable for infinite groups (general representations essentially reduce to unitary representations for finite groups), an extensive and manageable theory of unitary representations of general groups, and even of locally compact topological groups, can be developed.

Then we have the following important analogy of XXIII.3.1.7., whose proof is straightforward:

XXIII.3.1.15. PROPOSITION. Let G be a group and V a complex inner product space. There is a natural one-one correspondence between unitary representations of G on V and (unital) *-representations of $\mathbb{C}G$ on V: if G is regarded as a subgroup of the group of units of $\mathbb{C}G$, then any unital *-representation of $\mathbb{C}G$ on V restricts to a unitary representation of G on V, and every unitary representation of G on V extends uniquely to a *-representation of $\mathbb{C}G$ on V. The two are inverse processes.

XXIII.3.1.16. A faithful *-representation of $\mathbb{C}G$ evidently corresponds to a faithful unitary representation of G. But a faithful unitary representation of G does not necessarily correspond to a faithful *-representation of $\mathbb{C}G$. For example, if G is any subgroup of the circle group $\mathbb{T}$ (e.g. any cyclic group), the identity map on G gives a faithful one-dimensional unitary representation of G, but the corresponding *-representation of $\mathbb{C}G$ cannot be faithful if G is nontrivial. For this and many other reasons (e.g. ()) it is important to consider nonfaithful representations.

XXIII.3.2. The L^1 Algebra and the C*-Algebra of a Locally Compact Group

For (nondiscrete) topological groups, the group algebra is an inadequate object because it does not take the topology into consideration. Even for infinite discrete groups, it is useful to use a completion of the group algebra. In this section we show how to remedy both shortcomings for locally compact groups, ultimately associating to each locally compact group a group C*-algebra with the same representation theory.

XXIII.3.2.1. If G is a locally compact group, the most direct analog of the group algebra is $C_c(G)$, the set of complex-valued continuous functions on G with compact support. Note that if G has the discrete topology, then $C_c(G)$ is just $\mathbb{C}G$.

$C_c(G)$ is an algebra with pointwise multiplication, but we instead want to use convolution. To define convolution we use Haar measure. Fix a left Haar measure λ on G, and define

$$(f * g)(x) = \int_G f(y)g(y^{-1}x)\, d\lambda(y)$$

for $f, g \in C_c(G)$.

XXIII.3.2.2. PROPOSITION. Convolution is an associative binary operation of $C_c(G)$ making $C_c(G)$ into an algebra over $\mathbb{C}$.

XXIII.3.2.3. The definition of $C_c(G)$ as an algebra depends on the choice of left Haar measure λ. But if another left Haar measure μ is chosen, μ is just a scalar multiple of λ and an isomorphic algebra is obtained using μ (). If G is discrete and λ is chosen to be counting measure on G, then the multiplication so defined on $C_c(G) = \mathbb{C}G$ is just the standard convolution on $\mathbb{C}G$ defined in XXIII.3.1.1..

XXIII.3.2.4. **Caution:** It is common in the literature on representation theory to say that a locally compact group G is "separable" if $L^1(G)$ (or, equivalently, $C^*(G)$) is separable, i.e. if G is second countable. However, this use of the term "separable" can be misleading, since a locally compact group, even a compact abelian group, which is separable in the topological sense of having a countable dense subset is not necessarily "separable" in this sense (a product of $2^{\aleph_0}$ circle groups or nontrivial finite groups is a counterexample; cf. XIII.6.3.3.). Thus we will avoid using the term "separable" in any sense for topological groups.

XXIII.4. Lie Groups

A Lie group is a group which is a smooth manifold and whose multiplication and inversion are smooth maps. Since a smooth manifold has an underlying structure as a topological space and smooth functions are continuous, a Lie group has an underlying structure as a topological group (although it is technically not quite correct to say that a Lie group "is" a topological group), which is locally compact. Many of the most familiar and important topological groups are Lie groups. It turns out that every topological group whose topology is locally Euclidean has a unique structure as a Lie group. The theory of Lie groups bridges geometry, topology, linear and abstract algebra, and analysis, and impacts much of modern mathematics.

Lie groups are named in honor of Sophus Lie; note that "Lie" is pronounced "Lee."

> "In recent times the view becomes more and more prevalent that many branches of mathematics are nothing but the theory of invariants of special groups."
>
> *Sophus Lie*[2]

(This view was widely held in the late 19th/early 20th century, but has tempered since and only applies literally to some parts of modern mathematics, although it is still a good guiding principle in sufficiently general form.)

XXIII.4.1. The Classical Groups

XXIII.4.2. Lie Groups and Lie Algebras

XXIII.4.3. Locally Euclidean Groups

XXIII.4.3.1. Definition. A *locally Euclidean group* is a topological group whose topology is locally Euclidean (XIII.20.1.1.).

XXIII.4.3.2. A locally Euclidean space is T_1 (XIII.20.1.2.(viii)), and thus a locally Euclidean group G is Hausdorff, hence locally compact. By XIII.20.1.2.(vi), XXIII.1.2.36., and XXIII.1.4.4., the connected component of the identity is an open normal subgroup of G which is σ-compact. Thus, as a topological space, a locally Euclidean group is a topological manifold (and in particular metrizable; cf. XXIII.1.3.7.).

XXIII.4.3.3. Definition. Let G be a topological group. Then G has *no small subgroups*, or is an *NSS group*, if there is a neighborhood of the identity which contains no nontrivial subgroup of G.

An NSS group is Hausdorff, since $\overline{\{e\}}$ is contained in every neighborhood of e (Exercise XXIII.1.7.2.). Any Lie group is an NSS group (). By XXIII.1.4.11., a locally compact NSS group is metrizable.

XXIII.4.3.4. Hilbert asked in his 1900 problem list (#5) whether every locally Euclidean group is a Lie group (i.e. has a Lie group structure; Hilbert did not state the problem quite so cleanly). This proved to be a difficult problem and was solved in 1952 by A. Gleason, D. Montgomery, and L. Zippin ([Gle52], [MZ52]); special cases had been established by von Neumann (compact groups [vN33]), Pontryagin (abelian groups []), and Chevalley (solvable groups [Che41]). The proof of the general theorem was simplified by H. Yamabe ([Yam53a], [Yam53b]), although it is still deep and difficult. It is one of the remarkable results of mathematics, often described as "getting something for nothing."

[2] [Mor93, 1752].

XXIII.4.3.5. THEOREM. Let G be a locally compact group. The following are equivalent:

(i) G is locally Euclidean.

(ii) G is an NSS group.

(iii) G has a unique structure as a Lie group.

The proof is far beyond the scope of this book. See e.g. [MZ74] or [Kap71].

"[This result] shows that you can't have a little bit of orderliness without a lot of orderliness."

A. Gleason[3]

The implication (ii) ⇒ (i) of XXIII.4.3.5. has a generalization due to GLEASON and YAMABE:

XXIII.4.3.6. THEOREM. Let G be a locally compact group. Then G has an open subgroup H such that, if U is any neighborhood of e in G, there is a compact normal subgroup K of H, contained in U, such that H/K is locally Euclidean (and thus has a unique structure as a Lie group).

The K cannot be chosen normal in G in general (). But since H/K is a clopen subset of the homogeneous space G/K, it follows that G/K is locally Euclidean as a topological space, hence a manifold.

[3] [Yan02, p. 144].

XXIII.5. Locally Compact Abelian Groups and Pontryagin Duality

Locally compact abelian groups have special properties which make them an especially attractive class of objects to study, with important applications. There is a beautiful duality theory which leads to, among other things, a general theory of Fourier transform. Analysis on locally compact abelian groups, including the general Fourier transform, is called *harmonic analysis*.

XXIII.5.1. The Dual Group

To each locally compact abelian group G there is associated a dual group $\hat{G}$ which is also a locally compact abelian group. The major result, the Pontryagin Duality Theorem (), will be that the dual group $\hat{\hat{G}}$ of $\hat{G}$ is topologically isomorphic to G, so there is a true duality between G and $\hat{G}$. In this subsection, we define the dual group and examine some of its properties.

XXIII.5.1.1. Definition. Let G be a locally compact abelian group, and $\mathbb{T}$ the circle group (). A *character* of G is a continuous homomorphism $\chi : G \to \mathbb{T}$. If χ_1, χ_2 are characters, define the *product* $\chi_1\chi_2$ by $(\chi_1\chi_2)(g) = \chi_1(g)\chi_2(g)$ for $g \in G$, where the multiplication is in $\mathbb{T}$ (i.e. the pointwise product as complex-valued functions). Let $\hat{G}$ be the set of all characters of G, with the topology of uniform convergence on compact subsets of G (compact-open topology, ()). $\hat{G}$ is called the *dual group*, or *Pontryagin dual group*, of G.

The terminology is justified by the following result:

XXIII.5.1.2. Theorem. Let G be a locally compact abelian group. Then $\hat{G}$ is a locally compact abelian group under the product and topology of XXIII.5.1.1..

Proof: First note that $\hat{G}$ is an abelian group under the product: the product is obviously associative and commutative, the constant function 1 is an identity, and if $\chi \in \hat{G}$, then $\chi^{-1} \in \hat{G}$ defined by $\chi^{-1}(g) = [\chi(g)]^{-1} = \overline{\chi(g)}$ is an inverse for χ.

To show $\hat{G}$ is a topological group,

It remains to show that $\hat{G}$ is locally compact. 👍

XXIII.5.1.3. Examples. (i) Let $G = \mathbb{Z}$ with the discrete topology. Any homomorphism χ from $\mathbb{Z}$ to $\mathbb{T}$ is continuous, and completely determined by $\chi(1)$, which can be any element of $\mathbb{T}$; thus $\hat{\mathbb{Z}}$ can be identified as a set with $\mathbb{T}$. The product of two characters is just the product in $\mathbb{T}$ under this identification, so $\hat{\mathbb{Z}} \cong \mathbb{T}$ as a group. The topology on $\hat{\mathbb{Z}}$ is the topology of pointwise convergence since $\mathbb{Z}$ has the discrete topology. If (χ_j) is a net in $\hat{\mathbb{Z}}$, then $\chi_j \to \chi$ pointwise if and only if $\chi_j(1) \to \chi(1)$. Thus the topology on $\hat{Z}$ is just the usual topology on $\mathbb{T}$ under the identification, i.e. the identification $\chi \mapsto \chi(1)$ is a topological isomorphism from $\hat{\mathbb{Z}}$ onto $\mathbb{T}$.

(ii) Let $G = \mathbb{R}$ with the usual topology. If χ is a continuous homomorphism from $\mathbb{R}$ to $\mathbb{T}$, then χ lifts to a continuous function $\tilde{\chi} : \mathbb{R} \to \mathbb{R}$ (), and it is easily checked that $\tilde{\chi}$ is a homomorphism. But the only continuous homomorphisms from $\mathbb{R}$ to $\mathbb{R}$ are multiplication by a constant: if $\phi : \mathbb{R} \to \mathbb{R}$ is a continuous homomorphism,

then ϕ is uniquely determined on $\mathbb{Q}$ by $\phi(1) = \lambda$, and by continuity we must have $\phi(x) = \lambda x$ for all $x \in \mathbb{R}$. Thus, if $\tilde{\chi}(x) = \lambda x$ for fixed $\lambda \in \mathbb{R}$, we must have $\chi(x) = e^{2\pi i \lambda x}$, and we can identify χ with λ, i.e. call this character χ_λ. The map $\lambda \mapsto \chi_\lambda$ is a group-isomorphism from $\mathbb{R}$ onto $\hat{\mathbb{R}}$.

To show that this is a topological isomorphism, suppose $\chi_{\lambda_j} \to \chi_\lambda$ uniformly on compact sets. Then in particular

(iii) Let $G = \mathbb{T}$. Suppose χ is a continuous homomorphism from $\mathbb{T}$ to $\mathbb{T}$. Compose χ with the homomorphism $\phi : \mathbb{R} \to \mathbb{T}$ with $\phi(x) = e^{2\pi i x}$ to get a character $\bar{\chi}$ of $\mathbb{R}$, which must be of the form $\bar{\chi}(x) = e^{2\pi i \lambda x}$ for some $\lambda \in \mathbb{R}$, so we have $\chi(e^{2\pi i x}) = e^{2\pi i \lambda x}$. This function is well defined only if $\lambda \in \mathbb{Z}$. So a continuous homomorphism from $\mathbb{T}$ to $\mathbb{T}$ can only be of the form $\chi_n(\xi) = \xi^n$ for some fixed $n \in \mathbb{Z}$ (), so $\hat{\mathbb{T}} \cong \mathbb{Z}$ as groups. Since $\mathbb{T}$ is compact, the topology on $\hat{\mathbb{T}}$ is the topology of uniform convergence. But no χ_n for $n \neq 0$ can be uniformly close to the constant function 1, so the topology on $\hat{\mathbb{T}}$ is the discrete topology, i.e. $\hat{\mathbb{T}} \cong \mathbb{Z}$ with the discrete topology.

(iv) Let $G = \mathbb{Z}_n$ with the discrete topology. Then any $\chi \in \hat{G}$ is again completely determined by $\chi(1)$. But since 1 has order n in G, $\chi(1)$ must have order n in $\mathbb{T}$, i.e. $\chi(1)$ must be an n'th root of unity. Any n'th root of unity defines a character, and the characters multiply like the roots of unity, so we have $\hat{\mathbb{Z}}_n \cong \mathbb{Z}_n$, and the topology on $\hat{\mathbb{Z}}_n$ is obviously also the discrete topology. But there is no *natural* isomorphism between $\hat{\mathbb{Z}}_n$ and $\mathbb{Z}_n$: any isomorphism requires making a choice of generators for the groups.

XXIII.5.1.4. The map $G \mapsto \hat{G}$ is contravariantly functorial: if H is a locally compact abelian group and $\phi : G \to H$ is a continuous homomorphism, then there is an induced map $\hat{\phi} : \hat{H} \to \hat{G}$ defined by $\hat{\phi}(\chi) = \chi \circ \phi$. It is easily checked that $\hat{\phi}$ is also a continuous homomorphism, i.e. $G \mapsto \hat{G}$ is a contravariant functor from the category of locally compact abelian groups and continuous homomorphisms to itself.

XXIII.5.1.5. The characters of a locally compact abelian group G are just the one-dimensional unitary representations () of G. Every one-dimensional representation is obviously irreducible, and every irreducible unitary representation of an abelian group is one-dimensional (), so $\hat{G}$ is just the set of irreducible representations of G. Two one-dimensional representations are equivalent () if and only if they are identical as homomorphisms to $\mathbb{T}$, so $\hat{G}$ is just the set of equivalence classes of irreducible representations of G, i.e. the notation is consistent with the notation of (). But if G is abelian, $\hat{G}$ has the additional natural structure of a (topological) group; $\hat{G}$ for nonabelian G has no such structure.

XXIII.5.1.6. By (), every unitary representation of G defines representations of $L^1(G)$ and $C^*(G)$, and conversely. Thus, if G is locally compact abelian, each character of G defines a (bounded) *-homomorphism from $L^1(G)$ or $C^*(G)$ to $\mathbb{C}$, and these are precisely all the irreducible representations of these group algebras. Thus $\hat{G} \cong \widehat{L^1(G)} = \widehat{C^*(G)}$. The topology on $\hat{G}$ is precisely the hull-kernel topology on $\widehat{C^*(G)} \cong \mathrm{Prim}(C^*(G))$.

Since irreducible representations are separating (), we obtain:

XXIII.5.1.7. Proposition. Let G be a locally compact abelian group, and $g \in G$, $g \neq e$. Then there is a character χ of G with $\chi(g) \neq 1$.

XXIII.5.1.8. DEFINITION. If G is a locally compact abelian group and H is a closed subgroup, the *annihilator* of H in $\hat{G}$ is

$$H^\perp = \{\chi \in \hat{G} : \chi(h) = 1 \text{ for all } h \in H\} .$$

An element of $H^\perp$ defines a character of G/H in the obvious way. Conversely, every character of G/H can be regarded as a character of G whose kernel contains H, i.e. an element of $H^\perp$.

XXIII.5.1.9. PROPOSITION. Let G be a locally compact abelian group and H a closed subgroup. Then the above correspondence is a topological isomorphism between $H^\perp$ and $\widehat{G/H}$.

Pontryagin Duality

XXIII.5.1.10. Let G be a locally compact abelian group, with dual group $\hat{G}$. There is a natural homomorphism $\rho : G \to \hat{\hat{G}}$ given by $[\rho(g)](\chi) = \chi(g)$. This map is trivially injective, and almost trivially continuous.

The main result is:

XXIII.5.1.11. THEOREM. [PONTRYAGIN DUALITY] Let G be a locally compact abelian group, with dual group $\hat{G}$. The map ρ is a topological isomorphism from G onto $\hat{\hat{G}}$. Pontryagin dual gives a contravariant category isomorphism of period two on the category of locally compact abelian groups and continuous homomorphisms.

XXIII.5.1.12. In particular, we have a Galois-type correspondence between closed subgroups of G and closed subgroups of $\hat{G}$, with a subgroup of G corresponding to a quotient group of $\hat{G}$ and vice versa: the correspondence is $H \subseteq G \leftrightarrow \hat{H} = \hat{G}/(H^\perp)$.

Finer Structure

XXIII.5.1.13. THEOREM. Let G be a locally compact abelian group. Then

(i) $\hat{G}$ is second countable if and only if G is second countable.

(ii) $\hat{G}$ is compact [resp. discrete] if and only if G is discrete [resp. compact].

If G is discrete (so $\hat{G}$ is compact), there are further topological properties of $\hat{G}$ which reflect algebraic properties of G:

XXIII.5.1.14. PROPOSITION. Let G be a discrete abelian group, and $\hat{G}$ the compact dual group. Then

(i) $\hat{G}$ is connected if and only if G is torsion-free.

(ii) $\hat{G}$ is totally disconnected (zero-dimensional) if and only if G is a torsion group.

XXIII.5.1.15. This result does not hold in general if G is not discrete; there are many counterexamples. The best counterexample is perhaps the additive group $\mathbb{Q}_p$ of p-adic numbers (): it is locally compact, self-dual, torsion-free, and totally disconnected. The only implications which hold for general locally compact G are ($\hat{G}$ connected) $\Rightarrow$ (G torsion-free) [if H is a nontrivial finite subgroup of G, then $H \cong \hat{H} \cong \hat{G}/H^{\perp}$ so $\hat{G}$ has a nontrivial discrete quotient] and (G torsion) $\Rightarrow$ ($\hat{G}$ totally disconnected) [if $\hat{G}$ is not totally disconnected, it has a nontrivial closed connected subgroup H; thus $\hat{H} \cong G/H^{\perp}$ is torsion-free, so G has a nontrivial torsion-free quotient].

XXIII.5.2. Exercises

XXIII.5.2.1. (a) Let G be an abelian group with the discrete topology. Show that the topological dimension (covering dimension *dim*) of the compact group $\hat{G}$ equals the rank () of G.

(b) A torsion-free abelian group of finite rank is countable. Hence a connected compact abelian group of finite topological dimension is metrizable.

(c) If H is a connected compact abelian group of topological dimension 1, then H is either a circle or a solenoid (). [Apply (a) to $\hat{H}$.]

(d) The rank 2 torsion-free abelian groups, i.e. the subgroups of $\mathbb{Q}^2$ containing $\mathbb{Z}^2$, are "unclassifiable" (in a technically precise sense, cf. [Tho03]). Thus the connected compact abelian groups of topological dimension 2 (all of which are metrizable) are "unclassifiable" in the same sense. In particular, they can be far more complicated than products of two circles and/or solenoids. The classification problem for rank n becomes strictly more complex as n increases.

XXIII.5.2.2. **Almost Periodic Functions on $\mathbb{R}$.** Let $C_b(\mathbb{R})$ be the C*-algebra of bounded complex-valued continuous functions on $\mathbb{R}$, with supremum norm (topology of uniform convergence). A function $f : \mathbb{R} \to \mathbb{C}$ is *periodic* if there is a positive number p, called a *period* for f, such that $f(t+p) = f(t)$ for all $t \in \mathbb{R}$.

(a) If f is a continuous periodic function, show that f is necessarily bounded, i.e. in $C_b(\mathbb{R})$, and if f is not constant, there is a smallest period p_0 for f, and all other periods for f are of the form np_0 for some $n \in \mathbb{N}$.

(b) A sum of two periodic functions f and g is periodic if and only if their periods $p_0(f)$ and $p_0(g)$ are *commensurable*, i.e. $\frac{p_0(f)}{p_0(g)} \in \mathbb{Q}$. Thus a linear combination of periodic functions is not necessarily periodic.

(c) Let $AP(\mathbb{R})$ be the closure in $C_b(\mathbb{R})$ of the set of linear combinations of continuous periodic functions. The functions in $AP(\mathbb{R})$ are called *almost periodic functions*. Show that $AP(\mathbb{R})$ is closed under multiplication, and is thus a unital C*-subalgebra of $C_b(\mathbb{R})$.

(d) Another intrinsic description of almost periodic functions can be given. If $\lambda \in \mathbb{R}$, define $T_\lambda : C_b(\mathbb{R}) \to C_b(\mathbb{R})$ by $[T_\lambda f](t) = f(t-\lambda)$. Then T_λ is an isometric linear operator (algebra automorphism) on $C_b(\lambda)$,

and $\lambda \mapsto T_\lambda$ is a continuous homomorphism of the additive group $\mathbb{R}$ into the automorphism group of $C_b(\mathbb{R})$. For $f \in C_b(\mathbb{R})$ set

$$\Lambda(f) = \{T_\lambda f : \lambda \in \mathbb{R}\} \subseteq C_b(\mathbb{R}) \ .$$

The set $\Lambda(f)$ is a continuous image of $\mathbb{R}$. Show that $\Lambda(f)$ is compact (and homeomorphic to $\mathbb{T}$) if and only if f is periodic, and $\Lambda(f)$ is precompact if and only if $f \in AP(\mathbb{R})$.

(e) Let B be the dual space $\widehat{AP(\mathbb{R})} \cong \mathrm{Prim}(AP(\mathbb{R}))$ of $AP(\mathbb{R})$ (), so B is a compact Hausdorff space and $AP(\mathbb{R}) \cong C(B)$. There is a natural map of $\mathbb{R}$ into B: since $AP(\mathbb{R})$ is a unital C*-subalgebra of $C_b(\mathbb{R})$, there is a surjective map from $\widehat{C_b(\mathbb{R})} \cong \beta\mathbb{R}$ () to B, and $\mathbb{R}$ embeds naturally as a dense subset of $\beta\mathbb{R}$. Let $\tilde{\mathbb{R}}$ be the image of $\mathbb{R}$ in B. Then $\tilde{\mathbb{R}}$ is dense in B.

(f) The map $\mathbb{R} \to \tilde{\mathbb{R}}$ can be described simply and concretely: if $\lambda \in \mathbb{R}$, define χ_λ by $\chi_\lambda(f) = f(\lambda)$. Then χ_λ is a character on $C_b(\mathbb{R})$, and by restriction on $AP(\mathbb{R})$. In particular, the map $\mathbb{R} \to \tilde{\mathbb{R}}$ is injective, i.e. $\mathbb{R}$ "embeds" in B as a dense subspace. B is called the *Bohr compactification* of $\mathbb{R}$.

(g) The C*-algebra $AP(\mathbb{R})$ is nonseparable: for $\lambda \in \mathbb{R}$, let $\phi_\lambda(t) = e^{i\lambda t}$. Each ϕ_λ is periodic, hence $\phi_\lambda \in AP(\mathbb{R})$ for all $\lambda \in \mathbb{R}$, and $\|\phi_\lambda - \phi_\mu\| = 1$ if $\lambda, \nu \in \mathbb{R}$, $\lambda \neq \mu$. Thus B is not metrizable. Linear combinations of the ϕ_λ are uniformly dense in $AP(\mathbb{R})$.

(h) Show that the map from $\mathbb{R}$ to $\tilde{\mathbb{R}} \subseteq B$, although one-to-one and continuous, is not a homeomorphism, i.e. the relative topology on $\tilde{\mathbb{R}}$ is strictly weaker than the ordinary topology on $\mathbb{R}$ (and not first countable or locally compact). However, the two topologies have the same convergent sequences, i.e. if (λ_n) is a sequence in $\mathbb{R}$, then $\lambda_n \to \lambda$ in $\mathbb{R}$ if and only if $\chi_{\lambda_n} \to \chi_\lambda$ in $\tilde{\mathbb{R}}$. (Thus calling $\mathbb{R} \mapsto \tilde{\mathbb{R}}$ an "embedding" must be interpreted properly, and the Bohr compactification is not a compactification of $\mathbb{R}$ in the sense of XIII.11.9.1.; cf. XIII.11.9.2..)

(i) Show that B can be made into a compact abelian topological group. Specifically, B can be identified with $\widehat{\mathbb{R}_d}$, the dual group of the additive group $\mathbb{R}_d$ of real numbers with the discrete topology. This gives another description of the embedding of $\mathbb{R}$ into B: the dual of the identity map from $\mathbb{R}_d$ to $\mathbb{R}$, a continuous homomorphism, embeds $\tilde{\mathbb{R}} \cong \mathbb{R}$ into $\widehat{\mathbb{R}_d} \cong B$, i.e. $\tilde{\mathbb{R}}$ is the set of characters of $\mathbb{R}_d$ which are continuous when $\mathbb{R}$ is given its ordinary topology (in particular, $\tilde{\mathbb{R}}$ is a subgroup of B, and the embedding $\mathbb{R} \to \tilde{\mathbb{R}}$ is a group-homomorphism). It also gives another proof that B is not metrizable, since $\mathbb{R}_d$ is an uncountable discrete group. In fact, $\mathbb{R}_d \cong \mathbb{Q}^{\mathfrak{c}}$, a direct sum of $\mathfrak{c} = 2^{\aleph_0}$ copies of the additive group $\mathbb{Q}$, so B is topologically isomorphic to the product of $\mathfrak{c}$ copies of the solenoid $\hat{\mathbb{Q}}$. The copy $\tilde{\mathbb{R}}$ of $\mathbb{R}$ in B "winds around" densely in B. Since $\tilde{\mathbb{R}}$ is connected (or since $\mathbb{R}_d$ is torsion-free), B is connected (but far from path-connected).

(j) There is an interesting inner product which can be put on $AP(\mathbb{R})$. Show that

$$\langle f, g \rangle = \lim_{b \to +\infty} \left[\frac{1}{b} \int_0^b f(t)\overline{g(t)}\, dt \right] = \lim_{b \to +\infty} \left[\frac{1}{2b} \int_{-b}^b f(t)\overline{g(t)}\, dt \right]$$

for $f, g \in AP(\mathbb{R})$ gives a well-defined inner product. The set $\{\phi_\lambda : \lambda \in \mathbb{R}\}$ from (g) is an uncountable orthonormal set for this inner product. The inner product gives a strictly weaker topology than the uniform topology on $AP(\mathbb{R})$ from the supremum norm, and is not complete: for example, any periodic Lebesgue measurable and locally square-integrable function on $\mathbb{R}$ is in the completion. The completion can be identified with $L^2(B, \mu)$, where μ is Haar measure on B.

(k) The same construction can be done for any locally compact but noncompact abelian group G (e.g. any discrete abelian group): let $\hat{G}_d$ be the dual group $\hat{G}$ with the discrete topology, and then G embeds as a dense subgroup of the compact abelian group $B_G = \widehat{\hat{G}_d}$. In particular, the Bohr compactification of $\mathbb{R}^n$ can be formed this way. Since $\hat{\mathbb{R}}_d^n \cong \mathbb{R}_d^n$ is isomorphic to $\mathbb{R}_d$ (both are isomorphic to $\mathbb{Q}^{\mathfrak{c}}$), $B_{\mathbb{R}^n}$ is topologically isomorphic to $B_{\mathbb{R}} = B$, although not in a way that respects the embeddings of $\mathbb{R}^n$ and $\mathbb{R}$.

Chapter XXIV

Addenda

XXIV.1. Mathematical Names

One problem not often discussed, which every student and mathematician faces, is learning how to pronounce names of mathematicians when citing or describing their work. I know I have struggled with this on occasion, beginning with my student days, and judging from mispronunciations I have heard from other mathematicians I am hardly alone. Thus I have included this guide as a public service. The information here is correct to the best of my knowledge, but I make no guarantees, and I welcome corrections. I have generally omitted names whose pronunciation should be obvious to English speakers. There are a number of websites such as http://pronouncemath.blogspot.com which may be helpful, but none should be regarded as authoritative.

Since neither I nor most potential readers are professional linguists, I have written the pronunciations using English syllables instead of linguistic symbols. The pronunciations are only approximations, and reflect commonly accepted pronunciations by English-speaking mathematicians rather than exact pronunciations in the original language. Of course, languages vary significantly, particularly in the pronunciation of vowels and r's, and also l's, n's, and other consonants; stress patterns also vary. It is probably better for a mathematician speaking in English to use an English pronunciation instead of an exact original pronunciation anyway.

The English syllables and character combinations are slightly ambiguous in places, but should be pronounced in the usual English way; thus "ch" is always pronounced as in "chair". One sound not present in English is the German *ch* or Russian x, pronounced like an English "h" but farther back in the throat. This sound is written "kh".

The stressed syllable is written in capital letters.

Spellings of names not originally written in the Latin alphabet are also an issue. This arises most critically with Russian names, but can also occur with Arabic, Chinese, or other names. (It is potentially an issue with Indian and Japanese names, but these seem to have standard and universally-used transliterations into the Latin alphabet.)

Russian names are not always transliterated consistently, and the standard English, French, and German transliteration schemes are rather different; and since much mathematical literature has historically been written in German or French, French- and German-style transliterations have come into common use even in English texts. Thus, for example, the name of the well-known Russian mathematician Тихонов, who originally published his papers in German, is frequently transliterated TYCHONOFF instead of the proper English transliteration TIKHONOV (this difference is exacerbated by the fact that a final consonant like в in Russian is normally pronounced unvoiced). An initial *E* in Russian is usually pronounced "yeh", so should be properly transliterated *Ye* in this case (the name of the former Russian president Ельцин is transliterated YELTSIN), but Егоров is usually transliterated EGOROV or EGOROFF, not YEGOROV. We have given common spelling variations in the list. Another difficulty is that some Russian mathematicians, especially Jewish ones, have names which were originally German which were transliterated into Russian; there is a question whether these should be retransliterated into English or restored to their original German spellings. For example, Бернштейн (Sergei) is usually written BERNSTEIN, and Урысон is usually URYSOHN. Наймарк is sometimes spelled NAIMARK and sometimes NEUMARK. Yet another gray area concerns Russian mathematicians who emigrate and begin spelling their own names a certain way in the Latin alphabet. The prime example for this book is BESICOVITCH (his spelling). We will regard this example as a voluntary name change and use his spelling.

One last note of caution, more relevant for contemporary names than historical ones: many Americans (and Canadians) are of European or Asian ancestry, and their names are not always pronounced or spelled in the ancestral way (this is even true of BLACKADAR, which was originally BLACKADDER, although not of BBC fame!) There are particularly many German-Americans, Italian-Americans, Polish-Americans, and Chinese-Americans, and Jewish Americans whose names are of German, Polish, or Russian origin. (There are also a

great many Americans with Hispanic names, but unfortunately this group is seriously underrepresented in the world of mathematics.)

Here are some common general pronunciation conventions for some common languages:

German: *a* is normally pronounced "ah", never "eh" unless it has an umlaut (*ä*). Other vowels which can have umlauts are *ö* and *ü*, which are hard to pronounce for an English speaker; *ö* sounds something like "er", and *ü* is something like a deep "ee" with rounded lips. The vowels *ä, ö, ü* are sometimes written *ae, oe, ue* respectively.

Double vowels are just pronounced as longer versions of the corresponding single vowel: *aa* is pronounced "ah", *ee* is pronounced roughly like the name of the English letter *a*, and *oo* is pronounced "oh", not English "oo". (The combination *eh* is pronounced the same as *ee*, leading to pun jokes among German students concerning the word root *lehr*, "teach", and *leer*, "empty". *ah* and *oh* are similarly pronounced like *aa* and *oo* respectively.) A final *e* is always pronounced, normally as "uh" and not "ee".

Diphthongs are pronounced as follows: *au* as "ow", not "aw"; *eu* as "oy", not "oo" or "you"; *ei* as the name of the English letter *i*; *ie* as "ee".

The letter *v* is usually pronounced "f"; the letter *w* is usually pronounced roughly like English *v*, but a little softer with rounded lips. *z* is pronounced "ts". The combination *th* is pronounced "t" (the sound "th", voiced or unvoiced, does not occur in German). These letters also sometimes occur consecutively at the break between parts of a compound word, in which case they are pronounced separately; BEETHOVEN is an example (although this name is of Flemish origin). *st* is often, but not always, pronounced "sht". *ch* is pronounced "kh". In *sh*, which occurs rarely, the letters are pronounced separately; the sound "sh" is spelled *sch*. Thus *Monatsheft* is pronounced "MOE-nahts-heft", not "MOE-naht-sheft". The combination *sh* usually only occurs, as here, in compound words where the first part ends in *s* and the second part begins with *h*. This applies to names such as PRINGSHEIM.

Russian: *a* (а) is pronounced "ah". *e* (е) in initial position or following another vowel is pronounced "yeh"; after a consonant, some trace of the "y" usually remains, but it mainly disappears into the preceding consonant (which is technically pronounced soft). There is another letter *e* (э) which is pronounced without the "y", but this letter mostly appears in foreign words and rarely if ever in Russian names. Sometimes in a stressed position е is pronounced "yaw" (е pronounced this way should be written ё, but the "umlaut" is typically omitted). For example, the names of the former Soviet leaders Хрущев and Горбачев are properly pronounced "khrooshch-OFF" and "gar-ba-CHOFF" respectively; the most notable instance among mathematical names is in Чебышев. When this occurs in the list, it is noted in the pronunciation guide. The letter *o* (о) is pronounced "aw", or "uh" (sometimes "ah") in an unstressed position. The letter *u* (у) is pronounced "oo", not "uh"; the soft form ю is pronounced "you". The letter *i* (и) is pronounced "ee". There is another vowel ы, the hard version of и, transliterated *y*, which is pronounced similarly to the German *ü* but farther back in the throat. The vowel я, "ya", is the soft form of а.

There are no diphthongs in Russian: consecutive vowels are pronounced separately. Thus, for example, Воеводский is pronounced "vaw-yeh-VAWD-skee", and the chemist Менделеев is pronounced "men-del-YAY-yeff".

Most Russian consonants have a hard and soft form. The hard form is the "default", and consonants become soft only when followed by a soft vowel (я, е, и, ю) or a soft sign (ь), which is not pronounced. The soft sign is sometimes transliterated with an apostrophe (as in OL'SHANSKII), but we have avoided using this. There is also a "hard sign" or "separative sign" ъ, which occurs only rarely in modern Russian and which now usually has the same pronunciation effect as ь. The letter й, which occurs only after vowels, is pronounced with a slight "y" sound and usually transliterated *i*.

As mentioned earlier, some consonants at the end of words, or before other unvoiced consonants, are pronounced unvoiced.

Polish: Polish names are frequently mispronounced badly in English, and some have acquired widely accepted English pronunciations quite different from the Polish ones. This is mainly due to the fact that the Polish spelling conventions for many sounds are different than the English ones. As a result, some Polish names look "unpronounceable" to English speakers not familiar with the Polish conventions. But a little familiarity makes them relatively easy to pronounce, at least approximately.

In Polish, *w* is pronounced "v"; *ł* is pronounced "w", *c* is pronounced "ts" (except when followed by *i* or *z*), and *j* is pronounced "y".

The combination *sz* is pronounced "sh", *cz* is pronounced "ch", and *rz* is pronounced "zh". These are hard sounds. The accented letters *ś*, *ć*, *ź* (*si*, *ci*, *zi* before vowels) are soft forms of *sz*, *cz*, and *rz* respectively; *ż* is pronounced like *rz*.

The vowel *ó* is pronounced "oo", the same as *u*. There are also nasal vowels and a nasal *n* (*ń*), but these are perhaps too arcane to worry about here.

For example, the common first name *Jerzy* is pronounced "YEH-zhee", not "Jersey". (The Czech version of this name, *Jiři*, is a name I admit I cannot pronounce correctly, although I know how.)

In Polish words, including names, the stress is almost always on the next-to-last syllable.

Some Poles (mainly Jews, but not exclusively) have names which are originally German but which are written with Polish spelling conventions. Notable examples are the names *Szulc* and *Sznajder*, which are the same (and pronounced the same) as the German *Schulz* and *Schneider* respectively. Among mathematicians, the names Aronszajn and Szpilrajn come to mind.

Hungarian: Hungarian names also have the reputation of being hard for English speakers to pronounce, and the reason is again differences in spelling conventions. The Hungarian spelling conventions are in some instances the direct opposites of the Polish ones.

The vowels *a*, *e*, *i*, *o*, *ö*, *u*, *ü* are pronounced similarly to the corresponding German vowels. An accent denotes a long vowel; *ő* and *ű* are the long forms of *ö* and *ü* respectively.

Hungarian consonants and combinations are as follows: *c* is pronounced "ts", *cs* is "ch", *gy* is a soft "j" (actually similar to the British pronunciation of "due"), *j* is like "y"; *ly*, *ny*, *ty* are soft versions of *l*, *n*, *t*; *s* is pronounced "sh" and *sz* is pronounced "s"; and *zs* is "zh" (hence *dzs* is a hard "j").

The stress in Hungarian words is on the first syllable. Note that an accent on a vowel does *not* indicate stress.

French: French names truly are hard for many English speakers to pronounce correctly, although most English speakers know how to make a decent approximation since they are relatively familiar.

Italian:

Japanese: The syllables of Japanese words are all pronounced with roughly the same stress. However, some syllables are partially swallowed. For example, the name of the city *Fukushima*, the site of the recent nuclear disasters, is pronounced something like "FKOO-shi-muh" (at least it sounds like this to me).

Chinese: I will not attempt to describe the proper pronunciation of Chinese names, since it is far beyond my expertise. However, I will recall a conversation I had with a Chinese mathematician, about the Chinese name *Ng* (which is usually pronounced "ing" in English, which is at least better than "nig".) I asked the proper pronunciation, and he replied, "Mm?" I thought he had not understood what I said, so I repeated the question, and he again replied, "Mm?"

Of course, there are many other languages, each with its own peculiarities. For example, consider the name of the eminent, and recently tragically deceased, Danish mathematician Uffe Haagerup. Danes pronounce

his last name something like “OR-up”, but somewhat less distinctly. English-speaking mathematicians usually say “HOG-er-up”, which Uffe (“OOF-uh”) didn’t seem to mind too much.

Abel	AH-bull	*abelian* pronounced “uh-BEEL-yan”
Alaoglu	AL-uh-loo	Approximate; “g” very soft (Turkish)
Aleksandrov	ah-leks-AHN-druff	
Alexandrov	See Aleksandrov	
Aronszajn	AR-un-shine	
Arzelà	ahr-ZAY-la	
Ascoli	as-COAL-ee	s is unvoiced
Baire	BEAR	
Banach	BAHN-akh	Often pronounced BAHN-ock
Bernoulli	bear-NEW-lee	
Bernstein	BEARN-shtine	
Blackadar	BLACK-uh-dahr	
Bolzano	bol-TSAHN-o	Italian name, but Bohemian
Borel	burr-ELL	
Bourbaki	bour-bah-KEE	
Bożejko	bo-ZHAY-ko	
Brouwer	BROW-er	
Carathéodory	car-uh-thay-uh-DOOR-ee	“th” is unvoiced
Cartan	car-TAHN	n is nasal
Cauchy	KOH-shee	
Cavalieri	cav-ul-YAIR-ee	
Čech	CHEKH	As in “Czech”
Cesàro	chuh-SAH-row	Italian
Chebyshev	cheb-uh-SHOFF	often cheb-uh-SHEFF
d’Alembert	dahl-em-BEAR	
Daniell	dan-YELL	
Darboux	dahr-BOO	
Dedekind	DAY-duh-kind	“kind” as in “kin”
DeMoivre	duh-MWAVR	
Denjoy	don-ZHWAH	n is nasal
Desargues	days-ARG	
Descartes	day-CART	
Dirac	durr-ACK	
Dirichlet	DEER-ikh-lay	often DEER-ish-lay. See note
Egorov	ye-GOR-uff	Not EGG-o-roff!
Erdős	AIR-dosh	AIR-dush is more correct
Euclid	YOU-klid	
Euler	OY-ler	
Fatou	fat-TOO	
Fejér	FAY-er	FAY-air is closer to correct
Fermat	fair-MAH	
Fibonacci	fee-bun-AH-chee	Often fib-un-AH-chee
Fourier	FOUR-yay	
Fraenkel	FRENK-ul	
Fréchet	fresh-A	A as the name of the letter a
Frege	FRAY-guh	
Frobenius	fro-BEAN-ee-us	
Fubini	foo-BEE-nee	

Galois	gal-WAH	
Gauss	GOWSS	
Goursat	gor-SAH	
Haar	HAHR	
Hadamard	ad-uh-MAHR	
Hausdorff	HOUSE-dorf	
Heine	HIGH-nuh	
Hermite	air-MEET	*Hermitian* pronounced her-MEE-shun
Hilbert	HILL-burt	
Hölder	HEL-dur	Approximate; sometimes HULL-der
Jacobi	ya-KOE-bee	Actually German, of Jewish ancestry Sometimes ja-KOE-bee; *Jacobian* pronounced ja-KOE-bee-un
Jordan	zhor-DAHN	N is nasal
Khinchin	KHEEN-cheen	Often KHIN-chin
Kolmogorov	kul-muh-GOR-uff	
Kovalevskaya	ko-va-LYEV-skah-ya	
Krein	KRINE	
Kronecker	KRON-eck-ur	
Kuratowski	kur-a-TOV-skee	
Lagrange	la-GRAHNGE	Not la-GREHNGE!
Laplace	la-PLAHS	Final "s" unvoiced
Laurent	lor-ON	N is nasal
Lebesgue	le-BEG	Second syllable is long.
Legendre	le-ZHAHN-der	
Leibniz	LIBE-nits	
Levi-Civita	LEH-vee-CHIV-ee-tah	
Lévy	LAY-vee	
l'Hôpital	low-pee-TAHL	Often pronounced LOW-pit-ahl
l'Hospital	See l'Hôpital	
Lie	LEE	
Lindelöf	LIN-del-off	Finnish name
Lindemann	LIN-duh-mahn	
Liouville	LEE-oo-vill	
Lipschitz	LIP-shits	No delicate way to write it!
Łoś	WAUSH	
Lusin	See Luzin	French transliteration?
Luzin	LOO-zeen	Often LOO-zin
Marczewski	mar-CHEV-skee	Same person as Szpilrajn
Markov	MARK-uff	
Milman	MIL-mun	
Minkowski	min-KOV-skee	
Mycielski	mi-CHEL-skee	
Nagy	See Sz.-Nagy	
Neumann	NOY-mahn	
Nevanlinna	NEV-ann-lin-uh	
Nikodým	NICK-uh-deem	Polish mathematician, Czech name
Noether	NER-ter	Approximate; first "r" not really there
Ostrogradskii	ah-strah-GRAHD-skee	

Pascal	pass-KAL	
Peano	pay-AH-no	not “Piano”!
Perron	pair-RONE	See note
Picard	pee-CAR	
Plancherel	plahn-sher-EL	n is nasal
Poincaré	pwan-car-AY	
Poisson	pwah-SAWN	N is nasal
Pontryagin	pon-tree-AH-geen	g is hard (actually three syllables pon-TRYAH-geen)
Pringsheim	PRINGZ-hime	“hime” as in “time”
Prüfer	PREE-fer	approximate; often mispronounced PROOF-er
Pythagoras	pith-AG-or-us	
Raabe	RAH-buh	
Radon	RA-don	Not RAY-don
Ramanujan	ra-MAHN-oo-jun	
Riemann	REE-mahn	
Riesz	REESE	
Rolle	RAHL	
Schwartz (J., L.)	SHWARTS	
Schwarz (Hermann)	SHVARTS	Usually pronounced SHWARTS
Shilov	SHEE-luff	
Sierpiński	share-PEEN-skee	n is technically nasal
Sinai	SEEN-eye	
Smulian	SHMOOL-ee-un	S should be written Š
Sobolev	SO-buh-leff	SO-buh-lyeff is more accurate
Souslin	See Suslin	French transliteration
Stieltjes	STEELT-yes	Dutch
Suslin	SOOS-leen	Often SOOS-lin; not SUSS-lin!
Sylow	SEE-low	Norwegian, name apparently unrelated to *Shilov*
Sz.-Nagy	NAHDZH	DZH is very soft
Szegő	SAY-go	SAY-ger is closer to correct
Szpilrajn	SHPEEL-rine	Same person as Marczewski
Tchebysheff	See Chebyshev	
Tietze	TEET-suh	not TEET-see or TEET-zee!
Tikhonov	TEEKH-uh-noff	Often pronounced TICK-uh-noff
Toeplitz	TOE-plits	Correct pronunciation closer to TER-plits
Tonelli	ton-EL-lee	
Tychonoff	See Tikhonov	
Ulam	OO-lahm	
Urysohn	oor-uh-SAWN	not YOUR-i-sun
van Rooij	van ROY	
Vitali	vee-TAHL-ee	
Volterra	voal-TAIR-uh	
von Neumann	fun NOY-mun	
Weierstrass	VYE-er-shtrahss	

Weil (André)	VAY	As in "way" (see note)
Weyl (Hermann)	VILE	No reflection on character!
Wiener	VEE-nur	
Wroński	VRON-skee	often RON-skee; *Wronskian* pronounced RON-skee-un
Yegorov	See Egorov	
Zermelo	tser-MEL-o	See note

Notes:

Dirichlet These pronunciations are almost universally used, but there is some doubt about their correctness. Dirichlet was German, but his family originally came from the town of Richelette in the French-speaking part of Belgium. His full surname was *Lejeune Dirichlet*, originally *le Jeune de Richelette*. Even with a French pronunciation the *t* would be pronounced in this name. The logical pronunciation of *Dirichlet* should be something like deer-ish-LET. I have been unable to determine how he himself pronounced his name, although sources suggest he pronounced it with silent *t*.

Perron Perron was German, but the origin of his surname is obscure.

Weil/Weyl André Weil is sometimes called "der andre Weyl" (thanks to P. Muhly for this information!)

Zermelo The origin of this name is obscure. Zermelo, who was German (and not Jewish), told people who asked that it was a contraction of *Walzermelodie* (cf. [Rei70, p. 98]). More serious speculations on an East Prussian origin of the name, apparently also originating with Zermelo himself, can be found in [Ebb07, p. 1].

I must say I feel fortunate to be a native English speaker, not just because English has become the international language of mathematics (and many other subjects), but also because I am very happy I didn't have to learn the language as an adult. It seems to me like a difficult and irregular language, particularly because of the use of articles (very hard for nonnative speakers to get right) and the tenuous relationship between spelling and pronunciation for many words, along with other irregularities. There are other grammar rules which every native speaker knows but don't know they know, such as:

> "[English adjectives] absolutely have to be in this order: opinion-size-age-shape-colour-origin-material-purpose Noun. So you can have a lovely little old rectangular green French silver whittling knife. But if you mess with that order in the slightest you'll sound like a maniac."
>
> *Mark Forsyth*[1]

and I admire the ability of so many of my foreign colleagues to master the language quite well. Although it is sometimes said that "the international language of mathematics is bad English," I find most of it surprisingly good (although there is a story about a letter of recommendation written by a mathematician who was not a native English speaker, saying that the candidate "exposes himself well in the classroom.")

> "English is weird. It can be understood through tough, thorough thought though."
>
> *Unknown*

We could say the same thing about analysis!

[1] *The Elements of Eloquence: How to Turn the Perfect English Phrase.*

"Why English Is Hard to Learn"

We'll begin with *box*; the plural is *boxes*,
But the plural of ox is *oxen*, not *oxes*.
One fowl is a *goose*, and two are called *geese*,
Yet the plural of *moose* is never called *meese*.

You may find a lone *mouse* or a house full of *mice*;
But the plural of *house* is *houses*, not *hice*.
The plural of *man* is always *men*,
But the plural of *pan* is never *pen*.

If I speak of a *foot*, and you show me two *feet*,
And I give you a *book*, would a pair be a *beek*?
If one is a *tooth* and a whole set are *teeth*,
Why shouldn't two *booths* be called *beeth*?

If the singular's *this* and the plural is *these*,
Should the plural of *kiss* be ever called *keese*?

We speak of a *brother* and also of *brethren*,
But though we say *mother*, we never say *methren*.
Then the masculine pronouns are *he*, *his*, and *him*;
But imagine the feminine . . . *she*, *shis*, and *shim*!

— Anonymous

XXIV.1.1. The Greek Alphabet

One thing every mathematics student must learn is the Greek alphabet, or at least most of it. Greek letters are frequently used as mathematical symbols. Many upper-case Greek letters are essentially identical to Latin letters (although not necessarily the equivalent Latin letter!), and these upper-case Greek letters are rarely if ever used as mathematical symbols. The other upper-case letters are commonly used, but the lower-case letters are more common in mathematics. The only lower-case Greek letter I have never seen used as a mathematical symbol is omicron, although upsilon is rarely used since it is hard to distinguish from nu (or especially from Latin v).

Upper Case	Lower Case	Name	Latin Equivalent
A	α	alpha	a
B	β	beta	b
Γ	γ	gamma	g
Δ	δ	delta	d
E	ϵ	epsilon	e (short)
Z	ζ	zeta	z
H	η	eta	e (long)
Θ	θ	theta	th
I	ι	iota	i
K	κ	kappa	k
Λ	λ	lambda	l
M	μ	mu	m
N	ν	nu	n
Ξ	ξ	xi	ks
O	o	omicron	o (short)
Π	π	pi	p
P	ρ	rho	r
Σ	σ	sigma	s
T	τ	tau	t
Y	υ	upsilon	u
Φ	ϕ or φ	phi	ph (f)
X	χ	chi	kh
Ψ	ψ	psi	ps
Ω	ω	omega	o (long)

The name "omicron" is properly pronounced O-mi-kron, not OM-i-kron, since it means "o micron" ("little o"). The name "omega" is "o mega" ("big o").

The name "phi" is sometimes pronounced FEE and sometimes FY, and there does not seem to be an accepted correct pronunciation. The name "Psi" is SIGH, sometimes PSIGH, and "Xi" is KSEE. Pronunciations of other letter names are fairly evident.

XXIV.2. Origin of Terms and Notation

I have collected here my best information of when various standard mathematical terms were first introduced. Corrections and additions are solicited. Information is from [Caj93], http://jeff560.tripod.com/mathword.html, and http://jeff560.tripod.com/mathsym.html unless otherwise specified.

Terms

Many of these terms were introduced in languages other than English, in appropriate form. We have given the English form or translation.

Figure XXIV.1: A bonesetter in Croatia

algebra: originally *al-jabr*, Arabic for "restoring" (referring to adding or subtracting the same quantity from both sides of an equation), later meaning "bonesetter" (i.e. a restorer of broken bones, cf. Figure XXIV.1), Al-Khwarizmi, 825. Not used in the modern sense until much later.

algebraic topology: Lefschetz, 1936 [Jam99, p. 570]. Previously usually called "combinatorial topology" (not exactly the same thing; Emmy Noether was instrumental in the transition from "combinatorial topology" to algebraic topology in the late 1920s [Jam99, p. 564-565]).

algorithm: from Al-Khwarizmi, whose book (825) introduced "Arabic" numbers (actually originating in India) and modern calculation methods to Europe. "The method of Al-Khwarizmi" referred to solving a problem by calculation.

Banach space: Fréchet, 1928. Banach spaces were defined by Banach in 1920; he called them *espace du type (B)*. It is unclear what the B referred to.

calculus: The term, from the Latin meaning "small pebble," was used to refer to calculation (word of same origin) since Roman times. The modern usage of *calculus* (*differential calculus*) was introduced by LEIBNIZ around 1680. NEWTON first used the term in 1691. The original meaning survives in some other mathematical terms such as *predicate calculus*, *functional calculus*, and *calculus of residues*.

compact (topology): FRÉCHET, 1906 (not quite in the modern sense).

complex number: GAUSS. He used the term to resolve the ambiguity in the use of *imaginary number* to refer both to nonreal complex numbers and to pure imaginary numbers (an ambiguity which persists to a degree even today), and because GAUSS disliked the term "imaginary," which he considered misleading.

continued fraction: WALLIS, *Opera Mathematica I*, 1695 (published at age 79!) [Kli72, p. 255].

corollary: from Latin *corolla*, a small wreath; the English word dates from the 14th century and has been used in the modern mathematical sense (a theorem which is an immediate or easy consequence of another theorem) at least since 1669.

definite integral: LAPLACE, *Memoire sur les suites*, 1779.

derivative: LAGRANGE, *Théorie des fonctions analytiques*, 1797 [Gra10]. LAGRANGE'S term (which he used as early as 1772) was *fonction derivée*. Derivatives were previously described as differentials, fluxions, etc.; the general notion of a function was just appearing in LAGRANGE'S time.

eigenvalue: A hybrid German-English word, apparently first used by A. S. EDDINGTON in 1927. Many mathematicians have rebelled against the term and used alternates, but *eigenvalue* is now firmly established.

eigenvector: Apparently first used by R. BRAUER and H. WEYL, *Spinors in n dimensions*, 1935.

ergodic: coined by BOLTZMANN in 1884.

field (algebra): DEDEKIND used *Zahlenkörper* in 1858. The English *field* was first used by E. H. MOORE in 1893.

functional analysis: PAUL LÉVY, *Leçons de l'analyse fonctionelle*, 1922.

geometry: From Greek "measuring the earth." Used in ancient Greece before PLATO.

harmonic analysis: W. THOMPSON (LORD KELVIN), 1867.

Hilbert space: ERHARD SCHMIDT, *Über die Auflösung linearer Gleichungen mit unendlich vielen Unbekannten*, 1908 (for ℓ^2). According to [Jah03, p. 385], the name "Hilbert space" was first used in 1908 by A. SCHÖNFLIES. Abstract Hilbert spaces were defined by VON NEUMANN in 1928 [vN30].

homeomorphism: POINCARÉ, *Analysis Situs*, 1892 (not quite in the modern sense). The modern usage was standard by 1930.

homology: Used by POINCARÉ in *Analysis Situs*, 1895, but not clearly in the modern sense [Jam99, p. 85]. The word was used in a different sense by JAMES STIRLING in 1749.

homotopy: DEHN and HEEGAARD, *Analysis Situs*, 1907 [Jam99, p. 88]. The concept of homotopy, or continuous deformation, had been around a long time.

imaginary number: DESCARTES, *La Geometrie*, 1637. Such numbers had long been considered.

integral: JAKOB BERNOULLI, *Acta eruditorium*, 1690. JOHANN BERNOULLI disputed this (he disputed many things) and claimed originality for the term. JOHANN BERNOULLI first used the term *integral calculus*, and convinced LEIBNIZ to use it too.

kernel (integral equations): FREDHOLM, *Sur une classe des équations fonctionelles*, 1903.

kernel (algebra): PONTRYAGIN, *Topological Groups*, 1939?.

linear algebra: the term was used by BOMBELLI in about 1550, but the modern usage as the subject of vector spaces and linear transformations only dates from about 1950.

logarithm: JOHN NAPIER, 1614.

manifold: The term was used to denote affine subspaces of $\mathbb{R}^n$ long before the modern definition of manifold was given. First used in something approaching the modern sense by RIEMANN. The "correct" modern definition was nailed down by WHITNEY in the 1930s.

mathematics: from Greek *manthanein*, "to learn." The term *mathematike tekhne*, "mathematical science," already existed in ancient Greece. The word *mathematics* gradually shifted from a plural noun to a singular one (at least in American English; it is somewhat ambiguous in British English, where it is abbreviated "maths," and still plural in some other languages).

matrix: SYLVESTER, 1848. Matrix notation had been recently introduced by CAYLEY. Determinants (of arrays) were introduced by CAUCHY. The older meaning of *matrix* was "the place of origin of something else," and SYLVESTER apparently regarded mathematical matrices as the place of origin of determinants.

parallelepiped: EUCLID. The only controversy is about pronunciation: the accent is most commonly on the next-to-last syllable, although it is sometimes put on the previous syllable (more correct in Greek?) Some authors questionably spell this word *parallelopiped*, evidently with accent on the next-to-last syllable.

pathological: Used in medicine since the 17th century. The first documented use in mathematics is in MURRAY and VON NEUMANN, *On Rings of Operators*, 1936 (referring to non-type-I factors).

pure mathematics: FRANCIS BACON, *The Advancement of Learning*, 1605.

real number: DESCARTES, *La Geometrie*, 1637.

ring: DEDEKIND.

scalar: WILLIAM ROWAN HAMILTON, *On Quaternions*, 1844.

set: Apparently first used (German *Menge*) by BOLZANO, *Wissenschaftslehre*, 1837 [Fra66, p. 2].

topology: J. LISTING, 1847 [Jam99]. The term did not come into general use until the twentieth century; *analysis situs* (introduced by LEIBNIZ, used by POINCARÉ) predominated.

transcendental number: LEIBNIZ, 1704 [Rib00b]. Transcendental numbers were not proved to exist until 1844 (by LIOUVILLE).

trigonometry: BARTHOLOMAEUS PITISCUS, 1595.

vector: Used in astronomy to denote a *radius vector*. First used to denote a point in $\mathbb{R}^3$ by WILLIAM ROWAN HAMILTON in 1844. Only gradually became used to denote a point in a general vector space.

vector space: PEANO, *Formulario mathematico*, 1895.

Notation

a^n (exponent): DESCARTES, 1637 (natural number exponents); NEWTON, 1676 (negative and fractional exponents). Exponents were first used (with different notation) by NICOLE ORESME about 1360.

$|\cdot|$ (absolute value): evidently introduced by WEIERSTRASS.

$\binom{\cdot}{\cdot}$ (binomial coefficient): ANDREAS VON ETTINGSHAUSEN, 1826. EULER used this symbol, but with a fraction bar in the middle.

$\mathbb{C}$ (complex numbers): NATHAN JACOBSON, 1939.

. (decimal point): Unclear. Used by Bartholomaeus Pitiscus in 1612. Popularized by Napier. Decimals had long been used in the Middle East, and ancient Babylonians used a base 60 version. Simon Stevin used decimals, with different notation, in 1585, and, according to [Ste15], the decimal point evolved from Stevin's notation.

$\div$ (division): Johann Rahn, *Teutsche Algebra*, 1659.

δ (limit): Cauchy (for *différence*). Johann Bernoulli used δ for a difference of functions in 1706.

e ($2.718\cdots$): Euler, 1727. The reason for e is obscure, but it probably was not because of his name.

$\emptyset$ (empty set): Bourbaki, 1939. Introduced by Weil from the Norwegian alphabet.

ϵ (limit): Cauchy (for *erreur*).

$=$ (equals): Robert Recorde, *The Whetstone of Witte*, 1557. Developed independently in Bologna about the same time.

$f(x)$ (function): Euler, *Commentarii Academiae Scientarium Petropolitanae*, 1734.

$f : X \to Y$ (function): Hurewicz, 1940.

f' (derivative): Lagrange, *Théorie des fonctions analytiques*, 1797 [Gra10]. The notations $\frac{dy}{dx}$ (Leibniz) and $\dot{x}$ (Newton) previously predominated.

! (factorial): Christian Kramp, *Elements d'arithmétique universelle*, 1808. The alternate notation $\llcorner$, still occasionally seen, is actually newer (Thomas Jarrett, 1827).

$\frac{a}{b}$ (fraction): Fraction bar introduced by Arabs; fractions were used in ancient Greece and by Hindus. Fraction notation first used in Europe by Fibonacci in *Liber Abbaci* [Ste15].

$>$ (greater than): Thomas Harriott, *Artis Analyticae Praxis ad Aequationes Algebraicas Resolvendas*, 1631. Wallis used the first version of $\geq$ in 1670.

i ($\sqrt{-1}$): Euler, 1777. Complex numbers, especially square roots of negative real numbers, had long been considered, although they were still "imaginary."

∞ (infinity): Wallis, *De sectionibus conicis*, 1655.

$\lfloor \cdot \rfloor$ (integer part): Kenneth Iverson, 1962. Gauss defined and used this function and denoted it $[\cdot]$.

$\int$ (integral): Leibniz, 1675. The definite integral notation $\int_a^b$ was first used by Fourier in 1822.

$\cap$ (intersection): Peano, *Formulario mathematico*, 1895.

$<$ (less than): Thomas Harriott, *Artis Analyticae Praxis ad Aequationes Algebraicas Resolvendas*, 1631. Wallis used the first version of $\leq$ in 1670.

$\lim_{x \to a}$ (limit): John Leathem, *Volume and Surface Integrals Used in Physics*, 1905. Weierstrass used $\lim_{x=a}$.

$\in$ (member): Peano, *Formulario mathematico*, 1895.

$-$ (minus): Johannes Widmann, 1489.

$\mathbb{N}$ (natural numbers): Dedekind used N in *Was sind und was sollen die Zahlen*, 1888.

O (big-O): Paul Bachmann, *Analytische Zahlentheorie*, 1894; but see o.

o (little-o): first apparently used in the modern sense by Landau in 1909 (O and o are sometimes called *Landau symbols*). But o was used by Newton (not quite in the same sense, but to represent a negligibly small quantity; cf. [**?**, p. 204] and V.7.).

∂ (partial): Condorcet, 1768. $\frac{\partial u}{\partial x}$ first used by Legendre, 1786. This symbol is an italic Cyrillic d, and this may be the origin of the mathematical symbol (possibly through Euler?)

π ($3.14159\cdots$): William Jones, 1706 (for *perimeter*). Usage popularized by Euler. The number itself has been known and studied since antiquity.

$+$ (plus): Nicole Oresme, 1360.

$\mathbb{Q}$ (rational numbers): Bourbaki introduced Q in the 1930s, evidently for *Quotient*.

$\mathbb{R}$ (real numbers): Dedekind used $\mathbf{R}$ in *Stetigkeit und irrationale Zahlen*, 1872 (he used R for the rational numbers). The real numbers as a named set were rarely referred to before this. Use of "blackboard bold" for $\mathbb{R}$ and other sets of numbers, which is still not universal, is of uncertain origin.

$/$ (division): Thomas Twinin, 1718. May have evolved from fraction notation, which dates much earlier.

$\{\cdot\}$ (set): Zermelo, *Untersuchungen über die Grundlage der Mengenlehre*, 1907.

$\surd$ (radical): Christoff Rudolff, *Die Coss*, 1525. Descartes (1637) added the vinculum. The notation $\sqrt[n]{}$ was suggested by Albert Girard in 1629 and may have been first used by Rolle in *Traité d'Algèbre* in 1690.

$\sum$ (sum): Euler, *Institutiones calculi differentialis*, 1755.

$\times$ (multiplication): William Oughtred, 1631.

$\cup$ (union): Peano, *Formulario mathematico*, 1895.

$\mathbb{Z}$ (integers): Edmund Landau introduced $\bar{\mathfrak{Z}}$ (evidently for *Zahl*) in *Grundlagen der Analysis*, 1930. Bourbaki used Z.

XXIV.3. Miscellany

XXIV.3.1. Age and Mathematics

> "The mathematician lives long and lives young; the wings of the soul do not early drop off, nor do its pores become clogged with the earthly particles blown from the dusty highways of vulgar life."
>
> *J. Sylvester*[2]

> "Very few people do anything creative after the age of thirty-five. The reason is that very few people do anything creative before the age of thirty-five."
>
> *Joel Hildebrand*[3]

Weierstrass is a notable counterexample to the widely held belief that mathematics is exclusively an enterprise for the young. He never earned a doctorate (he was eventually awarded an honorary one), did not have a university position until age 41, and did most of his work on the foundations of analysis over the next twenty years after that. He did significant mathematical research well into his sixties and perhaps early seventies (he published the Weierstrass Approximation Theorem () at age 70), and lectured regularly about his work into his seventies. (He did do important mathematical work in his twenties and thirties while he was employed as a high-school [gymnasium] teacher, but this work was not published or known in the mathematical community until much later.)

Hausdorff did not do much mathematics until he was in his forties (he previously wrote two books on philosophy under the name Paul Mongré).

John Wallis (1616-1703) is perhaps an even more notable example. He continued to produce and write significant mathematics into his eighties, and retained his chair at Oxford until his death at age (almost) 87. (He apparently did not learn or do much serious mathematics until *after* his Oxford appointment at age 33, although he had about as much previous mathematics education as existed in England at the time.) Although he was 27 years older than Newton, he remained active and productive for several years after Newton had ceased to do creative mathematics. When Wallis was 81, Leibniz invited him to Hannover to instruct the Germans on cryptography (he had been England's Royal cryptographer for decades); Wallis declined for strategic reasons, not because he was physically incapable.

Wallis's contemporary Thomas Hobbes (1588-1679), a formidable philosopher but a lightweight mathematician, with whom Wallis had a longstanding polemical debate, lived to age 91. Newton lived to age 84 and remained intellectually sharp almost to the end, but produced little new mathematics after a serious illness at age 50, although he did finally publish part of the work he had done decades earlier.

> "... no old Men (excepting Dr. Wallis) love Mathematicks."
>
> *Isaac Newton*[4]

William Oughtred (1574-1660), one of the most important English mathematicians before Wallis, lived to age 86.

[2] [?, p. 405].
[3] R. Byrne, *The Other 637 Best Things Anybody Ever Said*, 616.
[4] William Whiston, *Memoirs*, p. 315-316; cf. Westfall, *Never at Rest*, p. 139.

Leopold Vietoris died in 2002, two months short of his 111th birthday. He was the oldest person in Austria at the time of his death (and the oldest documented Austrian man ever). He published his last research paper at the age of 103. Sergei Nikolskii (1905-2012) also published research papers until age 101, and Jacques Dixmier (1924-), who is still alive at this writing, recently published a paper at age 100. I am not aware of any other mathematician who published a research work after his/her 100th birthday.

"If you live to a hundred you have it made because very few people die past the age of a hundred."

George Burns[5]

Other notably long-lived mathematicians:

Dirk Struik (1894-2000) 106 years

Henri Cartan (1904-2008) 104 years

Boris Bukreev (1859-1962) 103 years

Notably short-lived mathematicians:

Évariste Galois (1811-1832) 20 years

Jacques Herbrand (1908-1931) 23 years

Mikhail Suslin (1894-1919) 24 years

Pavel Urysohn (1898-1924) 26 years

Niels Henrik Abel (1802-1829) 26 years

Frank Ramsey (1903-1930) 26 years

Rufus Bowen (1947-1978) 31 years

[5] R. Byrne, *The Other 637 Best Things Anybody Ever Said*, 585.

XXIV.3.2. The Mathematical Organ

It was fashionable at one time for phrenologists to make studies of the skulls of various classes of people, including mathematicians. The following is adapted from *The Mathematician as a Type*, by William Story.

It has been claimed that a very large number of mathematicians show a striking physiognomic peculiarity called the "mathematical organ." Franz Joseph Gall, the originator of phrenology, describes it thus:

> "The outer part of the roof of the orbita is depressed in such a manner that the upper edge of the hollow of the eve retains its natural arch only on the inner half, and that the outer half becomes a straight line, which runs sloping downward to its outer end. In consequence of this, the outer part of the upper lid falls and covers the eye, more than usually. Still more decided is the character when the lateral part of the orbita is pushed outward, so that the angular process of the frontal bone (the outer upper angle of the edge of the roof) projects sidewise over the front part of the temple."

Story continues:

> "I know a great part of the living mathematicians personally [and] I have studied the busts, and painted and engraved portraits of many others. In all, without exception, I have found the organ described. Consider the portrait of young Colburn; in him the outer part of the orbita is depressed and pushed out in such a way that this peculiarity did not escape the authors of the first notices about the young man in the American newspapers. Consider the portraits of Kepler, Newton, Leibnitz, Huyghens, Descartes, Euler, Roberval, Bernoulli, Lagrange, de la Place, Lalande, Herschell, Olbers, Bessel, Monge, Carnot, etc."

P. J. Möbius, a psychiatrist and disciple of Gall, and grandson of August Ferdinand Möbius, who published a book on *The Talent for Mathematics* (he also published a pamphlet "The Physiological Mental Weakness of Woman" which tarnished his reputation), says:

> "Gall's statements about the mathematical organ are entirely correct, but I have three remarks to make: 1. Nature varies the forms more than might appear from Gall's description. 2. The mathematical organ is not equally developed on both sides, but as a rule more strongly on the left. 3. The mathematical organ consists in part of a thickening of the soft parts. ... In fact, we find these modifications in almost all great mathematicians. However, sometimes the ridge running downward and backward from the lateral end of the eyebrows is more prominent and sometimes the slope of the outer edge of the orbita. Often the eye stands normally open, often the outer half of the lid hangs down so that the eye is half closed and seems to slant. If we observe the face from in front, it also strikes us that the distance between the outer angle of the eye and the contour of the face is strikingly great. Sometimes the space between the outer angle of the eye and the end of the eyebrow is particularly broad, the distance between the eye and the edge of the forehead magnified. In such cases there is usually neither a distinct ridge nor a slope; the origin is then, so to say, built upward. In individual cases the angular process is uniformly broadened with indefinite outlines, in others it projects with a sharp edge. The description is inaccurate in respect to the variety of nature. A definition that should be in accord with all variations is hard to be found. It would be, perhaps, best to say the mathematical organ consists in an abnormal formation of the angular process that amounts to magnification of the space inclosed by the process. We can say that on no two heads is the organ formed in exactly

> the same way. ... For the important fact that the mathematical organ is to be found prevalently on the left, I need only refer to portraits. In the case of only moderate mathematical ability a distinct modification is usually to be found only on the left. But at times there is scarcely a perceptible difference between the left and the right, for example, in Leibnitz. At times, again, the right as well as the left is abnormally formed, but the one is entirely different from the other, for example, in Gauss. Here, also, the variations are many and it is neither practicable nor advisable to describe all particular cases in words. ... Even in considering portraits one comes to the thought that the prominences are to be referred in part to an abnormally strong development of the skin. If we examine the living, we can convince ourselves by feeling that a considerable hyperplasia of the soft part exists. We feel distinctly that the angular process is indeed uncommonly strongly developed, but also that the skin, more definitely the hypodermal tissue, is thickened. The skin with an abundant cushion of fat forms a loose sack laid around the angular process. Very frequently we see also strikingly heavy eyebrows."

With this information, you will undoubtedly be able to recognize the next mathematician you meet on the street, and even judge the quality of this mathematician at a glance. And mathematics hiring and grad admissions committees will have a much easier job – candidates will not even have to fill out applications, just send a photo or preferably a bust. (Also note that the author has "strikingly heavy eyebrows," although he lacks an "abundant cushion of fat forming a loose sack laid around the angular process," making him a good but not great mathematician.)

XXIV.3.3. Mathematics and Mental Illness

This is a sensitive subject that I discuss with some hesitation. Mathematicians are often portrayed stereotypically in films and television as social misfits of borderline sanity. There are well-known examples of mathematicians who have suffered from mental illness, such as CANTOR, GÖDEL, and NASH, and other mathematicians whose behavior is at least quite odd by conventional standards (e.g. GROTHENDIECK, PERELMAN). And then there is TED KACZYNSKI. Popular books, particularly about logic, sometimes seem to suggest that sustained intense thought about mathematics and logic can, and typically will, drive a person insane.

An extreme (and fortunately not so well known) example was ANDRÉ BLOCH, who spent most of his life in an asylum for the criminally insane after killing his brother and two other family members out of fear that they were showing symptoms of hereditary mental illness present in his family history. While in the asylum he did a substantial amount of solid mathematics, particularly in Complex Analysis, and regularly corresponded with leading mathematicians, most of whom apparently did not know he was institutionalized. (He did do odd things such as date all his letters April 1 no matter when they were written.)

But mathematicians in fact appear to be no more, or less, susceptible to mental illness than any other group of people; in any category of people of substantial size, some percentage can be expected to have mental illness. For example, one can easily identify at least as many professional athletes as mathematicians who have had mental health problems, not even counting athletes who suffer brain injuries. Studies have shown that schizophrenics typically have below-average aptitude in mathematics.

Autism (which is not really mental illness) is possibly a different matter. There is evidence of positive correlation between certain types of autism (e.g. Asperger's) and some types of mathematical ability, at least the ability to focus and concentrate on the mental process needed to do mathematics. It is likely that some prominent mathematicians (possibly including NEWTON) have been mildly autistic (see [**?**]). But the vast majority of mathematicians are in no way autistic.

It is true that many mathematicians are free thinkers who have an unconventional view of the world; one might even expect that the ability to transcend conventional ways of thinking is an important, even necessary, part of being successful in mathematics. And many mathematicians have rather low regard for social customs and norms, although many more are quite conventional socially. Part of the reason many mathematicians are somewhat unconventional may be that they can feel rather free to be so, due to the extreme degree of tolerance in the world of mathematics: mathematicians, probably more than almost any other social group, judge each other to a great extent simply on the quality of their work and ideas and not on social conformity.

> "No one ever made a difference by being like everyone else."
>
> *P. T. Barnum*[6]

It is also not accurate to characterize mathematicians as misfits who are loners or uncomfortable around others and in social situations. There are some such mathematicians, just as there are such people in most other walks of life, and mathematics may indeed be a comfortable refuge for such a person with sufficient mathematical talent; but most mathematicians are pretty adept and comfortable in social situations (VON NEUMANN was reputedly the life of every party he attended, and he is far from unique among mathematicians

[6] Line from the 2017 film *The Greatest Showman.* There is no documentation that BARNUM actually said it.

in this respect). And mathematicians tend to have broad interests and knowledge, and are not at all single-minded (except when they get working intensively on a mathematical problem, or some other project – mathematicians are very good at focusing their attention when necessary); you will find that mathematicians are often very interesting to talk to about almost any subject.

> "[M]athematicians can be funny. They are the kings of logic, which gives them an extremely discriminating sense of the illogical."
>
> *Alex Bellos*[7]

[7] [?, p. xi].

Standard Notation in this Book

We will use the following standard (and sometimes not so standard) symbols to denote commonly used mathematical structures. In a few cases, the same letter is used to represent more than one structure; hopefully no confusion will result.

B^n	Closed unit ball in $\mathbb{R}^n$
$\mathbb{C}$	Field of complex numbers
$\mathbb{D}$	(1) Ring of dyadic rational numbers () (2) Open unit disk in $\mathbb{R}^2$
$\mathbb{F}$	A field, usually $\mathbb{R}$ or $\mathbb{C}$
$\mathbb{H}$	(1) Division ring of quaternions () (2) Hilbert cube $\mathbb{I}^{\mathbb{N}}$
$\mathbb{I}$	Closed unit interval $[0, 1]$ in $\mathbb{R}$
$\mathbb{J}$	Set of irrational numbers in $\mathbb{R}$
$\mathbb{K}$	C*-Algebra of compact operators on ℓ^2
$\mathbb{M}_n$	C*-algebra of $n \times n$ matrices over $\mathbb{C}$
$\mathbb{N}$	Natural numbers (positive integers)
$\mathbb{Q}$	Field of rational numbers
$\mathbb{R}$	Field of real numbers
$\mathbb{R}^n$	Euclidean space of dimension n (set of n-tuples from $\mathbb{R}$)
S^n	Unit sphere in $\mathbb{R}^{n+1}$
$\mathbb{T}$	Topological group of complex numbers of modulus 1
$\mathbb{Z}$	Ring of integers
$\mathbb{Z}_n$	Additive group or ring of integers mod n
$\mathbb{Z}_p$	(1) Additive group or field of integers mod p (p prime) (2) Ring of p-adic integers ()

The symbol 👍 denotes the end of a proof, and ✋ denotes "caution" or, at the end of an argument, "this is not really a proof as it stands." Other hand symbols occasionally used should have obvious meaning.

XXIV.4. Literature Review

"People who like this sort of thing will find this the sort of thing they like."

Abraham Lincoln[8]

We will give brief reviews here of some of the important books on real analysis and measure theory, and some other topics discussed in this book. In spite of any negative or qualifying comments I make here, almost all of these books are worthwhile to read and study. I have not yet included nearly all the books I am aware of that should be on the list, and I have not included any of the books that should be on the list that I am not aware of.

I generally try to write my own review before looking at any other reviews, and in most cases I have not read any other reviews; in cases where I have and other reviews differ substantially from mine or make additional points, I sometimes add comments to that effect (with attribution).

Undergraduate Analysis

Browder, *Mathematical Analysis: An Introduction* [Bro96]

This nice book covers undergraduate analysis, both one-variable and multivariable, as well as basic measure theory, and ends with some elementary differential geometry (manifolds and differential forms). Textbooks written by first-rate mathematicians often have a certain quality not found in some other books; the author's overall approach, insights, and perspectives are quite illuminating. This book covers a lot of ground in a readable way, although some topics covered are not treated in depth.

The author is one of three brothers who are or were all eminent mathematicians. Their father was Earl Browder, a well-known American communist.

Fichtenholz, *Differential and Integral Calculus* [Fic89]

In Russian. This classic three-volume treatise on undergraduate Real Analysis was used as a text by generations of students in the Soviet Union. Far more than just a calculus text. A German translation is available, but not an English one.

Fichtenholz, *Foundations of Mathematical Analysis* [Fc57]

In Russian. This two-volume set is a reworking of parts of *Differential and Integral Calculus*, and is aimed at a slightly higher (post-calculus) audience. A generally careful and readable exposition, although it suffers from excessive hand-waving in places (a criticism which can probably be made of most books on this list, including my own). Contains some material and viewpoints not readily found in Western texts. Unfortunately, no translation is available.

Godement, *Analysis I* [God04]

A rather unique treatment of basic analysis, written in an unusual (for a mathematics book) narrative style, with lots of digressions to apparently unrelated subjects, many of which are connected with the author's obsession with militarism and nuclear weapons (while I admire his dedication on these matters, and mostly agree with his sentiments, the comments about them in the personal preface would have sufficed). Not all of his other digressions are as lofty, including some rather shockingly crude sexism on p. 9. On the mathematical

[8]Book review; cf. R. Byrne, *The Third and Possibly the Best 637 Best Things Anybody Ever Said*, 514.

front, his frequent commentaries on the nature and history of the mathematics make interesting reading and are quite informative. Some of the pronouncements are dogmatic and even narrow-minded, for example the statements on p. 382 concerning a French textbook that defines e^{ix} to be $\cos x + i \sin x$:

> "It would be difficult to imagine a more aberrant conception of mathematics: Euler's most famous formula degenerating into a pure and simple *notation*, and furthermore incomprehensible! ... It is difficult to imagine that mathematicians, even "applied", could ever have advocated it."

(see III.6.2.14.; of course, I didn't leave it at that! cf. XII.1.1.8.(iii), XII.9.9.10.. To be fair, the author does not really suggest that e^{ix} has any intrinsic meaning, as some unsophisticated references seem to; the meaning is carefully defined over a number of pages before this comment.)

The mathematics in this book is more carefully and precisely presented than might be apparent from the narrative presentation, although I did find a few errors, obscurities, and misprints (as I do in almost every book). It is pure mathematics, emphasizing concepts over calculations and with almost no mention of applications.

The author's admonition that "One does not learn analysis or anything else from one single book; there is neither Bible, nor Gospel nor Koran in Mathematics" should be well taken. This is an interesting and useful book which can help give part of the big picture of analysis.

This book is Volume I of a four-volume sequence. I am not yet prepared to comment on Volumes II-IV.

Körner, *A Companion to Analysis* [Kör04]

An insightful and entertainingly written account of undergraduate analysis. Treatment of the topics covered is mostly excellent. Although the mathematics is "honest" and carefully done, it is unsystematic and somewhat informal in places, and not all essential topics are covered, which make the book rather unsuitable as a text. But for its intended purpose as a "companion", it is excellent.

Krantz, *Real Analysis and Foundations* [Kra05]

Like "little Rudin," bridges undergraduate- and graduate-level analysis. I am not terribly impressed with this book, although it has some good features: it is generally pretty solid and complete, and gives a good introduction and motivation for interesting and important applications. But the exposition and organization are of uneven quality, and there are more errors than there should be in a book like this, especially a second edition. (Krantz is very prolific as a writer, but this comes at a price: his writing tends to suffer from a lack of polish and attention to detail, although much of what he writes is pretty good.) He claims that the writing style of this book, unlike older books, speaks to modern-day students in their own language, but I fail to see much difference in style between this book and older books; maybe he simply means the substantial number of statements in the text specifically addressed to the reader, which is indeed rather unusual writing style for a mathematics text but which I don't imagine makes much practical difference to most readers.

The "preface" is primarily a masterpiece of self-promotion. It also contains the ridiculous assertion (written in 2005) that "real analysis has not appreciably changed in 150 years," overlooking such fundamental work as that of Cantor, Dedekind, Lebesgue, ..., as well as most of the foundational work of Weierstrass (he did not yet even have a university position in 1855) and almost all of topology and functional analysis (and much more). Even the Riemann integral had just barely been developed and was not yet published or widely known. At least half of the present book, and a substantial portion of Krantz's book, cover real analysis unknown, or at least not properly understood, in 1855.

If he had said "30 years" instead of "150 years," the statement would have been more defensible, and more in line with what he was claiming in the preface to the first edition: that some other authors of recent

analysis books have said that the subject *has* changed in the last 30 years. But this is a straw man; I am not aware of any author who has made such an assertion.

All in all, this book does not live up to the author's hype.

The above comments were written about the second edition. A third edition has recently appeared, which has been revised into more of a traditional undergraduate real analysis text: the chapters on Lebesgue measure, wavelets, and differential forms have been removed. A chapter on functional analysis has been added (complete with introductory text directly contradicting the "150 year" statement). The remaining text is a little more refined, but the general comments above still apply. A quick and cursory perusal of the third edition turned up some sample howlers: every metric space is separable (section 13.2 problem 17; he says that this is "fairly tricky to prove" – I'll say!); every bounded operator on L^2 is "essentially" a multiplication operator by the Spectral Theorem (section 14.4 problem 9); and in section 14.6 problem 6, a "norm" is defined which is not a norm (this topological vector space $\mathcal{C}^\infty([a,b])$ is in fact not normable, although it is completely metrizable with a metric defined by a formula similar to the "norm" formula, cf. XX.4.3.17.). There are also a number of inaccurate internal references, which is strange since accurate internal references are so easy in LaTeX. Judging by the new preface, the author still has a pretty high opinion of himself and his book. (I should note that the prefaces to some of Krantz's other books, such as [Kra15], have a far different tone and create a different picture of the author, who I must emphasize I do not know personally.)

Now there is a fourth edition. The slimming down of topics that began in the third edition has continued: for example, the chapter on functional analysis which appeared (with all its difficulties) in the third edition has disappeared just as suddenly. The author says he doesn't want people to think this is a "high-level" text (I don't think there is much danger of that; he also says he wants the text "to be the generational touchstone for the subject and the go-to text for developing young scientists" – a laudable but pretentious goal which is not likely either), but he still claims that this book is more rigorous and at the same time more readable than anything else since Little Rudin. But I don't see either more rigor or more readability than, say, in [Pug15] (or even as much in this case).

For example, the discussion on p. 1 of the inadequacy of $\mathbb{Q}$ for analysis is logical mush: the claim is that $\mathbb{Q}$ is "not closed under limits" (apparently meaning limits of sequences) and must be expanded to a number system which is. But this argument presupposes that we already have a (perhaps still ill-defined) larger number system in which limits can be taken: if $\mathbb{Q}$ is the only number system we have, it is tautologically closed under limits of convergent sequences. And if we want limits of all sequences, $\mathbb{R}$ is also not closed. He tries to assert that every sequence of real numbers which "should" converge actually does. This is evidently an informal reference to the idea of a Cauchy sequence, a somewhat subtle notion which would certainly not leap to mind for someone (other than a Cauchy) who hadn't seen it before. Many people would say the sequence $(1, 2, 3, \dots)$ "should" converge to $+\infty$, but $+\infty \notin \mathbb{R}$, so not every sequence in $\mathbb{R}$ which "should" converge does, i.e. $\mathbb{R}$ is not closed under limits either (e.g. in the extended real line). I'm not saying it is easy to give an elementary yet mathematically and logically honest introduction to the notion of completeness, but one can certainly do a lot better than the discussion in the book.

On p. 25, he proves that a sequence in $\mathbb{C}$ converges if and only if it is Cauchy (after proving this for real sequences) by making the "observation" that a sequence in $\mathbb{C}$ converges (resp. is Cauchy) if and only if the sequences of real and imaginary parts converge (resp. are Cauchy). There is no previous discussion of anything like this. In fact, both "observations" are propositions which need to be proved. Of course, the proofs are very easy, but they are not trivial, especially for someone who has just seen the definitions of the concepts; at the very least, these should be expressly designated as exercises for the reader, not just "observations."

On p. 290, it is asserted that "a moment's thought" shows that an open spherical shell cannot be written

as a disjoint union of open balls. Maybe so. But another moment's thought reveals that this is actually quite nontrivial to prove (and I'm not sure why the question is even relevant to the discussion on that page).

In fact, almost every page I looked at contained something I could quibble with, although many of the criticisms are petty ones concerning the author's writing style. For example, on p. 19, he says, "If a sequence does not converge then we frequently say that it *diverges*." Frequently? When do we not? (OK, I guess we don't always actually *say* it diverges, but we *could*.) Why not just say: "A sequence *diverges* if it does not converge."?

I guess *someone* (other than the author) must like this book, since it has been through four editions.

Pugh, *Real Mathematical Analysis* [Pug15]

This is overall an excellent book, and is one of the best references for learning and understanding real analysis. The author's explanations and insights on most topics are outstanding. The book is mathematically honest and generally rigorous. However, many arguments are written a little informally, with some routine details glossed over; thus a student using this as a textbook might have trouble developing the skill of writing complete rigorous analysis proofs if the book's proofs are taken as a model (to be sure, there are plenty of proofs in the book written out fully enough to meet anyone's standards).

Rudin, *Principles of Mathematical Analysis* [Rud76]

"Little Rudin" or "Baby Rudin." One of the most widely-used analysis books for a long time, with good reason. Covers pre-measure-theory analysis with a last chapter on Lebesgue measure.

Schumacher, *Closer and Closer* [**?**]

A leisurely and non-stressful introduction to undergraduate real analysis. This is a pretty good book, despite its problematic title (cf. IV.1.3.11.); it is nicely written, the mathematics is generally carefully done and is not "dumbed down," and a surprising amount of material is covered. The discussion of the Implicit Function Theorem is especially good. The treatment is mostly mathematically "honest" (I.8.), although some subtleties, e.g. the Axiom of Choice, are not mentioned. One mistake I noted is the wrong definition of countable compactness (p. 141), confusing *countably compact* with *Lindelöf*. The approach is an "active learning" one, based on the Socratic method: some arguments are given in great detail, but many are left as exercises for the reader, often with little hint as to how to proceed. Such an approach is certainly defensible pedagogically. This is a good supplementary text for a reader desiring a gentle but reasonably thorough treatment of the subject.

Stromberg, *An Introduction to Classical Real Analysis* [Str81]

This is a terrific book (although I would not describe the writing as a literary masterpiece). It is thorough and detailed, but also has much helpful explanatory material. The first few chapters cover standard (one-variable) undergraduate analysis at a similar level to most undergraduate texts, but the pace and depth increase when integration is reached. Riemann integration is not treated, except in passing after the fact; instead, the Riesz-Daniell approach to Lebesgue integration is followed. Some complex analysis is interwoven and integrated into the development at appropriate points. The exercises in this book are especially notable. This is not only a textbook (probably most suited to an honors-level analysis course), but also a great reference work even for mature analysts.

Wade, *An Introduction to Analysis* [**?**]

This is a decent book on undergraduate real analysis, covering both the one-variable and multivariable theories, but there are many small things I would wish to do differently. The fourth edition has a number of improvements over the third edition (although the deletion of the chapter on differential forms is not one of them), but the fourth edition seems "cheaper" than the third in both typesetting and binding. The author also did not do a very good job proofreading this edition before publication. There is a long list of typographical errors from the first printing on his website which have been corrected in later printings, but a significant number of typographical and mathematical errors remain.

Historical Calculus Texts

A selection of historical and/or obsolete calculus texts. These are interesting to peruse to see how exposition of the subject has evolved, if for no other reason.

Courant, *Differential and Integral Calculus* [CJ99]–[CJ89]

I only recently looked carefully at this two-volume book. I was somewhat concerned that it would be a cookbook-type treatment lacking in rigor after reading the introduction (as well as some comments in [CR79] on the nature of mathematics), which begins:

> "Although there is no lack of textbooks on the differential and integral calculus, the beginner will have difficulty in finding a book which leads him straight to the heart of the subject and gives him the power to apply it intelligently. He refuses to be bored by diffuseness and general statements which convey nothing to him, and will not tolerate a pedantry which makes no distinction between the essential and the non-essential, and which, for the sake of a systematic set of axioms, deliberately conceals the facts to which the growth of the subject is due."

My concern was unfounded. This was the best calculus/elementary real analysis textbook written up to its time of publication (1927 for the German edition, 1934 for the English edition), and is still a good treatment, although probably not suitable as a textbook today (but still worth reading as a supplemental text). The theme is to develop differentiation and integration simultaneously as inverse processes, an approach which is both conceptually and historically valuable. It is far more carefully written than, say, [Gri21] (which preceded it by only a few years), and is a model of maintaining mathematical honesty along with an appropriate level of detail in the exposition. In fact, I have found almost nothing substantial to quibble with. The author is not hesitant to express opinions on various points, which make for interesting reading (cf. V.3.1.26.). The English editions differ somewhat from the original German edition.

The review by R. Boas in the *Mathematical Reviews* is somewhat less complimentary, referring to the books as "museum pieces." The review also states that at least one fallacious proof from the 1927 German edition has not been corrected in later editions, but does not say what it is. I have found one seriously inadequate (not exactly wrong) proof, the argument on p. 291-292 of volume 2, that a curve with a continuous parametrization which is continuously differentiable except at finitely many points has Jordan content zero. The reduction in the argument is incorrect, and such a curve need not even be rectifiable (e.g. XIX.4.5.2.). But the difficulty can be avoided by first enclosing each singular point in a small square and then reducing subintervals away from the singularities as in the argument. (The result is also not stated precisely enough; the parametrization must be on a closed bounded interval.)

Edwards, *An Elementary Treatise on The Differential Calculus*

This was evidently a popular calculus text in the late nineteenth century, since it went through at least three editions; my copy is a later printing of the third edition from 1906.

This text is almost entirely mechanical; mathematical rigor is almost nonexistent. The most egregious gap is that there is, as far as I can determine, no suggestion that limits, and thus derivatives (called *differential coefficients*), do not always exist. Calculus is pretty easy if you don't worry about the existence of limits! (It is, of course, a remarkable and significant fact that they mostly do, at least if you stick to combinations of elementary functions, and you can get a long way by mere formula manipulation, although you can get into occasional trouble even here.)

For example, here is the entire treatment of the Implicit Function Theorem:

> "If we have
> $$\phi(x, y) = 0$$
> then
> $$\phi(x + h, y + k) = 0.$$
> Hence
> $$\frac{\phi(x + h, y + k) - \phi(x, y + k)}{h} + \frac{\phi(x, y + k) - \phi(x, y)}{k} \cdot \frac{k}{h} = 0;$$
> which, when h and k are indefinitely diminished, becomes (as explained in Art. 159 [total differential, similarly nonrigorous])
> $$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y} \cdot \frac{dy}{dx} = 0,$$
> or
> $$\frac{dy}{dx} = -\frac{\frac{\partial \phi}{\partial x}}{\frac{\partial \phi}{\partial y}} \ .$$
> This is a *very useful formula* for the determination of $\frac{dy}{dx}$ in cases in which the relation between x and y is *an implicit one*, of which the solution for y in terms of x is inconvenient or impossible."

The definition of limit in Article 10 is a fairly careful (narrative) version of the usual definition of an ordinary limit of a numerical function, not valid for an "infinite" limit (and he declares that the expression is "ultimately" equal to the limit, not really wrong if the meaning is defined to be this, but possibly misleading). But a much more expansive notion of limit seems to be in the author's mind: the first rather curious example of limit is

> "If an equilateral polygon be inscribed in any closed curve, and the sides of the polygon be decreased indefinitely and at the same time increased in number indefinitely, the polygon continually approximates to the form of the curve, *and ultimately differs from it in area by less than any assignable magnitude*, and the curve is said to be the *limit* of the polygon inscribed in it."

[There is an assertion here that needs to be proved, maybe with some restriction on the curve like rectifiability; and what does "continually" mean since the polygon is a discrete function of the number of sides? Also, what does "inscribed" mean if the curve is not convex? And how does this "limit" of curves illustrate the definition?]

The only whiff of suggestion that there might be a problem with existence of limits that I have found is in the discussion of tangents and concavity, where it is acknowledged that vertical tangents can occur, where

$\frac{dy}{dx}$ is "infinite" (the author then says that all higher derivatives are also "infinite" there). But not to worry: just interchange x and y, and the derivative then becomes zero.

Two arguments are given purporting to prove equality of mixed partials, both based on a vague assertion that "processes of differentiation take no cognizance of the *particular values* of any constants involved," neither of which hold water.

There is eventually a little more care, if not rigor. In the discussion of Taylor series, there is an (oversimplified) discussion of continuity (only jump discontinuities are considered), and an acknowledgment that the Taylor series of a function does not converge if the function or one of its derivatives becomes infinite or has a discontinuity, or even if the error terms do not approach zero – i.e. the Taylor series converges to the function except when it doesn't (evidently sequences can fail to have limits or series can fail to converge, but functions always have limits).

The Intermediate Value Theorem is considered "obvious," and it is asserted that a quantity can change from positive to negative or vice versa only by "passing through 0 or infinity." And in discussing maxima and minima, it is implicitly assumed that a function can change sign only at a discrete set of points (i.e. the converse of the First Derivative Test is essentially argued).

On the other hand, extensive and detailed applications are given to the geometric structure of curves, with intricate constructions rarely discussed in modern texts. For example, I learned what the "roulette" of a curve rolling on another curve is, and how to describe and calculate it.

The author argues that the term "indeterminate form" is not the best terminology since the limit is not really "indeterminate" (he of course does not worry about whether it *exists*, but merely whether and how it can be calculated; he calls the limit as $x \to a$ the *true value*, or sometimes the *true limiting value*, of the expression at $x = a$), and suggests the terms "undetermined" and "illusory" instead; but I don't find these terms any better, and he does acknowledge that even then the term "indeterminate form" was well established. A similar argument is given in Courant.

Euler, *Foundations of Differential Calculus* [Eul00]

English translation of the first part of Euler's 1755 treatise on calculus. Primarily of (considerable) historical interest today, although almost all of the mechanical parts of calculus covered today in first-semester courses are here and treated in a nicely understandable way, if not always too rigorously (this was the first text about which this can be reasonably said), and as in most writings of great mathematicians there is much wisdom and insight in the exposition. And the man certainly could calculate! But, on the other hand, it is remarkable and revealing that even one of the greatest mathematicians had such a degree of misunderstanding about things we today regard as fairly basic, both in mathematics and physics (e.g. Euler seemed to consider it self-evident that matter is infinitely divisible). Throughout this book there is much beating of gums about the nature of infinity and the "infinitely small," which he repeatedly states is actually zero or nothing while at the same time can be used as a divisor of another infinitely small quantity. This book graphically illustrates how far our understanding of the foundations of analysis has progressed since then.

Griffin, *An Introduction to Mathematical Analysis* [Gri21] and *Mathematical Analysis: Higher Course* [Gri27]

A widely-used two volume textbook sequence for the first two years of university mathematics, from the 1920s (would that more of our entering students today were able to take a course at this level! Granted, a much higher percentage of the population attends universities now than 100 years ago.) The books cover roughly what we do today in a two-year calculus sequence, along with trigonometry and some statistics. There is not a high level of rigor, and many things are oversimplified and/or not justified adequately, but

the books are fairly "honest" mathematically, with numerous cautionary comments of the type we might give today, such as:

> "**We cannot divide by zero.** Erroneous statements are often made in this connection about 'infinity' – whatever that may be. The correct statement is that we cannot divide by zero."

> "It is highly useful to give a meaning to a power x^n even when the exponent is negative, fractional, or zero. Obviously x^n for such n has no meaning [in the usual sense] and is quite absurd ... [The definition is then introduced.] ... These definitions are the only ones possible if the usual laws of exponents are to apply in all cases. ... It is a great advantage [to have these definitions of power functions]. This is possible because we have *generalized the meaning* of a power, to allow n to be negative or fractional. Such generalizations are very typical of modern mathematics."

> Concerning complex numbers, "The names 'real' and 'imaginary' are very misleading, as they suggest that one kind of number actually exists and that the other does not. The fact is, these are merely *different kinds* of numbers. Imaginary numbers can be given a perfectly concrete interpretation, which makes them exceedingly useful."

The definition of limit is actually correctly given, although just described in words (somewhat bizarrely using the symbol n to denote what we usually call ϵ). But some limits, including the crucial one defining e (V.5.3.5.), are simply computed (estimated) numerically with no proof that they actually exist, or even suggestion that such a proof is necessary.

There are a few misstatements and misleading statements due to oversimplification, such as an assertion that the converse of the First Derivative Test holds (cf. V.3.10.10.). The derivation and proof of the Product, Quotient, and Chain Rules are mathematically inadequate (V.3.10.5., V.5.5.8.). The following "proof" that two functions with the same derivative differ by a constant is typical of the level of rigor in the books:

> "For if the derivatives are equal, the functions must be changing at the same rate; and therefore their difference is not changing but remains constant."

(I have not found any mention of the Completeness Property of $\mathbb{R}$ in either volume; cf. V.12.3.5.(iv).) And there is apparently nothing to prove with the Implicit Function Theorem:

> "Any equation involving x and y requires y to vary with x in some definite way. If the value of y is not given in terms of x explicitly, i.e. in the form $y = f(x)$, we say that the equation defines y 'implicitly' as a function of x; or that y is an *implicit function*."

He does sometimes acknowledge things like

> "Certain critical questions arise in some of these steps which will not be discussed here."

The style is more cookbook than we like today, with many facts and formulas simply stated (one can usually find some justification by looking hard enough, although often not a mathematically adequate one), with the admonition that the student should "memorize" them.

These books give a picture of the state of lower-division undergraduate mathematics instruction in the early-to-mid twentieth century.

Osgood, *Advanced Calculus* [**?**]

This is the second volume of a two-volume sequence from the 1920s. The first volume is titled *Introduction to the Calculus*, but evidently (I have not yet had an opportunity to review the first volume) it would be

more accurate to describe the first volume as one-variable calculus and the second as multivariable calculus, although it also contains chapters on differential equations and the calculus of variations. The topics covered are similar to the ones in [CJ99]–[CJ89], to which it is compared in the review of that work by R. Boas in the *Mathematical Reviews*. That review complained that Courant's book relied excessively on motivations from physics, but Osgood's book is tied far more closely to physics. In fact, Osgood, although he was one of the best American mathematicians of the early twentieth century, seems to have had a decidedly old-fashioned view that mathematics and physics are not really distinct subjects. Indeed, on p. v he calls geometry "the noblest branch of physics" and again on p. 65 when he attempts to justify the integral formula for the area of a surface () he states:

> "It is a fundamental principle of elementary geometry to refer all geometrical truth back directly to the definitions and axioms. What are the axioms on which this formula depends? The answer is: *The formula itself is an axiom.* The justification for this axiom is the same as for any other physical law, namely, that the physical science, here geometry, built on it is in accord with experience."

The level of rigor in this book is higher than in the contemporary [Gri27], but still not entirely adequate, although the book is pretty honest mathematically and the author acknowledges many technicalities which must be proved but aren't, and references are often given. He does sometimes say things like "It is here not a question of a rigorous proof of a theorem, the truth of which no one doubts." (p. 193) And in discussing a problem in the calculus of variations, he states on p. 408:

> "[W]e are not concerned here with the difficult question of proving mathematically that our problem (after still further restrictions) has one and only one solution, and that this solution satisfies the further demand of possessing a second derivative. On the contrary, we take for granted, in a given case, as more or less plausible from the physical evidence, that the problem will admit a unique solution, continuous together with its derivatives of the first two orders, for we know from experience that problems with a physical pedigree do usually admit the kind of solution expected – and we then turn our efforts to finding this solution."

He does, though, go on to say: "Incidentally, we get some interesting surprises as to what was to be expected from the physical evidence."

In fact, a considerable portion of the book is devoted to applications of various aspects of calculus to physical problems.

I could not classify this book as a classic to the same degree as [CJ99]–[CJ89] (which was somewhat later), but it was about the best English-language text available at the time.

Real Analysis, Measure Theory, and Integration

These textbooks cover the basic theory of measure and integration, and most also treat the basics of functional analysis.

Many general measure theory texts follow what I call the "reinventing the wheel" plan: first develop Lebesgue measure and integration, then redo everything in general, in many cases just referring back to the Lebesgue case for proofs of results. This approach is certainly defensible pedagogically, and is preferred by many people, but it is not to my personal taste; I much prefer to start out with general measure theory, spending considerable time discussing and emphasizing the critical special case of Lebesgue measure as I go, as well as discussing other special cases such as probability spaces.

> "One of the many fundamental questions which any author on the subject must decide, is whether to begin with 'general' measure theory or with 'Lebesgue' measure and integration. The point is that Lebesgue measure is rather more than just the most important example of a measure space. It is so close to the heart of the subject that the great majority of the ideas of the elementary theory can be fully realised in theorems about Lebesgue measure. ... If you take the view, as I certainly do when it suits my argument, that the business of pure mathematics is to express and extend the logical capacity of the human mind, and that the actual theorems we work through are merely vehicles for these ideas, then you can correctly point out that all the really important things in [elementary measure theory] can be done without going to the trouble of formulating a general theory of abstract measure spaces; and that by studying the relatively concrete example of Lebesgue measure on r-dimensional Euclidean space you can avoid a variety of irrelevant distractions.
>
> If you are quite sure, as a teacher, that none of your pupils will wish to go beyond the elementary theory, there is something to be said for this view. I believe, however, that it becomes untenable if you wish to prepare any of your students for more advanced ideas. The difficulty is that, with the best will in the world, anyone who has worked through the full theory of Lebesgue measure, and then comes to the abstract theory of general measure spaces, is likely to go through it too fast, and at the end finds himself uncertain about just which ninety percent of the facts he knows are generally applicable. I believe it is safer to keep the special properties of Lebesgue measure clearly labelled as such from the beginning."
>
> *D. Fremlin*[9]

The "reinventing the wheel" approach seems to me like presenting Linear Algebra by first stating and proving all the theorems of the subject for $\mathbb{R}^n$, and then restating and partially reproving them for general vector spaces.

Bogachev, *Measure Theory* [Bog07]

A very thorough two-volume treatment of measure theory. In order to cover the huge volume of material, many topics, some of them important, are relegated to "exercises" where arguments are only sketched or outlined.

The English translation was apparently done by the author himself. Although this was a commendable effort, and in most places the translation is pretty good, the results are not entirely satisfactory, and in a

[9] [**?**], V. 1, p. 9.

few places the reader must puzzle out what the author is trying to say (of course, in many books written by native English speakers, probably including my own, the reader must do the same thing!)

Dieudonné, *Foundations of Modern Analysis* [Die60]

This well-regarded book, the first of a comprehensive nine-volume series on analysis, develops basic analysis from a "modern" point of view, in the BOURBAKI tradition (the author was a leading member of BOURBAKI). To illustrate the approach, note that Banach and Hilbert spaces are treated before reaching differential calculus, which is first done on Banach spaces and then specialized to the real numbers. The exposition is elegant and carefully done. The author has strong opinions on many subjects and is not hesitant to express them, not all of which I agree with; although he was a formidable mathematician with a strong command of the big picture of mathematics, he had his own point of view (among other things, very geometric) which I do not always share. This is a valuable and widely-used book, but I am not convinced the approach is necessarily the best one for someone learning the subject. Concerning the series as a whole, it has been suggested to me that my own book is unnecessary since Dieudonné already covered the entire subject (I of course disagree!)

My opinion of Dieudonné is colored by my personal experience with him, which is admittedly quite limited and may have given an inaccurate picture. My only encounter with him came when he gave a colloquium at Berkeley while I was a graduate student. The talk was about a technical result on Lie groups which was probably not appropriate for a general mathematical audience, made worse by the fact that he repeatedly refused to define terms or discuss general considerations, sneering that he didn't have to explain such things at *Berkeley*. The student sitting next to me seriously considered asking "What's a Lie group?" at the end (this student knew the answer very well). It was the most arrogant mathematics talk I have ever heard, and I remember thinking I had never met anyone whose name so exactly described his opinion of himself.

Doob, *Measure Theory* [Doo94]

This book, written by an eminent probabilist, is somewhat idiosyncratic, but valuable. It has nice, efficient treatments of a number of topics not readily found in standard texts. The approach is not especially wedded to probability theory, but the chapter on martingales (invented by the author) is especially valuable for probabilists. Many arguments represented as proofs in this book are really only outlines, and need many details to be filled in by the reader (not necessarily a bad thing so long as the necessity is recognized!)

Dunford and Schwartz, *Linear Operators I* [DS88]

This first of a three-volume set is usually regarded as an encyclopedic treatise on Operator Theory. But chapters 3 and 4 give an extensive treatment of measure theory and related topics. One of the best places to read about finitely additive measures and integration (from the beginning, a "measure" is a finitely additive complex measure), and vector measures.

Folland, *Real Analysis* [Fol99]

This is one of my personal favorite Real Analysis texts. It contains elegant and comprehensive treatments of many important topics. However, the basic measure theory part is much too concise to be a good choice as a text for a beginning course, especially for masters students, as I discovered when I tried it. The approach of this book is the exact opposite of the "reinventing the wheel" plan, in my opinion too much so: it treats Lebesgue measure almost as an afterthought, as a special case of Stieltjes (Radon) measures.

Fremlin, *Measure Theory* [Fre04]–[Fre06]

A monumental five-volume treatise on almost all aspects of the subject. Not suitable as a text, although the first two volumes are designed to be accessible to students, but a detailed and comprehensive reference work.

Halmos, *Measure Theory* [Hal50]

The first (1950) "modern" treatment of measure theory, and still one of the best. It is an excellent treatment of the basics of measure theory (done from the standpoint of what we call "premeasures on rings"), and includes some more advanced topics such as Haar measure. In fact, one can hardly improve on the exposition of many of the topics covered.

Hewitt and Stromberg, *Real and Abstract Analysis* [HS75]

A classic book. It is dense in places and not always easy going, but well written and contains a wealth of material.

Lieb and Loss, *Analysis* [LL97]

This is a valuable book with a little different emphasis than most. The authors' philosophy is to seamlessly merge classical and functional analysis, which they have done well. The treatments of measure theory and basic functional analysis are rather sketchy, but the coverage of L^p-spaces and Sobolev spaces is excellent, among the most complete in any general analysis book. The general approach is a low-tech and computational one, emphasizing inequalities and "hard analysis" arguments rather than abstract general theorems (quite the opposite of Pedersen), an approach which has much merit and should particularly appeal to applied analysts; the primary intended audience for the book is evidently applied mathematicians and mathematical physicists, and there are many physics-related applications woven throughout. The book is written in somewhat of a stream-of-consciousness style, and would have benefited from some more organizational attention and effort on the part of the authors; but on the other hand, it is full of insightful comments and observations. A few things are a little sloppy: for example, the proof of Hölder's Inequality 2.3 uses Jensen's Inequality and thus is only valid as written on finite measure spaces (the inequality is true in general, which can be shown by an additional MCT argument, or see XX.15.2.6. for a simpler proof). This is not a book I would be likely to use as a text, but it is a great supplementary text.

McDonald and Weiss, *A Course in Real Analysis* [MW99]

This is overall one of the better measure theory texts, and one that I have used several times. The treatments of most standard subjects range from fairly good to excellent. Some of the writing is somewhat turgid, and some of the definitions (e.g. Borel sets, absolutely continuous functions) are nonstandard but equivalent to the usual ones. A few proofs are more laborious or roundabout than necessary. A few important basic results, e.g. the Lebesgue Density Theorem, are not covered. This text follows the "reinventing the wheel" plan. This book has a lot of exercises, some of which are fairly challenging, but generally with hints and guidance.

Natanson, *Theory of Functions of a Real Variable*

Another standard Soviet text. Well done, and covers material not found in other books (e.g. the Banach-Tarski paradox). Volume I is pretty routine, but Volume II is more interesting. The English translation leaves something to be desired, and is confusing in places: for example, in several instances the phrase "replace x by y" should be "replace y by x" (this is simply a translation error; the original Russian text is correct).

Pedersen, *Analysis NOW* [Ped89]

The author, a specialist in Operator Algebras, takes an uncompromising approach to measure and integration using functional analysis methods (he says the title means "Analysis via norms, operators, and weak topologies"). This is a valid approach with much to recommend it (in my opinion as a fellow Operator Algebraist), but should probably be complemented by a more traditional treatment. The text is clearly written, and witty in places (different readers will have different opinions about the wit).

Royden, *Real Analysis* [Roy88]

This is one of the "classic" texts (and the one I learned measure theory from as a student). Despite its age, it is still a viable and worthwhile option. The third edition has some additions and improvements, but also more errors than the second edition. This book follows the "reinventing the wheel" plan, to an even greater extent than most. An expanded and updated fourth edition, prepared by M. Fitzpatrick, has recently appeared.

Rudin, *Real and Complex Analysis* [Rud87]

"Big Rudin." Also a classic book, widely used. The author rather uniquely covers and integrates Real Analysis (measure and integration) with Complex Analysis. These subjects are usually treated separately, but there is much merit in the author's approach which highlights the overlap and interplay of the two theories (although I have chosen not to follow this path in this book). Rudin does not follow the "reinventing the wheel" plan; general measure and integration is developed in Chapter 1, and Lebesgue measure is obtained by applying the Riesz Representation Theorem to the Riemann integral.

Saks, *Theory of the Integral* [Sak64]

This was the first comprehensive book on measure and integration (1933), and is very impressive in its breadth and depth, as well as giving a nice overall view of the logic and philosophy of the subject. While the abstract Lebesgue integral on general measure spaces is treated, it is somewhat in passing and the discussion is practically limited to subsets of Euclidean space. At least half the book is devoted to a study of the interrelated topics of indefinite integration, bounded variation, and absolute continuity. The book is still well worth careful study. Treatments of some topics have been improved since this book, but many have not, and indeed this book covers a number of important topics not treated adequately in most newer references. It is overall quite well written and readable, although dense and detailed. Some of the notation and terminology is outdated and requires care on the reader's part to decipher. Definitely a book for adults.

Swartz, *Measure, Integration and Function Spaces* [Swa94]

This book has a rather unconventional approach to the subject with much to recommend it. It treats finitely additive, signed, and complex measures from the beginning rather than as an afterthought. It has a good treatment of limits of measures, the Nikodým Convergence and Boundedness Theorems, and the Vitali-Hahn-Saks Theorem. The treatment of fundamentals of functional analysis includes ordered vector spaces.

Taylor, *Measure Theory and Integration* [Tay06]

A good general treatment of the subject, with topics leading in the direction of geometric measure theory not well covered in other texts in this group. However, the author is not as careful as he should be in specifying finite or σ-finite restrictions in some results and problems (I found several places where such restrictions are necessary and not mentioned).

Complex Analysis

There are dozens, perhaps hundreds, of complex analysis texts. We will only describe a few of the best. Many others are at least decent.

Ahlfors, *Complex Analysis* [Ahl78]

Generally regarded as *the* classic complex analysis text, and still worth studying.

Brown and Churchill

One of the classic complex analysis texts (I used an early edition as a textbook as a student, when it was just Churchill). Oriented primarily for nonmathematics students, e.g. physicists and engineers, but unlike some books of this type it is mathematically solid.

Gamelin, *Complex Analysis* [Gam01]

One of the very best complex analysis texts.

Greene and Krantz, *Function Theory of One Complex Variable* [GK06]

I had a somewhat better opinion of this book before I used it (third edition) as a text for a class. It is overall quite good, especially the later chapters (e.g. the treatment of the Riemann Mapping Theorem is generally excellent). But the first three chapters with the basic theory are somewhat of an organizational mess, and some of the exercises are not well thought out (in fact, I had some trouble finding enough good and suitable exercises for my class). And the authors beat the $\frac{\partial}{\partial z}$ and $\frac{\partial}{\partial \bar{z}}$ notation to death, and insist on writing $\frac{\partial f}{\partial \bar{z}}$ instead of f' for the derivative of a holomorphic function f throughout most of the book, and even $\left(\frac{\partial}{\partial z}\right)^n f$ for the n'th derivative, making for confusing formulas which are hard to read.

Krantz, *Complex Variables, A Physical Approach with Applications and MATLAB*

This book seems designed as a modern replacement for Brown and Churchill. It is a rather slow-paced treatment of basic complex analysis aimed at a nonmathematical audience. Far less detailed and sophisticated than [GK06]. Generally well-done, with good insights and explanations of standard results. The MATLAB part (also covering some other similar packages) is not at all deep, barely going beyond how to do complex arithmetic. A good book to read as an introduction to the subject.

Remmert, *Theory of Complex Functions* [Rem91] and *Classical Topics in Complex Function Theory* [Rem98]

This is more or less a two-volume sequence, but there is a vast difference in depth and sophistication between the two volumes. The first is a treatment of the basic theory, suitable for undergraduates, and the second is a dense, detailed study of more advanced topics. Both are entertainingly written with extensive historical notes, including anecdotes only loosely related to the subject at hand (such as noting that Pringsheim was at first denied Habilitation "on account of the great ignorance of the candidate"; he apparently refused to explain how to solve quadratic equations.) The books are probably not suitable as primary texts, but are excellent supplemental texts.

Stein and Sakarchi, *Complex Analysis* [SS03]

Part of the authors' series of books on analysis. This book stands on its own as well as a volume in the series. Covers basic complex analysis, not as thoroughly as in [Gam01] or [GK06] but well, and then has

detailed treatments of number-theoretic functions and the Prime Number Theorem, and of elliptic functions. A very worthwhile addition to the literature, but perhaps not the best choice as a text for an introductory complex analysis course.

Functional Analysis

Kreyszig, *Introductory Functional Analysis with Applications* [Kre89]

A classic text, and one of the few options for a class without a measure theory prerequisite. It has a vaguely applied orientation, but mainly just covers the basic theory, and covers it well. Still a good choice as a text for an introductory course at the advanced undergraduate level.

Lax, *Functional Analysis* [Lax02]

This is overall one of the best texts on functional analysis, by one of the leading applied analysts of the 20th century. It includes many topics not covered in other standard texts, and the treatment of most topics is excellent. It has thorough coverage of theoretical functional analysis as well as some applied areas. (There are, however, a rather large number of typographical errors, most of which are inconsequential.) The author's applied orientation shows through not only in his choice of material, but also in the style and tone of some of the presentation and his notation and terminology; however, this does not make the book less useful or valuable for "pure" mathematicians. Some of the exposition is more reflective of the 1950s than 2002, when the book was published: for one example close to my heart, the antiquated term "B*-algebra" is used, a term I have not otherwise seen since about 1980; specialists in this field have almost universally used the name "C*-algebra" since the 1960s.

Specialized Topics in Real Analysis

Diestel and Uhl, *Vector Measures* [DU77]

Despite the name, only the first two chapters cover the theory of vector measures and integration *per se*; the rest of the book consists of applications to the structure theory of Banach spaces. The first two chapters give a nice introduction to vector measures and Bochner integration. The authors' personalities and strong opinions make for interesting reading.

König, *Measure and Integration* [Kön97]

This is a highly original book and contains much material not available elsewhere about construction of measures from primitive data. But the author's opaque writing style and frequently nonstandard notation and terminology make for tough reading.

Krantz and Parks, *The Implicit Function Theorem* [KP02a]

The most thorough discussion available of the various versions of the Implicit Function Theorem and Inverse Function Theorem and their histories.

Krantz and Parks, *A Primer of Real Analytic Functions* [KP02b]

This is a quite thorough treatment of the theory of real analytic functions, covering not only the basic one-variable and multivariable theories, but also more advanced topics such as the Cauchy–Kovalevskaya Theorem, quasi-analytic and Gevrey classes, and the embedding theorem for real analytic manifolds. Complete (or at least semi-complete) proofs are given for most elementary results, but as the topics become more advanced the book becomes more of a survey. Generally well written and readable, although, as with many of Krantz's books, there is an annoying lack of quality control and attention to detail in places. (I do not mean to slight the contributions of Parks, who has long been an acquaintance of mine.)

Oxtoby, *Measure and Category* [Oxt71]

This book is rather unique and does not directly overlap with any other books I know of (except for [BJ95], which is a sequel of sorts), although most topics can be found scattered elsewhere. The theme is the duality between the theories of Lebesgue measure and Baire category. Many results in one of these theories have an analog in the other, which is often more than merely an analog. Along the way, topics like the Banach-Mazur game are discussed and woven into the story in an illuminating way.

Schechter, *Handbook of Analysis and its Foundations* [Sch97]

I think the review of this book on MathSciNet is far too negative. This book, if properly viewed and used, is a valuable resource. Despite the name, not too much classical analysis is covered; instead, the author concentrates on an efficient and logical development of much of the mathematics a modern analyst needs to know, beginning with sets, relations, and orderings, proceeding through algebra and logic, topology and uniformity, and concluding with an extensive treatment of topological vector spaces. This skeleton outline does not do justice to the range of mathematics covered. Dependence of results on set-theoretic axioms is carefully discussed.

Globally, this book is very much in the style of Bourbaki in its organization, attempting to present the most efficient logical path through the development of the material. But the local style is very different: Schechter allows himself much room for motivation, explanation, entertaining writing, and even some humor, things famously and deliberately excluded from Bourbaki (although there is some subtle humor in

Bourbaki reflecting the personalities of the members, beginning with the name itself; indeed, according to [RS09], Grothendieck was not a successful member of Bourbaki in part because he "lacked humor.")

I discovered this book when my manuscript was already well along, and I was struck by how many passages were similar to things I had written, tried to write, or planned to write, often done better than I could have myself. Needless to say, I approve of the author's views about many things in mathematics. (This is not to say that this book is overall very similar to my own; there are very significant differences.)

That said, I do not think this book would be an appropriate place to learn about most of the material covered; it would be most suitable for someone who had already been introduced to most of the major topics. The author did not assume any prerequisites beyond calculus except for a degree of mathematical maturity, but the book would be best used to fill in holes in one's background and to see how everything fits together logically.

This book would have been much more effective as an online book with hyperlinks, organized more in the manner I envision for my own manuscript (i.e. less linearly). The author's logical progression of development means that many results and ideas are introduced before they are actually used, and there are numerous cross-references to other parts of the book. If one simply wants to understand a certain topic or result, a maze of tedious searches through the book via cross-references is often necessary to get the full picture, which would be much more efficient and less annoying if done via hyperlinks. For example, there is a very nice and complete proof of the Brouwer Fixed-Point Theorem contained in the book, but pieces of the proof are scattered through several parts of the book. I hope eventually an online edition of this book can be produced with hyperlinks (there is currently a CD-ROM version, but it appears to be identical to the printed version).

van Rooij and Schikhof, *A Second Course on Real Functions* [vRS82]

This nice book concentrates on a detailed study of differentiation and integration of functions on the real numbers. The material is restricted in scope, but the treatment is quite complete, containing facts, results, and examples otherwise scattered through the literature.

Measure and Probability

These texts are generally very good, and could serve nicely for a first-semester course in measure theory, as well as for a probability course.

Billingsley, *Probability and Measure* [Bil95]

A current standard for this genre. Contains a lot of material on probabilistic number theory as well as general measure theory and, of course, standard probability theory.

Dudley, *Real Analysis and Probability* [Dud02]

An excellent treatment of both measure theory and probability. The two subjects are separated more strictly than in other books of this type, and emphasis is placed on Borel measures on metric spaces, which are especially important in probability. The advanced topics discussed are primarily, but not exclusively, directed towards probability. The writing is clear and readable, and in places rather informal and even chatty, with some important definitions and secondary results buried in passages of text. The writing style somewhat obscures the very careful treatment of the mathematics; I particularly admire the efforts the author made to present the most elegant proofs available of the results. He has a good sense of how to present material in a mathematically honest but non-overwhelming way. There are also extensive and valuable historical notes.

Kingman and Taylor, *Introduction to Measure and Probability* [KT66]

Parthasarathy, *Introduction to Probability and Measure* [Par05]

Geometric Measure Theory

Geometric Measure Theory fairly rapidly splits into two rather distinct parts: "smooth" geometric measure theory and the study of fractals. Some of these references (e.g. Morgan) concentrate on the first, and others (e.g. Edgar) the second. But the basic tools like Hausdorff measures are common to both, and all these references have at least some relevance to both parts.

Edgar, *Measure, Topology, and Fractal Geometry* [Edg08]

An undergraduate-level introduction to fractals and the tools needed to study them. Contains nice but somewhat "light" (focused on the needs of the book) introductions to metric spaces, topological dimension, and measure theory (Lebesgue and Hausdorff measures). A good place to begin reading about the subjects covered.

Edgar, *Integral, Probability, and Fractal Measures* [Edg98]

A "sequel" to *Measure, Topology, and Fractal Geometry*. The title gives a good summary of the topics covered.

Falconer

Federer, *Geometric Measure Theory* [Fed69]

The "bible" of Geometric Measure Theory, with encyclopedic coverage of the subject. The more I study this book, the more I appreciate it; it is a treasure trove of material. At first I found it tough going since the exposition is quite dense (but very efficient). Some of the notation and terminology is nonstandard, and some of the English is rather stilted, but one gets used to these things (and we have an excellent guide in Morgan [Mor09]). And there is more explanation and motivation than I gave credit for at first, along with occasional statements like "I do not know whether this [more general statement] is true" and "I would not know how to prove this [more general statement]." I have found *no* errors or questionable proofs (this doesn't mean there aren't any!), and the only thing I could quibble with is occasional language. I have used this book as primary source for my expositions of various topics. The author is (or was) clearly a master of this subject, and it is pretty much all here.

Mattila, *Geometry of Sets and Measures in Euclidean Spaces* [Mat95]

Morgan, *Geometric Measure Theory* [Mor09]

This is generally a delightful and stimulating book to read, and gives perhaps the most readable introduction to ("smooth") geometric measure theory. It is liberally supplied with computer-generated pictures of objects studied, along with snapshots and anecdotes about the author and other figures in geometric measure theory. Newer editions also have an extensive discussion of soap bubbles and other packing problems. Read this book first (and keep it on hand) before tackling Federer. Note, however, that some arguments represented as proofs in this book are too informal to be considered rigorous.

Rogers, *Hausdorff Measures* [Rog70]

This is an excellent treatment of Hausdorff measures and other basic topics of Geometric Measure Theory. Also discusses Suslin and analytic sets and some Descriptive Set Theory.

Descriptive Set Theory

Bartoszyński and Judah, *Set Theory: On the Structure of the Real Line* [BJ95]

This book more or less picks up where [Oxt71] ends. But the treatment is quite technical, and mostly of interest only to specialists in Set Theory.

Kechris, *Classical Descriptive Set Theory* [Kec95]

The best introductory treatment of Descriptive Set Theory. Covers the basics of the subject thoroughly from many points of view, and makes a convincing case for the importance of the subject and its place in the world of mathematics. More readable than Moschovakis for nonexperts in set theory, although it is more of a complement than a substitute.

Moschovakis, *Descriptive Set Theory* [Mos80]

The standard treatment of Descriptive Set Theory before Kechris. Requires more detailed familiarity with set theory and logic. Well written and readable, however, and a valuable supplement to Kechris.

Foundations, Set Theory, Logic, Large Cardinals

Kanamori, *The Higher Infinite* [Kan03]

This is, and will likely remain (additional volumes are planned), the definitive treatment of the theory of large cardinals. Much of the text is tough going for readers not expert in set theory and mathematical logic, but there are also extensive explanations and motivation for important topics and results, so the book is valuable even for nonspecialists. The order of topics follows the historical development, so the origins of the ideas can be traced. There are also numerous and quite candid descriptions and evaluations of the work of individual mathematicians involved in this subject, which make for interesting reading.

Landau, *Foundations of Analysis* [Lan51]

The first complete treatment of the construction of the real and complex numbers from the Peano axioms (although the various constructions had long since been known and carefully described). The text is rather dry and formal with little explanatory material (although the introduction is engagingly written), but not too much is really necessary and the arguments are easy to follow.

Lawvere and Rosebrugh, *Sets for Mathematics*

This is an appealing and readable treatment of set theory and the foundations of mathematics using categories, and makes a good case that this is the most natural and fruitful approach to foundations for most working mathematicians. However, I find somewhat unconvincing the authors' cavalier assertions that category theory and "naive set theory" (which is what is obtained when the category framework is stripped away) as presented in this way are free from logical contradiction and paradox. For one example, does every category have a skeleton? This is the Axiom of Choice on steroids: the AC is equivalent to the statement that every small category has a skeleton.

Lucas, *The Conceptual Roots of Mathematics* [Luc00]

This is an entertaining and enlightening book, as well as a good source of pithy quotes. The theme is an argument for a "chastened logicism" as the correct philosophy of mathematics; but there is much more of interest, such as one of the best discussions I have read of second-order logic. I know nothing of the author,

but he comes across as something of a character. The quality of both the mathematics and the writing is somewhat uneven, ranging from silly (arguing that Euclidean geometry is "better" than noneuclidean, or invoking stereotypes of Scotsmen and Welshmen to explain some terms) to trenchant.

Mendelson, *Introduction to Mathematical Logic* [Men15]

One of the standard texts on mathematical logic, now in its sixth edition. Gives a very good development of mathematical logic, first-order theories, Gödel's theorems, and various versions of set theory, and has extensive discussion of computability.

However, I got an uneasy feeling of circularity while reading this book (my uneasiness may not be specific to this book but may be with the subject in general, although it came into particular focus with the author's treatment of it). The book begins with a fairly informal introduction in which terms like *set*, *function*, and *countable set* are described. Then the more formal presentation beginning in Chapter 1 gives the axiomatization of a formal theory, starting with a countable set of symbols. Whoa! what exactly is our starting point? Is it set theory (perhaps a naive version)? Is it $\mathbb{N}$? If so, what is the point of eventually axiomatizing $\mathbb{N}$ (or set theory), as is done for $\mathbb{N}$ (in both first- and second-order ways) in Chapter 3 and for set theory (also in multiple ways) in Chapter 4? And if we axiomatize $\mathbb{N}$, don't we have to prove that the $\mathbb{N}$ we have satisfies the axioms (which seems like an impossible task if $\mathbb{N}$ exists without a real definition)? There is also a clear circularity, or at least logical *non sequitur*, when in Chapter 2 alephs and even the Axiom of Choice are used and ultraproducts constructed, before set theory, ordinals, cardinals, and the AC are discussed in Chapter 4. The author's philosophy, as expressed in the introduction, is that "Impeccable definitions have little value at the beginning of the study of a subject. The best way to find out what mathematical logic is about is to start doing it." He does say in a footnote in the introduction that "Care will be exercised to avoid using any ideas or procedures that may lead to the paradoxes ..." but I am not convinced. (My copy of the book is the third edition, but judging from descriptions of the changes in later editions these points do not seem to be treated differently there.)

Nagel and Newman, *Gödel's Proof* [NN01]

A nice introduction to Gödel's Incompleteness Theorem, readable for nonexperts, although it contains a serious misstatement (see H. Putnam's review in *Philos. Sci.* 27(1960), p. 205-207).

Potter, *Set Theory and its Philosophy* [Pot04]

This is an impressive and valuable treatment of set theory which bridges philosophy and mathematics. The mathematical part of the book contains good treatments of the construction of number systems, cardinals, ordinals, and the axiom of choice, as well as set theory itself. Set theory is axiomatized by the theory of levels, but there is also extensive discussion of other systems such as ZF which give theories essentially equivalent for the purposes of providing a foundation for mathematics. Includes extensive historical discussions of the development of the various topics and the philosophy underlying them. Very nicely written, and the philosophical part is varied and balanced. Nonetheless, mathematicians may not agree with all of the philosophical arguments given, and there are a few minor mathematical errors (perhaps no more than in any other book on the list!), such as the formula on p. 232 and accompanying comments.

Sierpiński, *Cardinal and Ordinal Numbers* [Sie65]

An encyclopedic treatment of ordered sets, ordinals, and cardinals. Contains much material about the order structure of the real line. Interesting reading, with many clever arguments and observations. Some of the language used is a little unusual mathematically, and logically ambiguous in places; for example, a

number of results are phrased as "We can prove with the aid of the Axiom of Choice that ...." Apparently this language was used because at the time of the publication of this book, it was not definitely established that these results were independent of ZF set theory (most, if not all, have been subsequently shown to be independent).

Smullyan, *Gödel's Incompleteness Theorems* [Smu92]

A very readable and mathematically complete treatment of various versions of Gödel's Incompleteness Theorem. Perhaps the best source to learn about the details of the theorem.

Nonstandard Analysis

Davis, *Applied Nonstandard Analysis* [Dav77]

Goldblatt, *Lectures on the Hyperreals* [Gol98]

Hurd and Loeb, *An Introduction to Nonstandard Real Analysis* [HL85]

Robinson, *Non-Standard Analysis* [Rob66]

The original treatment of Nonstandard Analysis, and as such of historical and conceptual value. But it is outdated as an exposition of the subject: for example, the hyperreals are constructed using the Compactness Theorem of model theory rather than via ultrafilters (the distinction is more apparent than real, since ultrafilters are used to prove the Compactness Theorem). No longer the best reference for learning about the subject. The last chapter is a discussion of Robinson's interpretation of the history and philosophy of calculus; while interesting and valuable as motivation for his development of Nonstandard Analysis, some of his opinions are questionable at best.

Constructive Analysis

Bishop and Bridges, *Constructive Analysis* [BB85]

This is a "second edition" of Bishop's treatise, largely prepared by Bridges after Bishop's death.

Bridges and Vîţă, *Techniques of Constructive Analysis* [BV06]

A sequel of sorts to [BB85], although it does not presuppose any knowledge about constructive analysis. It includes much material that postdates the publication of [BB85], and is more reflective of the state of the art in this subject. Nicely written, and a good place to learn about some constructive analysis without becoming embroiled in the philosophical controversies underlying it: the authors present the subject in the right way, in my opinion, as an interesting and useful part of mathematics rather than the only true way to do all of mathematics.

The authors' presentation does, however, have some foundational obscurities which must be sorted out. In their approach, a "set" is a collection of objects constructed according to some property, from objects which have "already" been constructed [if a construction is done once, is it permanent, or can it be "lost", e.g. with the death of its constructor?], along with an equivalence relation of "equality" on the objects. In practice the mathematician cannot distinguish between equivalent objects. This approach implicitly presupposes two levels of existence and knowledge: an omniscient level where the objects really exist and where true equality of objects makes sense, and where the equivalence relation can be truly defined, and a lower level

of perception on which human mathematicians operate where objects can only be described or distinguished by constructive arguments. Viewed this way, constructive analysis nicely models the way analysis is actually carried out by mathematicians and especially by computers, and the algorithmic arguments forced by this approach are of obvious importance.

From the point of view I take in the last paragraph, what the authors call the "equality" relation should be called "indistinguishability," and what the authors call "inequality" (constructive proof that two objects are not "equal") should be called "distinguishability." But there are still some logical difficulties: for example, in practice it is not obvious that "indistinguishability" is an equivalence relation, specifically that it is transitive. For (perhaps oversimplified) example, suppose we say we can only distinguish real numbers if they differ by at least 10^{-6} (this is reasonable from a computer architecture point of view, perhaps with a different constant). We can then have three numbers a, b, c with a and b indistinguishable, b and c indistinguishable, but a and c distinguishable. In fact, any type of archimedean property of the real numbers would seem to be incompatible with indistinguishability being transitive; real numbers indistinguishable from 0 would be analogous to infinitesimals in nonstandard analysis (ironically, constructivists, notably including BISHOP [Bis77], are some of the most vocal critics of nonstandard analysis).

Another somewhat jarring feature of the presentation of the book is the rather brief and unmotivated adoption of the set $\mathbb{N}$ as the foundation for all of analysis. The only justification given for this is two quotes from KRONECKER and BISHOP in effect saying that they regarded $\mathbb{N}$ as a gift from God; the authors seem to suggest that if it was good enough for them, it is good enough for us too. This approach is somewhat of an injustice: in fact, there are reasonable arguments in favor of viewing $\mathbb{N}$ as a starting point, such as ones described in [Hey66]. But I still think the worship of $\mathbb{N}$ as the starting point of mathematics is a philosophical weak point of intuitionism/constructivism.

Heyting, *Intuitionism: an Introduction* [Hey66]

Number Theory

Baker, *Transcendental Number Theory* [Bak90]

Perhaps the definitive work on the subject, covering the author's revolutionary contributions. The techniques cover a broad range, from algebra and number theory to geometry and hard analysis. Worth looking at, if only to get a feeling for the character of the subject.

Beiler, *Recreations in the Theory of Numbers* [**?**]

This book is a collection of an astounding supply of facts and problems about the positive integers, of varying depth ranging from high-school level puzzles to ones still unsolved by top mathematicians. It is mind-boggling how many person-hours must have been needed over the centuries to find and prove all these results and formulas. The properties of the natural numbers probably have such a combination of intricate patterns and baffling irregularities as to pique the curiosity and challenge the intellect of mankind for all time. And, as the author says,

> "Contemplating such efforts within the frame of a world troubled by war and ceaseless unrest, it seems that the men [sic] who spent so large a part of their lives in this kind of work must have found the secret to an inner peace and happiness that all men crave but that no exigent clamorer for worldly goods can attain."

This book dates from the mid-1960s and is somewhat out of date, especially with regard to what is known about primes and factoring; the best computers at that time were no more powerful, perhaps less, than cell phones of today (although maybe the comparison is not quite straightforward). However, this does not diminish the book's interest and appeal. I learned at least one new word (*aliquot*), and a couple of easily-remembered largish primes, 11111111111111111111111 (23 1's) and $9999999900000001 = 10^{16} - 10^8 + 1$. (The number consisting of n 1's is denoted R_n and called a *repunit* by the author. It is now known [Underwood 2022, using many hours of computer time] that R_{49081} is prime.)

The author is apparently an engineer, but he evidently has a deep understanding and appreciation of the nature of mathematics, and the book is almost entirely amply solid and rigorous, especially for one intended as a popular treatment. I noticed a few small misstatements, such as the assertion on p. 258 that the continued fraction expansion of an irrational number is periodic (he seems only to have quadratic numbers in mind in this discussion); he also calls 1 a prime on p. 211. His instincts as an engineer show through occasionally: on page 280 he states that "The Arabs knew that it was impossible [i.e. knew that FLT was true for $n = 3$] 700 years before Fermat's day and even possessed a proof, albeit a faulty one." (How did they "know" this if they did not have a valid proof? For that matter, how does one "know" something without possessing a proof at all, even a faulty one? Actually, can a faulty "proof" even be legitimately called a proof?) And on p. 124, after a long discussion of how close the acute angles are to 45° in what he calls the 100th Pythagorean triangle with consecutive legs, whose legs are 77-digit numbers differing by one, he concludes, "We had, therefore, best call the one-hundredth, a 45° isosceles right triangle and let it go at that." Spoken like a true engineer. (If we have a sequence converging to zero, would he say we had best call the terms zero from some point on and let it go at that?)

I had fun reading this nicely written book, although I am not inclined to spend hours working on numerical puzzles (maybe why I'm not a number theorist), and recommend it for recreational reading.

Hardy and Wright, *Introduction to the Theory of Numbers* [HW08]

Khinchin, *Continued Fractions* [Khi97]

This little gem is probably the best introduction to the theory of continued fractions. The first 2/3 of the book is an elementary and very readable introduction to the algebraic theory. The last part is on a considerably more sophisticated level, giving a nice and still very readable treatment of the probabilistic aspects of the theory and full proofs of the author's important results about the probabilistic distribution of terms in continued fractions.

Niven, *Irrational Numbers* [Niv56]

Geometry

Berger, *Geometry I, II* [Ber09]

Originally a single volume in French. A wide-ranging and informative treatment of geometry, including such topics as map projections for the earth.

Blumenthal, *Theory and Applications of Distance Geometry* [Blu70]

This is an interesting, valuable, and rather unique treatment of geometry from the metric space point of view. The subject matter is covered thoroughly, not only metric characterizations of Euclidean space, but also curvature and elliptic and hyperbolic spaces. Some of the notation and terminology is outdated, and some sections and arguments seem a bit laborious and unfocused. Nonetheless, it is the best reference on these topics, and virtually the only one on some of them.

Greenberg, *Euclidean and Non-Euclidean Geometry* [Gre93]

An elementary college-level text on axiomatic geometry, with emphasis on the history and nature of the Parallel Postulate. Very readable, and mostly carefully written, although EUCLID'S postulates are rather mangled (they are eventually written properly, but seemingly only as an afterthought).

Hartshorne, *Geometry: Euclid and Beyond* [Har00]

A careful and comprehensive axiomatic treatment of elementary geometry, both Euclidean and Noneuclidean. Written on a more sophisticated level than Greenberg, but very readable. The connections between geometry and modern algebra are extensively discussed and explained. The author has included nice touches such as hand-drawing most of the diagrams to maintain the spirit of EUCLID.

Moise, *Elementary Geometry from an Advanced Standpoint* [Moi90]

Topology

Topology, as covered in the literature, seems to be essentially two separate subjects: point-set topology and algebraic topology. Few books treat both parts of topology in any detail. Even within each part, standard references vary greatly in which topics are covered in detail, since the subjects are too large to be covered comprehensively in any one reference. Different standard references are better or more complete for different topics, to a much greater extent than in basic real analysis, and it is not feasible in brief reviews to give a full summary of which references are good for which topics (and this is a somewhat subjective matter anyway). Readers are encouraged to explore broadly.

Alexandroff (Aleksandrov) and Hopf, *Topologie I* [AH74]

In German. The first comprehensive book on topology, both point-set and algebraic (1935). I was rather surprised how much of the basics of topology had reached its modern form (some of it for the first time) in this book, since the whole subject had barely begun by the beginning of the twentieth century, although HAUSDORFF'S book [Hau49] must be regarded as more revolutionary. In particular, much of the topology we cover in this book appears here in essentially modern form. Although this is denoted "Volume I", there was never a Volume II or, unfortunately, an English translation.

Borsuk, *Theory of Retracts* [Bor67]

Dugundji, *Topology* [Dug78]

Engelking, *General Topology* [Eng89]

The third iteration of this book. This is the most comprehensive text on general topology, and seems to have become the standard reference, although there is essentially no mention of algebraic topology concepts, even the fundamental group (in fact, homotopy is barely mentioned at all). It is also nicely written, with considerable explanation, motivation, and historical notes. However, it is probably too detailed (and esoteric in many places) to be a good text for an introductory course. Copies are also rather difficult and expensive to come by.

Engelking, *Theory of Dimensions Finite and Infinite* [Eng95]

Revised version of *Dimension Theory* (available online). A modern version of Hurewicz and Wallman, covering the theory of dimension beyond the separable metric case, and the theory of infinite-dimensional spaces. Nicely written, and a good place to learn about dimension theory even for separable metric spaces, the case of most general interest.

Hatcher, *Algebraic Topology* [Hat02]

One of the best modern treatments of classical algebraic topology, and freely available online to boot. Very clearly written, with a highly readable exposition of most important basic aspects of algebraic topology. Perhaps the best source for learning the fundamentals of the subject, and a model for what I hope will someday be available online in all parts of mathematics, a goal to which I hope my own book will make a contribution. The author promises additional volumes, which I sincerely hope to see.

Hausdorff, *Grundzüge der Mengenlehre [Fundamentals of Set Theory]* [Hau49]

This was a path-breaking book (1914), and still merits study. The first half of the book is an exposition of set theory, ordered sets, ordinals, and cardinals; while it is undoubtedly a better treatment of these subjects than was available previously, this part does not really break new ground. But the second half of the book can be fairly regarded as the beginning of the modern subject of point-set topology, although the notion of an abstract topological space was first described by FRÉCHET in 1906. It contains the first modern definition of a metric space (modeled on previous work of FRÉCHET as well as Hausdorff himself), and essentially the modern definition of a topological space (there had also been previous work on this, notably by HILBERT). A quite remarkable percentage of the topology we cover in this book appears here. While the topology of the real numbers and Euclidean space was already well understood (primarily via convergence of sequences and series and continuity of functions), the transition to abstract spaces as we view them today sprang forth rather suddenly in amazingly detailed and polished form in this book.

Later editions of this book (e.g. [Hau44]), and the English translations (e.g. [Hau57]), are considerably abbreviated, leaving out much of the text of the first edition including most of the topology (but with a more refined exposition of what remains), with added material on Descriptive Set Theory. So the later editions are really a different book whose title more accurately describes the contents. This book is mainly of historical interest today, especially the first edition.

Hurewicz and Wallman, *Dimension Theory* [HW41]

Kelley, *General Topology* [Kel75]

Kunen and Vaughan, ed., *Handbook of Set-Theoretic Topology* [KV84]

The title of this collection of articles should be taken seriously (at least the "set-theoretic topology" part; the "handbook" part is pretty misleading – this is a massive 1273-page work which would qualify as a handbook only for the likes of Paul Bunyan, although I note that several "handbooks" of similar size on other subjects are also published by Oxford University Press, so maybe the British have bigger hands). Set-theoretic topology is not quite the same thing as point-set topology; the topology treated in this book is based on the intricacies of set theory, including set-theoretic axioms and large cardinal hypotheses. Almost all the results discussed are either trivial or inapplicable for metrizable spaces, and many of them even for spaces which are separable and/or first countable. The articles seem to be carefully written and comprehensive, but will be of interest primarily to specialists in this field, who would be characterized more as set theorists than mainstream topologists. Even the articles on Borel measures, Banach spaces, and topological groups, which should be of interest to a functional analyst such as myself, have a heavy dose of set-theoretic content, although I found parts of each to be of interest. Besides these, the only article which evinced more than a passing interest from me is P. NYIKOS's discussion of nonmetrizable manifolds, and these still strike me as being mostly a curiosity. Several other articles do have preliminary sections which are well-written overviews of parts of the subject for nonexperts.

Kuratowski, *Topology I, II* [Kur66], [Kur68]

Massey, *Algebraic Topology* [Mas77], [Mas91]

Munkres, *Algebraic Topology* [Mun84]

Munkres, *Differential Topology* [Mun66]

Munkres, *Topology* [Mun75]

Seifert and Threlfall, *A Textbook of Topology* [ST80]

An early (1934) treatment of algebraic topology. Nicely written and still very readable, and of the early topology texts it is the only one which is still worthwhile studying for content instead of just historical value. Parts are rather outdated today; the English translation, published in 1980, describes some but not all of these (and even an exposition current in 1980 is now a bit dated). The small amount of point-set topology covered is particularly rudimentary and outdated. A few things in the exposition are at least misleading if not inaccurate:

> In §52, an argument is given that purports to show that every finitely generated group occurs as the fundamental group of a closed 4-manifold (homogeneous 4-complex). But the argument () clearly only works as written for finitely *presented* groups, a much smaller class; and in fact the fundamental group of a closed manifold (and, more generally, a compact metrizable ANR, cf. ()), is always finitely presented. Actually the statement in the book is somewhat ambiguous since their complexes are not required to be finite; the question of whether every finitely generated group, or more generally any countable group, occurs as the fundamental group of a (possibly noncompact) 4-manifold appears to be up in the air, but the answer is positive for open subsets of $\mathbb{R}^5$; cf. http://math.stackexchange.com/questions/1362655/fundamental-group-of-open-subsets-of-mathbbrn.
>
> The definition of "manifold" in the book is what is now called a *combinatorial homology manifold*, which is significantly different from a topological manifold: a combinatorial homology manifold is compact, with no boundary, triangulable, but not necessarily homogeneous. Thus only closed manifolds are combinatorial homology manifolds, and only those which can be triangulated, but on the other hand there are combinatorial homology manifolds which are not manifolds, such as the suspension of the Poincaré homology 3-sphere ().

Spanier, *Algebraic Topology* [Spa81]

My immediate impression of this book when I first picked it up as a student was that it is quite heavy for its size. When I started reading it, this impression persisted in a metaphorical sense: it is pretty dense and detailed. But it is also pretty readable, and it was a standard reference and text at that time for good reason. It may not still be state of the art, but it is still a worthwhile reference.

Willard, *General Topology* [Wil04]

Numerical Analysis

Acton, *Numerical Methods That (Usually) Work* [Act90]

A lively and informative book. The contents could be uncharitably described as a large bag of tricks, but the book is really much more than that: it is a detailed discussion of the art of computation (with emphasis on the *art*), meaning finding, adapting, and using appropriate numerical procedures for computational problems. The author was an engineer, with a fairly typical engineering perspective on mathematics, but informed by extensive experience in computation, and there is much wisdom and common (even uncommon) sense here. His writing style is refreshing and somewhat self-effacing; although he was an acknowledged expert in computation, he never talks down to the reader. For example, he states, "I have tried to make my explanations clear, but sad experience has shown that you will not really understand what I am talking

about until you have made some of the same mistakes that I have made." There is not much attention to mathematical rigor, and even the mathematical details of standard procedures are not discussed in depth, but there are beautiful heuristic descriptions of many procedures. This book is a must-read for anyone preparing to work in computation.

Hamming, *Numerical Methods for Scientists and Engineers* [Ham86]

As a nonexpert in numerical analysis, I found this to be one of the most valuable books for understanding the philosophy of the subject. While many of the nuts and bolts of numerical analysis are treated in detail, and in a way I mostly found mathematically satisfactory, the book's main strength is extensive explanations of *why* things are done as they are, from the point of view of the user. Pure (and even applied) mathematicians may be occasionally offended by sarcastic comments of the author (his colleague Brian Kernighan has fondly called Hamming a "classic curmudgeon"[10]). For example, he describes the difference between Numerical Analysis and Numerical Methods thus:

> "Numerical analysis seems to be the study in depth of a few, somewhat arbitrarily selected, topics and is carried out in a formal mathematical way devoid of relevance to the real world. Numerical methods, on the other hand, try to meet the need for methods to cope with the potentially infinite variety of problems that can arise in practice. The methods given are generally chosen for their wide applicability in creating formulas and algorithms as well as for the particular result being found at that point."

(In fact, I disagree with much of the author's philosophy of mathematics as described in [Ham98], although I appreciate his point of view.) But from this book one really gets a feeling for how engineers and other consumers of numerical analysis view the subject and how their needs are accommodated. The author's stated motto is "The purpose of computing is insight, not numbers," and he delivers on this goal.

Whittaker and Robinson, *The Calculus of Observations* [WR67]

A book reflecting the state of the art in numerical analysis about a hundred years ago. Interesting to peruse, if for no other reason than to marvel at the extensive computations mathematicians of yesteryear carried out by hand (and the elaborate techniques developed to accomplish them) which few today would attempt. Nor would they usually need to with the availability of computers; but the ability (and willingness) to do such hand computations may be somewhat of a lost art, and may have even given these mathematicians insights not easily obtainable today (although, to be sure, we get other insights from computers which they could not).

Miscellaneous Topics

Wagon, *The Banach-Tarski Paradox* [Wag93]

This is one of the best mathematics books I have read. It covers an enormous range of fascinating topics in a very engaging way, and has succeeded in giving a quite readable treatment of some deep topics without pulling punches. Not all of the topics covered are directly related to measure theory, but many are, sometimes in surprising ways. This book really gives the reader a feeling for the way many diverse parts of mathematics fit together and interact.

[10] *Princeton Alumni Weekly*, 1/11/17.

History of Mathematics

Ball, *A Short Account of the History of Mathematics* [Bal60]

This book, first published in 1891, is badly out of date and inconsistent with modern historical scholarship in many parts; thus its modern-day value as a serious historical work is limited. It is still interesting reading, however, with many personal tidbits which are generally more reliable than those in BELL'S books.

Bell, *The Development of Mathematics* [Bel92]

This is a more solid and serious book than *Men of Mathematics*, and has been generally praised by historians of mathematics, although the early chapters have faced some criticism. It is written in an engaging style, with many interesting insights and strong opinions. But it should not be the only book one reads about the history of mathematics.

Boyer, *A History of Mathematics* [Boy89]

Eves, *An Introduction to the History of Mathematics* [Eve90]

Graham and Kantor, *Naming Infinity* [GK09]

The thesis of this book is that "Name Worshipping," a sect of the Russian Orthodox Church, played a significant role in the mathematical careers of DMITRI EGOROV and NIKOLAI LUZIN, and in the development of Descriptive Set Theory by the Moscow school. Part of the book is a detailed account of the lives of these mathematicians and their colleagues and students, which is one of the most detailed studies yet of the important group in Moscow commonly called "Lusitania." Other parts describe the practice of Name Worshipping and attempt to make the connection with the mathematical philosophies of EGOROV and, especially, LUZIN.

I found the book somewhat disappointing until I reached the last chapter, where the authors put things together nicely; this chapter is a glimpse of what the earlier part of the book could have been. Unfortunately, it seems that the authors, who are themselves certainly well versed in mathematics, shied away from depth and technicalities in most of the book in a misguided effort to make it accessible and interesting to non-mathematicians, and thus made their arguments less convincing to mathematicians. I found many of their arguments in the earlier part of the book strained and unconvincing. For example, they often seem to argue that due to the Name Worshipping philosophy, LUZIN *et al.* conflated naming mathematical objects with establishing their existence. No one with a significant background in mathematics could accept this, and it is clear from a quote of LUZIN in the Appendix that this was not what he thought (the authors also explain in the last chapter that they did not believe this argument or intend to make it). Several analogies proposed such as the comparison with GROTHENDIECK are quite strained: GROTHENDIECK'S talent described in the book (only one of his many talents) was his ability to come up with *good* names for mathematical objects which would inform and inspire himself and others; in the philosophy described in the book, where simply naming or explicitly describing mathematical objects was the crucial matter, the quality of the names chosen would seem to be irrelevant. And although the book draws extensive comparisons between the mathematics in Moscow and developments in France during the same period and immediately preceding, I was surprised that the religious influences on the work and philosophy of CANTOR, who got the whole subject of set theory going, were almost totally ignored (it seems clear from other sources that CANTOR was indeed significantly influenced by Christian theology and/or Jewish traditions).

This is overall an interesting book to read, but it could have been a lot better.

Grattan-Guinness, *From the Calculus to Set Theory, 1630-1910* [Gra00]

Gray, *Plato's Ghost: The Modernist Transformation of Mathematics* [Gra08]

This is a massive and thorough study of the revolution in the nature and conception of mathematics which took place primarily in the late nineteenth and early twentieth centuries, and represents a formidable piece of scholarship which is also beautifully and entertainingly written.

The book ends rather with a whimper than a bang, however (maybe I was just tired out when I got this far). The last chapter consists of speculations about the philosophy of mathematics, and ends with an assessment of whether the modernist approach "won." The author tries to claim that there are areas of mathematics where anti-modernism still reigns, such as the subject of differential equations (ODE and PDE). But I find this argument unconvincing. Before the modernist revolution, mathematics consisted almost exclusively of the study of objects mathematicians regard as "concrete", at that time numbers, Euclidean space, and well-behaved functions on them. Mathematics today consists of an entire spectrum of study of objects ranging from concrete to extremely abstract ones defined axiomatically, with no clear dividing line. Some parts of today's mathematics continue to study the traditional concrete objects, e.g. number theory and complex analysis; differential equations and differential geometry can be regarded as the principal remaining parts of traditional real analysis with an active research component (one might add probability). In addition, we now have an ever-increasing collection of things regarded by at least some mathematicians as specific concrete objects, e.g. manifolds, well-ordered sets, Hilbert space. But even the subjects superficially unchanged from 200 years ago, such as number theory and differential equations, use a range of techniques far expanded from the traditional ones which could be developed or even contemplated only as a result of the modernist revolution. For example, the modern study of differential equations heavily uses methods from functional analysis, listed by the author as one of the shining examples of modernist mathematics. (Of course, traditional techniques also continue to be used; after all, even calculus as known and understood in the eighteenth century is still extremely important and useful.) The subject of differential equations also heavily uses sophisticated modeling and simulation techniques made possible by the existence of powerful computers, a development not anticipated even at the end of the modernist revolution; the present use of computation in mathematics may mark another revolution which will turn out to be as profound as the modernist one.

Although parts of this book are dense and a challenge to slog through, it is highly recommended.

Jahnke (Ed.), *A History of Analysis* [Jah03]

Kline, *Mathematical Thought from Ancient to Modern Times* [Kli72]

This is Kline's *magnum opus* and principal scholarly work on the history of mathematics; he has a number of other books written more at the popular level (which are somewhat repetitious and not always as well researched). In this, as well as his other books, there is an undercurrent of Kline's philosophy of mathematics which I personally take some issue with, although this does not seriously undercut the value of these books as historical works. There are also small doses of sexism here and there in Kline's books.

Moore, *Zermelo's Axiom of Choice* [Moo82]

A careful and thorough study of the Axiom of Choice – its prehistory, history, controversy, variations, and intimate connections with the very nature of modern mathematics.

Pier, *Mathematical Analysis During the 20th Century* [Pie01]

The author has set himself a monumental and perhaps impossible task in trying to summarize and organize the development of analysis during the twentieth century, and he has partially succeeded, perhaps as well as any one individual could in a book of this length published at the immediate end of the period studied (he is well aware of the inherent problems of such a project, and indeed divides his description of each part of analysis into "evolution" covering the period 1900-1950 and "flashes" covering 1950-2000). But due to the sheer volume and scope of the material, the coverage is necessarily rather shallow, and the author's judgment about what the most important developments were is highly subjective. For example, in the area I personally know best, operator algebras, he hits some of the high points of the subject (with occasionally muddled description) but misses others, instead discussing some developments at length which are generally regarded as peripheral, such as the axioms for a C*-algebra; I doubt that any leading operator algebra specialist would regard the author's treatment as an adequate or satisfactory history of the subject of operator algebras during the 20th century. (To be fair, he seems to have done a more accurate and thorough job on some other parts of analysis he may be more personally familiar with.)

One of the most interesting parts of the book is the introduction, where the definition, meaning, and scope of the term "analysis" is discussed. The author then takes a fairly broad interpretation of its meaning, including subjects from topology to algebraic geometry under the umbrella of 20th century "analysis."

Much of the material is presented via extensive quotations from the writing of leading mathematicians. These make for interesting and thought-provoking reading. The book is very helpful in giving the reader a feeling for the overall flavor of twentieth-century analysis, although it is far from a definitive study.

Roberts, *King of Infinite Space* [Rob06]

A biography of Donald Coxeter (the title is an apparent allusion to *Hamlet*). This was a more engaging book than I expected. It is nicely written, and the author has really done her homework, with extensive and trenchant quotes from many leading mathematicians she apparently interviewed. The mathematics is pretty much right, both in detail and philosophical form, especially impressive from an author who does not claim any particular expertise in mathematics; it is conveyed more accurately than by some highly-trained authors who should know better. The general theme of the book, which I think is slightly (but only slightly) overblown, is that classical geometry was a dying subject kept alive primarily by Coxeter before finding a renaissance in such modern areas as computer graphics. In fact, classical geometry had been declining in importance since the eighteenth century, when analytic methods began to supplant geometric ones.

A subplot which is greatly oversimplified and rather inaccurate, in my opinion, is that there was a war between formal and visual mathematics in the twentieth century, which is roughly characterized as Bourbaki vs. Coxeter. Bourbaki was indeed a champion of a formal, logical approach to mathematics, but it would be totally wrong to claim that the members of Bourbaki (even Dieudonné, portrayed as the principal villain) did not approve of use of pictures, diagrams, and other visual aids in understanding and creating mathematics; they just felt that the ultimate logical justification for results which may have been found by such methods must be done formally, a sentiment with which even Coxeter would have largely agreed. And it is quite another matter that Bourbaki chose to leave pictures and diagrams almost completely out of their exposition of mathematics, which was never intended to supplant all other approaches. (And Bourbaki was hardly the first to do this: in his *Méchanique analytique*, Lagrange bragged:

> "No diagrams will be found in this work. The methods which I expound in it demand neither constructions nor geometrical or mechanical reasonings, but solely algebraic [analytic] operations subjected to a uniform and regular procedure."

(cf. [Kli72, p. 615]).) Blaming BOURBAKI for the failures of the "new math" is about as misguided as blaming JESUS for present-day fundamentalist Christianity. A new exposition of part of mathematics can *never* be a negative, except *possibly* if it is mathematically incorrect (but see the review of [**?**]); it can only help a competent reader, in combination with other expositions, gain a better understanding of the subject. The problem comes when some people who lack the vision and expertise of the authors decide that a particular work is gospel and should be followed (often with a twisted interpretation due to a lack of understanding) to the exclusion of all others, and a fashion (which mathematics is certainly not immune from) is established. This was the principal problem with the "new math," and even (as the author points out) with the mathematics curriculum at some leading universities, although it is questionable whether all these problems were even directly a result of the influence of BOURBAKI. In any event, it is nice to see that visual mathematics is making a comeback, and while COXETER was probably not as single-handedly responsible as this book portrays, he was certainly a major influence.

Struik, *A Concise History of Mathematics* [Str87]

Philosophy of Mathematics

Some of the books in other sections above are partially concerned with the philosophy of mathematics.

Chaitin, *Information-Theoretic Incompleteness* [Cha92] and *The Unknowable* [Cha99]

Entertainingly written accounts of Chaitin's philosophy of mathematics and knowledge, focusing on complexity. The presentation is unusual, intermixing autobiographical passages with the mathematics. It is easy to dismiss the autobiographical parts as egotistical self-promotion (e.g. "Gödel discovered incompleteness, Turing discovered uncomputability, and I discovered randomness"), but, although I have no personal knowledge about the author, I see a certain naiveté about the stories that suggests such a conclusion may be unfair. The mathematical part is heavy stuff, and I do not feel comfortable with my own understanding of it, but it is certainly a lot of food for thought.

Corfield, *Towards a Philosophy of Real Mathematics* [Cor03]

This is not the first criticism of the preoccupation of philosophers of mathematics with foundations at the expense of studying its actual practice, but it is the most detailed and articulate one to date. The author's knowledge and understanding of mathematics is clearly much broader and deeper than that of most other philosophers of mathematics, and is quite impressive. He makes a compelling case against traditional philosophy of mathematics, but I have a hard time figuring out exactly what he proposes as a replacement: he says he is arguing for a Bayesian theory, but spends a good bit of time pointing out the absurdities of a strict Bayesian interpretation of mathematics and science (e.g. that existing evidence cannot help confirm the plausibility of a new theory that explains it). In any event, as evidenced by his choice of title, he clearly thinks that answering the questions he raises is a work in progress. Although this cannot be considered the definitive work on the subject, it is a significant and thought-provoking contribution to the process.

Lakatos, *Proofs and Refutations* [Lak76]

A thought-provoking discussion of Lakatos' ideas on the nature of mathematical proof, and by transfer his whole philosophy of mathematics. Written primarily as a dialog based around EULER'S formula for the relation of the number of vertices, edges, and faces of a polyhedron ($V-E+F=2$). Interesting reading even for those, like me, who are somewhat skeptical of his conclusions. See [] and [Cor03] for detailed analyses of Lakatos' work.

Introduction to Proofs

I rarely spend time looking at books at this level, so I do not really know what is available. I imagine there are quite a few others, since there is a market for them as textbooks.

Hammack, *Book of Proof* [**?**]

Online. When my department created an Introduction to Proofs class, this was adopted as the text. I taught the course once, and I found this to be a reasonable text, although with some serious objections. I would use it again, especially since it has been improved since, and is freely available online. (I object to making students buy textbooks at inflated prices, especially ones which are regularly revised not to improve the text but to deliberately make used copies of previous editions worthless. These comments will undoubtedly not ingratiate me to textbook authors and publishers, but I don't care.) As I do with most texts I use in class, I assembled an extensive list of errata and comments, which I gave to my students and sent to the author. I was pleased to see that the next revision of the text incorporated most of my comments; I like to think this was a result of my list, but this may or may not be the case (anyway, the author never acknowledged my communication).

Houston, *How to Think Like a Mathematician* [**?**]

I recently found this at a local used book store for $1, and I am quite impressed by it. It is not exactly an Introduction to Proofs text, but advice on how to read, write, and do mathematics (it is called "A Companion to Undergraduate Mathematics"). It is very nicely written and contains a lot of solid advice for an aspiring young mathematician. Much of this advice echoes my own advice scattered through this manuscript, but more extensive and better organized together. (The similarity is neither coincidence nor plagiarism: most mathematicians would probably give similar advice if they took the time and effort to write it.) I found only a few small statements to quibble with. In a footnote, it is stated that a theorem is "a mathematical statement which is true." No: a theorem is a mathematical statement which has a proof, which is not quite the same thing (see GÖDEL). The description of the Diagonalization Argument on p. 226-7 is not quite correct: it must be assumed that the decimals in the list are written without an infinite string of 9s (otherwise the second number in the list could be $.24999\cdots$ and the generated number could be $.25000\cdots$, for example). In Theorem 27.15, EUCLID never said there were infinitely many primes (to be fair, the author never explicitly said he did); the proof, and EUCLID'S statement, just says there is no largest prime. And on p. 262, under "How to prove that something is unique," it is an overuse of contradiction to assume one has two distinct objects and then prove they are the same; it is simpler and more direct to just assume we have elements x and y and show directly they are the same (to be sure, this would often be proved by contradiction). Also, Example 8.7(iii) is wrong.

Nontechnical and Popular Books

Barrow, *Pi in the Sky* [**?**]

Another book about mathematics written by an astrophysicist (cf. LIVIO). This book can best be described as "very uneven": parts are very cogent and thought-provoking, with some deep insights, while others are way off base. The author's primary focus is understandably the use of mathematics as the basis for science, and how the philosophy of mathematics relates to the structure of the universe (in a broad sense). After an introduction and chapters on the origins of the number system and numerology, which are interesting but seemingly off the main subject (although the idea is that they represent the origins of the philosophies of mathematics), the bulk of the book is a discussion of intuitionism, formalism, and Platonism,

largely from the point of view of how these philosophies impact the relationship of mathematics to science, especially physics. The discussion of each of the philosophies is interesting but flawed, in some respects fatally flawed.

The discussion of intuitionism is quite flawed. The author conflates at least four distinct notions:

1. Intuitionism.
2. Constructivism.
3. n-Valued logic, $n \geq 3$.
4. Rejection of *reductio ad absurdum.*

Various intuitionists/constructivists believe some, but not all, of these, sometimes in more nuanced versions. See () and () for more comments on this. In his discussion of multivalued logics, he (correctly) credits Lukasiewicz, Post, and Tarski, leaving the impression that they were intuitionists. I have seen no evidence that this was the case; at least Tarski, with whom I was acquainted as a student, was not an intuitionist – if anything, he was a logicist, although, like most mathematicians, he was hard to categorize.

In the discussion of formalism, the author seems to conflate formalism and logicism, which may seem superficially similar but are quite distinct. Russell was a logicist, and certainly not a formalist, and definitely did not believe mathematics is meaningless. Hilbert also did not believe mathematics is meaningless and did not espouse the crude ("neutered") version of formalism that mathematics is just manipulation of symbols according to postulated rules, and neither, I think it is safe to say, did any member of Bourbaki, even Dieudonné. In fact, it is a stretch to even call Dieudonné a formalist; consider the quote in () and his very geometric approach to Analysis. I will not repeat here my comments about Bourbaki in the review of *King of Infinite Space*, but a formal approach to mathematics is not the same as formalism: saying that formal mathematical structures are "meaningless" is not at all the same thing as saying mathematics is meaningless. In fact, the quote from Bourbaki on p. 134 belies that they believed mathematics is meaningless.

Some of the misstatements in the book are just silly. For example, the author repeatedly states that Euclid's fifth postulate is that "parallel lines do not intersect." No: this is Euclid's *definition* of parallel lines; his fifth postulate has to do with existence and uniqueness of parallel lines (and not really even that: see I.6.1.48. and I.6.1.54.).

The author states on p. - that "Cantor was not Jewish." This is actually a somewhat complex matter which largely depends on one's definition of "Jewish," and a flat statement is not warranted or even helpful. Cantor was not a practicing Jew, at least openly. His religious beliefs appear to be Christian (whether Protestant or Catholic is unclear). His father was a devout Lutheran, of Jewish ancestry; his mother was from a Catholic family, likely also of Jewish ancestry, at least partially. There are indications that some Jewish traditions persisted in the family, and of course there is Cantor's use of Hebrew letters as mathematical symbols. One assessment I read somewhere concluded that Cantor was "barely a Jew." But Hitler would have considered him a Jew.

The heart of the problems of the book is the inadequate and misleading discussion of logic in its various forms. The only distinction the author makes in any detail is between "classical" (two-valued) and "intuitionist" (multivalued) logic. But mathematical logic, even "ordinary" two-valued mathematical logic, is not the same as Aristotelian logic, which is not precise enough to form a basis for mathematics. (There is also a "metalogic," essentially Aristotelian logic, which is used in the metalanguage, as the author does point out.) But both two-valued logic and multivalued logic come in different forms. Multivalued logic is off the mathematical mainstream (and it is inaccurate to equate it to intuitionist logic, which also comes in various forms). The biggest distinction which must be made is among two-valued logics: first-order logic,

used almost exclusively by logicians, and second-order logic, which seems to be used by most mainstream mathematicians. There is a whiff of discussion in the book of second-order logic, in the footnote on p. 121, but it is only a whiff and GENTZEN'S result is not really second-order logic.

GÖDEL'S Incompleteness Theorem is a theorem in first-order logic and there are grave difficulties in extending or interpreting it in second-order logic. Second-order Peano arithmetic is (presumably) consistent, finitely axiomatized, contains first-order Peano arithmetic, and is categorical and thus complete in a sense (). This is a crucial point about the Incompleteness Theorem which is overlooked by the author (and practically all other authors writing about the Theorem). This greatly limits the applicability of GÖDEL'S theorem, and many of the sweeping philosophical consequences claimed, in this book and elsewhere, are unwarranted.

While on the subject of the Incompleteness Theorem, there is also the often-overlooked hypothesis that the theory be "finitely describable" (recursively axiomatizable). This author, to his credit, does know that there is a hypothesis of this sort, but only mentions it inadequately in passing. He also gets it somewhat wrong: recursively axiomatizable theories need not be finitely axiomatizable, and even first-order Peano arithmetic is not finitely axiomatizable; the discussion of axiom schemes on p. 126 is incorrect.

So Gödel Incompleteness does not (directly) apply to second-order logic. But second-order logic has a different kind of incompleteness since there is no second-order mechanical proof theory (). Thus logicians regard second-order logic as an unsatisfactory foundation for mathematics, although mathematicians seem to freely use it (even the Completeness Axiom of the real numbers is second-order). I think a very interesting book along the lines of the one being reviewed could explore the implications of using second-order logic in mathematics and its relation to the physical world. But this book is not it.

Bellos, *The Grapes of Math* [**?**]

Although I am not impressed by the cutesy title (the title may not be the author's doing – the British version has the title *Alex Through the Looking Glass*), this is an interesting and fun book to read. It is not quite nontechnical, but does not presuppose any knowledge for the reader beyond some high-school algebra. Many interesting topics are discussed, in a clear, entertaining, and mostly mathematically satisfactory way. The examples in the next-to-last chapter on proofs are strikingly similar to ones in my book (to be clear, almost all of my versions were written and online before this book was published; it's almost as if the author read my manuscript, although probably not since it is not mentioned and he omits some difficulties I discuss).

Bellos, *Here's Looking at Euclid* [**?**]

An earlier book by the same author with a cutesy title (the British version is titled *Alex's Adventures in Numberland*). It is on a slightly more elementary level than *The Grapes of Math*. The author is an entertaining writer and does his homework, and there is enough here to make this book an interesting read even for professionals.

Part of this book is a discussion of how the human mind understands mathematics. Although it is a popular book and not intended as a scholarly publication, and although the author has no advanced training in either mathematics or psychology, I find the discussion (few if any of the ideas are original with the author) more intelligent and insightful than [LN00].

Most of the mathematics discussed is elementary. There is almost nothing to quibble with, although occasionally something is "dumbed down" to the point of making the discussion at least somewhat misleading. For example, on p. 107 he attempts to define transcendental numbers without mentioning the word *polynomial*, saying "a transcendental number is an irrational that cannot be described by an equation with a finite amount of terms." He adds that they are "so mysterious and evasive that finite mathematics could not capture them." But equations like $2^x = 3$ or $\sin x = 1$ have a finite amount of terms and transcendental

solutions (even $\sum_{k=0}^{\infty} \frac{1}{k!}$ is arguably a finite expression). His discussion of infinite series also only applies to nonnegative series, an excusable simplification in a book of this sort, although it may merit a comment.

He lionizes EUCLID (slightly) too much: on p. 56 he writes, "*The Elements* is a magnum opus of pedantry and rigor. Nothing is ever assumed. Every line follows rigorously from the line before." This is largely, but not entirely true; see the discussion in (). Indeed, compare the "proof" on that page with (); how do you know the circles intersect? (On the back cover, EUCLID is called "the greatest mathematician of all time," but this was undoubtedly written by a publicist and not the author.) And the discussion of the "Parallel Postulate" on p. 268-9 is flawed (cf. ()): WALLIS'S version is equivalent to Playfair's Axiom, the usual statement of the Parallel Postulate, and not to the version at the bottom of p. 268, and arguably not equivalent to EUCLID'S fifth postulate.

On p. 248, he refers to GALILEO measuring the "distances to stars." I doubt GALILEO ever tried to do this with any star but the sun, or got any reasonable answers if he did. People at that time, even geniuses like GALILEO, had no conception of how far away stars are or any way of estimating it. He was likely trying to measure the distance to planets, for which he had at least a hope of reasonably succeeding. (Even reasonably estimating the distance to the moon would have been a challenge at that time.)

Enough nitpicking. This is a good book.

Cheng, *How to Bake* π [Che15]

This is a generally very nicely-done book, intending to give a comfortable introduction to real mathematics (particularly category theory, the author's specialty) for a lay audience. A subtheme is a discussion of baking, one of the author's interests, and perceptive analogies are made between baking and mathematics. The author is very good at putting mathematical concepts in a form which should be understandable to someone without much mathematical background. However, the desire to be as nontechnical as possible does lead to some misstatements, or at least misleading statements, for a mathematically literate reader. The worst problem I found was in the discussion of topology on p. 90-95, where the concepts of *homeomorphism* and *homotopy equivalence* are confused (of course I mean the discussion confuses them, not that the author does): the equivalence described somewhat informally appears to be homeomorphism, but the examples, e.g. the capital letters of the alphabet, are of homotopy equivalence ("number of holes"). The discussion is continued on p. 174-175, somewhat more carefully but not quite adequately. A more minor misstatement is on p. 120, where some properties of addition on $\mathbb{Z}$ are listed, and it is asserted that these listed properties are the axioms for a group. But one needs also that $a+0=a$ for any a, which does not follow from the listed properties (one could define $+$ on $\mathbb{Z}$ by setting $a+b=b$ for any a and b). This is carefully and correctly done later on p. 133-136. The book concludes with very insightful discussions of knowledge vs. understanding and the place of mathematics in general society.

Elwes, *Mathematics 1001* []

This is an interesting compilation of "1001 bite-sized explanations" of "absolutely everything that matters in mathematics" (or maybe at least everything the author knows). The explanations, roughly a paragraph long, are of uneven quality, but mostly quite good, and are entertainingly written. The weakest chapter seems to be Analysis (maybe I'm just more attuned to noticing objectionable things here): difficulties range from outright misstatements, for example claiming (under "analytic continuation") that any analytic function on a piece of the plane extends to an analytic function on the whole plane, an amateurish mistake, to explanations not technically wrong but misleading or excessively shallow. For example, under "implicit differentiation" (one of my pet topics: I often use the treatment of the Implicit Function Theorem as an early benchmark in judging the quality of any basic analysis or general-purpose book) he first points out that $\frac{dy}{dx}$ can be found from an equation $y = f(x)$ by the techniques of calculus already discussed, and then states, "However, there is no law that says we have to begin with y alone on one side of the equation." Well, OK, there is no law that says we have to restrict ourselves to the hypotheses of any theorem; but if you want to assert the conclusion of the theorem in a situation where the hypotheses are not satisfied, you'd better be prepared to justify it, and quoting the theorem is of no help in this. In this case, there is no further hint that this situation is not a straightforward extension of ordinary calculus. On the same page is a fallacious "proof" of the Chain Rule (cf. V.3.10.5.). Another misleading explanation from the Algebra chapter is an incorrect statement of the cubic formula (the signs must be chosen opposite in the two terms). And he uses some nonstandard terminology (at least for the US; maybe it's different in the UK), such as "gradient" instead of "slope" of a line. The chapters on logic and metamathematics are the most interesting (to me) and appear to be the best, not surprising since these are the areas of the author's primary expertise. This book is interesting and entertaining to read, but with a bit of caution.

Klein, *Elementary Mathematics from an Advanced Standpoint: Arithmetic, Algebra, Analysis* [Kle04]

This is not intended to be a popular book, and is not exactly nontechnical. Its goal was twofold: to describe Klein's ideas on how mathematics should be presented and taught in schools, and to give schoolteachers knowledge and insight on the true nature of the mathematics they teach (he says on p. 162: "... the teacher's knowledge should be far greater than that which he presents to his pupils. He must be familiar with the cliffs and the whirlpools in order to guide his pupils safely past them.") Although it was written more than a hundred years ago, most of it is as relevant today as when it first appeared, and it is full of valuable insights even today from a first-rate mathematical mind which paid unusually great attention to how mathematics should be taught. I myself learned some things about mathematics and its development, such as a beautiful proof of Taylor's theorem with Lagrange remainder via difference calculus, regarded by Klein as the best and most natural proof of the theorem (and the way TAYLOR himself found the theorem, although he did not come close to giving what would be today recognized as a proof), which I have not found in modern texts, probably because difference calculus is rarely discussed except in numerical analysis texts. See () for the argument. And HILBERT in his *Grundlagen der Geometrie* described something close to the nonstandard real numbers (they may have even been found earlier by someone else). This book is well worth reading and studying by any potential mathematician or mathematics teacher. The reader is cautioned that the English translation in this edition contains an unusually large number of misprints, most of which are harmless.

Livio, *Is God a Mathematician?* [Liv09]

This is generally a well-written, informative, and entertaining study of the "unreasonable effectiveness of mathematics" as a basis for science and the underlying principles of the universe. There is little actual religious content, mainly just a discussion of the religious beliefs of major figures such as GALILEO, DESCARTES,

and NEWTON. The author is an astrophysicist and not a mathematician, and his primary interest (at least in this book) is the relation between mathematics and science; but he has deep knowledge and understanding of mathematics and gets it almost all right. There are a few misstatements, such as that "a fully consistent theory of analysis was only formulated in the 1960s" (an apparent reference to nonstandard analysis), and the crucial words *finitely describable* (technically, *recursively axiomatizable*) are omitted from the statements of Gödel's theorems (he is hardly the first author to make this mistake, and in his case it may well be an inadvertent error rather than a misunderstanding). His discussion of the philosophy of mathematics is extensive and intelligently argued, although he repeatedly makes rather unconvincing arguments against Platonism, and he rather too glowingly refers to [LN00], which in my opinion is hardly more than a work of fiction. He buys a little too much into the "crisis" characterization of the modernist revolution precipitated by the discovery of noneuclidean geometry, but his discussion of this subject is more accurate and intelligent than many others. He does not pretend to have the answers to the main questions he discusses (no one else does either), but makes worthwhile contributions to the discussion.

Maor, *e: the Story of a Number* [**?**]

A wide-ranging account of some parts of the history of mathematics, loosely based around the number e. The author is a historian of mathematics and knows his stuff. I found the book almost entirely mathematically accurate and honest, as well as being engagingly written, although I am skeptical of the author's claim that it is accessible to a general audience; I think at least a one-semester calculus course is pretty much necessary to understand and appreciate the book. I found very little to quibble with in the text. The only mathematical error I noticed was on p. 179, where the author asserts that if a complex function is differentiable at a point, then it is conformal there (see XII.1.1.14. for the correct statement). On p. 181 he says the three great achievements of nineteenth-century mathematics are complex analysis, abstract algebra, and noneuclidean geometry. Crucial advances all, especially if noneuclidean geometry includes Riemannian geometry; but I would say that set theory *á la* Cantor and the foundations of (real) analysis are just as important. I also question his assertion that most texts on calculus and analysis treat the calculus of the logarithm function before the exponential, suggesting (but never really claiming) that his approach of doing the exponential function first is somehow novel. I have always done the exponential function first in my calculus classes, in the same way he does it, and the textbooks I have used have almost always done the same. If one draws the graphs of 2^x and 3^x, it is geometrically very plausible that there is a b between 2 and 3 for which the tangent line to the graph of b^x at $(0, 1)$ has slope 1. Anyway, these are minor points and do not detract from the book.

Pickover, *The Math Book* []

Each summer I spend time at our family cottage on a lake in Ontario. I often check out popular math books from the local library (they have a better collection than one might expect) to read on the island while not doing more serious things like swimming and boating. This is one of those books.

This lavishly illustrated book, organized chronologically, gives one-page treatments of topics the author considers interesting and important, ranging from prehistoric to 2007. On the page facing each piece of text is a color illustration, many of which are visually stunning and some of which are even directly connected with the topic discussed. The topics range from deep and important subjects in mathematics to simple puzzles (although some of the puzzles turn out to be not so simple and do require some nontrivial mathematics to be developed to solve them). The author is not a mathematician (his degree is in biochemistry), but he is fairly knowledgable about mathematics and gets it mostly, but not entirely, right. The history is also not entirely right, and some of it seems to be straight out of BELL'S *Men of Mathematics*. He does correct some of the

problems and misconceptions in the notes at the end of the book: for example, after a text attributing sole responsibility for "Stirling's formula" to Stirling, in the notes he acknowledges it is largely (in fact almost entirely) due to de Moivre. Many, perhaps too many, of the photos are computer graphics of fractals and other mathematical art, one of the author's interests – he has been significantly involved in producing such images. This book is worth checking out if you spend a week on an island in Canada.

Rucker, *Infinity and the Mind* [Ruc82]

In my opinion, the most interesting of Rucker's books. Contains accurate and readable, although non-rigorous, treatments of the theory of ordinals and of Gödel's Incompleteness Theorem.

Smullyan, *The Lady or the Tiger?* [**?**]

The first half of this book is a collection of Smullyan's famous logic puzzles. The second half is a delightful treatment of Gödel's Incompleteness Theorem in the form of a "mathematical novel."

Smullyan, *Forever Undecided* [**?**]

This book falls somewhere between *The Lady or the Tiger?* and *Gödel's Incompleteness Theorems*. It is not a technical book, although it covers some symbolic logic, but it is also not nearly as lighthearted as Smullyan's other popular books. The topics discussed and explained are somewhere between philosophy and mathematics, based on various versions of Gödel's Incompleteness Theorem.

The two books *The Lady or the Tiger?* and *Forever Undecided* are available together in a single paperback volume.

Stillwell, *The Story of Proof* [Sti22]

This nice book does not cleanly fit into either the History of Mathematics or Popular Books category. It is an account of how the concepts of mathematics and their proofs developed, but is more about the substance of mathematics than its history. Although some parts, especially the earlier ones, can be understood at the popular level, the depth and sophistication of the mathematics increases significantly through the book (not a criticism at all!), and most of it is only understandable to someone with a significant background in mathematics (it would be accessible to graduate students or advanced undergraduates in mathematics).

Many of the arguments presented are clever and insightful, and some were even new to me; and they are accompanied by very nice illustrations and graphics. My only criticism is that it is not pointed out that many of the "proofs," especially earlier ones, are not rigorous or complete by modern standards. For example, some arguments concern tangent lines, which are not defined; the author also talks frequently about arc length and surface area without definitions, suggesting they have an intrinsic self-evident meaning. But even Archimedes understood that surface area is not self-evident and had to be defined, which is not easy to do carefully. Even carefully defining the area of a plane figure or volume of a solid takes some work. A few added comments here and there would remedy these shortcomings.

Books to be Wary of

Alexander, *Infinitesimal: How a Dangerous Mathematical Theory Shaped the Modern World* [Ale15]

The theme of this book is that the mathematical "theory of indivisibles" precipitated an intense battle in the sixteenth and seventeenth centuries, not just among mathematicians but even among political and social theorists. Throughout the book the author tries to characterize the opposition to the theory of indivisibles as a manifestation of a rigid, authoritarian social philosophy, and the belief in the theory of

indivisibles as representing ideals of free inquiry and, ultimately, democracy. While this may be rather a stretch, oversimplification, or extrapolation, it certainly has an element of truth, and the historical events are engagingly described in considerable detail in support of the thesis.

I saw and browsed this book in a bookstore and it looked interesting, so I got a copy and began reading it systematically. I could hardly get past the introduction, since it was so full of mathematical misconceptions. The most egregious, affecting the entire thesis of the book, is confusion of the mathematical terms *indivisible* and *infinitesimal* (which mean entirely different things – whatever an infinitesimal is, it is not indivisible! If it were, what could an equation like $dy = \frac{1}{2}\,dx$ possibly mean? Granted, before the late seventeenth century the difference was not well understood even by mathematicians. See [She18] for a detailed study.) In fact, the book probably should have been titled *Indivisible*, since this term is the one causing most of the controversy discussed in the book. (Debates about the existence of indivisibles and the nature of the continuum go back to ancient Greece, and were revived in Europe at least as early as the fourteenth century; cf. e.g. [Boy59].) The only mention of infinitesimals as mathematicians since Archimedes have almost always thought of them is a few oblique references to the development of calculus, which really has nothing to do with the theory of indivisibles; the only relevance to the book's thesis is that (early) calculus was based on controversial (although not actually new) ideas which were not rigorously established.

But there are other serious mathematical inadequacies, such as the attempt to describe what the theory of indivisibles means (it essentially means that a line is a set of points, or, what is not exactly the same thing, that a line is "made up" of a collection of points, and similarly a plane figure is "made up" of a collection of parallel line segments, etc., not that a line segment is actually indivisible). The author is a historian, not a mathematician, and it is perhaps unrealistic to expect him to get the mathematics right, but many authors of other books about mathematics have done better with no more formal mathematical training. Perhaps he was simply presenting the idea as it was (mis)understood by people like Renaissance Jesuits as well as many mathematicians of the time, but if so he should have said so and pointed out the misconception. And he never mentioned the resolution of the paradoxes discussed, not found until the twentieth century using measure theory and the difference between countably and uncountably infinite sets (see I.3.1.2. ff. for a discussion). The author seems to subscribe to the common picture of a line as a string of beads, each point having a "next" point, a picture every modern mathematician has had to try to correct in the classroom. This picture was common at one time even among mathematicians: Galileo believed that a line segment was made up of infinitely many infinitely small points separated by infinitely many infinitely small gaps.

Pushing on, I found the rest of the book more interesting, with much detailed history I didn't know which I assume is accurately portrayed since this should be the author's forte. The book traces the formation of the Jesuit order of the Catholic Church, largely as a response to the Reformation and resulting loss of influence and control of the Church, and the incorporation of mathematics into the curriculum of the Jesuit colleges and, more generally, as a subject as worthy of study as philosophy and theology. Mathematics as taught by the Jesuits was in a form compatible with overall Jesuit philosophy, as a body of eternal truths and not as an intellectual pursuit in which new ideas were sought or even tolerated. As the author puts it on p. 78:

> "But why study mathematics? Only because it provided a model of perfect rational order and certainty, and an example of how universal truths governed the world. If mathematics was to become a field of far-reaching innovation, in which new truths were proposed and then subjected to challenge and debate, then it would be worse than useless. It would be dangerous, as it would compromise the very foundations of the truth it was meant to buttress."

The Jesuits had enormous influence on the intellectual life of continental Europe in the sixteenth and seventeenth centuries, partially through their colleges, which were in some respects the best system of higher education at the time.

A good deal of the book is devoted to Thomas Hobbes and John Wallis. The mathematical part of their longstanding intellectual battle (there was a considerable nonmathematical component too, see e.g. [**?**]) is described as being mainly a disagreement about mathematical philosophy. While there is probably some truth to this, I think there is a more important reason. The author does point out that Hobbes's (later) mathematical work was not taken seriously by the English mathematical establishment, but attributes this to political prejudice. In fact, Hobbes was a hopeless mathematical charlatan, and his mathematical work was no more worthy of being taken seriously than that of modern-day cranks (cf. Figure I.13). Wallis was an excellent mathematician, one of the world's leading mathematicians of the seventeenth century (although overshadowed in Britain by Newton and Gregory), and very likely had the attitude widespread among mathematicians of not suffering fools gladly (see e.g. the quote in II.1.). The author may perhaps again be excused for not having the ability to make a judgment about the quality of Hobbes's mathematics. The statement on p. 213 that Hobbes was "one of the most respected English mathematicians of the day" [1640] is doubtful (although English mathematics was in a rather primitive state at the time); I am not aware of a single (correct) original contribution he made to mathematics.

The author's assertion that Wallis created a new kind of experimental mathematics, and especially that he did so to conform to the philosophy of the Royal Society, is nonsense. All mathematics is experimental when first being developed, and mathematical results have been found by induction since ancient Greece and even earlier. Wallis used techniques going back to Archimedes and probably even Euclid's predecessors (ancient Greeks apparently did not record how they obtained their results, and in any event knowledge about their methods has been lost), and in fact paid considerable homage to Greek mathematics and could be considered the leading historian of mathematics of his era. Wallis may not have paid sufficient attention to carefully proving his results, but he undoubtedly could have (and probably did mentally) in many cases using the elaborate double *reductio ad absurdum* technique of Archimedes, but evidently was more interested in using his time and effort to explore new things. Also note that it was not uncommon at that time for mathematicians to announce results without giving a hint of a proof, often in the form of an implicit challenge to other mathematicians (in effect saying, "I can prove this, can you?") Wallis was surely aware, as contemporaries like Newton were, that some of the techniques did not (at that time) have a sound logical footing, but these mathematicians had strong intuition and their results invariably turned out to be correct and logically justifiable (unlike Hobbes). It seems farfetched that Wallis declined to try to prove his results simply in order to adhere to the Royal Society philosophy. The author seems to be obsessively insistent on attributing the primary motivation for every mathematical or scientific study to adherence to one side or the other of the philosophical dichotomy which is the theme of the book (Maslow's hammer at work!)

Incidentally, Wallis did not initiate the idea that mathematical objects exist and only need to be explored, and that mathematical truths are discovered; this philosophy of mathematics is called *Platonism* since it goes back (at least) to Plato. (Hobbes was also a Platonist and, contrary to what is suggested in the book, Euclid probably was too.)

There is at least one historical inaccuracy I noticed. On p. 290, it is stated:

> "Following the war over the infinitely small, advanced mathematics in Italy came to a standstill, whereas English mathematics quickly became one of the dominant national traditions in Europe, rivaled only by the French."

This may be an accurate assessment about Italy. But although England in many respects, including technology, industrialization, and certain intellectual and social areas, became a world leader, it notably remained a mathematical backwater for more than 100 years after Newton, particularly in analysis (other than mathematical physics). In fact, there was a nineteenth century analysis renaissance in Italy before there was one

in England. It was French, Swiss, and German mathematicians, not English, who were at the forefront of analysis in the eighteenth and nineteenth centuries (I count LAGRANGE as French although he was actually born in Italy). The only British analyst of note during this period was MACLAURIN (who was Scottish).

There have been criticisms of the reasons the author attributes for the Jesuit opposition to the theory of indivisibles, that it is inconsistent with ARISTOTLE and EUCLID and the notion that mathematics represents eternal truth. In [She18] (which I find an articulate criticism of much of Alexander's book, although I cannot evaluate the historical aspects), it is argued that the principal reason for the opposition was that it contradicted the Catholic doctrine of transubstantiation of Christ's body and blood in the Eucharist (this idea was first presented in [Red87]). Note that I only discovered and read these other references after I had written most of this review.

It is remarkable that so many people, both mathematicians and nonmathematicians, spent so much time and effort and generated such acrimony over a dispute of such little ultimate (mathematical) consequence, with both sides advancing arguments which today would be regarded as foolishly misguided. I wish the author had been able to convey the obsolescence better. The book is worth reading for its historical content, as long as the author's attributions and conclusions are taken with a degree of skepticism.

Bell, *Men of Mathematics* [**?**]

This book is entertaining reading, but unreliable as history; some parts are downright fanciful. The chapters on GALOIS and CANTOR are the worst from the standpoint of historical accuracy. Although Bell was a respectable mathematician, some critics have asserted that as a biographer he seems to have been the type of writer who never lets the facts get in the way of a good story. Overall, however, the book is not nearly as bad as these critics have made it out to be: the vast majority of the book is factually accurate, and the errors appear to be entirely the result of careless or inadequate research and unwarranted extrapolation rather than deliberate falsification; the accounts are much closer to the actual events than in many modern "historical" movies. In fact, the author has gone to some pains to qualify historical assertions he felt were not adequately established. Despite the title, the book does not have a sexist tone, and in fact was fairly progressive for its time (1937), giving sympathetic treatment to several women mathematicians and the obstacles they faced; for example, Bell gave the first popular (if dated and flawed) account of SOFIA KOVALEVSKAYA. There is some gratuitous antisemitism in the chapter on CANTOR (there is controversy over to what degree, if any, CANTOR himself was Jewish, although he clearly had at least some Jewish ancestry). This book may be inspiring to a young reader who is aware of its historical inaccuracies, and it also serves a useful purpose in countering the stereotype of mathematicians as nerds of borderline sanity and little personality or variety. The description of Bell in [New88] seems fairly apt: "lively, stimulating, inoffensively crotchety and opinionated, with a good sense of historical circumstance, a fine impatience with humbug, a sound grasp of the entire mathematical scene, and a gift for clear and orderly explanation."

Griffiths and Hilton, *A Comprehensive Textbook of Classical Mathematics* [GH78]

This book is hard to categorize. The aim is to give a unified exposition of "classical mathematics" (or what may be loosely described as "undergraduate mathematics") from a modern perspective: logic and set theory, abstract algebra, elementary geometry and topology, and undergraduate analysis. Some things (generally simpler ones) are proved in detail, but most of the deeper or more difficult results are just stated with some informal or intuitive justification given (which is clearly represented as such; the book is pretty honest mathematically). I would not describe the treatment as inspired, and it is generally pretty conventional, but there is much wisdom and insight in the descriptions. And, importantly, the authors explicitly describe, and follow, what they call the *spiral principle*, which underlies both the historical development of mathematics

and the way it is, or should be, taught: fundamental topics and principles are first introduced and developed in a natural and intuitive way, and after they have become somewhat familiar are redeveloped in a more careful way. This is nicely summarized in this statement from p. 249, in the chapter "The Logic of Geometry", after Euclid's geometry (with modern improvements) is described:

> "A person might object to all this procedure on the grounds that the definitions given are artificial without a prior knowledge of Euclidean geometry; to which we can only reply that *once* they are given, a logically watertight system of geometry can be developed, and it matters not a whit how the definitions happened to be suggested. This is typical of the way in which a great deal of mathematics has grown. First a terminology and body of results is obtained by logically unsatisfactory (but often aesthetically pleasing) methods. Then the theory is seen to have flaws which prevent further progress. Finally the theory is reset in a possibly different language, and derived in a correct logical manner, usually gaining greater power."

On the other hand, the book contains surprisingly many (especially for an apparently revised second edition) missteps, most of which are fairly minor and many of little real consequence; I think at least nearly all of them could be described as "careless." For example, both the statement of the Implicit Function Theorem (37.4.2) and Theorem 15.5.2 are false as stated; additional hypotheses are needed (continuity of the relevant derivatives suffices). In contrast, the statement of the Mean Value Theorem, or more accurately of "Rolle's conditions" on p. 483 (ROLLE never stated, and probably never considered, such conditions), contains a superfluous continuity assumption on the derivative, which is not used in the proof or mentioned when the theorem is quoted in several other places. It is stated that the definition of "finite set" in 7.2.4 (what is usually called *Dedekind-finite*) is equivalent to the one in 7.1.4 (apparently meaning 2.11.1), but some form of the Axiom of Choice, which is only mentioned later, is needed. (Theorem 7.1.4 also has an obvious superfluous hypothesis.) And the authors seem to like to invent their own terminology, which is sometimes at odds with convention. Some of this invented terminology is picturesque, such as their name "mostest theorem" for what is normally called the Extreme Value Theorem, but some is not an improvement, such as "flat" for "affine subspace" or "laws of indices" for "rules of exponents" (maybe some of their terms are in more general use in Britain than in the U.S.). And what they call the "Axiom of Choice" (that an element can be chosen out of one nonempty set) is either trivial or a nonmathematical assertion depending on one's point of view (cf. II.6.1.6.); what is usually called the Axiom of Choice is called the "Strong Axiom of Choice".

This book could be quite helpful to an advanced undergraduate or knowledgeable nonmathematician in helping to "put the pieces together", somewhat in the manner of [Sch97] (although the books are very different), as long as it is recognized that the small inaccuracies mean that the details of the exposition must be regarded with a degree of skepticism. But, although this book is described and clearly intended as a textbook, I find it hard to think it could be suitable as a textbook for a course it would be worthwhile for a mathematics student to take; it might be suitable for a "capstone" course for students preparing to be math teachers at the high-school or community college level.

Guillen, *Bridges to Infinity* [Gui83]

This book is not entirely about mathematics, and I will not pass judgment on the nonmathematical part. But it is so riddled with mathematical errors and misconceptions that the credibility of the entire work is questionable. There are also sloppy historical errors, such as calling VON NEUMANN a "German mathematician."

Jackson (ed.), *Mathematics: an Illustrated History of Numbers* [**?**]

This book is representative of a genre of lavishly produced and marketed "popular" books about mathematics for mass audiences. It has received glowing reviews in the mainstream press (e.g. *The Booklist, Washington Post*) written by reviewers who were not competent to evaluate it.

The book is divided into 100 units ("ponderables"), many of which are actually physics. At first glance it is appealing, but one soon finds it full of misstatements, misconceptions, and outright nonsense (both mathematical and historical) in places. This is now apparently a third revised edition (I can only imagine what was revised and corrected since so many problems remain). For example, in the unit on e, the number is first described:

> "e arises from the construction of the so-called natural logarithm, which defines a new number – a fixed-value 'base' the natural logarithm of which is 1. The natural logarithm of any given number x is the power to which this base must be raised to equal x. In other words, $\ln(e^x) = x$ and $\ln(e) = 1$, since $e^1 = e$. This logarithmic function is natural in mathematical terms since it is defined around oneness. As you can see, e is the public face of the exponential function, e^x, where $x = 1$."

In fact, nearly every page seems to have a mathematical howler. A few other samples:

> $\sqrt{2}$ is made up of an infinite string of numbers and therefore has no exact value.
>
> In at least two places, it is stated that Euclid's axioms were "inconsistent."
>
> The three-body problem shows that the universe is indeterminate.
>
> Russell's Paradox was a death blow to Cantor's set theory.
>
> The real numbers are uncountable because between any two integers there are infinitely many of them.
>
> Unlike straight lines, geodesics are closed, and geodesics were used to build the geodesic dome.

Not everything in this book is nonsense, far from it; but there is so much that it takes a mathematically literate reader to separate the wheat from the chaff. To be perhaps overly charitable to the authors (none of whom are mathematicians, although this is really neither here nor there), some of the nonsense may be just an overzealous attempt to "dumb down" sophisticated mathematical ideas for a lay audience. But the book is not suitable even for one of its stated target audiences, young people interested in mathematics, since too many misconceptions could be ingrained from it.

Lakoff and Nuñez, *Where Mathematics Comes From* [LN00]

This book purports to be a study of how the human mind perceives and understands mathematics. But the authors, a linguist and a cognitive psychologist, repeatedly demonstrate an embarrassing lack of understanding of basic undergraduate mathematics (e.g. limits); they would be well advised to study a book like *Closer and Closer* to see what they are missing. They regard the equation $e^{i\pi} = -1$ as "one of the deepest equations in all of mathematics," and suggest that even most modern mathematicians do not understand it. There is also much discussion of the philosophy of mathematics, which is shallow and logically flawed, sometimes with a vicious undertone. While I cannot evaluate the authors' cognitive psychology arguments, this is not a book that mathematicians should take very seriously (how can they expound intelligently about how humans understand mathematics if they don't understand it themselves?) See http://www.bruceblackadar.com for a more extensive review.

Polya, *Induction and Analogy in Mathematics* [Pól90a] and *Patterns of Plausible Inference* [Pól90b]

This two-volume work is in many ways an admirable book. It is a thorough discussion of mathematical reasoning and problem solving by one of the masters, and it is filled with solid and valuable advice on how to approach and solve mathematical problems. The techniques are illustrated by numerous examples, containing clever and insightful arguments (originally dating back as far as ancient Greece) from which much can be learned. And he does draw and explain an important distinction between *plausible reasoning* and *demonstrative reasoning*.

But the treatment of demonstrative reasoning is seriously flawed: the book is unfortunately riddled with what I call "mathematical dishonesty." Many of the arguments represented as proofs are logically incomplete or nonrigorous (see I.6.1.7. for a discussion of some of these; earlier, he seems to represent the principle of induction as so self-evident that it merits no comment.) This is a much more serious problem in a book of this sort than in books like [Doo94] or [Mor09] (where there are gaps in arguments but no attempt is made to hide them, and the gaps are generally routine to fill in), since the main subject of this book is mathematical reasoning. Polya himself certainly knew better. Some rather minor changes in the language used, and a few added comments, could have maintained mathematical honesty while still making the main points the author wanted to convey. But he seemed to deliberately go out of his way to obscure or gloss over some of the mathematical difficulties in his arguments, and as a result many readers could be misled about the nature of full demonstrations in mathematics.

Seife, *Zero: The Biography of a Dangerous Idea* [Sei00]

Who knew mathematics was so dangerous (cf. [Ale15])? This book is a popular account of the history of zero in a broad sense, including limits and singularities; zero and infinity are treated together as the limiting cases of the positive real numbers, and "reciprocals" of each other. The "danger" described is mostly really discomfort; the only danger (other than true physical danger to a few people for expressing heretical ideas) is difficulties and absurdities caused by trying to divide by zero or carelessly add infinite series. The last third of the book is mostly physics, describing singularities like black holes and the big bang and the attempts to reconcile relativity and quantum mechanics. The author is a clear and entertaining writer, with enough background in mathematics that the actual mathematics is mostly described accurately, with occasional language imprecision (e.g. he repeatedly refers to sums like

$$1+\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+\cdots$$

as having "infinite terms" rather than an infinite *number* of terms), but his arguments and conclusions are often sensationalized: the introduction and acceptance of zero as a number was a slow and difficult process which certainly caused discomfort, but it is quite a stretch to call zero "dangerous." There is a lot of interesting history, which is for the most part well researched but not entirely accurate. Comparing with [Ale15], both books suffer from overly broad and simplistic interpretations and characterizations (sometimes in conflict between the two books, although the overlap in subject matter is not great), this book somewhat more so, although the mathematics is described more accurately. This is an interesting book to read so long as not everything is taken at face value.

Nonmathematical Books

Okrent, *Highly Irregular* [Okr21]

This is a delightfully written and engagingly scholarly account of how English came to be such an irregular language. It explains the origin of the spelling and grammatical irregularities, as well as some

common expressions which seem to defy logic. Well worth reading for both native and non-native English speakers.

A Stalin-era joke from the Soviet Union:[11]

> "Two militiamen are invited to Comrade Kozlov's birthday party. What should we give him? asks one. The best gift is a book, says the other. No, says the first militiaman. Comrade Kozlov already has a book."

[11] Elena Gorokhova, *A Mountain of Crumbs*, p. 7.
